        maths = manager.Maths()
        print(maths.add(4, 3)) # prints 7
        print(maths.mul(7, 8)) # prints 56
```

17.2.2.7.2. Using a remote manager

It is possible to run a manager server on one machine and have clients use it from other machines (assuming that the firewalls involved allow it).
Running the following commands creates a server for a single shared queue which remote clients can access:

```python
>>> from multiprocessing.managers import BaseManager
>>> import queue
>>> queue = queue.Queue()
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue', callable=lambda: queue)
>>> m = QueueManager(address=(' ', 50000), authkey=b'abracadabra')
>>> s = m.get_server()
>>> s.serve_forever()
```

One client can access the server as follows:

```python
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000),)
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.put('hello')
```

Another client can also use it:

```python
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000),)
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.get()
'hello'
```

Local processes can also access that queue, using the code from
above on the client to access it remotely:

```python
>>> from multiprocessing import Process, Queue
>>> from multiprocessing.managers import BaseManager

class Worker(Process):
    ...
    def __init__(self, q):
        ...
        self.q = q
        ...
        super(Worker, self).__init__()
        ...
    def run(self):
        ...
        self.q.put('local hello')

>>> queue = Queue()
>>> w = Worker(queue)
>>> w.start()

```

```
>>> class QueueManager(BaseManager): pass
... >>>

>>> QueueManager.register('get_queue', callable=lambda: queue)
>>> m = QueueManager(address=('172.2.2.8', 50000), authkey=b'abracadabra')
>>> s = m.get_server()
>>> s.serve_forever()
```

17.2.2.8. Proxy Objects

A proxy is an object which refers to a shared object which lives (presumably) in a different process. The shared object is said to be the referent of the proxy. Multiple proxy objects may have the same referent.

A proxy object has methods which invoke corresponding methods of its referent (although not every method of the referent will necessarily be available through the proxy). In this way, a proxy can be used just like its referent can:

```python
>>> from multiprocessing import Manager
```
Notice that applying \texttt{str()} to a proxy will return the representation of the referent, whereas applying \texttt{repr()} will return the representation of the proxy.

An important feature of proxy objects is that they are picklable so they can be passed between processes. As such, a referent can contain \texttt{Proxy Objects}. This permits nesting of these managed lists, dicts, and other \texttt{Proxy Objects}:

Similarly, dict and list proxies may be nested inside one another:
If standard (non-proxy) `list` or `dict` objects are contained in a referent, modifications to those mutable values will not be propagated through the manager because the proxy has no way of knowing when the values contained within are modified. However, storing a value in a container proxy (which triggers a `__setitem__` on the proxy object) does propagate through the manager and so to effectively modify such an item, one could re-assign the modified value to the container proxy:

```python
# create a list proxy and append a mutable object (a dictionary)
lproxy = manager.list()
lproxy.append({})
# now mutate the dictionary
d = lproxy[0]
d['a'] = 1
d['b'] = 2
# at this point, the changes to d are not yet synced
# updating the dictionary, the proxy is notified of
lproxy[0] = d
```

This approach is perhaps less convenient than employing nested Proxy Objects for most use cases but also demonstrates a level of control over the synchronization.

**Note:** The proxy types in `multiprocessing` do nothing to support comparisons by value. So, for instance, we have:
class multiprocessing.managers.BaseProxy

Proxy objects are instances of subclasses of BaseProxy.

_callmethod(methodname[, args[, kwds]])

Call and return the result of a method of the proxy's referent.

If proxy is a proxy whose referent is obj then the expression

proxy._callmethod(methodname, args, kwds)

will evaluate the expression

ggetattr(obj, methodname)(*args, **kwds)

in the manager's process.

The returned value will be a copy of the result of the call or a
proxy to a new shared object — see documentation for the
method_to_typeid argument of BaseManager.register().

If an exception is raised by the call, then is re-raised by
_callmethod(). If some other exception is raised in the
manager's process then this is converted into a RemoteError
exception and is raised by _callmethod().

Note in particular that an exception will be raised if
methodname has not been exposed.
An example of the usage of \_callmethod()::

```python
>>> l = manager.list(range(10))
>>> l._callmethod('\_len\_')
10
>>> l._callmethod('\_getitem\_', (slice(2, 7),))
[2, 3, 4, 5, 6]
>>> l._callmethod('\_getitem\_', (20,))
Traceback (most recent call last):
...
IndexError: list index out of range
```

**_getvalue()**

Return a copy of the referent.

If the referent is unpicklable then this will raise an exception.

**_repr_()**

Return a representation of the proxy object.

**_str_()**

Return the representation of the referent.

17.2.2.8.1. Cleanup

A proxy object uses a weakref callback so that when it gets garbage collected it deregisters itself from the manager which owns its referent.

A shared object gets deleted from the manager process when there are no longer any proxies referring to it.

17.2.2.9. Process Pools
One can create a pool of processes which will carry out tasks submitted to it with the `Pool` class.

```python
class multiprocessing.pool.Pool([processes[, initializer[, initargs[, maxtasksperchild[, context]]]]])
```

A process pool object which controls a pool of worker processes to which jobs can be submitted. It supports asynchronous results with timeouts and callbacks and has a parallel map implementation.

`processes` is the number of worker processes to use. If `processes` is `None` then the number returned by `os.cpu_count()` is used.

If `initializer` is not `None` then each worker process will call `initializer(*initargs)` when it starts.

`maxtasksperchild` is the number of tasks a worker process can complete before it will exit and be replaced with a fresh worker process, to enable unused resources to be freed. The default `maxtasksperchild` is `None`, which means worker processes will live as long as the pool.

`context` can be used to specify the context used for starting the worker processes. Usually a pool is created using the function `multiprocessing.Pool()` or the `Pool()` method of a context object. In both cases `context` is set appropriately.

Note that the methods of the pool object should only be called by the process which created the pool.

*New in version 3.2:* `maxtasksperchild`

*New in version 3.4:* `context`
**Note:** Worker processes within a Pool typically live for the complete duration of the Pool's work queue. A frequent pattern found in other systems (such as Apache, mod_wsgi, etc) to free resources held by workers is to allow a worker within a pool to complete only a set amount of work before being exiting, being cleaned up and a new process spawned to replace the old one. The `maxtasksperchild` argument to the Pool exposes this ability to the end user.

```python
apply(func[, args[, kwds]])
```

Call `func` with arguments `args` and keyword arguments `kwds`. It blocks until the result is ready. Given this blocks, `apply_async()` is better suited for performing work in parallel. Additionally, `func` is only executed in one of the workers of the pool.

```python
apply_async(func[, args[, kwds[, callback[, error_callback]]]]])
```

A variant of the `apply()` method which returns a result object.

If `callback` is specified then it should be a callable which accepts a single argument. When the result becomes ready `callback` is applied to it, that is unless the call failed, in which case the `error_callback` is applied instead.

If `error_callback` is specified then it should be a callable which accepts a single argument. If the target function fails, then the `error_callback` is called with the exception instance.

Callbacks should complete immediately since otherwise the thread which handles the results will get blocked.

```python
map(func, iterable[, chunksize])
```
A parallel equivalent of the \texttt{map()} built-in function (it supports only one \textit{iterable} argument though). It blocks until the result is ready.

This method chops the iterable into a number of chunks which it submits to the process pool as separate tasks. The (approximate) size of these chunks can be specified by setting \texttt{chunksize} to a positive integer.

\begin{verbatim}
map_async(func, iterable[, chunksize[, callback[, error_callback]]]])
\end{verbatim}

A variant of the \texttt{map()} method which returns a result object.

If \texttt{callback} is specified then it should be a callable which accepts a single argument. When the result becomes ready \texttt{callback} is applied to it, that is unless the call failed, in which case the \texttt{error_callback} is applied instead.

If \texttt{error_callback} is specified then it should be a callable which accepts a single argument. If the target function fails, then the \texttt{error_callback} is called with the exception instance.

Callbacks should complete immediately since otherwise the thread which handles the results will get blocked.

\begin{verbatim}
imap(func, iterable[, chunksize])
\end{verbatim}

A lazier version of \texttt{map()}. The \texttt{chunksize} argument is the same as the one used by the \texttt{map()} method. For very long iterables using a large value for \texttt{chunksize} can make the job complete \textbf{much} faster than using the default value of 1.
Also if `chunksize` is 1 then the `next()` method of the iterator returned by the `imap()` method has an optional `timeout` parameter: `next(timeout)` will raise `multiprocessing.TimeoutError` if the result cannot be returned within `timeout` seconds.

`imap_unordered(func, iterable[, chunksize])`

The same as `imap()` except that the ordering of the results from the returned iterator should be considered arbitrary. (Only when there is only one worker process is the order guaranteed to be “correct”.)

`starmap(func, iterable[, chunksize])`

Like `map()` except that the elements of the `iterable` are expected to be iterables that are unpacked as arguments.

Hence an `iterable` of `[(1,2), (3,4)]` results in `[func(1,2), func(3,4)]`.

*New in version 3.3.*

`starmap_async(func, iterable[, chunksize[, callback[, error_back]]]])`

A combination of `starmap()` and `map_async()` that iterates over `iterable` of iterables and calls `func` with the iterables unpacked. Returns a result object.

*New in version 3.3.*

`close()`

Prevents any more tasks from being submitted to the pool. Once all the tasks have been completed the worker processes
will exit.

**terminate()**

Stops the worker processes immediately without completing outstanding work. When the pool object is garbage collected **terminate()** will be called immediately.

**join()**

Wait for the worker processes to exit. One must call **close()** or **terminate()** before using **join()**.

*New in version 3.3:* Pool objects now support the context management protocol – see **Context Manager Types**. **__enter__()** returns the pool object, and **__exit__()** calls **terminate()**.

**class multiprocessing.pool.AsyncResult**

The class of the result returned by **Pool.apply_async()** and **Pool.map_async()**.

**get([timeout])**

Return the result when it arrives. If **timeout** is not None and the result does not arrive within **timeout** seconds then **multiprocessing.TimeoutError** is raised. If the remote call raised an exception then that exception will be reraised by **get()**.

**wait([timeout])**

Wait until the result is available or until **timeout** seconds pass.

**ready()**

Return whether the call has completed.
successful()

Return whether the call completed without raising an exception. Will raise `AssertionError` if the result is not ready.

The following example demonstrates the use of a pool:

```python
from multiprocessing import Pool
import time

def f(x):
    return x**x

if __name__ == '__main__':
    with Pool(processes=4) as pool:
        result = pool.apply_async(f, (10,))  # evaluate "f(10)" asynchronously in a single process
        print(result.get(timeout=1))  # prints "100" unless your computer is *very* slow

        print(pool.map(f, range(10)))  # prints 
[0, 1, 4, ..., 81]

        it = pool.imap(f, range(10))
        print(next(it))  # prints
        print(next(it))  # prints
        print(it.next(timeout=1))  # prints

        result = pool.apply_async(time.sleep, (10,))
        print(result.get(timeout=1))  # raises
```

17.2.2.10. Listeners and Clients

Usually message passing between processes is done using queues or by using `Connection` objects returned by `Pipe()`.

However, the `multiprocessing.connection` module allows some extra flexibility. It basically gives a high level message oriented API for
dealing with sockets or Windows named pipes. It also has support for *digest authentication* using the `hmac` module, and for polling multiple connections at the same time.

```python
multiprocessing.connection.deliver_challenge(connection, authkey)
```

Send a randomly generated message to the other end of the connection and wait for a reply.

If the reply matches the digest of the message using `authkey` as the key then a welcome message is sent to the other end of the connection. Otherwise `AuthenticationError` is raised.

```python
multiprocessing.connection.answer_challenge(connection, authkey)
```

Receive a message, calculate the digest of the message using `authkey` as the key, and then send the digest back.

If a welcome message is not received, then `AuthenticationError` is raised.

```python
multiprocessing.connection.Client(address[, family[, authenticate[, authkey]]]])
```

Attempt to set up a connection to the listener which is using address `address`, returning a `Connection`.

The type of the connection is determined by `family` argument, but this can generally be omitted since it can usually be inferred from the format of `address`. (See Address Formats)

If `authenticate` is `True` or `authkey` is a byte string then digest authentication is used. The key used for authentication will be either `authkey` or `current_process().authkey` if `authkey` is
None. If authentication fails then `AuthenticationError` is raised. See `Authentication keys`.

class multiprocessing.connection.Listener([address[, family[, backlog[, authenticate[, authkey]]]]])

A wrapper for a bound socket or Windows named pipe which is 'listening' for connections.

`address` is the address to be used by the bound socket or named pipe of the listener object.

**Note:** If an address of '0.0.0.0' is used, the address will not be a connectable end point on Windows. If you require a connectable end-point, you should use '127.0.0.1'.

`family` is the type of socket (or named pipe) to use. This can be one of the strings 'AF_INET' (for a TCP socket), 'AF_UNIX' (for a Unix domain socket) or 'AF_PIPE' (for a Windows named pipe). Of these only the first is guaranteed to be available. If `family` is None then the family is inferred from the format of `address`. If `address` is also None then a default is chosen. This default is the family which is assumed to be the fastest available. See `Address Formats`. Note that if `family` is 'AF_UNIX' and `address` is None then the socket will be created in a private temporary directory created using `tempfile.mkstemp()`.

If the listener object uses a socket then `backlog` (1 by default) is passed to the `listen()` method of the socket once it has been bound.

If `authenticate` is `True` (`False` by default) or `authkey` is not None then digest authentication is used.
If *authkey* is a byte string then it will be used as the authentication key; otherwise it must be None.

If *authkey* is None and *authenticate* is True then `current_process().authkey` is used as the authentication key. If *authkey* is None and *authenticate* is False then no authentication is done. If authentication fails then *AuthenticationError* is raised. See *Authentication keys*.

**accept()**

Accept a connection on the bound socket or named pipe of the listener object and return a *Connection* object. If authentication is attempted and fails, then *AuthenticationError* is raised.

**close()**

Close the bound socket or named pipe of the listener object. This is called automatically when the listener is garbage collected. However it is advisable to call it explicitly.

Listener objects have the following read-only properties:

**address**

The address which is being used by the Listener object.

**last_accepted**

The address from which the last accepted connection came. If this is unavailable then it is None.

*New in version 3.3:* Listener objects now support the context management protocol – see *Context Manager Types.* `__enter__()` returns the listener object, and `__exit__()` calls `close()`.
multiprocessing.connection.\texttt{wait}(object\_list, \texttt{timeout}=\texttt{None})

Wait till an object in \texttt{object\_list} is ready. Returns the list of those objects in \texttt{object\_list} which are ready. If \texttt{timeout} is a float then the call blocks for at most that many seconds. If \texttt{timeout} is \texttt{None} then it will block for an unlimited period. A negative timeout is equivalent to a zero timeout.

For both Unix and Windows, an object can appear in \texttt{object\_list} if it is

- a readable \texttt{Connection} object;
- a connected and readable \texttt{socket.socket} object; or
- the \texttt{sentinel} attribute of a \texttt{Process} object.

A connection or socket object is ready when there is data available to be read from it, or the other end has been closed.

**Unix:** \texttt{wait(object\_list, \texttt{timeout})} almost equivalent \texttt{select.select(object\_list, [], [], \texttt{timeout})}. The difference is that, if \texttt{select.select()} is interrupted by a signal, it can raise \texttt{OSError} with an error number of \texttt{EINTR}, whereas \texttt{wait()} will not.

**Windows:** An item in \texttt{object\_list} must either be an integer handle which is waitable (according to the definition used by the documentation of the Win32 function \texttt{WaitForMultipleObjects()}) or it can be an object with a \texttt{fileno()} method which returns a socket handle or pipe handle. (Note that pipe handles and socket handles are \texttt{not} waitable handles.)

\textit{New in version 3.3.}
Examples

The following server code creates a listener which uses 'secret password' as an authentication key. It then waits for a connection and sends some data to the client:

```python
from multiprocessing.connection import Listener
from array import array

address = ('localhost', 6000)  # family is deduced

with Listener(address, authkey=b'secret password') as listener:
    with listener.accept() as conn:
        print('connection accepted from', listener.last_accepted)
        conn.send([2.25, None, 'junk', float])
        conn.send_bytes(b'hello')
        conn.send_bytes(array('i', [42, 1729]))
```

The following code connects to the server and receives some data from the server:

```python
from multiprocessing.connection import Client
from array import array

address = ('localhost', 6000)

with Client(address, authkey=b'secret password') as conn:
    print(conn.recv())  # => [2.25,
    print(conn.recv_bytes())  # => 'hello'

arr = array('i', [0, 0, 0, 0, 0])
```
The following code uses `wait()` to wait for messages from multiple processes at once:

```python
import time, random
from multiprocessing import Process, Pipe, current_process
from multiprocessing.connection import wait

def foo(w):
    for i in range(10):
        w.send(((i, current_process().name))
    w.close()

if __name__ == '__main__':
    readers = []

    for i in range(4):
        r, w = Pipe(duplex=False)
        readers.append(r)
        p = Process(target=foo, args=(w,))
        p.start()
        # We close the writable end of the pipe now
        # p is the only process which owns a handle
        # ensures that when p closes its handle for
        # wait() will promptly report the readable end
        w.close()

    while readers:
        for r in wait(readers):
            try:
                msg = r.recv()
            except EOFError:
                readers.remove(r)
            else:
```

```python
```
17.2.2.10.1. Address Formats

- An 'AF_INET' address is a tuple of the form (hostname, port) where hostname is a string and port is an integer.
- An 'AF_UNIX' address is a string representing a filename on the filesystem.
- An 'AF_PIPE' address is a string of the form r'\.pipe\PipeName'. To use Client() to connect to a named pipe on a remote computer called ServerName one should use an address of the form r'\\ServerName\pipe\PipeName' instead.

Note that any string beginning with two backslashes is assumed by default to be an 'AF_PIPE' address rather than an 'AF_UNIX' address.

17.2.2.11. Authentication keys

When one uses Connection.recv, the data received is automatically unpickled. Unfortunately unpickling data from an untrusted source is a security risk. Therefore Listener and Client() use the hmac module to provide digest authentication.

An authentication key is a byte string which can be thought of as a password: once a connection is established both ends will demand proof that the other knows the authentication key. (Demonstrating that both ends are using the same key does not involve sending the key over the connection.)

If authentication is requested but no authentication key is specified
then the return value of `current_process().authkey` is used (see `Process`). This value will be automatically inherited by any `Process` object that the current process creates. This means that (by default) all processes of a multi-process program will share a single authentication key which can be used when setting up connections between themselves.

Suitable authentication keys can also be generated by using `os.urandom()`.

### 17.2.2.12. Logging

Some support for logging is available. Note, however, that the `logging` package does not use process shared locks so it is possible (depending on the handler type) for messages from different processes to get mixed up.

**multiprocessing.get_logger()**

Returns the logger used by `multiprocessing`. If necessary, a new one will be created.

When first created the logger has level `logging.NOTSET` and no default handler. Messages sent to this logger will not by default propagate to the root logger.

Note that on Windows child processes will only inherit the level of the parent process’s logger – any other customization of the logger will not be inherited.

**multiprocessing.log_to_stderr()**

This function performs a call to `get_logger()` but in addition to returning the logger created by `get_logger`, it adds a handler which
sends output to \texttt{sys.stderr} using format '(%(levelname)s/\%(processName)s) %(message)s'.

Below is an example session with logging turned on:

```python
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
>>> logger.setLevel(logging.INFO)
>>> logger.warning('doomed')
[WARNING/MainProcess] doomed
>>> m = multiprocessing.Manager()
[INFO/SyncManager-....] child process calling self.run()
[INFO/SyncManager-....] created temp directory /.../pymp-...
[INFO/SyncManager-....] manager serving at '/.../listener-...' 
>>> del m
[INFO/MainProcess] sending shutdown message to manager
[INFO/SyncManager-....] manager exiting with exitcode
```

For a full table of logging levels, see the \texttt{logging} module.

17.2.2.13. The \texttt{multiprocessing.dummy} module

\texttt{multiprocessing.dummy} replicates the API of \texttt{multiprocessing} but is no more than a wrapper around the \texttt{threading} module.
17.2.3. Programming guidelines

There are certain guidelines and idioms which should be adhered to when using multiprocessing.

17.2.3.1. All start methods

The following applies to all start methods.

Avoid shared state

As far as possible one should try to avoid shifting large amounts of data between processes.

It is probably best to stick to using queues or pipes for communication between processes rather than using the lower level synchronization primitives.

Picklability

Ensure that the arguments to the methods of proxies are picklable.

Thread safety of proxies

Do not use a proxy object from more than one thread unless you protect it with a lock.

(There is never a problem with different processes using the same proxy.)

Joining zombie processes

On Unix when a process finishes but has not been joined it
becomes a zombie. There should never be very many because each time a new process starts (or `active_children()` is called) all completed processes which have not yet been joined will be joined. Also calling a finished process’s `Process.is_alive` will join the process. Even so it is probably good practice to explicitly join all the processes that you start.

Better to inherit than pickle/unpickle

When using the `spawn` or `forkserver` start methods many types from `multiprocessing` need to be picklable so that child processes can use them. However, one should generally avoid sending shared objects to other processes using pipes or queues. Instead you should arrange the program so that a process which needs access to a shared resource created elsewhere can inherit it from an ancestor process.

Avoid terminating processes

Using the `Process.terminate` method to stop a process is liable to cause any shared resources (such as locks, semaphores, pipes and queues) currently being used by the process to become broken or unavailable to other processes.

Therefore it is probably best to only consider using `Process.terminate` on processes which never use any shared resources.

Joining processes that use queues

Bear in mind that a process that has put items in a queue will wait before terminating until all the buffered items are fed by the “feeder” thread to the underlying pipe. (The child process can call the `Queue.cancel_join_thread` method of the queue to
avoid this behaviour.)

This means that whenever you use a queue you need to make sure that all items which have been put on the queue will eventually be removed before the process is joined. Otherwise you cannot be sure that processes which have put items on the queue will terminate. Remember also that non-daemonic processes will be joined automatically.

An example which will deadlock is the following:

```python
from multiprocessing import Process, Queue

def f(q):
    q.put('X' * 1000000)

if __name__ == '__main__':
    queue = Queue()
    p = Process(target=f, args=(queue,))
    p.start()
    p.join()  # this deadlocks
    obj = queue.get()
```

A fix here would be to swap the last two lines (or simply remove the `p.join()` line).

Explicitly pass resources to child processes

On Unix using the `fork` start method, a child process can make use of a shared resource created in a parent process using a global resource. However, it is better to pass the object as an argument to the constructor for the child process.

Apart from making the code (potentially) compatible with Windows
and the other start methods this also ensures that as long as the child process is still alive the object will not be garbage collected in the parent process. This might be important if some resource is freed when the object is garbage collected in the parent process.

So for instance

```python
from multiprocessing import Process, Lock

def f():
    ... do something using "lock" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f).start()
```

should be rewritten as

```python
from multiprocessing import Process, Lock

def f(l):
    ... do something using "l" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f, args=(lock,)).start()
```

Beware of replacing `sys.stdin` with a “file like object”

```python
multiprocessing originally unconditionally called:

os.close(sys.stdin.fileno())
```
in the `multiprocessing.Process._bootstrap()` method — this resulted in issues with processes-in-processes. This has been changed to:

```python
sys.stdin.close()
sys.stdin = open(os.open(os.devnull, os.O_RDONLY),
```

Which solves the fundamental issue of processes colliding with each other resulting in a bad file descriptor error, but introduces a potential danger to applications which replace `sys.stdin()` with a “file-like object” with output buffering. This danger is that if multiple processes call `close()` on this file-like object, it could result in the same data being flushed to the object multiple times, resulting in corruption.

If you write a file-like object and implement your own caching, you can make it fork-safe by storing the pid whenever you append to the cache, and discarding the cache when the pid changes. For example:

```python
@property
def cache(self):
    pid = os.getpid()
    if pid != self._pid:
        self._pid = pid
        self._cache = []
    return self._cache
```

For more information, see `bpo-5155`, `bpo-5313` and `bpo-5331`

17.2.3.2. The `spawn` and `forkserver` start methods

There are a few extra restriction which don’t apply to the `fork` start
method.

More picklability

Ensure that all arguments to `Process.__init__()` are picklable. Also, if you subclass `Process` then make sure that instances will be picklable when the `Process.start` method is called.

Global variables

Bear in mind that if code run in a child process tries to access a global variable, then the value it sees (if any) may not be the same as the value in the parent process at the time that `Process.start` was called.

However, global variables which are just module level constants cause no problems.

Safe importing of main module

Make sure that the main module can be safely imported by a new Python interpreter without causing unintended side effects (such as starting a new process).

For example, using the `spawn` or `forkserver` start method running the following module would fail with a `RuntimeError`:

```python
from multiprocessing import Process

def foo():
    print('hello')

p = Process(target=foo)
p.start()
```
Instead one should protect the “entry point” of the program by using `if __name__ == '__main__':` as follows:

```python
from multiprocessing import Process, freeze_support

def foo():
    print('hello')

if __name__ == '__main__':
    freeze_support()
    set_start_method('spawn')
    p = Process(target=foo)
    p.start()

(The `freeze_support()` line can be omitted if the program will be run normally instead of frozen.)

This allows the newly spawned Python interpreter to safely import the module and then run the module’s `foo()` function.

Similar restrictions apply if a pool or manager is created in the main module.
Demonstration of how to create and use customized managers and proxies:

```python
from multiprocessing import freeze_support
from multiprocessing.managers import BaseManager, BaseProxy
import operator

##

class Foo:
    def f(self):
        print('you called Foo.f()')
    def g(self):
        print('you called Foo.g()')
    def _h(self):
        print('you called Foo._h()')

# A simple generator function
def baz():
    for i in range(10):
        yield i*i

# Proxy type for generator objects
class GeneratorProxy(BaseProxy):
    _exposed_ = ['__next__']
    def __iter__(self):
        return self
    def __next__(self):
        return self._callmethod('__next__')

# Function to return the operator module
def get_operator_module():
    return operator
```
```python
##

class MyManager(BaseManager):
    pass

# register the Foo class; make `f()` and `g()` accessible via proxy
MyManager.register('Foo1', Foo)

# register the Foo class; make `g()` and `_h()` accessible via proxy
MyManager.register('Foo2', Foo, exposed=('g', '_h'))

# register the generator function baz; use `GeneratorProxy` to make proxies
MyManager.register('baz', baz, proxytype=GeneratorProxy)

# register get_operator_module(); make public functions accessible via proxy
MyManager.register('operator', get_operator_module)

##

def test():
    manager = MyManager()
    manager.start()

    print('-' * 20)

    f1 = manager.Foo1()
    f1.f()
    f1.g()
    assert not hasattr(f1, '_h')
    assert sorted(f1._exposed_) == sorted(['f', 'g'])

    print('-' * 20)

    f2 = manager.Foo2()
    f2.g()
    f2._h()
```
assert not hasattr(f2, 'f')
assert sorted(f2._exposed_) == sorted(['g', '_h'])

print('-' * 20)

it = manager.baz()
for i in it:
    print('<%d>' % i, end=' ')  
print()

print('-' * 20)

op = manager.operator()
print('op.add(23, 45) =', op.add(23, 45))
print('op.pow(2, 94) =', op.pow(2, 94))
print('op._exposed_ =', op._exposed_)

17.3. The concurrent package

Currently, there is only one module in this package:

- **concurrent.futures** – Launching parallel tasks
17.4. concurrent.futures — Launching parallel tasks

New in version 3.2.

Source code: Lib/concurrent/futures/thread.py and Lib/concurrent/futures/process.py

The concurrent.futures module provides a high-level interface for asynchronously executing callables.

The asynchronous execution can be performed with threads, using ThreadPoolExecutor, or separate processes, using ProcessPoolExecutor. Both implement the same interface, which is defined by the abstract Executor class.
17.4.1. Executor Objects

class concurrent.futures.Executor

An abstract class that provides methods to execute calls asynchronously. It should not be used directly, but through its concrete subclasses.

submit(fn, *args, **kwargs)

Schedules the callable, fn, to be executed as `fn(*args, **kwargs)` and returns a Future object representing the execution of the callable.

```python
with ThreadPoolExecutor(max_workers=1) as executor:
    future = executor.submit(pow, 323, 1235)
    print(future.result())
```

map(func, *iterables, timeout=None, chunksize=1)

Equivalent to `map(func, *iterables)` except `func` is executed asynchronously and several calls to `func` may be made concurrently. The returned iterator raises a concurrent.futures.TimeoutError if `__next__()` is called and the result isn’t available after `timeout` seconds from the original call to `Executor.map()`. `timeout` can be an int or a float. If `timeout` is not specified or `None`, there is no limit to the wait time. If a call raises an exception, then that exception will be raised when its value is retrieved from the iterator. When using `ProcessPoolExecutor`, this method chops `iterables` into a number of chunks which it submits to the pool as separate tasks. The (approximate) size of these chunks can be specified by setting `chunksize`
to a positive integer. For very long iterables, using a large value for `chunksize` can significantly improve performance compared to the default size of 1. With `ThreadPoolExecutor`, `chunksize` has no effect.

Changed in version 3.5: Added the `chunksize` argument.

`shutdown(wait=True)`

Signal the executor that it should free any resources that it is using when the currently pending futures are done executing. Calls to `Executor.submit()` and `Executor.map()` made after shutdown will raise `RuntimeError`.

If `wait` is `True` then this method will not return until all the pending futures are done executing and the resources associated with the executor have been freed. If `wait` is `False` then this method will return immediately and the resources associated with the executor will be freed when all pending futures are done executing. Regardless of the value of `wait`, the entire Python program will not exit until all pending futures are done executing.

You can avoid having to call this method explicitly if you use the `with` statement, which will shutdown the `Executor` (waiting as if `Executor.shutdown()` were called with `wait` set to `True`):

```python
import shutil
with ThreadPoolExecutor(max_workers=4) as e:
    e.submit(shutil.copy, 'src1.txt', 'dest1.txt')
    e.submit(shutil.copy, 'src2.txt', 'dest2.txt')
    e.submit(shutil.copy, 'src3.txt', 'dest3.txt')
```
e.submit(shutil.copy, 'src4.txt', 'dest4.txt')
17.4.2. ThreadPoolExecutor

ThreadPoolExecutor is an Executor subclass that uses a pool of threads to execute calls asynchronously.

Deadlocks can occur when the callable associated with a Future waits on the results of another Future. For example:

```python
import time
def wait_on_b():
    time.sleep(5)
    print(b.result())  # b will never complete because...
    return 5
def wait_on_a():
    time.sleep(5)
    print(a.result())  # a will never complete because...
    return 6

executor = ThreadPoolExecutor(max_workers=2)
a = executor.submit(wait_on_b)
b = executor.submit(wait_on_a)
```

And:

```python
def wait_on_future():
    f = executor.submit(pow, 5, 2)
    # This will never complete because there is only...
    # it is executing this function.
    print(f.result())

executor = ThreadPoolExecutor(max_workers=1)
executor.submit(wait_on_future)
```
class concurrent.futures.ThreadPoolExecutor(max_workers=None, thread_name_prefix='')

An Executor subclass that uses a pool of at most max_workers threads to execute calls asynchronously.

Changed in version 3.5: If max_workers is None or not given, it will default to the number of processors on the machine, multiplied by 5, assuming that ThreadPoolExecutor is often used to overlap I/O instead of CPU work and the number of workers should be higher than the number of workers for ProcessPoolExecutor.

New in version 3.6: The thread_name_prefix argument was added to allow users to control the threading.Thread names for worker threads created by the pool for easier debugging.

17.4.2.1. ThreadPoolExecutor Example

```python
import concurrent.futures
import urllib.request

URLS = ['http://www.foxnews.com/',
        'http://www.cnn.com/',
        'http://europe.wsj.com/',
        'http://www.bbc.co.uk/',
        'http://some-made-up-domain.com/']

# Retrieve a single page and report the URL and content
def load_url(url, timeout):
    with urllib.request.urlopen(url, timeout=timeout):
        return conn.read()

# We can use a with statement to ensure threads are
```
with concurrent.futures.ThreadPoolExecutor(max_workers=max_workers):
    # Start the load operations and mark each future
    future_to_url = {executor.submit(load_url, url, url)
        for future in concurrent.futures.as_completed(future_to_url)
    url = future_to_url[future]
    try:
        data = future.result()
    except Exception as exc:
        print('%r generated an exception: %s' % (url, exc))
    else:
        print('%r page is %d bytes' % (url, len(data)))
17.4.3. ProcessPoolExecutor

The `ProcessPoolExecutor` class is an `Executor` subclass that uses a pool of processes to execute calls asynchronously. `ProcessPoolExecutor` uses the `multiprocessing` module, which allows it to side-step the `Global Interpreter Lock` but also means that only picklable objects can be executed and returned.

The `__main__` module must be importable by worker subprocesses. This means that `ProcessPoolExecutor` will not work in the interactive interpreter.

Calling `Executor` or `Future` methods from a callable submitted to a `ProcessPoolExecutor` will result in deadlock.

```python
class concurrent.futures.ProcessPoolExecutor(max_workers=
    An `Executor` subclass that executes calls asynchronously using a pool of at most `max_workers` processes. If `max_workers` is `None` or not given, it will default to the number of processors on the machine. If `max_workers` is lower or equal to 0, then a `ValueError` will be raised.

*Changed in version 3.3:* When one of the worker processes terminates abruptly, a `BrokenProcessPool` error is now raised. Previously, behaviour was undefined but operations on the executor or its futures would often freeze or deadlock.

17.4.3.1. ProcessPoolExecutor Example

```
import math

PRIMES = [
    112272535095293,
    112582705942171,
    112272535095293,
    115280095190773,
    115797848077099,
    1099726899285419
]

def is_prime(n):
    if n % 2 == 0:
        return False

    sqrt_n = int(math.floor(math.sqrt(n)))
    for i in range(3, sqrt_n + 1, 2):
        if n % i == 0:
            return False
    return True

def main():
    with concurrent.futures.ProcessPoolExecutor() as executor:
        for number, prime in zip(PRIMES, executor.map(is_prime, PRIMES)):
            print(f'{number} is prime: {prime}

if __name__ == '__main__':
    main()
17.4.4. Future Objects

The `Future` class encapsulates the asynchronous execution of a callable. `Future` instances are created by `Executor.submit()`.

```python
class concurrent.futures.Future
    Encapsulates the asynchronous execution of a callable. `Future` instances are created by `Executor.submit()` and should not be created directly except for testing.
```

- **cancel()**
  Attempt to cancel the call. If the call is currently being executed and cannot be cancelled then the method will return `False`, otherwise the call will be cancelled and the method will return `True`.

- **cancelled()**
  Return `True` if the call was successfully cancelled.

- **running()**
  Return `True` if the call is currently being executed and cannot be cancelled.

- **done()**
  Return `True` if the call was successfully cancelled or finished running.

- **result**(timeout=None)
  Return the value returned by the call. If the call hasn't yet completed then this method will wait up to `timeout` seconds. If the call hasn't completed in `timeout` seconds,
then a `concurrent.futures.TimeoutError` will be raised. `timeout` can be an int or float. If `timeout` is not specified or `None`, there is no limit to the wait time.

If the future is cancelled before completing then `CancelledError` will be raised.

If the call raised, this method will raise the same exception.

`exception(timeout=None)`

Return the exception raised by the call. If the call hasn’t yet completed then this method will wait up to `timeout` seconds. If the call hasn’t completed in `timeout` seconds, then a `concurrent.futures.TimeoutError` will be raised. `timeout` can be an int or float. If `timeout` is not specified or `None`, there is no limit to the wait time.

If the future is cancelled before completing then `CancelledError` will be raised.

If the call completed without raising, `None` is returned.

`add_done_callback(fn)`

Attaches the callable `fn` to the future. `fn` will be called, with the future as its only argument, when the future is cancelled or finishes running.

Added callables are called in the order that they were added and are always called in a thread belonging to the process that added them. If the callable raises an `Exception` subclass, it will be logged and ignored. If the callable raises a `BaseException` subclass, the behavior is undefined.
If the future has already completed or been cancelled, \( fn \) will be called immediately.

The following \texttt{Future} methods are meant for use in unit tests and \texttt{Executor} implementations.

\textbf{set\_running\_or\_notify\_cancel()}

This method should only be called by \texttt{Executor} implementations before executing the work associated with the \texttt{Future} and by unit tests.

If the method returns \texttt{False} then the \texttt{Future} was cancelled, i.e. \texttt{Future.cancel()} was called and returned \texttt{True}. Any threads waiting on the \texttt{Future} completing (i.e. through \texttt{as\_completed()} or \texttt{wait()}) will be woken up.

If the method returns \texttt{True} then the \texttt{Future} was not cancelled and has been put in the running state, i.e. calls to \texttt{Future.running()} will return \texttt{True}.

This method can only be called once and cannot be called after \texttt{Future.set\_result()} or \texttt{Future.set\_exception()} have been called.

\textbf{set\_result(result)}

Sets the result of the work associated with the \texttt{Future} to \texttt{result}.

This method should only be used by \texttt{Executor} implementations and unit tests.

\textbf{set\_exception(exception)}
Sets the result of the work associated with the `Future` to the `Exception` exception.

This method should only be used by `Executor` implementations and unit tests.
17.4.5. Module Functions

concurrent.futures.\texttt{wait}(fs, timeout=None, 
\texttt{return\_when=ALL\_COMPLETED})

Wait for the \texttt{Future} instances (possibly created by different \texttt{Executor} instances) given by \texttt{fs} to complete. Returns a named 2-tuple of sets. The first set, named \texttt{done}, contains the futures that completed (finished or were cancelled) before the wait completed. The second set, named \texttt{not\_done}, contains uncompleted futures.

\texttt{timeout} can be used to control the maximum number of seconds to wait before returning. \texttt{timeout} can be an int or float. If \texttt{timeout} is not specified or \texttt{None}, there is no limit to the wait time.

\texttt{return\_when} indicates when this function should return. It must be one of the following constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIRST_COMPLETED</td>
<td>The function will return when any future finishes or is cancelled.</td>
</tr>
<tr>
<td>FIRST_EXCEPTION</td>
<td>The function will return when any future finishes by raising an exception. If no future raises an exception then it is equivalent to ALL_COMPLETED.</td>
</tr>
<tr>
<td>ALL_COMPLETED</td>
<td>The function will return when all futures finish or are cancelled.</td>
</tr>
</tbody>
</table>

concurrent.futures.\texttt{as\_completed}(fs, timeout=None)

Returns an iterator over the \texttt{Future} instances (possibly created by different \texttt{Executor} instances) given by \texttt{fs} that yields futures as
they complete (finished or were cancelled). Any futures given by fs that are duplicated will be returned once. Any futures that completed before \texttt{as\_completed()} is called will be yielded first. The returned iterator raises a \texttt{concurrent.futures.TimeoutError} if \texttt{\_next\_()} is called and the result isn’t available after \texttt{timeout} seconds from the original call to \texttt{as\_completed()}. \texttt{timeout} can be an int or float. If \texttt{timeout} is not specified or \texttt{None}, there is no limit to the wait time.

  \item See also:
  \begin{itemize}
    \item \textbf{PEP 3148} – \texttt{futures} - \texttt{execute computations asynchronously}
  \end{itemize}
\end{itemize}
17.4.6. Exception classes

```python
exception concurrent.futures.CancelledError

Raised when a future is cancelled.
```

```python
exception concurrent.futures.TimeoutError

Raised when a future operation exceeds the given timeout.
```

```python
exception concurrent.futures.process.BrokenProcessPool

Derived from RuntimeError, this exception class is raised when one of the workers of a ProcessPoolExecutor has terminated in a non-clean fashion (for example, if it was killed from the outside).
```

*New in version 3.3.*
The `subprocess` module allows you to spawn new processes, connect to their input/output/error pipes, and obtain their return codes. This module intends to replace several older modules and functions:

```python
os.system
os.spawn*
```

Information about how the `subprocess` module can be used to replace these modules and functions can be found in the following sections.

**See also:** [PEP 324](https://www.python.org/dev/peps/pep-0324/) – PEP proposing the subprocess module
17.5.1. Using the subprocess Module

The recommended approach to invoking subprocesses is to use the \texttt{run()} function for all use cases it can handle. For more advanced use cases, the underlying \texttt{Popen} interface can be used directly.

The \texttt{run()} function was added in Python 3.5; if you need to retain compatibility with older versions, see the Older high-level API section.

\begin{verbatim}
subprocess.run(args, *, stdin=None, input=None, stdout=None, stderr=None, shell=False, cwd=None, timeout=None, check=False, encoding=None, errors=None)
\end{verbatim}

Run the command described by \texttt{args}. Wait for command to complete, then return a \texttt{CompletedProcess} instance.

The arguments shown above are merely the most common ones, described below in Frequently Used Arguments (hence the use of keyword-only notation in the abbreviated signature). The full function signature is largely the same as that of the \texttt{Popen} constructor - apart from \texttt{timeout}, \texttt{input} and \texttt{check}, all the arguments to this function are passed through to that interface.

This does not capture stdout or stderr by default. To do so, pass \texttt{PIPE} for the \texttt{stdout} and/or \texttt{stderr} arguments.

The \texttt{timeout} argument is passed to \texttt{Popen.communicate()}. If the timeout expires, the child process will be killed and waited for. The \texttt{TimeoutExpired} exception will be re-raised after the child process has terminated.

The \texttt{input} argument is passed to \texttt{Popen.communicate()} and thus to the subprocess's stdio. If used it must be a byte sequence,
or a string if `encoding` or `errors` is specified or `universal_newlines` is true. When used, the internal `Popen` object is automatically created with `stdin=PIPE`, and the `stdin` argument may not be used as well.

If `check` is true, and the process exits with a non-zero exit code, a `CalledProcessError` exception will be raised. Attributes of that exception hold the arguments, the exit code, and stdout and stderr if they were captured.

If `encoding` or `errors` are specified, or `universal_newlines` is true, file objects for stdin, stdout and stderr are opened in text mode using the specified `encoding` and `errors` or the `io.TextIOWrapper` default. Otherwise, file objects are opened in binary mode.

Examples:

```python
>>> subprocess.run(['ls', '-l'])  # doesn't capture output
CompletedProcess(args=['ls', '-l'], returncode=0)

>>> subprocess.run('exit 1', shell=True, check=True)  # raises CalledProcessError
Traceback (most recent call last):
  ...
subprocess.CalledProcessError: Command 'exit 1' returned non-zero exit status 1

>>> subprocess.run(['ls', '-l', '/dev/null'], stdout=subprocess.PIPE)
CompletedProcess(args=['ls', '-l', '/dev/null'], returncode=0, stdout=b'crw-rw-rw- 1 root root 1, 3 Jan 23 16:23 /dev/null')
```

*New in version 3.5.*

*Changed in version 3.6:* Added `encoding` and `errors` parameters
**class subprocess.CompletedProcess**

The return value from `run()`, representing a process that has finished.

**args**

The arguments used to launch the process. This may be a list or a string.

**returncode**

Exit status of the child process. Typically, an exit status of 0 indicates that it ran successfully.

A negative value `-N` indicates that the child was terminated by signal `N` (POSIX only).

**stdout**

Captured stdout from the child process. A bytes sequence, or a string if `run()` was called with an encoding or errors. `None` if stdout was not captured.

If you ran the process with `stderr=subprocess.STDOUT`, stdout and stderr will be combined in this attribute, and `stderr` will be `None`.

**stderr**

Captured stderr from the child process. A bytes sequence, or a string if `run()` was called with an encoding or errors. `None` if stderr was not captured.

**check_returncode()**

If `returncode` is non-zero, raise a `CalledProcessError`.

*New in version 3.5.*
subprocess.DEVNULL

Special value that can be used as the stdin, stdout or stderr argument to Popen and indicates that the special file os.devnull will be used.

New in version 3.3.

subprocess.PIPE

Special value that can be used as the stdin, stdout or stderr argument to Popen and indicates that a pipe to the standard stream should be opened. Most useful with Popen.communicate().

subprocess.STDOUT

Special value that can be used as the stderr argument to Popen and indicates that standard error should go into the same handle as standard output.

exception subprocess.SubprocessError

Base class for all other exceptions from this module.

New in version 3.3.

exception subprocess.TimeoutExpired

Subclass of SubprocessError, raised when a timeout expires while waiting for a child process.

cmd

Command that was used to spawn the child process.

timeout

Timeout in seconds.
**output**
Output of the child process if it was captured by `run()` or `check_output()`. Otherwise, None.

**stdout**
Alias for output, for symmetry with `stderr`.

**stderr**
Stderr output of the child process if it was captured by `run()`. Otherwise, None.

*New in version 3.3.*

*Changed in version 3.5: stdout and stderr attributes added*

**exception** `subprocess.CalledProcessError`
Subclass of `SubprocessError`, raised when a process run by `check_call()` or `check_output()` returns a non-zero exit status.

**returncode**
Exit status of the child process. If the process exited due to a signal, this will be the negative signal number.

**cmd**
Command that was used to spawn the child process.

**output**
Output of the child process if it was captured by `run()` or `check_output()`. Otherwise, None.

**stdout**
Alias for output, for symmetry with `stderr`.
**stderr**

Stderr output of the child process if it was captured by `run()`.
Otherwise, None.

*Changed in version 3.5: stdout and stderr attributes added*

### 17.5.1.1. Frequently Used Arguments

To support a wide variety of use cases, the `Popen` constructor (and the convenience functions) accept a large number of optional arguments. For most typical use cases, many of these arguments can be safely left at their default values. The arguments that are most commonly needed are:

- **args** is required for all calls and should be a string, or a sequence of program arguments. Providing a sequence of arguments is generally preferred, as it allows the module to take care of any required escaping and quoting of arguments (e.g. to permit spaces in file names). If passing a single string, either `shell` must be `True` (see below) or else the string must simply name the program to be executed without specifying any arguments.

- **stdin**, **stdout** and **stderr** specify the executed program’s standard input, standard output and standard error file handles, respectively. Valid values are `PIPE`, `DEVNULL`, an existing file descriptor (a positive integer), an existing file object, and `None`. `PIPE` indicates that a new pipe to the child should be created. `DEVNULL` indicates that the special file `os.devnull` will be used. With the default settings of `None`, no redirection will occur; the child’s file handles will be inherited from the parent. Additionally, **stderr** can be `STDOUT`, which indicates that the stderr data from the child process should be captured into the same file handle as
for stdout.

If encoding or errors are specified, or universal_newlines is true, the file objects stdin, stdout and stderr will be opened in text mode using the encoding and errors specified in the call or the defaults for io.TextIOWrapper.

For stdin, line ending characters '\n' in the input will be converted to the default line separator os.linesep. For stdout and stderr, all line endings in the output will be converted to '\n'. For more information see the documentation of the io.TextIOWrapper class when the newline argument to its constructor is None.

If text mode is not used, stdin, stdout and stderr will be opened as binary streams. No encoding or line ending conversion is performed.

New in version 3.6: Added encoding and errors parameters.

Note: The newlines attribute of the file objects Popen.stdin, Popen.stdout and Popen.stderr are not updated by the Popen.communicate() method.

If shell is True, the specified command will be executed through the shell. This can be useful if you are using Python primarily for the enhanced control flow it offers over most system shells and still want convenient access to other shell features such as shell pipes, filename wildcards, environment variable expansion, and expansion of ~ to a user's home directory. However, note that Python itself offers implementations of many shell-like features (in particular, glob, fnmatch, os.walk),
Changed in version 3.3: When universal_newlines is True, the class uses the encoding locale.getpreferredencoding(False) instead of locale.getpreferredencoding(). See the io.TextIOWrapper class for more information on this change.

Note: Read the Security Considerations section before using shell=True.

These options, along with all of the other options, are described in more detail in the Popen constructor documentation.

17.5.1.2. Popen Constructor

The underlying process creation and management in this module is handled by the Popen class. It offers a lot of flexibility so that developers are able to handle the less common cases not covered by the convenience functions.

class subprocess.Popen(args, bufsize=-1, executable=None, stdin=None, stdout=None, stderr=None, preexec_fn=None, close_fds=True, shell=False, cwd=None, env=None, universal_newlines=False, startupinfo=None, creationflags=0, restore_signals=True, start_new_session=False, pass_fds=(), *, encoding=None, errors=None)

Execute a child program in a new process. On POSIX, the class uses os.execvp() -like behavior to execute the child program. On Windows, the class uses the Windows CreateProcess() function. The arguments to Popen are as follows.
args should be a sequence of program arguments or else a single string. By default, the program to execute is the first item in args if args is a sequence. If args is a string, the interpretation is platform-dependent and described below. See the shell and executable arguments for additional differences from the default behavior. Unless otherwise stated, it is recommended to pass args as a sequence.

On POSIX, if args is a string, the string is interpreted as the name or path of the program to execute. However, this can only be done if not passing arguments to the program.

Note: shlex.split() can be useful when determining the correct tokenization for args, especially in complex cases:

```python
>>> import shlex, subprocess
>>> command_line = input()
/bin/vikings -input eggs.txt -output "spam spam. >>> args = shlex.split(command_line) >>> print(args) ['/bin/vikings', '-input', 'eggs.txt', '-output' >>> p = subprocess.Popen(args) # Success!
```

Note in particular that options (such as -input) and arguments (such as eggs.txt) that are separated by whitespace in the shell go in separate list elements, while arguments that need quoting or backslash escaping when used in the shell (such as filenames containing spaces or the echo command shown above) are single list elements.

On Windows, if args is a sequence, it will be converted to a string in a manner described in Converting an argument sequence to a string on Windows. This is because the underlying
CreateProcess() operates on strings.

The shell argument (which defaults to False) specifies whether to use the shell as the program to execute. If shell is True, it is recommended to pass args as a string rather than as a sequence.

On POSIX with shell=True, the shell defaults to /bin/sh. If args is a string, the string specifies the command to execute through the shell. This means that the string must be formatted exactly as it would be when typed at the shell prompt. This includes, for example, quoting or backslash escaping filenames with spaces in them. If args is a sequence, the first item specifies the command string, and any additional items will be treated as additional arguments to the shell itself. That is to say, Popen does the equivalent of:

```
Popen(['/bin/sh', '-c', args[0], args[1], ...])
```

On Windows with shell=True, the COMSPEC environment variable specifies the default shell. The only time you need to specify shell=True on Windows is when the command you wish to execute is built into the shell (e.g. dir or copy). You do not need shell=True to run a batch file or console-based executable.

**Note:** Read the Security Considerations section before using shell=True.

bufsize will be supplied as the corresponding argument to the open() function when creating the stdin/stdout/stderr pipe file objects:

- 0 means unbuffered (read and write are one system call and can return short)
1 means line buffered (only usable if `universal_newlines=True` i.e., in a text mode) any other positive value means use a buffer of approximately that size negative bufsize (the default) means the system default of `io.DEFAULT_BUFFER_SIZE` will be used.

*Changed in version 3.3.1:* bufsize now defaults to -1 to enable buffering by default to match the behavior that most code expects. In versions prior to Python 3.2.4 and 3.3.1 it incorrectly defaulted to 0 which was unbuffered and allowed short reads. This was unintentional and did not match the behavior of Python 2 as most code expected.

The `executable` argument specifies a replacement program to execute. It is very seldom needed. When `shell=False`, `executable` replaces the program to execute specified by `args`. However, the original `args` is still passed to the program. Most programs treat the program specified by `args` as the command name, which can then be different from the program actually executed. On POSIX, the `args` name becomes the display name for the executable in utilities such as `ps`. If `shell=True`, on POSIX the `executable` argument specifies a replacement shell for the default `/bin/sh`.

`stdin`, `stdout` and `stderr` specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are `PIPE`, `DEVNULL`, an existing file descriptor (a positive integer), an existing file object, and `None`. `PIPE` indicates that a new pipe to the child should be created. `DEVNULL` indicates that the special file `os.devnull` will be used. With the default settings of `None`, no redirection will occur; the child's file handles will be inherited from the parent. Additionally, `stderr` can be
STDOUT, which indicates that the stderr data from the applications should be captured into the same file handle as for stdout.

If preexec_fn is set to a callable object, this object will be called in the child process just before the child is executed. (POSIX only)

**Warning:** The preexec_fn parameter is not safe to use in the presence of threads in your application. The child process could deadlock before exec is called. If you must use it, keep it trivial! Minimize the number of libraries you call into.

**Note:** If you need to modify the environment for the child use the env parameter rather than doing it in a preexec_fn. The start_new_session parameter can take the place of a previously common use of preexec_fn to call os.setsid() in the child.

If close_fds is true, all file descriptors except 0, 1 and 2 will be closed before the child process is executed. (POSIX only). The default varies by platform: Always true on POSIX. On Windows it is true when stdin/stdout/stderr are None, false otherwise. On Windows, if close_fds is true then no handles will be inherited by the child process. Note that on Windows, you cannot set close_fds to true and also redirect the standard handles by setting stdin, stdout or stderr.

*Changed in version 3.2:* The default for close_fds was changed from False to what is described above.

pass_fds is an optional sequence of file descriptors to keep open between the parent and child. Providing any pass_fds forces close_fds to be True. (POSIX only)

*New in version 3.2:* The pass_fds parameter was added.
If `cwd` is not `None`, the function changes the working directory to `cwd` before executing the child. `cwd` can be a `str` and `path-like` object. In particular, the function looks for `executable` (or for the first item in `args`) relative to `cwd` if the executable path is a relative path.

*Changed in version 3.6:* `cwd` parameter accepts a `path-like object`.

If `restore_signals` is true (the default) all signals that Python has set to SIG_IGN are restored to SIG_DFL in the child process before the exec. Currently this includes the SIGPIPE, SIGXFZ and SIGXFSZ signals. (POSIX only)

*Changed in version 3.2:* `restore_signals` was added.

If `start_new_session` is true the `setsid()` system call will be made in the child process prior to the execution of the subprocess. (POSIX only)

*Changed in version 3.2:* `start_new_session` was added.

If `env` is not `None`, it must be a mapping that defines the environment variables for the new process; these are used instead of the default behavior of inheriting the current process’ environment.

**Note:** If specified, `env` must provide any variables required for the program to execute. On Windows, in order to run a side-by-side assembly the specified `env` **must** include a valid `SystemRoot`.

If `encoding` or `errors` are specified, the file objects `stdin`, `stdout` and `stderr` are opened in text mode with the specified encoding and `errors`, as described above in `Frequently Used Arguments`. If
universal_newlines is True, they are opened in text mode with default encoding. Otherwise, they are opened as binary streams.

New in version 3.6: encoding and errors were added.

If given, startupinfo will be a STARTUPINFO object, which is passed to the underlying CreateProcess function. creationflags, if given, can be CREATE_NEW_CONSOLE or CREATE_NEW_PROCESS_GROUP. (Windows only)

Popen objects are supported as context managers via the with statement: on exit, standard file descriptors are closed, and the process is waited for for.

```python
with Popen(['ifconfig'], stdout=PIPE) as proc:
    log.write(proc.stdout.read())
```

Changed in version 3.2: Added context manager support.

Changed in version 3.6: Popen destructor now emits a ResourceWarning warning if the child process is still running.

17.5.1.3. Exceptions

Exceptions raised in the child process, before the new program has started to execute, will be re-raised in the parent. Additionally, the exception object will have one extra attribute called child_traceback, which is a string containing traceback information from the child’s point of view.

The most common exception raised is OSError. This occurs, for example, when trying to execute a non-existent file. Applications should prepare for OSError exceptions.
A `ValueError` will be raised if `Popen` is called with invalid arguments.

`check_call()` and `check_output()` will raise `CalledProcessError` if the called process returns a non-zero return code.

All of the functions and methods that accept a `timeout` parameter, such as `call()` and `Popen.communicate()` will raise `TimeoutExpired` if the timeout expires before the process exits.

Exceptions defined in this module all inherit from `SubprocessError`.

*New in version 3.3:* The `SubprocessError` base class was added.
17.5.2. Security Considerations

Unlike some other popen functions, this implementation will never implicitly call a system shell. This means that all characters, including shell metacharacters, can safely be passed to child processes. If the shell is invoked explicitly, via `shell=True`, it is the application’s responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid shell injection vulnerabilities.

When using `shell=True`, the `shlex.quote()` function can be used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.
17.5.3. Popen Objects

Instances of the Popen class have the following methods:

Popen. poll()
Check if child process has terminated. Set and return returncode attribute.

Popen. wait(timeout=None)
Wait for child process to terminate. Set and return returncode attribute.

If the process does not terminate after timeout seconds, raise a TimeoutExpired exception. It is safe to catch this exception and retry the wait.

Note: This will deadlock when using stdout=PIPE or stderr=PIPE and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use Popen.communicate() when using pipes to avoid that.

Note: The function is implemented using a busy loop (non-blocking call and short sleeps). Use the asyncio module for an asynchronous wait: see asyncio.create_subprocess_exec.

Changed in version 3.3: timeout was added.

Deprecated since version 3.4: Do not use the endtime parameter. It is was unintentionally exposed in 3.3 but was left undocumented as
it was intended to be private for internal use. Use `timeout` instead.

**Popen.communicate**(*input=None, timeout=None*)

Interact with process: Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate. The optional `input` argument should be data to be sent to the child process, or `None`, if no data should be sent to the child. If streams were opened in text mode, `input` must be a string. Otherwise, it must be bytes.

`communicate()` returns a tuple `(stdout_data, stderr_data)`. The data will be strings if streams were opened in text mode; otherwise, bytes.

Note that if you want to send data to the process’s stdin, you need to create the Popen object with `stdin=PIPE`. Similarly, to get anything other than `None` in the result tuple, you need to give `stdout=PIPE` and/or `stderr=PIPE` too.

If the process does not terminate after `timeout` seconds, a `TimeoutExpired` exception will be raised. Catching this exception and retrying communication will not lose any output.

The child process is not killed if the timeout expires, so in order to cleanup properly a well-behaved application should kill the child process and finish communication:

```python
proc = subprocess.Popen(...)  
try:  
    outs, errs = proc.communicate(timeout=15)  
except TimeoutExpired:  
    proc.kill()  
    outs, errs = proc.communicate()
```
**Note:** The data read is buffered in memory, so do not use this method if the data size is large or unlimited.

*Changed in version 3.3: timeout was added.*

**Popen**. `send_signal(signal)`

Sends the signal `signal` to the child.

**Note:** On Windows, SIGTERM is an alias for `terminate()`. CTRL_C_EVENT and CTRL_BREAK_EVENT can be sent to processes started with a `creationflags` parameter which includes `CREATE_NEW_PROCESS_GROUP`.

**Popen**. `terminate()`

Stop the child. On Posix OSs the method sends SIGTERM to the child. On Windows the Win32 API function `TerminateProcess()` is called to stop the child.

**Popen**. `kill()`

Kills the child. On Posix OSs the function sends SIGKILL to the child. On Windows `kill()` is an alias for `terminate()`.

The following attributes are also available:

**Popen**. `args`

The `args` argument as it was passed to **Popen** – a sequence of program arguments or else a single string.

*New in version 3.3.*

**Popen**. `stdin`

If the `stdin` argument was `PIPE`, this attribute is a writeable stream.
object as returned by `open()`. If the `encoding` or `errors` arguments were specified or the `universal_newlines` argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the `stdin` argument was not `PIPE`, this attribute is `None`.

**Popen. `stdout`**

If the `stdout` argument was `PIPE`, this attribute is a readable stream object as returned by `open()`. Reading from the stream provides output from the child process. If the `encoding` or `errors` arguments were specified or the `universal_newlines` argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the `stdout` argument was not `PIPE`, this attribute is `None`.

**Popen. `stderr`**

If the `stderr` argument was `PIPE`, this attribute is a readable stream object as returned by `open()`. Reading from the stream provides error output from the child process. If the `encoding` or `errors` arguments were specified or the `universal_newlines` argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the `stderr` argument was not `PIPE`, this attribute is `None`.

**Warning:** Use `communicate()` rather than `.stdin.write`, `.stdout.read` or `.stderr.read` to avoid deadlocks due to any of the other OS pipe buffers filling up and blocking the child process.

**Popen. `pid`**

The process ID of the child process.

Note that if you set the `shell` argument to `True`, this is the process ID of the spawned shell.

**Popen. `returncode`**
The child return code, set by `poll()` and `wait()` (and indirectly by `communicate()`). A `None` value indicates that the process hasn't terminated yet.

A negative value `-N` indicates that the child was terminated by signal N (POSIX only).
17.5.4. Windows Popen Helpers

The `STARTUPINFO` class and following constants are only available on Windows.

```python
si = subprocess.STARTUPINFO()
si.dwFlags = subprocess.STARTF_USESTDHANDLES |
```

**class subprocess.STARTUPINFO**

Partial support of the Windows `STARTUPINFO` structure is used for `Popen` creation.

**dwFlags**

A bit field that determines whether certain `STARTUPINFO` attributes are used when the process creates a window.

**hStdInput**

If `dwFlags` specifies `STARTF_USESTDHANDLES`, this attribute is the standard input handle for the process. If `STARTF_USESTDHANDLES` is not specified, the default for standard input is the keyboard buffer.

**hStdOutput**

If `dwFlags` specifies `STARTF_USESTDHANDLES`, this attribute is the standard output handle for the process. Otherwise, this attribute is ignored and the default for standard output is the console window's buffer.

**hStdError**

If `dwFlags` specifies `STARTF_USESTDHANDLES`, this attribute is the standard error handle for the process. Otherwise, this
attribute is ignored and the default for standard error is the console window's buffer.

**wShowWindow**

If `dwFlags` specifies `STARTF_USESHOWWINDOW`, this attribute can be any of the values that can be specified in the `nCmdShow` parameter for the `ShowWindow` function, except for `SW_SHOWDEFAULT`. Otherwise, this attribute is ignored.

`SW_HIDE` is provided for this attribute. It is used when `Popen` is called with `shell=True`.

### 17.5.4.1. Constants

The `subprocess` module exposes the following constants.

*subprocess.* **STD_INPUT_HANDLE**

The standard input device. Initially, this is the console input buffer, `CONIN$`.

*subprocess.* **STD_OUTPUT_HANDLE**

The standard output device. Initially, this is the active console screen buffer, `CONOUT$`.

*subprocess.* **STD_ERROR_HANDLE**

The standard error device. Initially, this is the active console screen buffer, `CONOUT$`.

*subprocess.* **SW_HIDE**

Hides the window. Another window will be activated.

*subprocess.* **STARTF_USESTDHANDLES**
Specifies that the STARTUPINFO.hStdInput, STARTUPINFO.hStdOutput, and STARTUPINFO.hStdError attributes contain additional information.

subprocess. **STARTF_USESHOWWINDOW**
Specifies that the STARTUPINFO.wShowWindow attribute contains additional information.

subprocess. **CREATE_NEW_CONSOLE**
The new process has a new console, instead of inheriting its parent's console (the default).

subprocess. **CREATE_NEW_PROCESS_GROUP**
A `Popen` `creationflags` parameter to specify that a new process group will be created. This flag is necessary for using `os.kill()` on the subprocess.

This flag is ignored if **CREATE_NEW_CONSOLE** is specified.
17.5.5. Older high-level API

Prior to Python 3.5, these three functions comprised the high-level API to subprocess. You can now use `run()` in many cases, but lots of existing code calls these functions.

```
subprocess.call(args, *, stdin=None, stdout=None, stderr=None, shell=False, cwd=None, timeout=None)
```

Run the command described by `args`. Wait for command to complete, then return the `returncode` attribute.

This is equivalent to:

```
run(...).returncode
```

(Except that the `input` and `check` parameters are not supported)

The arguments shown above are merely the most common ones. The full function signature is largely the same as that of the `Popen` constructor - this function passes all supplied arguments other than `timeout` directly through to that interface.

**Note:** Do not use `stdout=PIPE` or `stderr=PIPE` with this function. The child process will block if it generates enough output to a pipe to fill up the OS pipe buffer as the pipes are not being read from.

*Changed in version 3.3:* `timeout` was added.

```
subprocess.check_call(args, *, stdin=None, stdout=None, stderr=None, shell=False, cwd=None, timeout=None)
```

Run command with arguments. Wait for command to complete. If
the return code was zero then return, otherwise raise `CalledProcessError`. The `CalledProcessError` object will have the return code in the `returncode` attribute.

This is equivalent to:

```python
run(..., check=True)
```

(except that the `input` parameter is not supported)

The arguments shown above are merely the most common ones. The full function signature is largely the same as that of the `Popen` constructor - this function passes all supplied arguments other than `timeout` directly through to that interface.

**Note:** Do not use `stdout=PIPE` or `stderr=PIPE` with this function. The child process will block if it generates enough output to a pipe to fill up the OS pipe buffer as the pipes are not being read from.

*Changed in version 3.3: timeout was added.*

`subprocess.check_output(args, *, stdin=None, stderr=None, shell=False, cwd=None, encoding=None, errors=None, universal_newlines=False, timeout=None)`

Run command with arguments and return its output.

If the return code was non-zero it raises a `CalledProcessError`. The `CalledProcessError` object will have the return code in the `returncode` attribute and any output in the `output` attribute.

This is equivalent to:
run(..., check=True, stdout=PIPE).stdout

The arguments shown above are merely the most common ones. The full function signature is largely the same as that of run() - most arguments are passed directly through to that interface. However, explicitly passing input=None to inherit the parent's standard input file handle is not supported.

By default, this function will return the data as encoded bytes. The actual encoding of the output data may depend on the command being invoked, so the decoding to text will often need to be handled at the application level.

This behaviour may be overridden by setting universal_newlines to True as described above in Frequently Used Arguments.

To also capture standard error in the result, use stderr=subprocess.STDOUT:

```python
>>> subprocess.check_output(... "ls non_existent_file; exit 0", ...
stderr=subprocess.STDOUT,
shell=True)
'ls: non_existent_file: No such file or directory
```

New in version 3.1.

Changed in version 3.3: timeout was added.

Changed in version 3.4: Support for the input keyword argument was added.
17.5.6. Replacing Older Functions with the subprocess Module

In this section, “a becomes b” means that b can be used as a replacement for a.

**Note:** All “a” functions in this section fail (more or less) silently if the executed program cannot be found; the “b” replacements raise OSError instead.

In addition, the replacements using check_output() will fail with a CalledProcessError if the requested operation produces a non-zero return code. The output is still available as the output attribute of the raised exception.

In the following examples, we assume that the relevant functions have already been imported from the subprocess module.

### 17.5.6.1. Replacing /bin/sh shell backquote

```bash
output=`mycmd myarg`
```

becomes:

```python
output = check_output(['mycmd', 'myarg'])
```

### 17.5.6.2. Replacing shell pipeline

```bash
output=`dmesg | grep hda`
```
becomes:

```python
p1 = Popen(['dmesg'], stdout=PIPE)
p2 = Popen(['grep', 'hda'], stdin=p1.stdout, stdout=p1.stdout)
p1.stdout.close()  # Allow p1 to receive a SIGPIPE if p2 exits before p1.
output = p2.communicate()[0]
```

The `p1.stdout.close()` call after starting the `p2` is important in order for `p1` to receive a SIGPIPE if `p2` exits before `p1`.

Alternatively, for trusted input, the shell's own pipeline support may still be used directly:

```python
output = 'dmesg | grep hda`
```

becomes:

```python
output = check_output(['dmesg', 'grep hda'], shell=True)
```

### 17.5.6.3. Replacing `os.system()`

```python
sts = os.system('mycmd + myarg')
# becomes
sts = call('mycmd + 'myarg', shell=True)
```

Notes:

- Calling the program through the shell is usually not required.

A more realistic example would look like this:

```python
try:
    retcode = call('mycmd + myarg', shell=True)
if retcode < 0:
```
print("Child was terminated by signal", -retcode)
else:
    print("Child returned", retcode, file=sys.stderr)
except OSError as e:
    print("Execution failed:", e, file=sys.stderr)

17.5.6.4. Replacing the `os.spawn` family

P_NOWAIT example:

```python
pid = os.spawnlp(os.P_NOWAIT, "/bin/mycmd", "mycmd",
                
```
```
==>
pid = Popen(['"/bin/mycmd", "myarg"]).pid
```

P_WAIT example:

```python
retcode = os.spawnlp(os.P_WAIT, "/bin/mycmd", "mycmd",
                
```
```
==>
retcode = call(['"/bin/mycmd", "myarg"])
```

Vector example:

```python
os.spawnvp(os.P_NOWAIT, path, args)
```
```
==>
Popen([path] + args[1:])
```

Environment example:

```python
os.spawnlpe(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg",
```
```
==>
Popen(['"/bin/mycmd", "myarg"], env={"PATH": "/usr/bin"})
```
```
17.5.6.5. Replacing \texttt{os.popen()}, \texttt{os.popen2()}, \texttt{os.popen3()}

\begin{verbatim}
(child_stdin, child_stdout) = os.popen2(cmd, mode, bufsize=bufsize, child_stdin=PIPE, child_stdout=PIPE, close_fds=True)
\end{verbatim}

\begin{verbatim}
(child_stdin, child_stdout, child_stderr) = os.popen3(cmd, mode, bufsize=bufsize)
\end{verbatim}

\begin{verbatim}
(child_stdin, child_stdout_and_stderr) = os.popen4(cmd, mode, bufsize=bufsize)
\end{verbatim}

Return code handling translates as follows:

\begin{verbatim}
pipe = os.popen(cmd, 'w')
...
rc = pipe.close()
if rc is not None and rc >> 8:
    print("There were some errors")
\end{verbatim}
process = Popen(cmd, stdin=PIPE)
...
process.stdin.close()
if process.wait() != 0:
    print("There were some errors")

17.5.6.6. Replacing functions from the popen2 module

**Note:** If the cmd argument to popen2 functions is a string, the command is executed through `/bin/sh`. If it is a list, the command is directly executed.

```python
(child_stdout, child_stdin) = popen2.popen2("somestring")
```  
```python
p = Popen("somestring", shell=True, bufsize=bufsize, stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```  
```python
(child_stdout, child_stdin) = popen2.popen2(['"mycmd"'])
```  
```python
p = Popen(['"mycmd", "myarg"'], bufsize=bufsize, stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```
op

popen2.Popen3 and popen2.Popen4 basically work as `subprocess.Popen`, except that:

- **Popen** raises an exception if the execution fails.
- the `capturestderr` argument is replaced with the `stderr` argument.
- `stdin=PIPE` and `stdout=PIPE` must be specified.
• popen2 closes all file descriptors by default, but you have to specify `close_fds=True` with `Popen` to guarantee this behavior on all platforms or past Python versions.
17.5.7. Legacy Shell Invocation Functions

This module also provides the following legacy functions from the 2.x commands module. These operations implicitly invoke the system shell and none of the guarantees described above regarding security and exception handling consistency are valid for these functions.

subprocess.\texttt{getstatusoutput}(\textit{cmd})

Return \texttt{(exitcode, output)} of executing \textit{cmd} in a shell.

Execute the string \textit{cmd} in a shell with \texttt{Popen.check_output()} and return a 2-tuple \texttt{(exitcode, output)}. The locale encoding is used; see the notes on Frequently Used Arguments for more details.

A trailing newline is stripped from the output. The exit code for the command can be interpreted as the return code of subprocess. Example:

\begin{verbatim}
>>> subprocess.getstatusoutput('ls /bin/ls')
(0, '/bin/ls')
>>> subprocess.getstatusoutput('cat /bin/junk')
(1, 'cat: /bin/junk: No such file or directory')
>>> subprocess.getstatusoutput('/bin/junk')
(127, 'sh: /bin/junk: not found')
>>> subprocess.getstatusoutput('/bin/kill $$')
(-15, '')
\end{verbatim}

Availability: POSIX & Windows

\textit{Changed in version 3.3.4}: Windows support was added.

The function now returns \texttt{(exitcode, output)} instead of \texttt{(status,
output) as it did in Python 3.3.3 and earlier. See WEXITSTATUS().

subprocess.**getoutput**(cmd)
Return output (stdout and stderr) of executing *cmd* in a shell.

Like **getstatusoutput()**, except the exit status is ignored and the return value is a string containing the command’s output. Example:

```python
>>> subprocess.getoutput('ls /bin/ls')
'/bin/ls'
```

Availability: POSIX & Windows

*Changed in version 3.3.4:* Windows support added
17.5.8. Notes

17.5.8.1. Converting an argument sequence to a string on Windows

On Windows, an args sequence is converted to a string that can be parsed using the following rules (which correspond to the rules used by the MS C runtime):

1. Arguments are delimited by white space, which is either a space or a tab.
2. A string surrounded by double quotation marks is interpreted as a single argument, regardless of white space contained within. A quoted string can be embedded in an argument.
3. A double quotation mark preceded by a backslash is interpreted as a literal double quotation mark.
4. Backslashes are interpreted literally, unless they immediately precede a double quotation mark.
5. If backslashes immediately precede a double quotation mark, every pair of backslashes is interpreted as a literal backslash. If the number of backslashes is odd, the last backslash escapes the next double quotation mark as described in rule 3.

Created using Sphinx 1.6.3.
17.6. sched — Event scheduler

Source code: Lib/sched.py

The sched module defines a class which implements a general purpose event scheduler:

```python
class sched.scheduler(timefunc=time.monotonic,
delayfunc=time.sleep)
```

The scheduler class defines a generic interface to scheduling events. It needs two functions to actually deal with the “outside world” — `timefunc` should be callable without arguments, and return a number (the “time”, in any units whatsoever). If `time.monotonic` is not available, the `timefunc` default is `time.time` instead. The `delayfunc` function should be callable with one argument, compatible with the output of `timefunc`, and should delay that many time units. `delayfunc` will also be called with the argument 0 after each event is run to allow other threads an opportunity to run in multi-threaded applications.

*Changed in version 3.3:* `timefunc` and `delayfunc` parameters are optional.

*Changed in version 3.3:* `scheduler` class can be safely used in multi-threaded environments.

Example:

```python
>>> import sched, time
>>> s = sched.scheduler(time.time, time.sleep)
>>> def print_time(a='default'):
```
>>> def print_some_times():
...     print(time.time())
...     s.enter(10, 1, print_time)
...     s.enter(5, 2, print_time, argument=('positional',
...     s.enter(5, 1, print_time, kwargs={'a': 'keyword'}
...     s.run()
...     print(time.time())

>>> print_some_times()
930343690.257
From print_time 930343695.274 positional
From print_time 930343695.275 keyword
From print_time 930343700.273 default
930343700.276
17.6.1. Scheduler Objects

scheduler instances have the following methods and attributes:

```python
scheduler.enterabs(time, priority, action, argument=(), kwargs={})
```

Schedule a new event. The `time` argument should be a numeric type compatible with the return value of the `timefunc` function passed to the constructor. Events scheduled for the same `time` will be executed in the order of their `priority`.

Executing the event means executing `action(*argument, **kwargs)`. `argument` is a sequence holding the positional arguments for `action`. `kwargs` is a dictionary holding the keyword arguments for `action`.

Return value is an event which may be used for later cancellation of the event (see `cancel()`).

*Changed in version 3.3:* `argument` parameter is optional.

*New in version 3.3:* `kwargs` parameter was added.

```python
scheduler.enter(delay, priority, action, argument=(), kwargs={})
```

Schedule an event for `delay` more time units. Other than the relative time, the other arguments, the effect and the return value are the same as those for `enterabs()`.

*Changed in version 3.3:* `argument` parameter is optional.

*New in version 3.3:* `kwargs` parameter was added.

```python
scheduler.cancel(event)
```
Remove the event from the queue. If \textit{event} is not an event currently in the queue, this method will raise a \texttt{ValueError}.

\texttt{scheduler.empty()}

Return true if the event queue is empty.

\texttt{scheduler.run(blocking=True)}

Run all scheduled events. This method will wait (using the \texttt{delayfunc()} function passed to the constructor) for the next event, then execute it and so on until there are no more scheduled events.

If \texttt{blocking} is false executes the scheduled events due to expire soonest (if any) and then return the deadline of the next scheduled call in the scheduler (if any).

Either \texttt{action} or \texttt{delayfunc} can raise an exception. In either case, the scheduler will maintain a consistent state and propagate the exception. If an exception is raised by \texttt{action}, the event will not be attempted in future calls to \texttt{run()}. If a sequence of events takes longer to run than the time available before the next event, the scheduler will simply fall behind. No events will be dropped; the calling code is responsible for canceling events which are no longer pertinent.

\textit{New in version 3.3:} \texttt{blocking} parameter was added.

\texttt{scheduler.queue}

Read-only attribute returning a list of upcoming events in the order they will be run. Each event is shown as a \texttt{named tuple} with the following fields: time, priority, action, argument, kwargs.
17.7. queue — A synchronized queue class

Source code: Lib/queue.py

The queue module implements multi-producer, multi-consumer queues. It is especially useful in threaded programming when information must be exchanged safely between multiple threads. The Queue class in this module implements all the required locking semantics. It depends on the availability of thread support in Python; see the threading module.

The module implements three types of queue, which differ only in the order in which the entries are retrieved. In a FIFO queue, the first tasks added are the first retrieved. In a LIFO queue, the most recently added entry is the first retrieved (operating like a stack). With a priority queue, the entries are kept sorted (using the heapq module) and the lowest valued entry is retrieved first.

Internally, the module uses locks to temporarily block competing threads; however, it is not designed to handle reentrancy within a thread.

The queue module defines the following classes and exceptions:

class queue.Queue(maxsize=0)

Constructor for a FIFO queue. maxsize is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If maxsize is less than or equal to
zero, the queue size is infinite.

class queue. `LifoQueue`(maxsize=0)
Constructor for a LIFO queue. `maxsize` is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If `maxsize` is less than or equal to zero, the queue size is infinite.

class queue. `PriorityQueue`(maxsize=0)
Constructor for a priority queue. `maxsize` is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If `maxsize` is less than or equal to zero, the queue size is infinite.

The lowest valued entries are retrieved first (the lowest valued entry is the one returned by `sorted(list(entries))[0]`). A typical pattern for entries is a tuple in the form: `(priority_number, data).

exception queue. `Empty`
Exception raised when non-blocking `get()` (or `get_nowait()`) is called on a `Queue` object which is empty.

exception queue. `Full`
Exception raised when non-blocking `put()` (or `put_nowait()`) is called on a `Queue` object which is full.
17.7.1. Queue Objects

Queue objects (Queue, LifoQueue, or PriorityQueue) provide the public methods described below.

Queue.qsize()

Return the approximate size of the queue. Note, qsize() > 0 doesn’t guarantee that a subsequent get() will not block, nor will qsize() < maxsize guarantee that put() will not block.

Queue.empty()

Return True if the queue is empty, False otherwise. If empty() returns True it doesn’t guarantee that a subsequent call to put() will not block. Similarly, if empty() returns False it doesn’t guarantee that a subsequent call to get() will not block.

Queue.full()

Return True if the queue is full, False otherwise. If full() returns True it doesn’t guarantee that a subsequent call to get() will not block. Similarly, if full() returns False it doesn’t guarantee that a subsequent call to put() will not block.

Queue.put(item, block=True, timeout=None)

Put item into the queue. If optional args block is true and timeout is None (the default), block if necessary until a free slot is available. If timeout is a positive number, it blocks at most timeout seconds and raises the Full exception if no free slot was available within that time. Otherwise (block is false), put an item on the queue if a free slot is immediately available, else raise the Full exception (timeout is ignored in that case).
Queue.**put_nowait**(item)
Equivalent to put(item, False).

Queue.**get**(block=True, timeout=None)
Remove and return an item from the queue. If optional args block is true and timeout is None (the default), block if necessary until an item is available. If timeout is a positive number, it blocks at most timeout seconds and raises the Empty exception if no item was available within that time. Otherwise (block is false), return an item if one is immediately available, else raise the Empty exception (timeout is ignored in that case).

Queue.**get_nowait**()
Equivalent to get(False).

Two methods are offered to support tracking whether enqueued tasks have been fully processed by daemon consumer threads.

Queue.**task_done**()
Indicate that a formerly enqueued task is complete. Used by queue consumer threads. For each get() used to fetch a task, a subsequent call to task_done() tells the queue that the processing on the task is complete.

If a join() is currently blocking, it will resume when all items have been processed (meaning that a task_done() call was received for every item that had been put() into the queue).

 Raises a ValueError if called more times than there were items placed in the queue.

Queue.**join**()
Blocks until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls task_done() to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, join() unblocks.

Example of how to wait for enqueued tasks to be completed:

```python
def worker():
    while True:
        item = q.get()
        if item is None:
            break
        do_work(item)
        q.task_done()

q = queue.Queue()
threads = []
for i in range(num_worker_threads):
    t = threading.Thread(target=worker)
    t.start()
    threads.append(t)

for item in source():
    q.put(item)

# block until all tasks are done
q.join()

# stop workers
for i in range(num_worker_threads):
    q.put(None)
for t in threads:
```
t.join()

See also:

**Class** `multiprocessing.Queue`

A queue class for use in a multi-processing (rather than multi-threading) context.

`collections.deque` is an alternative implementation of unbounded queues with fast atomic `append()` and `popleft()` operations that do not require locking.
17.8. `dummy_threading` — Drop-in replacement for the `threading` module

**Source code:** Lib/dummy_threading.py

This module provides a duplicate interface to the `threading` module. It is meant to be imported when the `_thread` module is not provided on a platform.

Suggested usage is:

```python
try:
    import threading
except ImportError:
    import dummy_threading as threading
```

Be careful to not use this module where deadlock might occur from a thread being created that blocks waiting for another thread to be created. This often occurs with blocking I/O.
This module provides low-level primitives for working with multiple threads (also called light-weight processes or tasks) — multiple threads of control sharing their global data space. For synchronization, simple locks (also called mutexes or binary semaphores) are provided. The \texttt{threading} module provides an easier to use and higher-level threading API built on top of this module.

The module is optional. It is supported on Windows, Linux, SGI IRIX, Solaris 2.x, as well as on systems that have a POSIX thread (a.k.a. “pthread”) implementation. For systems lacking the \texttt{_thread} module, the \texttt{_dummy_thread} module is available. It duplicates this module's interface and can be used as a drop-in replacement.

It defines the following constants and functions:

\begin{verbatim}
exception _thread.error
    Raised on thread-specific errors.

    Changed in version 3.3: This is now a synonym of the built-in
    RuntimeError.

_thread.LockType
    This is the type of lock objects.

_thread.start_new_thread(function, args[, kwargs])
    Start a new thread and return its identifier. The thread executes
    the function \texttt{function} with the argument list \texttt{args} (which must be a
\end{verbatim}
tuple). The optional `kwargs` argument specifies a dictionary of keyword arguments. When the function returns, the thread silently exits. When the function terminates with an unhandled exception, a stack trace is printed and then the thread exits (but other threads continue to run).

```python
_thread.interrupt_main()
```
Raise a `KeyboardInterrupt` exception in the main thread. A subthread can use this function to interrupt the main thread.

```python
_thread.exit()
```
Raise the `SystemExit` exception. When not caught, this will cause the thread to exit silently.

```python
_thread.allocate_lock()
```
Return a new lock object. Methods of locks are described below. The lock is initially unlocked.

```python
_thread.get_ident()
```
Return the ‘thread identifier’ of the current thread. This is a nonzero integer. Its value has no direct meaning; it is intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

```python
_thread.stack_size([size])
```
Return the thread stack size used when creating new threads. The optional `size` argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If `size` is not specified, 0 is used. If changing the thread stack size is unsupported, a `RuntimeError` is raised. If the specified
stack size is invalid, a `ValueError` is raised and the stack size is unmodified. 32 KiB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32 KiB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4 KiB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information). Availability: Windows, systems with POSIX threads.

`_thread.TIMEOUT_MAX`

The maximum value allowed for the `timeout` parameter of `Lock.acquire()`. Specifying a timeout greater than this value will raise an `OverflowError`.

*New in version 3.2.*

Lock objects have the following methods:

`lock.acquire(waitflag=1, timeout=-1)`

Without any optional argument, this method acquires the lock unconditionally, if necessary waiting until it is released by another thread (only one thread at a time can acquire a lock — that’s their reason for existence).

If the integer `waitflag` argument is present, the action depends on its value: if it is zero, the lock is only acquired if it can be acquired immediately without waiting, while if it is nonzero, the lock is acquired unconditionally as above.

If the floating-point `timeout` argument is present and positive, it
specifies the maximum wait time in seconds before returning. A negative timeout argument specifies an unbounded wait. You cannot specify a timeout if waitflag is zero.

The return value is True if the lock is acquired successfully, False if not.

*Changed in version 3.2:* The timeout parameter is new.

*Changed in version 3.2:* Lock acquires can now be interrupted by signals on POSIX.

**lock.release()**

Releases the lock. The lock must have been acquired earlier, but not necessarily by the same thread.

**lock.locked()**

Return the status of the lock: True if it has been acquired by some thread, False if not.

In addition to these methods, lock objects can also be used via the with statement, e.g.:

```python
import _thread

a_lock = _thread.allocate_lock()

with a_lock:
    print("a_lock is locked while this executes")
```

**Caveats:**

- Threads interact strangely with interrupts: the KeyboardInterrupt exception will be received by an arbitrary
thread. (When the `signal` module is available, interrupts always go to the main thread.)

- Calling `sys.exit()` or raising the `SystemExit` exception is equivalent to calling `_thread.exit()`.
- It is not possible to interrupt the `acquire()` method on a lock — the `KeyboardInterrupt` exception will happen after the lock has been acquired.
- When the main thread exits, it is system defined whether the other threads survive. On most systems, they are killed without executing `try ... finally` clauses or executing object destructors.
- When the main thread exits, it does not do any of its usual cleanup (except that `try ... finally` clauses are honored), and the standard I/O files are not flushed.
17.10. \_dummy\_thread — Drop-in replacement for the \_thread module

Source code: Lib/_dummy_thread.py

This module provides a duplicate interface to the \_thread module. It is meant to be imported when the \_thread module is not provided on a platform.

Suggested usage is:

```
try:
    import _thread
except ImportError:
    import _dummy_thread as _thread
```

Be careful to not use this module where deadlock might occur from a thread being created that blocks waiting for another thread to be created. This often occurs with blocking I/O.
18. Interprocess Communication and Networking

The modules described in this chapter provide mechanisms for different processes to communicate.

Some modules only work for two processes that are on the same machine, e.g. `signal` and `mmap`. Other modules support networking protocols that two or more processes can use to communicate across machines.

The list of modules described in this chapter is:

- **18.1. socket — Low-level networking interface**
  - 18.1.1. Socket families
  - 18.1.2. Module contents
    - 18.1.2.1. Exceptions
    - 18.1.2.2. Constants
    - 18.1.2.3. Functions
      - 18.1.2.3.1. Creating sockets
      - 18.1.2.3.2. Other functions
  - 18.1.3. Socket Objects
  - 18.1.4. Notes on socket timeouts
    - 18.1.4.1. Timeouts and the `connect` method
    - 18.1.4.2. Timeouts and the `accept` method
  - 18.1.5. Example
- **18.2. ssl — TLS/SSL wrapper for socket objects**
  - 18.2.1. Functions, Constants, and Exceptions
    - 18.2.1.1. Socket creation
    - 18.2.1.2. Context creation
    - 18.2.1.3. Random generation
    - 18.2.1.4. Certificate handling
18.2.1.5. Constants

18.2.2. SSL Sockets

18.2.3. SSL Contexts

18.2.4. Certificates

- 18.2.4.1. Certificate chains
- 18.2.4.2. CA certificates
- 18.2.4.3. Combined key and certificate
- 18.2.4.4. Self-signed certificates

18.2.5. Examples

- 18.2.5.1. Testing for SSL support
- 18.2.5.2. Client-side operation
- 18.2.5.3. Server-side operation

18.2.6. Notes on non-blocking sockets

18.2.7. Memory BIO Support

18.2.8. SSL session

18.2.9. Security considerations

- 18.2.9.1. Best defaults
- 18.2.9.2. Manual settings
  - 18.2.9.2.1. Verifying certificates
  - 18.2.9.2.2. Protocol versions
  - 18.2.9.2.3. Cipher selection
- 18.2.9.3. Multi-processing

18.3. select — Waiting for I/O completion

- 18.3.1. /dev/poll Polling Objects
- 18.3.2. Edge and Level Trigger Polling (epoll) Objects
- 18.3.3. Polling Objects
- 18.3.4. Kqueue Objects
- 18.3.5. Kevent Objects

18.4. selectors — High-level I/O multiplexing

- 18.4.1. Introduction
- 18.4.2. Classes
- 18.4.3. Examples

18.5. asyncio — Asynchronous I/O, event loop, coroutines and tasks
- **18.5.1. Base Event Loop**
  - **18.5.1.1. Run an event loop**
  - **18.5.1.2. Calls**
  - **18.5.1.3. Delayed calls**
  - **18.5.1.4. Futures**
  - **18.5.1.5. Tasks**
  - **18.5.1.6. Creating connections**
  - **18.5.1.7. Creating listening connections**
  - **18.5.1.8. Watch file descriptors**
  - **18.5.1.9. Low-level socket operations**
  - **18.5.1.10. Resolve host name**
  - **18.5.1.11. Connect pipes**
  - **18.5.1.12. UNIX signals**
  - **18.5.1.13. Executor**
  - **18.5.1.14. Error Handling API**
  - **18.5.1.15. Debug mode**
  - **18.5.1.16. Server**
  - **18.5.1.17. Handle**
  - **18.5.1.18. Event loop examples**
    - **18.5.1.18.1. Hello World with call_soon()**
    - **18.5.1.18.2. Display the current date with call_later()**
    - **18.5.1.18.3. Watch a file descriptor for read events**
    - **18.5.1.18.4. Set signal handlers for SIGINT and SIGTERM**
- **18.5.2. Event loops**
  - **18.5.2.1. Event loop functions**
  - **18.5.2.2. Available event loops**
  - **18.5.2.3. Platform support**
    - **18.5.2.3.1. Windows**
    - **18.5.2.3.2. Mac OS X**
  - **18.5.2.4. Event loop policies and the default policy**
  - **18.5.2.5. Event loop policy interface**
  - **18.5.2.6. Access to the global loop policy**
- **18.5.3. Tasks and coroutines**
- 18.5.3.1. Coroutines
  - 18.5.3.1.1. Example: Hello World coroutine
  - 18.5.3.1.2. Example: Coroutine displaying the current date
  - 18.5.3.1.3. Example: Chain coroutines
- 18.5.3.2. InvalidStateError
- 18.5.3.3. TimeoutError
- 18.5.3.4. Future
  - 18.5.3.4.1. Example: Future with run_until_complete()
  - 18.5.3.4.2. Example: Future with run_forever()
- 18.5.3.5. Task
  - 18.5.3.5.1. Example: Parallel execution of tasks
- 18.5.3.6. Task functions
- 18.5.4. Transports and protocols (callback based API)
  - 18.5.4.1. Transports
    - 18.5.4.1.1. BaseTransport
    - 18.5.4.1.2. ReadTransport
    - 18.5.4.1.3. WriteTransport
    - 18.5.4.1.4. DatagramTransport
    - 18.5.4.1.5. BaseSubprocessTransport
  - 18.5.4.2. Protocols
    - 18.5.4.2.1. Protocol classes
    - 18.5.4.2.2. Connection callbacks
    - 18.5.4.2.3. Streaming protocols
    - 18.5.4.2.4. Datagram protocols
    - 18.5.4.2.5. Flow control callbacks
    - 18.5.4.2.6. Coroutines and protocols
  - 18.5.4.3. Protocol examples
    - 18.5.4.3.1. TCP echo client protocol
    - 18.5.4.3.2. TCP echo server protocol

18.9. mmap — Memory-mapped file support
18.1. **socket** — Low-level networking interface

**Source code:** Lib/socket.py

This module provides access to the BSD **socket** interface. It is available on all modern Unix systems, Windows, MacOS, and probably additional platforms.

**Note:** Some behavior may be platform dependent, since calls are made to the operating system socket APIs.

The Python interface is a straightforward transliteration of the Unix system call and library interface for sockets to Python’s object-oriented style: the `socket()` function returns a **socket object** whose methods implement the various socket system calls. Parameter types are somewhat higher-level than in the C interface: as with `read()` and `write()` operations on Python files, buffer allocation on receive operations is automatic, and buffer length is implicit on send operations.

**See also:**

**Module** `socketserver`

Classes that simplify writing network servers.

**Module** `ssl`

A TLS/SSL wrapper for socket objects.
18.1.1. Socket families

Depending on the system and the build options, various socket families are supported by this module.

The address format required by a particular socket object is automatically selected based on the address family specified when the socket object was created. Socket addresses are represented as follows:

- The address of an AF_UNIX socket bound to a file system node is represented as a string, using the file system encoding and the 'surrogateescape' error handler (see PEP 383). An address in Linux's abstract namespace is returned as a bytes-like object with an initial null byte; note that sockets in this namespace can communicate with normal file system sockets, so programs intended to run on Linux may need to deal with both types of address. A string or bytes-like object can be used for either type of address when passing it as an argument.

  Changed in version 3.3: Previously, AF_UNIX socket paths were assumed to use UTF-8 encoding.

  Changed in version 3.5: Writable bytes-like object is now accepted.

- A pair (host, port) is used for the AF_INET address family, where host is a string representing either a hostname in Internet domain notation like 'daring.cwi.nl' or an IPv4 address like '100.50.200.5', and port is an integer.

- For AF_INET6 address family, a four-tuple (host, port,
flowinfo, scopeid) is used, where flowinfo and scopeid represent the sin6_flowinfo and sin6_scope_id members in struct sockaddr_in6 in C. For socket module methods, flowinfo and scopeid can be omitted just for backward compatibility. Note, however, omission of scopeid can cause problems in manipulating scoped IPv6 addresses.

- AF_NETLINK sockets are represented as pairs (pid, groups).

- Linux-only support for TIPC is available using the AF_TIPC address family. TIPC is an open, non-IP based networked protocol designed for use in clustered computer environments. Addresses are represented by a tuple, and the fields depend on the address type. The general tuple form is (addr_type, v1, v2, v3 [, scope]), where:

  - **addr_type** is one of TIPC_ADDR_NAMESEQ, TIPC_ADDR_NAME, or TIPC_ADDR_ID.
  - **scope** is one of TIPC_ZONE_SCOPE, TIPC_CLUSTER_SCOPE, and TIPC_NODE_SCOPE.

  - If addr_type is TIPC_ADDR_NAME, then v1 is the server type, v2 is the port identifier, and v3 should be 0.

    If addr_type is TIPC_ADDR_NAMESEQ, then v1 is the server type, v2 is the lower port number, and v3 is the upper port number.

    If addr_type is TIPC_ADDR_ID, then v1 is the node, v2 is the reference, and v3 should be set to 0.
A tuple (interface,) is used for the AF_CAN address family, where interface is a string representing a network interface name like 'can0'. The network interface name '' can be used to receive packets from all network interfaces of this family.

A string or a tuple (id, unit) is used for the SYSPROTO_CONTROL protocol of the PF_SYSTEM family. The string is the name of a kernel control using a dynamically-assigned ID. The tuple can be used if ID and unit number of the kernel control are known or if a registered ID is used.

New in version 3.3.

AF_BLUETOOTH supports the following protocols and address formats:

- BTPROTO_L2CAP accepts (bdaddr, psm) where bdaddr is the Bluetooth address as a string and psm is an integer.

- BTPROTO_RFCOMM accepts (bdaddr, channel) where bdaddr is the Bluetooth address as a string and channel is an integer.

- BTPROTO_HCI accepts (device_id,) where device_id is either an integer or a string with the Bluetooth address of the interface. (This depends on your OS; NetBSD and DragonFlyBSD expect a Bluetooth address while everything else expects an integer.)

  Changed in version 3.2: NetBSD and DragonFlyBSD support added.

- BTPROTO_SCO accepts bdaddr where bdaddr is a bytes
object containing the Bluetooth address in a string format. (ex. b'12:23:34:45:56:67') This protocol is not supported under FreeBSD.

- **AF_ALG** is a Linux-only socket based interface to Kernel cryptography. An algorithm socket is configured with a tuple of two to four elements \((\text{type}, \text{name} [, \text{feat} [, \text{mask}]]))\), where:
  - \(\text{type}\) is the algorithm type as string, e.g. aead, hash, sccipher or rng.
  - \(\text{name}\) is the algorithm name and operation mode as string, e.g. sha256, hmac(sha256), cbc(aes) or drbg_nopr_ctr_aes256.
  - \(\text{feat}\) and \(\text{mask}\) are unsigned 32bit integers.

Availability Linux 2.6.38, some algorithm types require more recent Kernels.

*New in version 3.6.*

- Certain other address families (AF_PACKET, AF_CAN) support specific representations.

For IPv4 addresses, two special forms are accepted instead of a host address: the empty string represents INADDR_ANY, and the string '\(<broadcast>\)' represents INADDR_BROADCAST. This behavior is not compatible with IPv6, therefore, you may want to avoid these if you intend to support IPv6 with your Python programs.

If you use a hostname in the host portion of IPv4/v6 socket address, the program may show a nondeterministic behavior, as Python uses the first address returned from the DNS resolution. The socket address will be resolved differently into an actual IPv4/v6 address,
depending on the results from DNS resolution and/or the host configuration. For deterministic behavior use a numeric address in host portion.

All errors raise exceptions. The normal exceptions for invalid argument types and out-of-memory conditions can be raised; starting from Python 3.3, errors related to socket or address semantics raise OSError or one of its subclasses (they used to raise socket.error).

Non-blocking mode is supported through setblocking(). A generalization of this based on timeouts is supported through settimeout().
18.1.2. Module contents

The module `socket` exports the following elements.

18.1.2.1. Exceptions

`exception socket.error`
A deprecated alias of `OSError`.

*Changed in version 3.3:* Following [PEP 3151](https://www.python.org/dev/peps/pep-03151/), this class was made an alias of `OSError`.

`exception socket.herror`
A subclass of `OSError`, this exception is raised for address-related errors, i.e. for functions that use `h_errno` in the POSIX C API, including `gethostbyname_ex()` and `gethostbyaddr()`. The accompanying value is a pair `(h_errno, string)` representing an error returned by a library call. `h_errno` is a numeric value, while `string` represents the description of `h_errno`, as returned by the `hstrerror()` C function.

*Changed in version 3.3:* This class was made a subclass of `OSError`.

`exception socket.gaierror`
A subclass of `OSError`, this exception is raised for address-related errors by `getaddrinfo()` and `getnameinfo()`. The accompanying value is a pair `(error, string)` representing an error returned by a library call. `string` represents the description of `error`, as returned by the `gai_strerror()` C function. The numeric `error` value will match one of the EAI_* constants defined
in this module.

_Changed in version 3.3_: This class was made a subclass of `OSError`.

```python
exception socket.timeout
```

A subclass of `OSError`, this exception is raised when a timeout occurs on a socket which has had timeouts enabled via a prior call to `settimeout()` (or implicitly through `setdefaulttimeout()`). The accompanying value is a string whose value is currently always “timed out”.

_Changed in version 3.3_: This class was made a subclass of `OSError`.

### 18.1.2.2. Constants

The `AF_*` and `SOCK_*` constants are now `AddressFamily` and `SocketKind` `IntEnum` collections.

_New in version 3.4._

```python
socket.AF_UNIX
socket.AF_INET
socket.AF_INET6
```

These constants represent the address (and protocol) families, used for the first argument to `socket()`. If the `AF_UNIX` constant is not defined then this protocol is unsupported. More constants may be available depending on the system.

```python
socket.SOCK_STREAM
socket.SOCK_DGRAM
socket.SOCK_RAW
```
socket. **SOCK_RDM**
socket. **SOCK_SEQPACKET**

These constants represent the socket types, used for the second argument to `socket()`. More constants may be available depending on the system. (Only **SOCK_STREAM** and **SOCK_DGRAM** appear to be generally useful.)

socket. **SOCK_CLOEXEC**
socket. **SOCK_NONBLOCK**

These two constants, if defined, can be combined with the socket types and allow you to set some flags atomically (thus avoiding possible race conditions and the need for separate calls).

**See also:** Secure File Descriptor Handling for a more thorough explanation.

Availability: Linux >= 2.6.27.

*New in version 3.2.*

**SO_***
socket. **SOMAXCONN**
**MSG_***
**SOL_***
**SCM_***
**IPPROTO_***
**IPPORT_***
**INADDR_***
**IP_***
**IPV6_***
**EAI_***
**AI_***
**NI_***
TCP_*

Many constants of these forms, documented in the Unix documentation on sockets and/or the IP protocol, are also defined in the socket module. They are generally used in arguments to the setsockopt() and getsockopt() methods of socket objects. In most cases, only those symbols that are defined in the Unix header files are defined; for a few symbols, default values are provided.

Changed in version 3.6: SO_DOMAIN, SO_PROTOCOL, SO_PEERSEC, SO_PASSSEC, TCP_USER_TIMEOUT, TCP_CONGESTION were added.

socket.AF_CAN
socket.PF_CAN
SOL_CAN_*
CAN_*

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.6.25.

New in version 3.3.

socket.CAN_BCM
CAN_BCM_*

CAN_BCM, in the CAN protocol family, is the broadcast manager (BCM) protocol. Broadcast manager constants, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.6.25.

New in version 3.4.
socket.CAN_RAW_FD_FRAMES

Enables CAN FD support in a CAN_RAW socket. This is disabled by default. This allows your application to send both CAN and CAN FD frames; however, you must accept both CAN and CAN FD frames when reading from the socket.

This constant is documented in the Linux documentation.

Availability: Linux >= 3.6.

New in version 3.5.

socket.AF_RDS
socket.PF_RDS
socket.SOL_RDS
RDS_*

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.6.30.

New in version 3.3.

socket.SIO_RCVALL
socket.SIO_KEEPALIVE_VALS
socket.SIO_LOOPBACK_FAST_PATH
RCVALL_*

Constants for Windows’ WSAIoctl(). The constants are used as arguments to the ioctl() method of socket objects.

Changed in version 3.6: SIO_LOOPBACK_FAST_PATH was added.

TIPC_*

TIPC related constants, matching the ones exported by the C
socket API. See the TIPC documentation for more information.

socket.AF_ALG
socket.SOL_ALG
ALG_ *

Constants for Linux Kernel cryptography.

Availability: Linux >= 2.6.38.

New in version 3.6.

socket.AF_LINK

Availability: BSD, OSX.

New in version 3.4.

socket.has_ipv6

This constant contains a boolean value which indicates if IPv6 is supported on this platform.

socket.BDADDR_ANY
socket.BDADDR_LOCAL

These are string constants containing Bluetooth addresses with special meanings. For example, BDADDR_ANY can be used to indicate any address when specifying the binding socket with BTPROTO_RFCOMM.

socket.HCI_FILTER
socket.HCI_TIME_STAMP
socket.HCI_DATA_DIR

For use with BTPROTO_HCI. HCI_FILTER is not available for NetBSD or DragonFlyBSD. HCI_TIME_STAMP and HCI_DATA_DIR are not available for FreeBSD, NetBSD, or
18.1.2.3. Functions

18.1.2.3.1. Creating sockets

The following functions all create socket objects.

socket.socket(family=AF_INET, type=SOCK_STREAM, proto=0, fileno=None)

Create a new socket using the given address family, socket type and protocol number. The address family should be AF_INET (the default), AF_INET6, AF_UNIX, AF_CAN or AF_RDS. The socket type should be SOCK_STREAM (the default), SOCK_DGRAM, SOCK_RAW or perhaps one of the other SOCK_ constants. The protocol number is usually zero and may be omitted or in the case where the address family is AF_CAN the protocol should be one of CAN_RAW or CAN_BCM. If fileno is specified, the other arguments are ignored, causing the socket with the specified file descriptor to return. Unlike socket.fromfd(), fileno will return the same socket and not a duplicate. This may help close a detached socket using socket.close().

The newly created socket is non-inheritable.

Changed in version 3.3: The AF_CAN family was added. The AF_RDS family was added.

Changed in version 3.4: The CAN_BCM protocol was added.

Changed in version 3.4: The returned socket is now non-inheritable.
socket.socketpair([family[, type[, proto]]])

Build a pair of connected socket objects using the given address family, socket type, and protocol number. Address family, socket type, and protocol number are as for the socket() function above. The default family is AF_UNIX if defined on the platform; otherwise, the default is AF_INET.

The newly created sockets are non-inheritable.

Changed in version 3.2: The returned socket objects now support the whole socket API, rather than a subset.

Changed in version 3.4: The returned sockets are now non-inheritable.

Changed in version 3.5: Windows support added.

socket.create_connection(address[, timeout[, source_address]])

Connect to a TCP service listening on the Internet address (a 2-tuple (host, port)), and return the socket object. This is a higher-level function than socket.connect(): if host is a non-numeric hostname, it will try to resolve it for both AF_INET and AF_INET6, and then try to connect to all possible addresses in turn until a connection succeeds. This makes it easy to write clients that are compatible to both IPv4 and IPv6.

Passing the optional timeout parameter will set the timeout on the socket instance before attempting to connect. If no timeout is supplied, the global default timeout setting returned by getdefaulttimeout() is used.
If supplied, `source_address` must be a 2-tuple `(host, port)` for the socket to bind to as its source address before connecting. If host or port are " or 0 respectively the OS default behavior will be used.

*Changed in version 3.2: source_address was added.*

```python
socket.fromfd(fd, family, type, proto=0)
```
Duplicate the file descriptor `fd` (an integer as returned by a file object's `fileno()` method) and build a socket object from the result. Address family, socket type and protocol number are as for the `socket()` function above. The file descriptor should refer to a socket, but this is not checked — subsequent operations on the object may fail if the file descriptor is invalid. This function is rarely needed, but can be used to get or set socket options on a socket passed to a program as standard input or output (such as a server started by the Unix inet daemon). The socket is assumed to be in blocking mode.

The newly created socket is non-inheritable.

*Changed in version 3.4: The returned socket is now non-inheritable.*

```python
socket.fromshare(data)
```
Instantiate a socket from data obtained from the `socket.share()` method. The socket is assumed to be in blocking mode.

*Availability: Windows.*

*New in version 3.3.*
socket.SocketType

This is a Python type object that represents the socket object type. It is the same as `type(socket(...))`.

18.1.2.3.2. Other functions

The `socket` module also offers various network-related services:

```python
socket.getaddrinfo(host, port, family=0, type=0, proto=0, flags=0)
```

Translate the `host/port` argument into a sequence of 5-tuples that contain all the necessary arguments for creating a socket connected to that service. `host` is a domain name, a string representation of an IPv4/v6 address or None. `port` is a string service name such as `'http'`, a numeric port number or None. By passing None as the value of `host` and `port`, you can pass NULL to the underlying C API.

The `family`, `type` and `proto` arguments can be optionally specified in order to narrow the list of addresses returned. Passing zero as a value for each of these arguments selects the full range of results. The `flags` argument can be one or several of the `AI_*` constants, and will influence how results are computed and returned. For example, `AI_NUMERICHOST` will disable domain name resolution and will raise an error if `host` is a domain name.

The function returns a list of 5-tuples with the following structure:

```
(family, type, proto, canonname, sockaddr)
```

In these tuples, `family`, `type`, `proto` are all integers and are meant to be passed to the `socket()` function. `canonname` will be a string
representing the canonical name of the host if AI_CANONNAME is part of the flags argument; else canonname will be empty. sockaddr is a tuple describing a socket address, whose format depends on the returned family (a (address, port) 2-tuple for AF_INET, a (address, port, flow info, scope id) 4-tuple for AF_INET6), and is meant to be passed to the socket.connect() method.

The following example fetches address information for a hypothetical TCP connection to example.org on port 80 (results may differ on your system if IPv6 isn’t enabled):

```python
>>> socket.getaddrinfo("example.org", 80, proto=socket[<AddressFamily.AF_INET6: 10>, <SocketType.SOCK_STREAM: 1>, 6, '', ('2606:2800:220:1:248:1893:25c8:1946', 80) (<AddressFamily.AF_INET: 2>, <SocketType.SOCK_STREAM: 1>, 6, '', ('93.184.216.34', 80))]
```

*Changed in version 3.2*: parameters can now be passed using keyword arguments.

socket.getfqdn([name])

Return a fully qualified domain name for name. If name is omitted or empty, it is interpreted as the local host. To find the fully qualified name, the hostname returned by gethostbyaddr() is checked, followed by aliases for the host, if available. The first name which includes a period is selected. In case no fully qualified domain name is available, the hostname as returned by gethostname() is returned.

socket.gethostbyname(hostname)

Translate a host name to IPv4 address format. The IPv4 address is
returned as a string, such as '100.50.200.5'. If the host name is an IPv4 address itself it is returned unchanged. See `gethostbyname_ex()` for a more complete interface. `gethostbyname()` does not support IPv6 name resolution, and `getaddrinfo()` should be used instead for IPv4/v6 dual stack support.

socket. **gethostbyname_ex** *(hostname)*

Translate a host name to IPv4 address format, extended interface. Return a triple (hostname, aliaslist, ipaddrlist) where *hostname* is the primary host name responding to the given *ip_address*, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4 addresses for the same interface on the same host (often but not always a single address). `gethostbyname_ex()` does not support IPv6 name resolution, and `getaddrinfo()` should be used instead for IPv4/v6 dual stack support.

socket. **gethostname()**

Return a string containing the hostname of the machine where the Python interpreter is currently executing.

Note: `gethostname()` doesn’t always return the fully qualified domain name; use `getfqdn()` for that.

socket. **gethostbyaddr** *(ip_address)*

Return a triple (hostname, aliaslist, ipaddrlist) where *hostname* is the primary host name responding to the given *ip_address*, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4/v6 addresses for the same interface on the same host (most likely containing only a single address). To find the fully qualified domain
name, use the function `getfqdn()`. `gethostbyaddr()` supports both IPv4 and IPv6.

socket. `getnameinfo(sockaddr, flags)`
Translate a socket address `sockaddr` into a 2-tuple `(host, port)`. Depending on the settings of `flags`, the result can contain a fully-qualified domain name or numeric address representation in `host`. Similarly, `port` can contain a string port name or a numeric port number.

socket. `getprotobynam(protocolname)`
Translate an Internet protocol name (for example, `'icmp'`) to a constant suitable for passing as the (optional) third argument to the `socket()` function. This is usually only needed for sockets opened in “raw” mode (`SOCK_RAW`); for the normal socket modes, the correct protocol is chosen automatically if the protocol is omitted or zero.

socket. `getservbyname(servicename[, protocolname])`
Translate an Internet service name and protocol name to a port number for that service. The optional protocol name, if given, should be `'tcp'` or `'udp'`, otherwise any protocol will match.

socket. `getservbyport(port[, protocolname])`
Translate an Internet port number and protocol name to a service name for that service. The optional protocol name, if given, should be `'tcp'` or `'udp'`, otherwise any protocol will match.

socket. `ntohl(x)`
Convert 32-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte
order, this is a no-op; otherwise, it performs a 4-byte swap operation.

socket.\texttt{nths}(x)
Convert 16-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

socket.\texttt{htonl}(x)
Convert 32-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

socket.\texttt{htons}(x)
Convert 16-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

socket.\texttt{inet\_aton}(ip\_string)
Convert an IPv4 address from dotted-quad string format (for example, ‘123.45.67.89’) to 32-bit packed binary format, as a bytes object four characters in length. This is useful when conversing with a program that uses the standard C library and needs objects of type \texttt{struct in\_addr}, which is the C type for the 32-bit packed binary this function returns.

\texttt{inet\_aton()} also accepts strings with less than three dots; see the Unix manual page \texttt{inet(3)} for details.

If the IPv4 address string passed to this function is invalid,
**OSError** will be raised. Note that exactly what is valid depends on the underlying C implementation of `inet_aton()`.

`inet_aton()` does not support IPv6, and `inet_pton()` should be used instead for IPv4/v6 dual stack support.

```python
socket.inet_aton(packed_ip)
```

Convert a 32-bit packed IPv4 address (a bytes-like object four bytes in length) to its standard dotted-quad string representation (for example, ‘123.45.67.89’). This is useful when conversing with a program that uses the standard C library and needs objects of type `struct in_addr`, which is the C type for the 32-bit packed binary data this function takes as an argument.

If the byte sequence passed to this function is not exactly 4 bytes in length, **OSError** will be raised. `inet_aton()` does not support IPv6, and `inet_ntop()` should be used instead for IPv4/v6 dual stack support.

*Changed in version 3.5:* Writable bytes-like object is now accepted.

```python
socket.inet_ntoa(packed_ip)
```

Convert a 32-bit packed IPv4 address (a bytes-like object four bytes in length) to its standard dotted-quad string representation (for example, ‘123.45.67.89’). This is useful when conversing with a program that uses the standard C library and needs objects of type `struct in_addr`, which is the C type for the 32-bit packed binary data this function takes as an argument.

If the byte sequence passed to this function is not exactly 4 bytes in length, **OSError** will be raised. `inet_aton()` does not support IPv6, and `inet_ntop()` should be used instead for IPv4/v6 dual stack support.

*Changed in version 3.5:* Writable bytes-like object is now accepted.

```python
socket.inet_pton(address_family, ip_string)
```

Convert an IP address from its family-specific string format to a packed, binary format. `inet_pton()` is useful when a library or network protocol calls for an object of type `struct in_addr` (similar to `inet_aton()`) or `struct in6_addr`.

Supported values for `address_family` are currently **AF_INET** and **AF_INET6**. If the IP address string `ip_string` is invalid, **OSError** will be raised. Note that exactly what is valid depends on both the value of `address_family` and the underlying implementation of `inet_pton()`.
Availability: Unix (maybe not all platforms), Windows.

*Changed in version 3.4:* Windows support added

socket.`inet_ntop`(address_family, packed_ip)

Convert a packed IP address (a bytes-like object of some number of bytes) to its standard, family-specific string representation (for example, '7.10.0.5' or '5aef:2b::8'). `inet_ntop()` is useful when a library or network protocol returns an object of type `struct in_addr` (similar to `inet_ntoa()`) or `struct in6_addr`.

Supported values for `address_family` are currently `AF_INET` and `AF_INET6`. If the bytes object `packed_ip` is not the correct length for the specified address family, `ValueError` will be raised. `OSError` is raised for errors from the call to `inet_ntop()`.

Availability: Unix (maybe not all platforms), Windows.

*Changed in version 3.4:* Windows support added

*Changed in version 3.5:* Writable bytes-like object is now accepted.

socket.`CMSG_LEN`(length)

Return the total length, without trailing padding, of an ancillary data item with associated data of the given length. This value can often be used as the buffer size for `recvmsg()` to receive a single item of ancillary data, but RFC 3542 requires portable applications to use `CMSG_SPACE()` and thus include space for padding, even when the item will be the last in the buffer. Raises `OverflowError` if `length` is outside the permissible range of values.
Availability: most Unix platforms, possibly others.

New in version 3.3.

socket.\texttt{CMSG\_SPACE}(length)

Return the buffer size needed for \texttt{recvmsg()} to receive an ancillary data item with associated data of the given \texttt{length}, along with any trailing padding. The buffer space needed to receive multiple items is the sum of the \texttt{CMSG\_SPACE()} values for their associated data lengths. Raises \texttt{OverflowError} if \texttt{length} is outside the permissible range of values.

Note that some systems might support ancillary data without providing this function. Also note that setting the buffer size using the results of this function may not precisely limit the amount of ancillary data that can be received, since additional data may be able to fit into the padding area.

Availability: most Unix platforms, possibly others.

New in version 3.3.

socket.\texttt{getdefaulttimeout}()

Return the default timeout in seconds (float) for new socket objects. A value of \texttt{None} indicates that new socket objects have no timeout. When the socket module is first imported, the default is \texttt{None}.

socket.\texttt{setdefaulttimeout}(timeout)

Set the default timeout in seconds (float) for new socket objects. When the socket module is first imported, the default is \texttt{None}. See \texttt{settimeout()} for possible values and their respective meanings.
socket.\texttt{sethostname}(\textit{name})

Set the machine's hostname to \textit{name}. This will raise an \texttt{OSError} if you don’t have enough rights.

Availability: Unix.

\textit{New in version 3.3.}

socket.\texttt{if\_nameindex}()

Return a list of network interface information (index int, name string) tuples. \texttt{OSError} if the system call fails.

Availability: Unix.

\textit{New in version 3.3.}

socket.\texttt{if\_nametoindex}(\textit{if\_name})

Return a network interface index number corresponding to an interface name. \texttt{OSError} if no interface with the given name exists.

Availability: Unix.

\textit{New in version 3.3.}

socket.\texttt{if\_indextoname}(\textit{if\_index})

Return a network interface name corresponding to an interface index number. \texttt{OSError} if no interface with the given index exists.

Availability: Unix.

\textit{New in version 3.3.}
18.1.3. Socket Objects

Socket objects have the following methods. Except for `makefile()`, these correspond to Unix system calls applicable to sockets.

*Changed in version 3.2:* Support for the context manager protocol was added. Exiting the context manager is equivalent to calling `close()`.

`socket.accept()`

Accept a connection. The socket must be bound to an address and listening for connections. The return value is a pair (conn, address) where conn is a new socket object usable to send and receive data on the connection, and address is the address bound to the socket on the other end of the connection.

The newly created socket is non-inheritable.

*Changed in version 3.4:* The socket is now non-inheritable.

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an `InterruptedError` exception (see PEP 475 for the rationale).

`socket.bind(address)`

Bind the socket to address. The socket must not already be bound. (The format of address depends on the address family — see above.)

`socket.close()`

Mark the socket closed. The underlying system resource (e.g. a file descriptor) is also closed when all file objects from `makefile()`
are closed. Once that happens, all future operations on the socket object will fail. The remote end will receive no more data (after queued data is flushed).

Sockets are automatically closed when they are garbage-collected, but it is recommended to close() them explicitly, or to use a with statement around them.

*Changed in version 3.6:* OSError is now raised if an error occurs when the underlying close() call is made.

**Note:** close() releases the resource associated with a connection but does not necessarily close the connection immediately. If you want to close the connection in a timely fashion, call shutdown() before close().

socket.connect(address)

Connect to a remote socket at address. (The format of address depends on the address family — see above.)

If the connection is interrupted by a signal, the method waits until the connection completes, or raise a socket.timeout on timeout, if the signal handler doesn't raise an exception and the socket is blocking or has a timeout. For non-blocking sockets, the method raises an InterruptedError exception if the connection is interrupted by a signal (or the exception raised by the signal handler).

*Changed in version 3.5:* The method now waits until the connection completes instead of raising an InterruptedError exception if the connection is interrupted by a signal, the signal handler doesn't raise an exception and the socket is blocking or has a timeout (see
the PEP 475 for the rationale).

socket.connect_ex(address)
Like connect(address), but return an error indicator instead of raising an exception for errors returned by the C-level connect() call (other problems, such as “host not found,” can still raise exceptions). The error indicator is 0 if the operation succeeded, otherwise the value of the errno variable. This is useful to support, for example, asynchronous connects.

socket.detach()
Put the socket object into closed state without actually closing the underlying file descriptor. The file descriptor is returned, and can be reused for other purposes.

New in version 3.2.

socket.dup()
Duplicate the socket.

The newly created socket is non-inheritable.

Changed in version 3.4: The socket is now non-inheritable.

socket.fileno()
Return the socket’s file descriptor (a small integer), or -1 on failure. This is useful with select.select().

Under Windows the small integer returned by this method cannot be used where a file descriptor can be used (such as os.fdopen()). Unix does not have this limitation.

socket.get_inheritable()
Get the **inheritable flag** of the socket's file descriptor or socket's handle: **True** if the socket can be inherited in child processes, **False** if it cannot.

*New in version 3.4.*

**socket.getpeername()**

Return the remote address to which the socket is connected. This is useful to find out the port number of a remote IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.) On some systems this function is not supported.

**socket.getsockname()**

Return the socket's own address. This is useful to find out the port number of an IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.)

**socket.getsockopt**(level, optname[, buflen])

Return the value of the given socket option (see the Unix man page *getsockopt*(2)). The needed symbolic constants (SO_* etc.) are defined in this module. If `buflen` is absent, an integer option is assumed and its integer value is returned by the function. If `buflen` is present, it specifies the maximum length of the buffer used to receive the option in, and this buffer is returned as a bytes object. It is up to the caller to decode the contents of the buffer (see the optional built-in module *struct* for a way to decode C structures encoded as byte strings).

**socket.gettimeout()**

Return the timeout in seconds (float) associated with socket operations, or **None** if no timeout is set. This reflects the last call to
setblocking() or settimeout().

socket.

**ioctl()**

Platform: Windows

The **ioctl()** method is a limited interface to the WSAIoctl system interface. Please refer to the Win32 documentation for more information.

On other platforms, the generic **fcntl.fcntl()** and **fcntl.ioctl()** functions may be used; they accept a socket object as their first argument.

Currently only the following control codes are supported: **SIO_RCVALL**, **SIO_KEEPALIVE_VALS**, and **SIO_LOOPBACK_FAST_PATH**.

*Changed in version 3.6:* **SIO_LOOPBACK_FAST_PATH** was added.

socket.

**listen()**

Enable a server to accept connections. If **backlog** is specified, it must be at least 0 (if it is lower, it is set to 0); it specifies the number of unaccepted connections that the system will allow before refusing new connections. If not specified, a default reasonable value is chosen.

*Changed in version 3.5:* The **backlog** parameter is now optional.

socket.

**makefile()**

Return a file object associated with the socket. The exact returned type depends on the arguments given to **makefile()**. These arguments are interpreted the same way as by the built-in **open()**
function, except the only supported mode values are 'r' (default), 'w' and 'b'.

The socket must be in blocking mode; it can have a timeout, but the file object's internal buffer may end up in an inconsistent state if a timeout occurs.

Closing the file object returned by `makefile()` won't close the original socket unless all other file objects have been closed and `socket.close()` has been called on the socket object.

Note: On Windows, the file-like object created by `makefile()` cannot be used where a file object with a file descriptor is expected, such as the stream arguments of `subprocess.Popen()`.

```python
socket.recv(bufsize[, flags])
```

Receive data from the socket. The return value is a bytes object representing the data received. The maximum amount of data to be received at once is specified by `bufsize`. See the Unix manual page `recv(2)` for the meaning of the optional argument `flags`; it defaults to zero.

Note: For best match with hardware and network realities, the value of `bufsize` should be a relatively small power of 2, for example, 4096.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an `InterruptedError` exception (see PEP 475 for the rationale).
socket.recvfrom(bufsize[, flags])

Receive data from the socket. The return value is a pair (bytes, address) where bytes is a bytes object representing the data received and address is the address of the socket sending the data. See the Unix manual page recv(2) for the meaning of the optional argument flags; it defaults to zero. (The format of address depends on the address family — see above.)

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an InterruptedError exception (see PEP 475 for the rationale).

socket.recvmsg(bufsize[, ancbufsize[, flags]])

Receive normal data (up to bufsize bytes) and ancillary data from the socket. The ancbufsize argument sets the size in bytes of the internal buffer used to receive the ancillary data; it defaults to 0, meaning that no ancillary data will be received. Appropriate buffer sizes for ancillary data can be calculated using CMSG_SPACE() or CMSG_LEN(), and items which do not fit into the buffer might be truncated or discarded. The flags argument defaults to 0 and has the same meaning as for recv().

The return value is a 4-tuple: (data, ancdata, msg_flags, address). The data item is a bytes object holding the non-ancillary data received. The ancdata item is a list of zero or more tuples (cmsg_level, cmsg_type, cmsg_data) representing the ancillary data (control messages) received: cmsg_level and cmsg_type are integers specifying the protocol level and protocol-specific type respectively, and cmsg_data is a bytes object holding the associated data. The msg_flags item is the bitwise OR
of various flags indicating conditions on the received message; see your system documentation for details. If the receiving socket is unconnected, address is the address of the sending socket, if available; otherwise, its value is unspecified.

On some systems, `sendmsg()` and `recvmsg()` can be used to pass file descriptors between processes over an AF_UNIX socket. When this facility is used (it is often restricted to SOCK_STREAM sockets), `recvmsg()` will return, in its ancillary data, items of the form `(socket.SOL_SOCKET, socket.SCM_RIGHTS, fds)`, where `fds` is a `bytes` object representing the new file descriptors as a binary array of the native C `int` type. If `recvmsg()` raises an exception after the system call returns, it will first attempt to close any file descriptors received via this mechanism.

Some systems do not indicate the truncated length of ancillary data items which have been only partially received. If an item appears to extend beyond the end of the buffer, `recvmsg()` will issue a `RuntimeWarning`, and will return the part of it which is inside the buffer provided it has not been truncated before the start of its associated data.

On systems which support the SCM_RIGHTS mechanism, the following function will receive up to `maxfds` file descriptors, returning the message data and a list containing the descriptors (while ignoring unexpected conditions such as unrelated control messages being received). See also `sendmsg()`.

```python
import socket, array

def recv_fds(sock, msglen, maxfds):
    fds = array.array("i")  # Array of ints
    msg, ancdata, flags, addr = sock.recvmsg(msglen
```
for cmsg_level, cmsg_type, cmsg_data in ancdata:
    if (cmsg_level == socket.SOL_SOCKET and cmsg_type == socket.SCM_RIGHTS):
        # Append data, ignoring any truncated entries.
        fds.fromstring(cmsg_data[:len(cmsg_data) - 1])
return msg, list(fds)

Availability: most Unix platforms, possibly others.

*New in version 3.3.*

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](https://www.python.org/dev/peps/pep-0475) for the rationale).

```
socket.recvmsg_into(buffers, ancbufsize, flags)
```

Receive normal data and ancillary data from the socket, behaving as `recvmsg()` would, but scatter the non-ancillary data into a series of buffers instead of returning a new bytes object. The `buffers` argument must be an iterable of objects that export writable buffers (e.g. `bytearray` objects); these will be filled with successive chunks of the non-ancillary data until it has all been written or there are no more buffers. The operating system may set a limit (via `sysconf()` value `SC_IOV_MAX`) on the number of buffers that can be used. The `ancbufsize` and `flags` arguments have the same meaning as for `recvmsg()`.

The return value is a 4-tuple: `(nbytes, ancdata, msg_flags, address)`, where `nbytes` is the total number of bytes of non-ancillary data written into the buffers, and `ancdata`, `msg_flags` and `address` are the same as for `recvmsg()`.  

Example:

```python
>>> import socket
>>> s1, s2 = socket.socketpair()
>>> b1 = bytearray(b'----')
>>> b2 = bytearray(b'0123456789')
>>> b3 = bytearray(b'----------')
>>> s1.send(b'Mary had a little lamb')
22
>>> s2.recvmsg_into([b1, memoryview(b2)[2:9], b3])
(22, [], 0, None)
>>> [b1, b2, b3]
[bytearray(b'Mary'), bytearray(b'01 had a 9'), bytearray(b'little lamb---')]
```

Availability: most Unix platforms, possibly others.

*New in version 3.3.*

`socket.recvfrom_into(buffer[, nbytes[, flags]])`

Receive data from the socket, writing it into `buffer` instead of creating a new bytestring. The return value is a pair `(nbytes, address)` where `nbytes` is the number of bytes received and `address` is the address of the socket sending the data. See the Unix manual page `recv(2)` for the meaning of the optional argument `flags`; it defaults to zero. (The format of `address` depends on the address family — see above.)

`socket.recv_into(buffer[, nbytes[, flags]])`

Receive up to `nbytes` bytes from the socket, storing the data into a buffer rather than creating a new bytestring. If `nbytes` is not specified (or 0), receive up to the size available in the given buffer. Returns the number of bytes received. See the Unix manual page `recv(2)` for the meaning of the optional argument `flags`; it defaults to
socket.send(bytes[, flags])

Send data to the socket. The socket must be connected to a remote socket. The optional flags argument has the same meaning as for recv() above. Returns the number of bytes sent. Applications are responsible for checking that all data has been sent; if only some of the data was transmitted, the application needs to attempt delivery of the remaining data. For further information on this topic, consult the Socket Programming HOWTO.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an InterruptedError exception (see PEP 475 for the rationale).

socket.sendall(bytes[, flags])

Send data to the socket. The socket must be connected to a remote socket. The optional flags argument has the same meaning as for recv() above. Unlike send(), this method continues to send data from bytes until either all data has been sent or an error occurs. None is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully sent.

Changed in version 3.5: The socket timeout is no more reset each time data is sent successfully. The socket timeout is now the maximum total duration to send all data.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries
the system call instead of raising an \texttt{InterruptedError} exception (see \texttt{PEP 475} for the rationale).

\begin{verbatim}
socket.sendto(bytes, address)
socket.sendto(bytes, flags, address)
\end{verbatim}

Send data to the socket. The socket should not be connected to a remote socket, since the destination socket is specified by \texttt{address}. The optional \texttt{flags} argument has the same meaning as for \texttt{recv()} above. Return the number of bytes sent. (The format of \texttt{address} depends on the address family — see above.)

\textit{Changed in version 3.5}: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an \texttt{InterruptedError} exception (see \texttt{PEP 475} for the rationale).

\begin{verbatim}
socket.sendmsg(buffers[, ancdata[, flags[, address]]])
\end{verbatim}

Send normal and ancillary data to the socket, gathering the non-ancillary data from a series of buffers and concatenating it into a single message. The \texttt{buffers} argument specifies the non-ancillary data as an iterable of \texttt{bytes-like objects} (e.g. \texttt{bytes} objects); the operating system may set a limit (\texttt{sysconf()} value \texttt{SC_IOV_MAX}) on the number of buffers that can be used. The \texttt{ancdata} argument specifies the ancillary data (control messages) as an iterable of zero or more tuples (\texttt{cmsg_level, cmsg_type, cmsg_data}), where \texttt{cmsg_level} and \texttt{cmsg_type} are integers specifying the protocol level and protocol-specific type respectively, and \texttt{cmsg_data} is a \texttt{bytes-like object} holding the associated data. Note that some systems (in particular, systems without \texttt{CMSG_SPACE( )}) might support sending only one control message per call. The \texttt{flags} argument defaults to 0 and has the same meaning as for \texttt{send()}. 
If `address` is supplied and not `None`, it sets a destination address for the message. The return value is the number of bytes of non-ancillary data sent.

The following function sends the list of file descriptors `fds` over an `AF_UNIX` socket, on systems which support the `SCM_RIGHTS` mechanism. See also `recvmsg()`.

```python
import socket, array

def send_fds(sock, msg, fds):
    return sock.sendmsg([msg], [(socket.SOL_SOCKET, 0)])
```

Availability: most Unix platforms, possibly others.

*New in version 3.3.*

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](https://www.python.org/dev/peps/pep-0475) for the rationale).

```python
socket.sendmsg_afalg([msg,*], op[, iv[, assoclen[, flags]]])
```

Specialized version of `sendmsg()` for `AF_ALG` socket. Set mode, IV, AEAD associated data length and flags for `AF_ALG` socket.

Availability: Linux >= 2.6.38

*New in version 3.6.*

```python
socket.sendfile(file, offset=0, count=None)
```

Send a file until EOF is reached by using high-performance `os.sendfile` and return the total number of bytes which were
sent. `file` must be a regular file object opened in binary mode. If `os.sendfile` is not available (e.g. Windows) or `file` is not a regular file `send()` will be used instead. `offset` tells from where to start reading the file. If specified, `count` is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is updated on return or also in case of error in which case `file.tell()` can be used to figure out the number of bytes which were sent. The socket must be of `SOCK_STREAM` type. Non-blocking sockets are not supported.

*New in version 3.5.*

socket. `.set_inheritable(inheritable)`
Set the `inheritable` flag of the socket's file descriptor or socket's handle.

*New in version 3.4.*

socket. `.setblocking(flag)`
Set blocking or non-blocking mode of the socket: if `flag` is false, the socket is set to non-blocking, else to blocking mode.

This method is a shorthand for certain `settimeout()` calls:

- `sock.setblocking(True)` is equivalent to `sock.settimeout(None)`
- `sock.setblocking(False)` is equivalent to `sock.settimeout(0.0)`

socket. `.settimeout(value)`
Set a timeout on blocking socket operations. The `value` argument can be a nonnegative floating point number expressing seconds, or `None`. If a non-zero value is given, subsequent socket operations
will raise a timeout exception if the timeout period value has elapsed before the operation has completed. If zero is given, the socket is put in non-blocking mode. If None is given, the socket is put in blocking mode.

For further information, please consult the notes on socket timeouts.

socket.setsockopt((level, optname, value: int))

socket.setsockopt((level, optname, value: buffer))

socket.setsockopt((level, optname, None, optlen: int))

Set the value of the given socket option (see the Unix manual page setsockopt(2)). The needed symbolic constants are defined in the socket module (SO_* etc.). The value can be an integer, None or a bytes-like object representing a buffer. In the later case it is up to the caller to ensure that the bytestring contains the proper bits (see the optional built-in module struct for a way to encode C structures as bytestrings). When value is set to None, optlen argument is required. It’s equivalent to call setsockopt C function with optval=NULL and optlen=optlen.

Changed in version 3.5: Writable bytes-like object is now accepted.

Changed in version 3.6: setsockopt(level, optname, None, optlen: int) form added.

socket.shutdown((how))

Shut down one or both halves of the connection. If how is SHUT_RD, further receives are disallowed. If how is SHUT_WR, further sends are disallowed. If how is SHUT_RDWR, further sends and receives are disallowed.
socket. **share**(process_id)

Duplicate a socket and prepare it for sharing with a target process. The target process must be provided with `process_id`. The resulting bytes object can then be passed to the target process using some form of interprocess communication and the socket can be recreated there using `fromshare()`. Once this method has been called, it is safe to close the socket since the operating system has already duplicated it for the target process.

Availability: Windows.

*New in version 3.3.*

Note that there are no methods `read()` or `write()`; use `recv()` and `send()` without `flags` argument instead.

Socket objects also have these (read-only) attributes that correspond to the values given to the `socket` constructor.

socket. **family**

The socket family.

socket. **type**

The socket type.

socket. **proto**

The socket protocol.
18.1.4. Notes on socket timeouts

A socket object can be in one of three modes: blocking, non-blocking, or timeout. Sockets are by default always created in blocking mode, but this can be changed by calling `setdefaulttimeout()`.

- In **blocking mode**, operations block until complete or the system returns an error (such as connection timed out).
- In **non-blocking mode**, operations fail (with an error that is unfortunately system-dependent) if they cannot be completed immediately: functions from the `select` can be used to know when and whether a socket is available for reading or writing.
- In **timeout mode**, operations fail if they cannot be completed within the timeout specified for the socket (they raise a timeout exception) or if the system returns an error.

**Note:** At the operating system level, sockets in timeout mode are internally set in non-blocking mode. Also, the blocking and timeout modes are shared between file descriptors and socket objects that refer to the same network endpoint. This implementation detail can have visible consequences if e.g. you decide to use the `fileno()` of a socket.

18.1.4.1. Timeouts and the connect method

The `connect()` operation is also subject to the timeout setting, and in general it is recommended to call `settimeout()` before calling `connect()` or pass a timeout parameter to `create_connection()`. However, the system network stack may also return a connection timeout error of its own regardless of any Python socket timeout setting.
18.1.4.2. Timeouts and the accept method

If `getdefaulttimeout()` is not `None`, sockets returned by the `accept()` method inherit that timeout. Otherwise, the behaviour depends on settings of the listening socket:

- if the listening socket is in `blocking mode` or in `timeout mode`, the socket returned by `accept()` is in `blocking mode`;
- if the listening socket is in `non-blocking mode`, whether the socket returned by `accept()` is in blocking or non-blocking mode is operating system-dependent. If you want to ensure cross-platform behaviour, it is recommended you manually override this setting.
18.1.5. Example

Here are four minimal example programs using the TCP/IP protocol: a server that echoes all data that it receives back (servicing only one client), and a client using it. Note that a server must perform the sequence `socket()`, `bind()`, `listen()`, `accept()` (possibly repeating the `accept()` to service more than one client), while a client only needs the sequence `socket()`, `connect()`. Also note that the server does not `sendall()/recv()` on the socket it is listening on but on the new socket returned by `accept()`.

The first two examples support IPv4 only.

```python
# Echo server program
import socket

HOST = ''  # Symbolic name meaning all available interfaces
PORT = 50007  # Arbitrary non-privileged port

with socket.socket(socket.AF_INET, socket.SOCK_STREAM) as s:
    s.bind((HOST, PORT))
    s.listen(1)
    conn, addr = s.accept()
    with conn:
        print('Connected by', addr)
        while True:
            data = conn.recv(1024)
            if not data: break
            conn.sendall(data)
```

```python
# Echo client program
import socket

HOST = 'daring.cwi.nl'  # The remote host
```
PORT = 50007  # The same port as used by

with socket.socket(socket.AF_INET, socket.SOCK_STREAM)
    s.connect((HOST, PORT))
    s.sendall(b'Hello, world')
    data = s.recv(1024)
    print('Received', repr(data))

The next two examples are identical to the above two, but support both IPv4 and IPv6. The server side will listen to the first address family available (it should listen to both instead). On most of IPv6-ready systems, IPv6 will take precedence and the server may not accept IPv4 traffic. The client side will try to connect to the all addresses returned as a result of the name resolution, and sends traffic to the first one connected successfully.

# Echo server program
import socket
import sys

HOST = None  # Symbolic name meaning all available interfaces
PORT = 50007  # Arbitrary non-privileged port
s = None

for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC, socket.SOCK_STREAM, 0, socket.AI_PASSIVE):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except OSError as msg:
        s = None
        continue
    try:
        s.bind(sa)
        s.listen(1)
    except OSError as msg:
        s.close()
```
# Echo client program
import socket
import sys

HOST = 'daring.cwi.nl'       # The remote host
PORT = 50007                 # The same port as used by the server
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC, socket.SOCK_STREAM, 0, socket.AI_PASSIVE):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except OSError as msg:
        s = None
        continue
    try:
        s.connect(sa)
    except OSError as msg:
        s.close()
        s = None
        continue
    break
if s is None:
    s = None
continue
break
if s is None:
    print('could not open socket')
    sys.exit(1)

conn, addr = s.accept()
with conn:
    print('Connected by', addr)
    while True:
        data = conn.recv(1024)
        if not data: break
        conn.send(data)
```

The next example shows how to write a very simple network sniffer with raw sockets on Windows. The example requires administrator privileges to modify the interface:

```python
import socket

# the public network interface
HOST = socket.gethostbyname(socket.gethostname())

# create a raw socket and bind it to the public interface
s = socket.socket(socket.AF_INET, socket.SOCK_RAW, socket.IPPROTO_IP)
s.bind((HOST, 0))

# Include IP headers
s.setsockopt(socket.IPPROTO_IP, socket.IP_HDRINCL, 1)

# receive all packages
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_ON)

# receive a package
print(s.recvfrom(65565))

# disabled promiscuous mode
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_OFF)
```

The last example shows how to use the socket interface to communicate to a CAN network using the raw socket protocol. To use
CAN with the broadcast manager protocol instead, open a socket with:

```python
socket.socket(socket.AF_CAN, socket.SOCK_DGRAM, socket.SO_REUSEADDR)
```

After binding (CAN_RAW) or connecting (CAN_BCM) the socket, you can use the `socket.send()`, and the `socket.recv()` operations (and their counterparts) on the socket object as usual.

This example might require special privileges:

```python
import socket
import struct

# CAN frame packing/unpacking (see 'struct can_frame' in <linux/can.h>)
can_frame_fmt = "=IB3x8s"
can_frame_size = struct.calcsize(can_frame_fmt)

def build_can_frame(can_id, data):
    can_dlc = len(data)
    data = data.ljust(8, b'\x00')
    return struct.pack(can_frame_fmt, can_id, can_dlc)

def dissect_can_frame(frame):
    can_id, can_dlc, data = struct.unpack(can_frame_fmt, frame)
    return (can_id, can_dlc, data[:can_dlc])

# create a raw socket and bind it to the 'vcan0' interface
s = socket.socket(socket.AF_CAN, socket.SOCK_RAW, socket.SO_REUSEADDR)
s.bind(('vcan0',))

while True:
    cf, addr = s.recvfrom(can_frame_size)
```
print('Received: can_id=%x, can_dlc=%x, data=%s')

try:
    s.send(cf)
except OSError:
    print('Error sending CAN frame')

try:
    s.send(build_can_frame(0x01, b'\x01\x02\x03'))
except OSError:
    print('Error sending CAN frame')

Running an example several times with too small delay between executions, could lead to this error:

**OSError: [Errno 98] Address already in use**

This is because the previous execution has left the socket in a **TIME_WAIT** state, and can't be immediately reused.

There is a **socket** flag to set, in order to prevent this, `socket.SO_REUSEADDR`:

```python
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.setsockopt(socket.SOL_SOCKET, socket.SO_REUSEADDR, 1)
s.bind((HOST, PORT))
```

the **SO_REUSEADDR** flag tells the kernel to reuse a local socket in **TIME_WAIT** state, without waiting for its natural timeout to expire.

**See also:** For an introduction to socket programming (in C), see the following papers:
- *An Introductory 4.3BSD Interprocess Communication Tutorial*, by Stuart Sechrest
- *An Advanced 4.3BSD Interprocess Communication Tutorial*, by Samuel J. Leffler et al,

both in the UNIX Programmer's Manual, Supplementary Documents 1 (sections PS1:7 and PS1:8). The platform-specific reference material for the various socket-related system calls are also a valuable source of information on the details of socket semantics. For Unix, refer to the manual pages; for Windows, see the WinSock (or Winsock 2) specification. For IPv6-ready APIs, readers may want to refer to [RFC 3493](https://www.rfc-editor.org/rfc/rfc3493) titled Basic Socket Interface Extensions for IPv6.
18.2. **ssl** — TLS/SSL wrapper for socket objects

**Source code:** Lib/ssl.py

This module provides access to Transport Layer Security (often known as “Secure Sockets Layer”) encryption and peer authentication facilities for network sockets, both client-side and server-side. This module uses the OpenSSL library. It is available on all modern Unix systems, Windows, Mac OS X, and probably additional platforms, as long as OpenSSL is installed on that platform.

**Note:** Some behavior may be platform dependent, since calls are made to the operating system socket APIs. The installed version of OpenSSL may also cause variations in behavior. For example, TLSv1.1 and TLSv1.2 come with openssl version 1.0.1.

**Warning:** Don’t use this module without reading the Security considerations. Doing so may lead to a false sense of security, as the default settings of the ssl module are not necessarily appropriate for your application.

This section documents the objects and functions in the ssl module; for more general information about TLS, SSL, and certificates, the reader is referred to the documents in the “See Also” section at the bottom.

This module provides a class, `ssl.SSLsocket`, which is derived from the `socket.socket` type, and provides a socket-like wrapper that
also encrypts and decrypts the data going over the socket with SSL. It supports additional methods such as getpeercert(), which retrieves the certificate of the other side of the connection, and cipher(), which retrieves the cipher being used for the secure connection.

For more sophisticated applications, the `ssl.SSLContext` class helps manage settings and certificates, which can then be inherited by SSL sockets created through the `SSLContext.wrap_socket()` method.

*Changed in version 3.6:* OpenSSL 0.9.8, 1.0.0 and 1.0.1 are deprecated and no longer supported. In the future the `ssl` module will require at least OpenSSL 1.0.2 or 1.1.0.
18.2.1. Functions, Constants, and Exceptions

**exception ssl.SSLError**

Raised to signal an error from the underlying SSL implementation (currently provided by the OpenSSL library). This signifies some problem in the higher-level encryption and authentication layer that’s superimposed on the underlying network connection. This error is a subtype of OSError. The error code and message of SSLError instances are provided by the OpenSSL library.

*Changed in version 3.3:* SSLError used to be a subtype of socket.error.

**library**

A string mnemonic designating the OpenSSL submodule in which the error occurred, such as SSL, PEM or X509. The range of possible values depends on the OpenSSL version.

*New in version 3.3.*

**reason**

A string mnemonic designating the reason this error occurred, for example CERTIFICATE_VERIFY_FAILED. The range of possible values depends on the OpenSSL version.

*New in version 3.3.*

**exception ssl.SSLZeroReturnError**

A subclass of SSLError raised when trying to read or write and the SSL connection has been closed cleanly. Note that this doesn’t
mean that the underlying transport (read TCP) has been closed.

*New in version 3.3.*

**exception ssl.**\texttt{SSLWantReadError}

A subclass of \texttt{SSLError} raised by a non-blocking SSL socket when trying to read or write data, but more data needs to be received on the underlying TCP transport before the request can be fulfilled.

*New in version 3.3.*

**exception ssl.**\texttt{SSLWantWriteError}

A subclass of \texttt{SSLError} raised by a non-blocking SSL socket when trying to read or write data, but more data needs to be sent on the underlying TCP transport before the request can be fulfilled.

*New in version 3.3.*

**exception ssl.**\texttt{SSLSyscallError}

A subclass of \texttt{SSLError} raised when a system error was encountered while trying to fulfill an operation on a SSL socket. Unfortunately, there is no easy way to inspect the original errno number.

*New in version 3.3.*

**exception ssl.**\texttt{SSLEOFError}

A subclass of \texttt{SSLError} raised when the SSL connection has been terminated abruptly. Generally, you shouldn’t try to reuse the underlying transport when this error is encountered.

*New in version 3.3.*
exception ssl.CertificateError

Raised to signal an error with a certificate (such as mismatching hostname). Certificate errors detected by OpenSSL, though, raise an SSLError.

18.2.1.1. Socket creation

The following function allows for standalone socket creation. Starting from Python 3.2, it can be more flexible to use SSLContext.wrap_socket() instead.

ssl.wrap_socket(sock, keyfile=None, certfile=None, server_side=False, cert_reqs=CERT_NONE, ssl_version={see docs}, ca_certs=None, do_handshake_on_connect=True, suppress_ragged_eofs=True, ciphers=None)

Takes an instance sock of socket.socket, and returns an instance of ssl.SSLSocket, a subtype of socket.socket, which wraps the underlying socket in an SSL context. sock must be a SOCK_STREAM socket; other socket types are unsupported.

For client-side sockets, the context construction is lazy; if the underlying socket isn’t connected yet, the context construction will be performed after connect() is called on the socket. For server-side sockets, if the socket has no remote peer, it is assumed to be a listening socket, and the server-side SSL wrapping is automatically performed on client connections accepted via the accept() method. wrap_socket() may raise SSLError.

The keyfile and certfile parameters specify optional files which contain a certificate to be used to identify the local side of the connection. See the discussion of Certificates for more information on how the certificate is stored in the certfile.
The parameter `server_side` is a boolean which identifies whether server-side or client-side behavior is desired from this socket.

The parameter `cert_reqs` specifies whether a certificate is required from the other side of the connection, and whether it will be validated if provided. It must be one of the three values `CERT_NONE` (certificates ignored), `CERT_OPTIONAL` (not required, but validated if provided), or `CERT_REQUIRED` (required and validated). If the value of this parameter is not `CERT_NONE`, then the `ca_certs` parameter must point to a file of CA certificates.

The `ca_certs` file contains a set of concatenated “certification authority” certificates, which are used to validate certificates passed from the other end of the connection. See the discussion of Certificates for more information about how to arrange the certificates in this file.

The parameter `ssl_version` specifies which version of the SSL protocol to use. Typically, the server chooses a particular protocol version, and the client must adapt to the server’s choice. Most of the versions are not interoperable with the other versions. If not specified, the default is `PROTOCOL_TLS`; it provides the most compatibility with other versions.

Here’s a table showing which versions in a client (down the side) can connect to which versions in a server (along the top):

<table>
<thead>
<tr>
<th>client / server</th>
<th>SSLv2</th>
<th>SSLv3</th>
<th>TLS [3]</th>
<th>TLSv1</th>
<th>TLSv1.1</th>
<th>TLSv1</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSLv2</td>
<td>yes</td>
<td>no</td>
<td>no [1]</td>
<td>no</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td></td>
<td>no</td>
<td>yes</td>
<td>no</td>
<td>no</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td>----------</td>

<td>no</td>
</tr>
<tr>
<td><strong>TLSv1.2</strong></td>
<td>no</td>
<td>no</td>
<td>yes</td>
<td>no</td>
<td>no</td>
<td>yes</td>
</tr>
</tbody>
</table>

Footnotes

[1] (1, 2) **SSLContext** disables SSLv2 with **OP_NO_SSLv2** by default.

[2] (1, 2) **SSLContext** disables SSLv3 with **OP_NO_SSLv3** by default.

[3] (1, 2) **TLS 1.3 protocol** will be available with **PROTOCOL_TLS** in OpenSSL >= 1.1.1. There is no dedicated **PROTOCOL** constant for just TLS 1.3.

Note: Which connections succeed will vary depending on the version of OpenSSL. For example, before OpenSSL 1.0.0, an SSLv23 client would always attempt SSLv2 connections.

The *ciphers* parameter sets the available ciphers for this SSL object. It should be a string in the **OpenSSL cipher list format**.

The parameter **do_handshake_on_connect** specifies whether to do the SSL handshake automatically after doing a socket.connect(), or whether the application program will call it explicitly, by invoking the **SSLSocket.do_handshake()** method. Calling **SSLSocket.do_handshake()** explicitly gives
the program control over the blocking behavior of the socket I/O involved in the handshake.

The parameter `suppress_ragged_eofs` specifies how the `SSLSocket.recv()` method should signal unexpected EOF from the other end of the connection. If specified as `True` (the default), it returns a normal EOF (an empty bytes object) in response to unexpected EOF errors raised from the underlying socket; if `False`, it will raise the exceptions back to the caller.

*Changed in version 3.2:* New optional argument `ciphers`.

### 18.2.1.2. Context creation

A convenience function helps create `SSLContext` objects for common purposes.

```python
going 
ssl.create_default_context(purpose=Purpose.SERVER_AUTH, cafile=None, capath=None, cadata=None)
```

Return a new `SSLContext` object with default settings for the given `purpose`. The settings are chosen by the `ssl` module, and usually represent a higher security level than when calling the `SSLContext` constructor directly.

`cafile`, `capath`, `cadata` represent optional CA certificates to trust for certificate verification, as in `SSLContext.load_verify_locations()`. If all three are `None`, this function can choose to trust the system's default CA certificates instead.

The settings are: `PROTOCOL_TLS`, `OP_NO_SSLv2`, and `OP_NO_SSLv3` with high encryption cipher suites without RC4 and
without unauthenticated cipher suites. Passing `SERVER_AUTH` as `purpose` sets `verify_mode` to `CERT_REQUIRED` and either loads CA certificates (when at least one of `cafile`, `capath` or `cadata` is given) or uses `SSLCtxContext.load_default_certs()` to load default CA certificates.

---

**Note:** The protocol, options, cipher and other settings may change to more restrictive values anytime without prior deprecation. The values represent a fair balance between compatibility and security. If your application needs specific settings, you should create a `SSLCtxContext` and apply the settings yourself.

---

**Note:** If you find that when certain older clients or servers attempt to connect with a `SSLCtxContext` created by this function that they get an error stating “Protocol or cipher suite mismatch”, it may be that they only support SSL3.0 which this function excludes using the `OP_NO_SSLv3`. SSL3.0 is widely considered to be completely broken. If you still wish to continue to use this function but still allow SSL 3.0 connections you can re-enable them using:

```python
ctx = ssl.create_default_context(Purpose.CLIENT
ctx.options &= ~ssl.OP_NO_SSLv3
```

*New in version 3.4.*

*Changed in version 3.4.4:* RC4 was dropped from the default cipher string.

*Changed in version 3.6:* ChaCha20/Poly1305 was added to the
default cipher string.

3DES was dropped from the default cipher string.

*Changed in version 3.6.3:* TLS 1.3 cipher suites TLS_AES_128_GCM_SHA256, TLS_AES_256_GCM_SHA384, and TLS_CHACHA20_POLY1305_SHA256 were added to the default cipher string.

### 18.2.1.3. Random generation

**ssl.** `RAND_bytes(num)`

Return *num* cryptographically strong pseudo-random bytes. Raises an *SSLError* if the PRNG has not been seeded with enough data or if the operation is not supported by the current RAND method. `RAND_status()` can be used to check the status of the PRNG and `RAND_add()` can be used to seed the PRNG.

For almost all applications `os.urandom()` is preferable.

Read the Wikipedia article, *Cryptographically secure pseudorandom number generator (CSPRNG)*, to get the requirements of a cryptographically generator.

*New in version 3.3.*

**ssl.** `RAND_pseudo_bytes(num)`

Return *(bytes, is_cryptographic)*: bytes are *num* pseudo-random bytes, *is_cryptographic* is `True` if the bytes generated are cryptographically strong. Raises an *SSLError* if the operation is not supported by the current RAND method.

Generated pseudo-random byte sequences will be unique if they
are of sufficient length, but are not necessarily unpredictable. They can be used for non-cryptographic purposes and for certain purposes in cryptographic protocols, but usually not for key generation etc.

For almost all applications `os.urandom()` is preferable.

*New in version 3.3.*

*Deprecated since version 3.6:* OpenSSL has deprecated `ssl.RAND_pseudo_bytes()`, use `ssl.RAND_bytes()` instead.

`ssl.RAND_status()`

Return `True` if the SSL pseudo-random number generator has been seeded with ‘enough’ randomness, and `False` otherwise. You can use `ssl.RAND_egd()` and `ssl.RAND_add()` to increase the randomness of the pseudo-random number generator.

`ssl.RAND_egd(path)`

If you are running an entropy-gathering daemon (EGD) somewhere, and `path` is the pathname of a socket connection open to it, this will read 256 bytes of randomness from the socket, and add it to the SSL pseudo-random number generator to increase the security of generated secret keys. This is typically only necessary on systems without better sources of randomness.

*Availability: not available with LibreSSL and OpenSSL > 1.1.0*

`ssl.RAND_add(bytes, entropy)`
Mix the given bytes into the SSL pseudo-random number generator. The parameter entropy (a float) is a lower bound on the entropy contained in string (so you can always use 0.0). See RFC 1750 for more information on sources of entropy.

Changed in version 3.5: Writable bytes-like object is now accepted.

18.2.1.4. Certificate handling

ssl.match_hostname(cert, hostname)

Verify that cert (in decoded format as returned by SSLSocket.getpeercert()) matches the given hostname. The rules applied are those for checking the identity of HTTPS servers as outlined in RFC 2818, RFC 5280 and RFC 6125. In addition to HTTPS, this function should be suitable for checking the identity of servers in various SSL-based protocols such as FTPS, IMAPS, POPS and others.

CertificateError is raised on failure. On success, the function returns nothing:

```python
>>> cert = {'subject': (('commonName', 'example.com'))
>>> ssl.match_hostname(cert, "example.com")
>>> ssl.match_hostname(cert, "example.org")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/py3k/Lib/ssl.py", line 130, in match_hostname
ssl.CertificateError: hostname 'example.org' doesn't match 'example.com'
```

New in version 3.2.

Changed in version 3.3.3: The function now follows RFC 6125, section 6.4.3 and does neither match multiple wildcards (e.g.
*.com or *a*.example.org) nor a wildcard inside an internationalized domain names (IDN) fragment. IDN A-labels such as www*.xn--thon-kva.org are still supported, but x*.python.org no longer matches xn--tda.python.org.

* Changed in version 3.5: Matching of IP addresses, when present in the subjectAltName field of the certificate, is now supported.

ssl.certificate_to_seconds(cert_time)

Return the time in seconds since the Epoch, given the cert_time string representing the “notBefore” or “notAfter” date from a certificate in "%b %d %H:%M:%S %Y %Z" strftime format (C locale).

Here’s an example:

```python
>>> import ssl
>>> timestamp = ssl.cert_time_to_seconds("Jan 5 09:34:43 2018 GMT")
>>> timestamp
1515144883
>>> from datetime import datetime
>>> print(datetime.utcfromtimestamp(timestamp))
2018-01-05 09:34:43
```

“notBefore” or “notAfter” dates must use GMT (RFC 5280).

* Changed in version 3.5: Interpret the input time as a time in UTC as specified by ‘GMT’ timezone in the input string. Local timezone was used previously. Return an integer (no fractions of a second in the input format)

ssl.get_server_certificate(addr, ssl_version=PROTOCOL_TLS, ca_certs=None)
Given the address `addr` of an SSL-protected server, as a `(hostname, port-number)` pair, fetches the server’s certificate, and returns it as a PEM-encoded string. If `ssl_version` is specified, uses that version of the SSL protocol to attempt to connect to the server. If `ca_certs` is specified, it should be a file containing a list of root certificates, the same format as used for the same parameter in `wrap_socket()`. The call will attempt to validate the server certificate against that set of root certificates, and will fail if the validation attempt fails.

*Changed in version 3.3:* This function is now IPv6-compatible.

*Changed in version 3.5:* The default `ssl_version` is changed from `PROTOCOL_SSLv3` to `PROTOCOL_TLS` for maximum compatibility with modern servers.

```python
ssl.DER_cert_to_PEM_cert(DER_cert_bytes)
```

Given a certificate as a DER-encoded blob of bytes, returns a PEM-encoded string version of the same certificate.

```python
ssl.PEM_cert_to_DER_cert(PEM_cert_string)
```

Given a certificate as an ASCII PEM string, returns a DER-encoded sequence of bytes for that same certificate.

```python
ssl.get_default_verify_paths()
```

Returns a named tuple with paths to OpenSSL’s default cafile and capath. The paths are the same as used by `SSLContext.set_default_verify_paths()`. The return value is a named tuple `DefaultVerifyPaths`:

- `cafile` - resolved path to cafile or `None` if the file doesn’t exist,
- `capath` - resolved path to capath or `None` if the directory
doesn't exist,

- `openssl_cafile_env` - OpenSSL's environment key that points to a cafile,
- `openssl_cafile` - hard coded path to a cafile,
- `openssl_capath_env` - OpenSSL's environment key that points to a capath,
- `openssl_capath` - hard coded path to a capath directory

Availability: LibreSSL ignores the environment vars `openssl_cafile_env` and `openssl_capath_env`  

*New in version 3.4.*

```python
ssl.enum_certificates(store_name)
```

Retrieve certificates from Windows' system cert store. `store_name` may be one of CA, ROOT or MY. Windows may provide additional cert stores, too.

The function returns a list of (cert_bytes, encoding_type, trust) tuples. The encoding_type specifies the encoding of cert_bytes. It is either `x509_asn` for X.509 ASN.1 data or `pkcs_7_asn` for PKCS#7 ASN.1 data. Trust specifies the purpose of the certificate as a set of OIDS or exactly `True` if the certificate is trustworthy for all purposes.

Example:

```python
>>> ssl.enum_certificates("CA")
[(b'data...', 'x509_asn', {'1.3.6.1.5.5.7.3.1', '1.3.6.1.5.5.7.3.2'}),
 (b'data...', 'x509_asn', True)]
```

Availability: Windows.

*New in version 3.4.*
ssl.\texttt{enum\_crls}(\texttt{store\_name})

Retrieve CRLs from Windows’ system cert store. \texttt{store\_name} may be one of \texttt{CA}, \texttt{ROOT} or \texttt{MY}. Windows may provide additional cert stores, too.

The function returns a list of (\texttt{cert\_bytes}, \texttt{encoding\_type}, \texttt{trust}) tuples. The \texttt{encoding\_type} specifies the encoding of \texttt{cert\_bytes}. It is either \texttt{x509\_asn} for X.509 ASN.1 data or \texttt{pkcs\_7\_asn} for PKCS#7 ASN.1 data.

Availability: Windows.

\textit{New in version 3.4.}

18.2.1.5. Constants

All constants are now \texttt{enum.IntEnum} or \texttt{enum.IntFlag} collections.

\textit{New in version 3.6.}

\texttt{ssl.CERT\_NONE}

Possible value for \texttt{SSLContext.verify\_mode}, or the \texttt{cert\_reqs} parameter to \texttt{wrap\_socket()}. In this mode (the default), no certificates will be required from the other side of the socket connection. If a certificate is received from the other end, no attempt to validate it is made.

See the discussion of \texttt{Security\_considerations} below.

\texttt{ssl.CERT\_OPTIONAL}

Possible value for \texttt{SSLContext.verify\_mode}, or the
The `cert_reqs` parameter to `wrap_socket()`. In this mode no certificates will be required from the other side of the socket connection; but if they are provided, validation will be attempted and an `SSLError` will be raised on failure.

Use of this setting requires a valid set of CA certificates to be passed, either to `SSLContext.load_verify_locations()` or as a value of the `ca_certs` parameter to `wrap_socket()`.

**ssl.CERT_REQUIRED**
Possible value for `SSLContext.verify_mode`, or the `cert_reqs` parameter to `wrap_socket()`. In this mode, certificates are required from the other side of the socket connection; an `SSLError` will be raised if no certificate is provided, or if its validation fails.

Use of this setting requires a valid set of CA certificates to be passed, either to `SSLContext.load_verify_locations()` or as a value of the `ca_certs` parameter to `wrap_socket()`.

**class ssl.VerifyMode**
`enum.IntEnum` collection of `CERT_*` constants.

*New in version 3.6.*

**ssl.VERIFY_DEFAULT**
Possible value for `SSLContext.verify_flags`. In this mode, certificate revocation lists (CRLs) are not checked. By default OpenSSL does neither require nor verify CRLs.

*New in version 3.4.*

**ssl.VERIFY_CRL_CHECK_LEAF**
Possible value for `SSLContext.verify_flags`. In this mode, only the peer cert is check but non of the intermediate CA certificates. The mode requires a valid CRL that is signed by the peer cert’s issuer (its direct ancestor CA). If no proper has been loaded `SSLContext.load_verify_locations`, validation will fail.

*New in version 3.4.*

```python
ssl.VERIFY_CRL_CHECK_CHAIN
```
Possible value for `SSLContext.verify_flags`. In this mode, CRLs of all certificates in the peer cert chain are checked.

*New in version 3.4.*

```python
ssl.VERIFY_X509 STRICT
```
Possible value for `SSLContext.verify_flags` to disable workarounds for broken X.509 certificates.

*New in version 3.4.*

```python
ssl.VERIFY_X509 TRUSTED FIRST
```
Possible value for `SSLContext.verify_flags`. It instructs OpenSSL to prefer trusted certificates when building the trust chain to validate a certificate. This flag is enabled by default.

*New in version 3.4.4.*

```python
class ssl.VerifyFlags
```
`enum.IntFlag` collection of VERIFY_* constants.

*New in version 3.6.*

```python
ssl.PROTOCOL_TLS
```
Selects the highest protocol version that both the client and server support. Despite the name, this option can select both “SSL” and “TLS” protocols.

*New in version 3.6.*

**ssl.PROTOCOL_TLS_CLIENT**

Auto-negotiate the highest protocol version like `PROTOCOL_TLS`, but only support client-side `SSLSocket` connections. The protocol enables `CERT_REQUIRED` and `check_hostname` by default.

*New in version 3.6.*

**ssl.PROTOCOL_TLS_SERVER**

Auto-negotiate the highest protocol version like `PROTOCOL_TLS`, but only support server-side `SSLSocket` connections.

*New in version 3.6.*

**ssl.PROTOCOL_SSLv23**

Alias for data: `PROTOCOL_TLS`.

*Deprecated since version 3.6:* Use `PROTOCOL_TLS` instead.

**ssl.PROTOCOL_SSLv2**

Selects SSL version 2 as the channel encryption protocol.

This protocol is not available if OpenSSL is compiled with the `OPENSSL_NO_SSL2` flag.

**Warning:** SSL version 2 is insecure. Its use is highly discouraged.

*Deprecated since version 3.6:* OpenSSL has removed support for
SSLv2.

ssl. **PROTOCOL_SSLv3**
Selects SSL version 3 as the channel encryption protocol.

This protocol is not be available if OpenSSL is compiled with the OPENSSL_NO_SSLv3 flag.

**Warning:** SSL version 3 is insecure. Its use is highly discouraged.

*Deprecated since version 3.6:* OpenSSL has deprecated all version specific protocols. Use the default protocol PROTOCOL_TLS with flags like OP_NO_SSLv3 instead.

ssl. **PROTOCOL_TLSv1**
Selects TLS version 1.0 as the channel encryption protocol.

*Deprecated since version 3.6:* OpenSSL has deprecated all version specific protocols. Use the default protocol PROTOCOL_TLS with flags like OP_NO_SSLv3 instead.

ssl. **PROTOCOL_TLSv1_1**
Selects TLS version 1.1 as the channel encryption protocol. Available only with openssl version 1.0.1+.

*New in version 3.4.*

*Deprecated since version 3.6:* OpenSSL has deprecated all version specific protocols. Use the default protocol PROTOCOL_TLS with flags like OP_NO_SSLv3 instead.

ssl. **PROTOCOL_TLSv1_2**
Selects TLS version 1.2 as the channel encryption protocol. This is
the most modern version, and probably the best choice for maximum protection, if both sides can speak it. Available only with openssl version 1.0.1+.

*New in version 3.4.*

*Deprecated since version 3.6:* OpenSSL has deprecated all version specific protocols. Use the default protocol PROTOCOL_TLS with flags like OP_NO_SSLv3 instead.

**ssl.OP_ALL**

Enables workarounds for various bugs present in other SSL implementations. This option is set by default. It does not necessarily set the same flags as OpenSSL’s SSL.OP_ALL constant.

*New in version 3.2.*

**ssl.OP_NO_SSLv2**

Prevents an SSLv2 connection. This option is only applicable in conjunction with PROTOCOL_TLS. It prevents the peers from choosing SSLv2 as the protocol version.

*New in version 3.2.*

*Deprecated since version 3.6:* SSLv2 is deprecated

**ssl.OP_NO_SSLv3**

Prevents an SSLv3 connection. This option is only applicable in conjunction with PROTOCOL_TLS. It prevents the peers from choosing SSLv3 as the protocol version.

*New in version 3.2.*
Deprecated since version 3.6: SSLv3 is deprecated

ssl.**OP_NO_TLSv1**
Prevents a TLSv1 connection. This option is only applicable in conjunction with PROTOCOL_TLS. It prevents the peers from choosing TLSv1 as the protocol version.

*New in version 3.2.*

ssl.**OP_NO_TLSv1_1**
Prevents a TLSv1.1 connection. This option is only applicable in conjunction with PROTOCOL_TLS. It prevents the peers from choosing TLSv1.1 as the protocol version. Available only with openssl version 1.0.1+.

*New in version 3.4.*

ssl.**OP_NO_TLSv1_2**
Prevents a TLSv1.2 connection. This option is only applicable in conjunction with PROTOCOL_TLS. It prevents the peers from choosing TLSv1.2 as the protocol version. Available only with openssl version 1.0.1+.

*New in version 3.4.*

ssl.**OP_NO_TLSv1_3**
Prevents a TLSv1.3 connection. This option is only applicable in conjunction with PROTOCOL_TLS. It prevents the peers from choosing TLSv1.3 as the protocol version. TLS 1.3 is available with OpenSSL 1.1.1 or later. When Python has been compiled against an older version of OpenSSL, the flag defaults to 0.

*New in version 3.6.3.*
ssl.**OP_CIPHER_SERVER_PREFERENCE**
Use the server's cipher ordering preference, rather than the client's. This option has no effect on client sockets and SSLv2 server sockets.

*New in version 3.3.*

ssl.**OP_SINGLE_DH_USE**
Prevents re-use of the same DH key for distinct SSL sessions. This improves forward secrecy but requires more computational resources. This option only applies to server sockets.

*New in version 3.3.*

ssl.**OP_SINGLE_ECDH_USE**
Prevents re-use of the same ECDH key for distinct SSL sessions. This improves forward secrecy but requires more computational resources. This option only applies to server sockets.

*New in version 3.3.*

ssl.**OP_NO_COMPRESSION**
Disable compression on the SSL channel. This is useful if the application protocol supports its own compression scheme.

This option is only available with OpenSSL 1.0.0 and later.

*New in version 3.3.*

class ssl.**Options**
enum.**IntFlag** collection of OP_* constants.

ssl.**OP_NO_TICKET**
Prevent client side from requesting a session ticket.
New in version 3.6.

ssl. HAS_ALPN
Whether the OpenSSL library has built-in support for the Application-Layer Protocol Negotiation TLS extension as described in RFC 7301.

New in version 3.5.

ssl. HAS_ECDH
Whether the OpenSSL library has built-in support for Elliptic Curve-based Diffie-Hellman key exchange. This should be true unless the feature was explicitly disabled by the distributor.

New in version 3.3.

ssl. HAS_SNI
Whether the OpenSSL library has built-in support for the Server Name Indication extension (as defined in RFC 6066).

New in version 3.2.

ssl. HAS_NPN
Whether the OpenSSL library has built-in support for Next Protocol Negotiation as described in the NPN draft specification. When true, you can use the SSLContext.set_npn_protocols() method to advertise which protocols you want to support.

New in version 3.3.

ssl. HAS_TLSv1_3
Whether the OpenSSL library has built-in support for the TLS 1.3 protocol.
New in version 3.6.3.

**ssl. CHANNEL_BINDING_TYPES**
List of supported TLS channel binding types. Strings in this list can be used as arguments to `SSLSocket.get_channel_binding()`.

New in version 3.3.

**ssl. OPENSSL_VERSION**
The version string of the OpenSSL library loaded by the interpreter:

```python
>>> ssl.OPENSSL_VERSION
'OpenSSL 1.0.2k  26 Jan 2017'
```

New in version 3.2.

**ssl. OPENSSL_VERSION_INFO**
A tuple of five integers representing version information about the OpenSSL library:

```python
>>> ssl.OPENSSL_VERSION_INFO
(1, 0, 2, 11, 15)
```

New in version 3.2.

**ssl. OPENSSL_VERSION_NUMBER**
The raw version number of the OpenSSL library, as a single integer:

```python
>>> ssl.OPENSSL_VERSION_NUMBER
268443839
>>> hex(ssl.OPENSSL_VERSION_NUMBER)
'0x100020bf'
```
New in version 3.2.

ssl. ALERT_DESCRIPTION_HANDSHAKE_FAILURE
ssl. ALERT_DESCRIPTION_INTERNAL_ERROR
ALERT_DESCRIPTION_*

Alert Descriptions from RFC 5246 and others. The IANA TLS Alert Registry contains this list and references to the RFCs where their meaning is defined.

Used as the return value of the callback function in SSLContext.set_servername_callback().

New in version 3.4.

class ssl.AlertDescription
    enum.IntEnum collection of ALERT_DESCRIPTION_* constants.

New in version 3.6.

Purpose. SERVER_AUTH
Option for create_default_context() and SSLContext.load_default_certs(). This value indicates that the context may be used to authenticate Web servers (therefore, it will be used to create client-side sockets).

New in version 3.4.

Purpose. CLIENT_AUTH
Option for create_default_context() and SSLContext.load_default_certs(). This value indicates that the context may be used to authenticate Web clients (therefore, it will be used to create server-side sockets).

New in version 3.4.
class ssl.SSLErrorNumber
    enum.IntEnum collection of SSL_ERROR_* constants.

    New in version 3.6.
18.2.2. SSL Sockets

```python
class ssl.SSLSocket(socket.socket)
```

SSL sockets provide the following methods of `Socket Objects`:

- `accept()`
- `bind()`
- `close()`
- `connect()`
- `detach()`
- `fileno()`
- `getpeername()`, `getsockname()`
- `getsockopt()`, `setsockopt()`
- `gettimeout()`, `settimeout()`, `setblocking()`
- `listen()`
- `makefile()`
- `recv()`, `recv_into()` (but passing a non-zero `flags` argument is not allowed)
- `send()`, `sendall()` (with the same limitation)
- `sendfile()` (but `os.sendfile` will be used for plain-text sockets only, else `send()` will be used)
- `shutdown()`

However, since the SSL (and TLS) protocol has its own framing atop of TCP, the SSL sockets abstraction can, in certain respects, diverge from the specification of normal, OS-level sockets. See especially the notes on non-blocking sockets.

Usually, `SSLSocket` are not created directly, but using the `SSLContext.wrap_socket()` method.

*Changed in version 3.5:* The `sendfile()` method was added.
Changed in version 3.5: The `shutdown()` does not reset the socket timeout each time bytes are received or sent. The socket timeout is now to maximum total duration of the shutdown.

Deprecated since version 3.6: It is deprecated to create a `SSLSocket` instance directly, use `SSLContext.wrap_socket()` to wrap a socket.

SSL sockets also have the following additional methods and attributes:

**SSLSocket.**

**read(len=1024, buffer=None)**

Read up to `len` bytes of data from the SSL socket and return the result as a `bytes` instance. If `buffer` is specified, then read into the buffer instead, and return the number of bytes read.

Raise `SSLWantReadError` or `SSLWantWriteError` if the socket is non-blocking and the read would block.

As at any time a re-negotiation is possible, a call to `read()` can also cause write operations.

Changed in version 3.5: The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration to read up to `len` bytes.

Deprecated since version 3.6: Use `recv()` instead of `read()`.

**SSLSocket.**

**write(buf)**

Write `buf` to the SSL socket and return the number of bytes written. The `buf` argument must be an object supporting the buffer interface.

Raise `SSLWantReadError` or `SSLWantWriteError` if the
socket is non-blocking and the write would block.

As at any time a re-negotiation is possible, a call to write() can also cause read operations.

*Changed in version 3.5:* The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration to write *buf*.

*Deprecated since version 3.6:* Use send() instead of write().

**Note:** The read() and write() methods are the low-level methods that read and write unencrypted, application-level data and decrypt/encrypt it to encrypted, wire-level data. These methods require an active SSL connection, i.e. the handshake was completed and SSLSocket.unwrap() was not called.

Normally you should use the socket API methods like recv() and send() instead of these methods.

SSLSocket.do_handshake()

Perform the SSL setup handshake.

*Changed in version 3.4:* The handshake method also performs match_hostname() when the check_hostname attribute of the socket's context is true.

*Changed in version 3.5:* The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration of the handshake.

SSLSocket.getpeercert(binary_form=False)

If there is no certificate for the peer on the other end of the
connection, return `None`. If the SSL handshake hasn’t been done yet, raise `ValueError`.

If the `binary_form` parameter is `False`, and a certificate was received from the peer, this method returns a `dict` instance. If the certificate was not validated, the dict is empty. If the certificate was validated, it returns a dict with several keys, amongst them `subject` (the principal for which the certificate was issued) and `issuer` (the principal issuing the certificate). If a certificate contains an instance of the `Subject Alternative Name` extension (see `RFC 3280`), there will also be a `subjectAltName` key in the dictionary.

The `subject` and `issuer` fields are tuples containing the sequence of relative distinguished names (RDNs) given in the certificate's data structure for the respective fields, and each RDN is a sequence of name-value pairs. Here is a real-world example:

```python
{'issuer': (((('countryName', 'IL'),),
             (((('organizationName', 'StartCom Ltd.'
                'organizationalUnitName',
                'Secure Digital Certificate Signing
                'commonName',
                'StartCom Class 2 Primary Intermediate

'serialNumber': '95F0',
'subject': (((('description', '571208-SLe257oHY9f
             (((('countryName', 'US'),),
             (((('stateOrProvinceName', 'California
                'localityName', 'San Francisco'),)
             (((('organizationName', 'Electronic Fr
                ('commonName', '*.eff.org'),),
                (((('emailAddress', 'hostmaster@eff.or
```
'subjectAltName': (('DNS', '*.eff.org'), ('DNS', 'version': 3)}

**Note:** To validate a certificate for a particular service, you can use the `match_hostname()` function.

If the `binary_form` parameter is `True`, and a certificate was provided, this method returns the DER-encoded form of the entire certificate as a sequence of bytes, or `None` if the peer did not provide a certificate. Whether the peer provides a certificate depends on the SSL socket's role:

- for a client SSL socket, the server will always provide a certificate, regardless of whether validation was required;
- for a server SSL socket, the client will only provide a certificate when requested by the server; therefore `getpeercert()` will return `None` if you used `CERT_NONE` (rather than `CERT_OPTIONAL` or `CERT_REQUIRED`).

*Changed in version 3.2:* The returned dictionary includes additional items such as `issuer` and `notBefore`.

*Changed in version 3.4:* `ValueError` is raised when the handshake isn’t done. The returned dictionary includes additional X509v3 extension items such as `crlDistributionPoints`, `caIssuers` and OCSP URIs.

**SSLSocket**. `cipher()`

Returns a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used. If no connection has been established, returns `None`. 
SSLsocket. **shared_ciphers()**

Return the list of ciphers shared by the client during the handshake. Each entry of the returned list is a three-value tuple containing the name of the cipher, the version of the SSL protocol that defines its use, and the number of secret bits the cipher uses. `shared_ciphers()` returns `None` if no connection has been established or the socket is a client socket.

*New in version 3.5.*

SSLsocket. **compression()**

Return the compression algorithm being used as a string, or `None` if the connection isn’t compressed.

If the higher-level protocol supports its own compression mechanism, you can use `OP_NO_COMPRESSION` to disable SSL-level compression.

*New in version 3.3.*

SSLsocket. **get_channel_binding**(cb_type="tls-unique")

Get channel binding data for current connection, as a bytes object. Returns `None` if not connected or the handshake has not been completed.

The `cb_type` parameter allow selection of the desired channel binding type. Valid channel binding types are listed in the `CHANNEL_BINDING_TYPES` list. Currently only the ‘tls-unique’ channel binding, defined by RFC 5929, is supported. `ValueError` will be raised if an unsupported channel binding type is requested.

*New in version 3.3.*
SSL Socket. `selected_alpn_protocol()`

Return the protocol that was selected during the TLS handshake. If `SSLContext.set_alpn_protocols()` was not called, if the other party does not support ALPN, if this socket does not support any of the client's proposed protocols, or if the handshake has not happened yet, `None` is returned.

*New in version 3.5.*

SSL Socket. `selected_npn_protocol()`

Return the higher-level protocol that was selected during the TLS/SSL handshake. If `SSLContext.set_npn_protocols()` was not called, or if the other party does not support NPN, or if the handshake has not yet happened, this will return `None`.

*New in version 3.3.*

SSL Socket. `unwrap()`

Performs the SSL shutdown handshake, which removes the TLS layer from the underlying socket, and returns the underlying socket object. This can be used to go from encrypted operation over a connection to unencrypted. The returned socket should always be used for further communication with the other side of the connection, rather than the original socket.

SSL Socket. `version()`

Return the actual SSL protocol version negotiated by the connection as a string, or `None` is no secure connection is established. As of this writing, possible return values include "SSLv2", "SSLv3", "TLSv1", "TLSv1.1" and "TLSv1.2". Recent OpenSSL versions may define more return values.
New in version 3.5.

SSLSocket. `pending()`
Returns the number of already decrypted bytes available for read, pending on the connection.

SSLSocket. `context`  
The SSLContext object this SSL socket is tied to. If the SSL socket was created using the top-level `wrap_socket()` function (rather than `SSLContext.wrap_socket()`), this is a custom context object created for this SSL socket.

New in version 3.2.

SSLSocket. `server_side`  
A boolean which is `True` for server-side sockets and `False` for client-side sockets.

New in version 3.2.

SSLSocket. `server_hostname`  
Hostname of the server: `str` type, or `None` for server-side socket or if the hostname was not specified in the constructor.

New in version 3.2.

SSLSocket. `session`  
The SSLSession for this SSL connection. The session is available for client and server side sockets after the TLS handshake has been performed. For client sockets the session can be set before `do_handshake()` has been called to reuse a session.

New in version 3.6.
SSL\texttt{Socket}::\texttt{session\_reused}

\textit{New in version 3.6.}
18.2.3. SSL Contexts

New in version 3.2.

An SSL context holds various data longer-lived than single SSL connections, such as SSL configuration options, certificate(s) and private key(s). It also manages a cache of SSL sessions for server-side sockets, in order to speed up repeated connections from the same clients.

```python
class ssl.SSLContext(protocol=PROTOCOL_TLS)

Create a new SSL context. You may pass protocol which must be one of the PROTOCOL_* constants defined in this module. PROTOCOL_TLS is currently recommended for maximum interoperability and default value.

See also: create_default_context() lets the ssl module choose security settings for a given purpose.

Changed in version 3.6: The context is created with secure default values. The options OP_NO_COMPRESSION, OP_CIPHER_SERVER_PREFERENCE, OP_SINGLE_DH_USE, OP_SINGLE_ECDH_USE, OP_NO_SSLv2 (except for PROTOCOL_SSLv2), and OP_NO_SSLv3 (except for PROTOCOL_SSLv3) are set by default. The initial cipher suite list contains only HIGH ciphers, no NULL ciphers and no MD5 ciphers (except for PROTOCOL_SSLv2).
```

SSLContext objects have the following methods and attributes:

```python
SSLContext.cert_store_stats()
```

Get statistics about quantities of loaded X.509 certificates, count of X.509 certificates flagged as CA certificates and certificate revocation lists as dictionary.

Example for a context with one CA cert and one other cert:

```python
>>> context.cert_store_stats()
{'crl': 0, 'x509_ca': 1, 'x509': 2}
```

New in version 3.4.

SSLContext.load_cert_chain(certfile, keyfile=None, password=None)

Load a private key and the corresponding certificate. The `certfile` string must be the path to a single file in PEM format containing the certificate as well as any number of CA certificates needed to establish the certificate’s authenticity. The `keyfile` string, if present, must point to a file containing the private key in. Otherwise the private key will be taken from `certfile` as well. See the discussion of Certificates for more information on how the certificate is stored in the `certfile`.

The `password` argument may be a function to call to get the password for decrypting the private key. It will only be called if the private key is encrypted and a password is necessary. It will be called with no arguments, and it should return a string, bytes, or bytearray. If the return value is a string it will be encoded as UTF-8 before using it to decrypt the key. Alternatively a string, bytes, or bytearray value may be supplied directly as the `password` argument. It will be ignored if the private key is not encrypted and no password is needed.

If the `password` argument is not specified and a password is
required, OpenSSL's built-in password prompting mechanism will be used to interactively prompt the user for a password.

An SSLError is raised if the private key doesn’t match with the certificate.

*Changed in version 3.3:* New optional argument `password`.

**SSLContext.load_default_certs**

```
SSLContext.load_default_certs(purpose=Purpose.SERVER_AUTH)
```

Load a set of default “certification authority” (CA) certificates from default locations. On Windows it loads CA certs from the CA and ROOT system stores. On other systems it calls `SSLContext.set_default_verify_paths()`. In the future the method may load CA certificates from other locations, too.

The `purpose` flag specifies what kind of CA certificates are loaded. The default settings `Purpose.SERVER_AUTH` loads certificates, that are flagged and trusted for TLS web server authentication (client side sockets). `Purpose.CLIENT_AUTH` loads CA certificates for client certificate verification on the server side.

*New in version 3.4.*

**SSLContext.load_verify_locations**

```
SSLContext.load_verify_locations(cafile=None, capath=None, cadata=None)
```

Load a set of “certification authority” (CA) certificates used to validate other peers’ certificates when `verify_mode` is other than `CERT_NONE`. At least one of `cafile` or `capath` must be specified.

This method can also load certification revocation lists (CRLs) in PEM or DER format. In order to make use of CRLs, `SSLContext.verify_flags` must be configured properly.
The `cafile` string, if present, is the path to a file of concatenated CA certificates in PEM format. See the discussion of `Certificates` for more information about how to arrange the certificates in this file.

The `capath` string, if present, is the path to a directory containing several CA certificates in PEM format, following an OpenSSL specific layout.

The `cadata` object, if present, is either an ASCII string of one or more PEM-encoded certificates or a `bytes-like object` of DER-encoded certificates. Like with `capath` extra lines around PEM-encoded certificates are ignored but at least one certificate must be present.

*Changed in version 3.4:* New optional argument `cadata`

`SSLContext.get_ca_certs(binary_form=False)`

Get a list of loaded “certification authority” (CA) certificates. If the `binary_form` parameter is `False` each list entry is a dict like the output of `SSLSocket.getpeercert()`. Otherwise the method returns a list of DER-encoded certificates. The returned list does not contain certificates from `capath` unless a certificate was requested and loaded by a SSL connection.

**Note:** Certificates in a capath directory aren’t loaded unless they have been used at least once.

*New in version 3.4.*

`SSLContext.get_ciphers()`

Get a list of enabled ciphers. The list is in order of cipher priority. See `SSLContext.set_ciphers()`.
Example:

```python
>>> ctx = ssl.SSLContext(ssl.PROTOCOL_SSLv23)
>>> ctx.set_ciphers('ECDHE+AESGCM:!ECDSA')
>>> ctx.get_ciphers()  # OpenSSL 1.0.x
[['alg_bits': 256,
  'description': 'ECDHE-RSA-AES256-GCM-SHA384 TLS
  Enc=AESGCM(256) Mac=AEAD',
  'id': 50380848,
  'name': 'ECDHE-RSA-AES256-GCM-SHA384',
  'protocol': 'TLSv1/SSLv3',
  'strength_bits': 256},
[{'alg_bits': 128,
  'description': 'ECDHE-RSA-AES128-GCM-SHA256 TLS
  Enc=AESGCM(128) Mac=AEAD',
  'id': 50380847,
  'name': 'ECDHE-RSA-AES128-GCM-SHA256',
  'protocol': 'TLSv1/SSLv3',
  'strength_bits': 128}]
```

On OpenSSL 1.1 and newer the cipher dict contains additional fields:

```python
>>> ctx.get_ciphers()  # OpenSSL 1.1+
[{'aead': True,
  'alg_bits': 256,
  'auth': 'auth-rsa',
  'description': 'ECDHE-RSA-AES256-GCM-SHA384 TLS
  Enc=AESGCM(256) Mac=AEAD',
  'digest': None,
  'id': 50380848,
  'kea': 'kx-ecdhe',
  'name': 'ECDHE-RSA-AES256-GCM-SHA384',
  'protocol': 'TLSv1.2',
  'strength_bits': 256,
  'symmetric': 'aes-256-gcm'},
```
Availability: OpenSSL 1.0.2+

*New in version 3.6.*

**SSLContext**. `set_default_verify_paths()`

Load a set of default “certification authority” (CA) certificates from a filesystem path defined when building the OpenSSL library. Unfortunately, there's no easy way to know whether this method succeeds: no error is returned if no certificates are to be found. When the OpenSSL library is provided as part of the operating system, though, it is likely to be configured properly.

**SSLContext**. `set_ciphers(ciphers)`

Set the available ciphers for sockets created with this context. It should be a string in the OpenSSL cipher list format. If no cipher can be selected (because compile-time options or other configuration forbids use of all the specified ciphers), an SSLError will be raised.

**Note:** when connected, the `SSLSocket.cipher()` method of
SSL sockets will give the currently selected cipher.

**SSLContext.set_alpn_protocols(protocols)**

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of ASCII strings, like ['http/1.1', 'spdy/2'], ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to RFC 7301. After a successful handshake, the SSLSocket.selected_alpn_protocol() method will return the agreed-upon protocol.

This method will raise `NotImplementedError` if HAS_ALPN is False.

OpenSSL 1.1.0 to 1.1.0e will abort the handshake and raise `SSLError` when both sides support ALPN but cannot agree on a protocol. 1.1.0f+ behaves like 1.0.2, SSLSocket.selected_alpn_protocol() returns None.

*New in version 3.5.*

**SSLContext.set_npn_protocols(protocols)**

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of strings, like ['http/1.1', 'spdy/2'], ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to the NPN draft specification. After a successful handshake, the SSLSocket.selected_npn_protocol() method will return the agreed-upon protocol.

This method will raise `NotImplementedError` if HAS_NPN is False.
New in version 3.3.

```python
SSLContext.set_servername_callback(server_name_callback)
```

Register a callback function that will be called after the TLS Client Hello handshake message has been received by the SSL/TLS server when the TLS client specifies a server name indication. The server name indication mechanism is specified in RFC 6066 section 3 - Server Name Indication.

Only one callback can be set per SSLContext. If `server_name_callback` is `None`, then the callback is disabled. Calling this function a subsequent time will disable the previously registered callback.

The callback function, `server_name_callback`, will be called with three arguments; the first being the `ssl.SSLSocket`, the second is a string that represents the server name that the client is intending to communicate (or `None` if the TLS Client Hello does not contain a server name) and the third argument is the original `SSLContext`. The server name argument is the IDNA decoded server name.

A typical use of this callback is to change the `ssl.SSLSocket`’s `SSLSocket.context` attribute to a new object of type `SSLContext` representing a certificate chain that matches the server name.

Due to the early negotiation phase of the TLS connection, only limited methods and attributes are usable like `SSLSocket.selected_alpn_protocol()` and `SSLSocket.context`, `SSLSocket.getpeercert()`, `SSLSocket.cipher()` and
SSLThreadPool(): methods require that the TLS connection has progressed beyond the TLS Client Hello and therefore will not contain return meaningful values nor can they be called safely.

The `server_name_callback` function must return `None` to allow the TLS negotiation to continue. If a TLS failure is required, a constant `ALERT_DESCRIPTION_*` can be returned. Other return values will result in a TLS fatal error with `ALERT_DESCRIPTION_INTERNAL_ERROR`.

If there is an IDNA decoding error on the server name, the TLS connection will terminate with an `ALERT_DESCRIPTION_INTERNAL_ERROR` fatal TLS alert message to the client.

If an exception is raised from the `server_name_callback` function the TLS connection will terminate with a fatal TLS alert message `ALERT_DESCRIPTION_HANDSHAKE_FAILURE`.

This method will raise `NotImplementedError` if the OpenSSL library had `OPENSSL_NO_TLSEXT` defined when it was built.

*New in version 3.4.*

**SSLContext.load_dh_params(dhfile)**

Load the key generation parameters for Diffie-Helman (DH) key exchange. Using DH key exchange improves forward secrecy at the expense of computational resources (both on the server and on the client). The `dhfile` parameter should be the path to a file containing DH parameters in PEM format.

This setting doesn't apply to client sockets. You can also use the
OP_SINGLE_DH_USE option to further improve security.

*New in version 3.3.*

**SSLCrypt.apply** .**set_eccdh_curve**(curve_name)

Set the curve name for Elliptic Curve-based Diffie-Hellman (ECDH) key exchange. ECDH is significantly faster than regular DH while arguably as secure. The curve_name parameter should be a string describing a well-known elliptic curve, for example prime256v1 for a widely supported curve.

This setting doesn’t apply to client sockets. You can also use the OP_SINGLE_ECDH_USE option to further improve security.

This method is not available if HAS_ECDH is False.

*New in version 3.3.*

See also:
SSL/TLS & Perfect Forward Secrecy
Vincent Bernat.

**SSLCrypt.apply** .**wrap_socket**(sock, server_side=False, do_handshake_on_connect=True, suppress_ragged_eofs=True, server_hostname=None, session=None)

Wrap an existing Python socket sock and return an SSLsocket object. sock must be a SOCK_STREAM socket; other socket types are unsupported.

The returned SSL socket is tied to the context, its settings and certificates. The parameters server_side, do_handshake_on_connect and suppress_ragged_eofs have the
same meaning as in the top-level `wrap_socket()` function.

On client connections, the optional parameter `server_hostname` specifies the hostname of the service which we are connecting to. This allows a single server to host multiple SSL-based services with distinct certificates, quite similarly to HTTP virtual hosts. Specifying `server_hostname` will raise a `ValueError` if `server_side` is true.

`session`, see `session`.

*Changed in version 3.5:* Always allow a server_hostname to be passed, even if OpenSSL does not have SNI.

*Changed in version 3.6:* `session` argument was added.

`SSLContext.wrap_bio(incoming, outgoing, server_side=False, server_hostname=None, session=None)`

Create a new `SSLObject` instance by wrapping the BIO objects `incoming` and `outgoing`. The SSL routines will read input data from the incoming BIO and write data to the outgoing BIO.

The `server_side`, `server_hostname` and `session` parameters have the same meaning as in `SSLContext.wrap_socket()`.

*Changed in version 3.6:* `session` argument was added.

`SSLContext.session_stats()`

Get statistics about the SSL sessions created or managed by this context. A dictionary is returned which maps the names of each piece of information to their numeric values. For example, here is the total number of hits and misses in the session cache since the context was created:
>>> stats = context.session_stats()
>>> stats['hits'], stats['misses']
(0, 0)

SSLContext.**check_hostname**

Whether to match the peer cert's hostname with **match_hostname()** in **SSLSocket.do_handshake()**. The context's **verify_mode** must be set to **CERT_OPTIONAL** or **CERT_REQUIRED**, and you must pass **server_hostname** to **wrap_socket()** in order to match the hostname.

Example:

```
import socket, ssl

context = ssl.SSLContext(ssl.PROTOCOL_TLSv1)
context.verify_mode = ssl.CERT_REQUIRED
context.check_hostname = True
context.load_default_certs()

s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
ssl_sock = context.wrap_socket(s, server_hostname=
ssl_sock.connect(('www.verisign.com', 443))
```

*New in version 3.4.*

**Note:** This features requires OpenSSL 0.9.8f or newer.

SSLContext.**options**

An integer representing the set of SSL options enabled on this context. The default value is **OP_ALL**, but you can specify other options such as **OP_NO_SSLv2** by ORing them together.
**Note:** With versions of OpenSSL older than 0.9.8m, it is only possible to set options, not to clear them. Attempting to clear an option (by resetting the corresponding bits) will raise a ValueError.

*Changed in version 3.6:* `SSLContext.options` returns `Options` flags:

```python
>>> ssl.create_default_context().options
<Options.OP_ALL|OP_NO_SSLv3|OP_NO_SSLv2|OP_NO_COMPRESSION: 2197947391>
```

`SSLContext.protocol`

The protocol version chosen when constructing the context. This attribute is read-only.

`SSLContext.verify_flags`

The flags for certificate verification operations. You can set flags like `VERIFY_CRL_CHECK_LEAF` by ORing them together. By default OpenSSL does neither require nor verify certificate revocation lists (CRLs). Available only with openssl version 0.9.8+.

*New in version 3.4.*

*Changed in version 3.6:* `SSLContext.verify_flags` returns `VerifyFlags` flags:

```python
>>> ssl.create_default_context().verify_flags
<VerifyFlagsVERIFY_X509_TRUSTED_FIRST: 32768>
```

`SSLContext.verify_mode`

Whether to try to verify other peers’ certificates and how to behave if verification fails. This attribute must be one of `CERT_NONE`,
CERT_OPTIONAL or CERT_REQUIRED.

*Changed in version 3.6:* `SSLContext.verify_mode` returns `VerifyMode` enum:

```python
>>> ssl.create_default_context().verify_mode
<VerifyMode.CERT_REQUIRED: 2>
```
18.2.4. Certificates

Certificates in general are part of a public-key / private-key system. In this system, each principal, (which may be a machine, or a person, or an organization) is assigned a unique two-part encryption key. One part of the key is public, and is called the public key; the other part is kept secret, and is called the private key. The two parts are related, in that if you encrypt a message with one of the parts, you can decrypt it with the other part, and only with the other part.

A certificate contains information about two principals. It contains the name of a subject, and the subject’s public key. It also contains a statement by a second principal, the issuer, that the subject is who he claims to be, and that this is indeed the subject’s public key. The issuer’s statement is signed with the issuer’s private key, which only the issuer knows. However, anyone can verify the issuer’s statement by finding the issuer’s public key, decrypting the statement with it, and comparing it to the other information in the certificate. The certificate also contains information about the time period over which it is valid. This is expressed as two fields, called “notBefore” and “notAfter”.

In the Python use of certificates, a client or server can use a certificate to prove who they are. The other side of a network connection can also be required to produce a certificate, and that certificate can be validated to the satisfaction of the client or server that requires such validation. The connection attempt can be set to raise an exception if the validation fails. Validation is done automatically, by the underlying OpenSSL framework; the application need not concern itself with its mechanics. But the application does usually need to provide sets of certificates to allow this process to take place.

Python uses files to contain certificates. They should be formatted as
“PEM” (see RFC 1422), which is a base-64 encoded form wrapped with a header line and a footer line:

```plaintext
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

18.2.4.1. Certificate chains

The Python files which contain certificates can contain a sequence of certificates, sometimes called a certificate chain. This chain should start with the specific certificate for the principal who “is” the client or server, and then the certificate for the issuer of that certificate, and then the certificate for the issuer of that certificate, and so on up the chain till you get to a certificate which is self-signed, that is, a certificate which has the same subject and issuer, sometimes called a root certificate. The certificates should just be concatenated together in the certificate file. For example, suppose we had a three certificate chain, from our server certificate to the certificate of the certification authority that signed our server certificate, to the root certificate of the agency which issued the certification authority’s certificate:

```plaintext
-----BEGIN CERTIFICATE-----
... (certificate for your server)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the certificate for the CA)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the root certificate for the CA's issuer)...
-----END CERTIFICATE-----
```

18.2.4.2. CA certificates
If you are going to require validation of the other side of the connection's certificate, you need to provide a “CA certs” file, filled with the certificate chains for each issuer you are willing to trust. Again, this file just contains these chains concatenated together. For validation, Python will use the first chain it finds in the file which matches. The platform’s certificates file can be used by calling `SSLContext.load_default_certs()`, this is done automatically with `create_default_context()`.

18.2.4.3. Combined key and certificate

Often the private key is stored in the same file as the certificate; in this case, only the `certfile` parameter to `SSLContext.load_cert_chain()` and `wrap_socket()` needs to be passed. If the private key is stored with the certificate, it should come before the first certificate in the certificate chain:

```
-----BEGIN RSA PRIVATE KEY-----
... (private key in base64 encoding) ...
-----END RSA PRIVATE KEY-----
-----BEGIN RSA PRIVATE KEY-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

18.2.4.4. Self-signed certificates

If you are going to create a server that provides SSL-encrypted connection services, you will need to acquire a certificate for that service. There are many ways of acquiring appropriate certificates, such as buying one from a certification authority. Another common practice is to generate a self-signed certificate. The simplest way to do
this is with the OpenSSL package, using something like the following:

```bash
% openssl req -new -x509 -days 365 -nodes -out cert.pem
Generating a 1024 bit RSA private key
........++++++
.........................++++++
writing new private key to 'cert.pem'
-----
You are about to be asked to enter information that into your certificate request.
What you are about to enter is what is called a Distinguished
There are quite a few fields but you can leave some
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MyState
Locality Name (eg, city) []:Some City
Organization Name (eg, company) [Internet Widgits Pty]:
Organizational Unit Name (eg, section) []:My Group
Common Name (eg, YOUR name) []:myserver.mygroup.myorganization
Email Address []:ops@myserver.mygroup.myorganization
%
```

The disadvantage of a self-signed certificate is that it is its own root certificate, and no one else will have it in their cache of known (and trusted) root certificates.
18.2.5. Examples

18.2.5.1. Testing for SSL support

To test for the presence of SSL support in a Python installation, user code should use the following idiom:

```
try:
    import ssl
except ImportError:
    pass
else:
    ...  # do something that requires SSL support
```

18.2.5.2. Client-side operation

This example creates a SSL context with the recommended security settings for client sockets, including automatic certificate verification:

```
>>> context = ssl.create_default_context()
```

If you prefer to tune security settings yourself, you might create a context from scratch (but beware that you might not get the settings right):

```
>>> context = ssl.SSLContext(ssl.PROTOCOL_TLS)
>>> context.verify_mode = ssl.CERT_REQUIRED
>>> context.check_hostname = True
>>> context.load_verify_locations("/etc/ssl/certs/ca-bundle.crt")
```

(this snippet assumes your operating system places a bundle of all CA certificates in `/etc/ssl/certs/ca-bundle.crt`; if not, you'll get
an error and have to adjust the location)

When you use the context to connect to a server, `CERT_REQUIRED` validates the server certificate: it ensures that the server certificate was signed with one of the CA certificates, and checks the signature for correctness:

```python
>>> conn = context.wrap_socket(socket.socket(socket, ...
    server_hostname="www.
>>> conn.connect(('www.python.org', 443))
```

You may then fetch the certificate:

```python
>>> cert = conn.getpeercert()
```

Visual inspection shows that the certificate does identify the desired service (that is, the HTTPS host `www.python.org`):

```python
>>> pprint.pprint(cert)
{'OCSP': ('http://ocsp.digicert.com',),
 'caIssuers': ('http://cacerts.digicert.com/DigiCert
    http://crl3.digicert.com/sha2-ev-server-g1.crl,
    http://crl4.digicert.com/sha2-ev-server-g1.crl'),
 'issuer': (((('countryName', 'US'),),
    ('organizationName', 'DigiCert Inc'),),
    ('organizationalUnitName', 'www.digicert
    ('commonName', 'DigiCert SHA2 Extended
 'notAfter': 'Sep  9 12:00:00 2016 GMT',
 'notBefore': 'Sep  5 00:00:00 2014 GMT',
 'serialNumber': '01BB6F00122B177F36CAB49CEA8B6B26',
 'subject': (((('businessCategory', 'Private Organiza
    ('1.3.6.1.4.1.311.60.2.1.3', 'US'),),
    ('1.3.6.1.4.1.311.60.2.1.2', 'Delaware
    ('serialNumber', '3359300'),),
    ('streetAddress', '16 Allen Rd'),),
```
Now the SSL channel is established and the certificate verified, you can proceed to talk with the server:

```python
>>> conn.sendall(b"HEAD / HTTP/1.0\r\nHost: linuxfr.

>>> pprint.pprint(conn.recv(1024).split(b"\r\n"))
[b'HTTP/1.1 200 OK',
b'Date: Sat, 18 Oct 2014 18:27:20 GMT',
b'Server: nginx',
b'Content-Type: text/html; charset=utf-8',
b'X-Frame-Options: SAMEORIGIN',
b'Content-Length: 45679',
b'Accept-Ranges: bytes',
b'Via: 1.1 varnish',
```
See the discussion of Security considerations below.

18.2.5.3. Server-side operation

For server operation, typically you'll need to have a server certificate, and private key, each in a file. You'll first create a context holding the key and the certificate, so that clients can check your authenticity. Then you'll open a socket, bind it to a port, call listen() on it, and start waiting for clients to connect:

```python
import socket, ssl

context = ssl.create_default_context(ssl.Purpose.CLIENT_AUTH)
context.load_cert_chain(certfile="mycertfile", keyfile="mykeyfile")

bindsocket = socket.socket()
bindsocket.bind(('myaddr.mydomain.com', 10023))
bindsocket.listen(5)
```

When a client connects, you'll call accept() on the socket to get the new socket from the other end, and use the context's `SSLContext.wrap_socket()` method to create a server-side SSL socket for the connection:
while True:
    newsocket, fromaddr = bindsocket.accept()
    connstream = context.wrap_socket(newsocket, server_side=True)
    try:
        deal_with_client(connstream)
    finally:
        connstream.shutdown(socket.SHUT_RDWR)
        connstream.close()

Then you'll read data from the connstream and do something with it till you are finished with the client (or the client is finished with you):

```python
def deal_with_client(connstream):
    data = connstream.recv(1024)
    # empty data means the client is finished with us
    while data:
        if not do_something(connstream, data):
            # we'll assume do_something returns False
            # when we're finished with client
            break
        data = connstream.recv(1024)
    # finished with client
```

And go back to listening for new client connections (of course, a real server would probably handle each client connection in a separate thread, or put the sockets in non-blocking mode and use an event loop).
18.2.6. Notes on non-blocking sockets

SSL sockets behave slightly different than regular sockets in non-blocking mode. When working with non-blocking sockets, there are thus several things you need to be aware of:

- Most SSLSocket methods will raise either SSLWantWriteError or SSLWantReadError instead of BlockingIOError if an I/O operation would block. SSLWantReadError will be raised if a read operation on the underlying socket is necessary, and SSLWantWriteError for a write operation on the underlying socket. Note that attempts to write to an SSL socket may require reading from the underlying socket first, and attempts to read from the SSL socket may require a prior write to the underlying socket.

  Changed in version 3.5: In earlier Python versions, the SSLSocket.send() method returned zero instead of raising SSLWantWriteError or SSLWantReadError.

- Calling select() tells you that the OS-level socket can be read from (or written to), but it does not imply that there is sufficient data at the upper SSL layer. For example, only part of an SSL frame might have arrived. Therefore, you must be ready to handle SSLSocket.recv() and SSLSocket.send() failures, and retry after another call to select().

- Conversely, since the SSL layer has its own framing, a SSL socket may still have data available for reading without select() being aware of it. Therefore, you should first call SSLSocket.recv() to drain any potentially available data, and
then only block on a `select()` call if still necessary.

(of course, similar provisions apply when using other primitives such as `poll()`, or those in the `selectors` module)

- The SSL handshake itself will be non-blocking: the `SSLSocket.do_handshake()` method has to be retried until it returns successfully. Here is a synopsis using `select()` to wait for the socket's readiness:

```python
while True:
    try:
        sock.do_handshake()
    break
except ssl.SSLWantReadError:
    select.select([sock], [], [])
except ssl.SSLWantWriteError:
    select.select([], [sock], [])
```

**See also:** The `asyncio` module supports non-blocking SSL sockets and provides a higher level API. It polls for events using the `selectors` module and handles `SSLWantWriteError`, `SSLWantReadError` and `BlockingIOError` exceptions. It runs the SSL handshake asynchronously as well.
18.2.7. Memory BIO Support

*New in version 3.5.*

Ever since the SSL module was introduced in Python 2.6, the `SSLSocket` class has provided two related but distinct areas of functionality:

- SSL protocol handling
- Network IO

The network IO API is identical to that provided by `socket.socket`, from which `SSLSocket` also inherits. This allows an SSL socket to be used as a drop-in replacement for a regular socket, making it very easy to add SSL support to an existing application.

Combining SSL protocol handling and network IO usually works well, but there are some cases where it doesn’t. An example is async IO frameworks that want to use a different IO multiplexing model than the “select/poll on a file descriptor” (readiness based) model that is assumed by `socket.socket` and by the internal OpenSSL socket IO routines. This is mostly relevant for platforms like Windows where this model is not efficient. For this purpose, a reduced scope variant of `SSLSocket` called `SSLObject` is provided.

```python
class ssl.SSLObject
```

A reduced-scope variant of `SSLSocket` representing an SSL protocol instance that does not contain any network IO methods. This class is typically used by framework authors that want to implement asynchronous IO for SSL through memory buffers.

This class implements an interface on top of a low-level SSL object
as implemented by OpenSSL. This object captures the state of an SSL connection but does not provide any network IO itself. IO needs to be performed through separate “BIO” objects which are OpenSSL's IO abstraction layer.

An SSLObject instance can be created using the wrap_bio() method. This method will create the SSLObject instance and bind it to a pair of BIOs. The incoming BIO is used to pass data from Python to the SSL protocol instance, while the outgoing BIO is used to pass data the other way around.

The following methods are available:

- context
- server_side
- server_hostname
- session
- session_reused
- read()
- write()
- getpeercert()
- selected_npn_protocol()
- cipher()
- shared_ciphers()
- compression()
- pending()
- do_handshake()
- unwrap()
- get_channel_binding()

When compared to SSLSocket, this object lacks the following features:
- Any form of network IO; `recv()` and `send()` read and write only to the underlying `MemoryBIO` buffers.
- There is no `do_handshake_on_connect` machinery. You must always manually call `do_handshake()` to start the handshake.
- There is no handling of `suppress_ragged_eofs`. All end-of-file conditions that are in violation of the protocol are reported via the `SSLEOFError` exception.
- The method `unwrap()` call does not return anything, unlike for an SSL socket where it returns the underlying socket.
- The `server_name_callback` callback passed to `SSLContext.set_servername_callback()` will get an `SSLObject` instance instead of a `SSLSocket` instance as its first parameter.

Some notes related to the use of `SSLObject`:

- All IO on an `SSLObject` is non-blocking. This means that for example `read()` will raise an `SSLWantReadError` if it needs more data than the incoming BIO has available.
- There is no module-level `wrap_bio()` call like there is for `wrap_socket()`. An `SSLObject` is always created via an `SSLContext`.

An `SSLObject` communicates with the outside world using memory buffers. The class `MemoryBIO` provides a memory buffer that can be used for this purpose. It wraps an OpenSSL memory BIO (Basic IO) object:

```python
class ssl.MemoryBIO
```

A memory buffer that can be used to pass data between Python and an SSL protocol instance.

`pending`
Return the number of bytes currently in the memory buffer.

**eof**
A boolean indicating whether the memory BIO is current at the end-of-file position.

**read**\((n=-1)\)
Read up to \(n\) bytes from the memory buffer. If \(n\) is not specified or negative, all bytes are returned.

**write**\((buf)\)
Write the bytes from \(buf\) to the memory BIO. The \(buf\) argument must be an object supporting the buffer protocol.

The return value is the number of bytes written, which is always equal to the length of \(buf\).

**write_eof()**
Write an EOF marker to the memory BIO. After this method has been called, it is illegal to call **write()**. The attribute **eof** will become true after all data currently in the buffer has been read.
18.2.8. SSL session

New in version 3.6.

```
class ssl.SSLSession
    Session object used by session.

    id
    time
    timeout
    ticket_lifetime_hint
    has_ticket
```
18.2.9. Security considerations

18.2.9.1. Best defaults

For **client use**, if you don’t have any special requirements for your security policy, it is highly recommended that you use the `create_default_context()` function to create your SSL context. It will load the system’s trusted CA certificates, enable certificate validation and hostname checking, and try to choose reasonably secure protocol and cipher settings.

For example, here is how you would use the `smtplib.SMTP` class to create a trusted, secure connection to a SMTP server:

```python
>>> import ssl, smtplib
>>> smtp = smtplib.SMTP("mail.python.org", port=587)
>>> context = ssl.create_default_context()
>>> smtp.starttls(context=context)
(220, b'2.0.0 Ready to start TLS')
```

If a client certificate is needed for the connection, it can be added with `SSLContext.load_cert_chain()`.

By contrast, if you create the SSL context by calling the `SSLContext` constructor yourself, it will not have certificate validation nor hostname checking enabled by default. If you do so, please read the paragraphs below to achieve a good security level.

18.2.9.2. Manual settings

18.2.9.2.1. Verifying certificates
When calling the `SSLCertificate` constructor directly, `CERT_NONE` is the default. Since it does not authenticate the other peer, it can be insecure, especially in client mode where most of time you would like to ensure the authenticity of the server you’re talking to. Therefore, when in client mode, it is highly recommended to use `CERT_REQUIRED`. However, it is in itself not sufficient; you also have to check that the server certificate, which can be obtained by calling `SSLSocket.getpeerCert()`, matches the desired service. For many protocols and applications, the service can be identified by the hostname; in this case, the `match_hostname()` function can be used. This common check is automatically performed when `SSLCertificate.check_hostname` is enabled.

In server mode, if you want to authenticate your clients using the SSL layer (rather than using a higher-level authentication mechanism), you’ll also have to specify `CERT_REQUIRED` and similarly check the client certificate.

**Note:** In client mode, `CERT_OPTIONAL` and `CERT_REQUIRED` are equivalent unless anonymous ciphers are enabled (they are disabled by default).

### 18.2.9.2.2. Protocol versions

SSL versions 2 and 3 are considered insecure and are therefore dangerous to use. If you want maximum compatibility between clients and servers, it is recommended to use `PROTOCOL_TLS_CLIENT` or `PROTOCOL_TLS_SERVER` as the protocol version. SSLv2 and SSLv3 are disabled by default.

```python
>>> client_context = ssl.SSLContext(ssl.PROTOCOL_TLS)  # For client mode.
```
```python
>>> client_context.options |= ssl.OP_NO_TLSv1
>>> client_context.options |= ssl.OP_NO_TLSv1_1
```

The SSL context created above will only allow TLSv1.2 and later (if supported by your system) connections to a server. `PROTOCOL_TLS_CLIENT` implies certificate validation and hostname checks by default. You have to load certificates into the context.

18.2.9.2.3. Cipher selection

If you have advanced security requirements, fine-tuning of the ciphers enabled when negotiating a SSL session is possible through the `SSLContext.set_ciphers()` method. Starting from Python 3.2.3, the ssl module disables certain weak ciphers by default, but you may want to further restrict the cipher choice. Be sure to read OpenSSL's documentation about the cipher list format. If you want to check which ciphers are enabled by a given cipher list, use `SSLContext.get_ciphers()` or the `openssl ciphers` command on your system.

18.2.9.3. Multi-processing

If using this module as part of a multi-processed application (using, for example the `multiprocessing` or `concurrent.futures` modules), be aware that OpenSSL's internal random number generator does not properly handle forked processes. Applications must change the PRNG state of the parent process if they use any SSL feature with `os.fork()`. Any successful call of `RAND_add()`, `RAND_bytes()` or `RAND_pseudo_bytes()` is sufficient.

18.3. **select** — Waiting for I/O completion

This module provides access to the `select()` and `poll()` functions available in most operating systems, `devpoll()` available on Solaris and derivatives, `epoll()` available on Linux 2.5+ and `kqueue()` available on most BSD. Note that on Windows, it only works for sockets; on other operating systems, it also works for other file types (in particular, on Unix, it works on pipes). It cannot be used on regular files to determine whether a file has grown since it was last read.

**Note:** The `selectors` module allows high-level and efficient I/O multiplexing, built upon the `select` module primitives. Users are encouraged to use the `selectors` module instead, unless they want precise control over the OS-level primitives used.

The module defines the following:

**exception** `select.error`

A deprecated alias of `OSError`.

*Changed in version 3.3:* Following [PEP 3151](https://www.python.org/dev/peps/pep-03151/), this class was made an alias of `OSError`.

`select.devpoll()`

(Only supported on Solaris and derivatives.) Returns a `/dev/poll` polling object; see section `/dev/poll Polling Objects` below for the methods supported by devpoll objects.
devpoll() objects are linked to the number of file descriptors allowed at the time of instantiation. If your program reduces this value, devpoll() will fail. If your program increases this value, devpoll() may return an incomplete list of active file descriptors.

The new file descriptor is **non-inheritable**.

*New in version 3.3.*

*Changed in version 3.4:* The new file descriptor is now non-inheritable.

```python
select.epoll(sizehint=-1, flags=0)
```

(Only supported on Linux 2.5.44 and newer.) Return an edge polling object, which can be used as Edge or Level Triggered interface for I/O events. `sizehint` and `flags` are deprecated and completely ignored.

See the Edge and Level Trigger Polling (epoll) Objects section below for the methods supported by epolling objects.

**epoll** objects support the context management protocol: when used in a `with` statement, the new file descriptor is automatically closed at the end of the block.

The new file descriptor is **non-inheritable**.

*Changed in version 3.3:* Added the `flags` parameter.

*Changed in version 3.4:* Support for the `with` statement was added. The new file descriptor is now non-inheritable.

*Deprecated since version 3.4:* The `flags` parameter. `select.EPOLL_CLOEXEC` is used by default now. Use
os.set_inheritable() to make the file descriptor inheritable.

select.poll()
(Not supported by all operating systems.) Returns a polling object, which supports registering and unregistering file descriptors, and then polling them for I/O events; see section Polling Objects below for the methods supported by polling objects.

select.kqueue()
(Only supported on BSD.) Returns a kernel queue object; see section Kqueue Objects below for the methods supported by kqueue objects.

The new file descriptor is non-inheritable.

Changed in version 3.4: The new file descriptor is now non-inheritable.

select.kevent(ident, filter=KQ_FILTER_READ, flags=KQ_EV_ADD, fflags=0, data=0, udata=0)
(Only supported on BSD.) Returns a kernel event object; see section Kevent Objects below for the methods supported by kevent objects.

select.select(rlist, wlist, xlist[, timeout])
This is a straightforward interface to the Unix select() system call. The first three arguments are sequences of ‘waitable objects’: either integers representing file descriptors or objects with a parameterless method named fileno() returning such an integer:

- rlist: wait until ready for reading
- wlist: wait until ready for writing
- \textit{xlist}: wait for an “exceptional condition” (see the manual page for what your system considers such a condition)

Empty sequences are allowed, but acceptance of three empty sequences is platform-dependent. (It is known to work on Unix but not on Windows.) The optional \textit{timeout} argument specifies a time-out as a floating point number in seconds. When the \textit{timeout} argument is omitted the function blocks until at least one file descriptor is ready. A time-out value of zero specifies a poll and never blocks.

The return value is a triple of lists of objects that are ready: subsets of the first three arguments. When the time-out is reached without a file descriptor becoming ready, three empty lists are returned.

Among the acceptable object types in the sequences are Python \texttt{file objects} (e.g. \texttt{sys.stdin}, or objects returned by \texttt{open()}) or \texttt{os.popen()}), socket objects returned by \texttt{socket.socket()}. You may also define a \textit{wrapper} class yourself, as long as it has an appropriate \texttt{fileno()} method (that really returns a file descriptor, not just a random integer).

\begin{quote}
\textbf{Note:} File objects on Windows are not acceptable, but sockets are. On Windows, the underlying \texttt{select()} function is provided by the WinSock library, and does not handle file descriptors that don’t originate from WinSock.
\end{quote}

\textit{Changed in version 3.5:} The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see \texttt{PEP 475} for the rationale), instead of raising \texttt{InterruptedError}.

\texttt{select.PIPE\_BUF}
The minimum number of bytes which can be written without blocking to a pipe when the pipe has been reported as ready for writing by `select()`, `poll()` or another interface in this module. This doesn’t apply to other kind of file-like objects such as sockets.

This value is guaranteed by POSIX to be at least 512. Availability: Unix.

*New in version 3.2.*
18.3.1. /dev/poll Polling Objects

Solaris and derivatives have /dev/poll. While select() is \(O(\text{highest file descriptor})\) and poll() is \(O(\text{number of file descriptors})\), /dev/poll is \(O(\text{active file descriptors})\).

/dev/poll behaviour is very close to the standard poll() object.

devpoll.close()

   Close the file descriptor of the polling object.

   New in version 3.4.

devpoll.closed

   True if the polling object is closed.

   New in version 3.4.

devpoll.fileno()

   Return the file descriptor number of the polling object.

   New in version 3.4.

devpoll.register(fd[, eventmask])

   Register a file descriptor with the polling object. Future calls to the poll() method will then check whether the file descriptor has any pending I/O events. \(fd\) can be either an integer, or an object with a fileno() method that returns an integer. File objects implement fileno(), so they can also be used as the argument.

   eventmask is an optional bitmask describing the type of events you want to check for. The constants are the same that with poll()
object. The default value is a combination of the constants POLLIN, POLLPRI, and POLLOUT.

**Warning:** Registering a file descriptor that’s already registered is not an error, but the result is undefined. The appropriate action is to unregister or modify it first. This is an important difference compared with poll().

devpoll.\texttt{modify}(fd[, eventmask])

This method does an unregister() followed by a register(). It is (a bit) more efficient than doing the same explicitly.

devpoll.\texttt{unregister}(fd)

Remove a file descriptor being tracked by a polling object. Just like the register() method, fd can be an integer or an object with a fileno() method that returns an integer.

Attempting to remove a file descriptor that was never registered is safely ignored.

devpoll.\texttt{poll}([timeout])

Polls the set of registered file descriptors, and returns a possibly-empty list containing \( (fd, \text{event}) \) 2-tuples for the descriptors that have events or errors to report. \( fd \) is the file descriptor, and \( \text{event} \) is a bitmask with bits set for the reported events for that descriptor — POLLIN for waiting input, POLLOUT to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If \( \text{timeout} \) is given, it specifies the length of time in milliseconds which the system will wait for events before returning. If \( \text{timeout} \) is omitted, -1, or None, the call will block until there is an
event for this poll object.

*Changed in version 3.5:* The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see [PEP 475](https://www.python.org/dev/peps/pep-0475/) for the rationale), instead of raising `InterruptedError`. 
18.3.2. Edge and Level Trigger Polling (epoll) Objects

</tr>
</tbody>
</table>
EPOLLMSG | Ignored.

epoll.close()
Close the control file descriptor of the epoll object.

epoll.closed
True if the epoll object is closed.

epoll.fileno()
Return the file descriptor number of the control fd.

epoll.fromfd(fd)
Create an epoll object from a given file descriptor.

epoll.register(fd[, eventmask])
Register a fd descriptor with the epoll object.

epoll.modify(fd, eventmask)
Modify a registered file descriptor.

epoll.unregister(fd)
Remove a registered file descriptor from the epoll object.

epoll.poll(timeout=-1, maxevents=-1)
Wait for events. timeout in seconds (float)

*Changed in version 3.5:* The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see PEP 475 for the rationale), instead of raising InterruptedError.
18.3.3. Polling Objects

The `poll()` system call, supported on most Unix systems, provides better scalability for network servers that service many, many clients at the same time. `poll()` scales better because the system call only requires listing the file descriptors of interest, while `select()` builds a bitmap, turns on bits for the fds of interest, and then afterward the whole bitmap has to be linearly scanned again. `select()` is \( O(\text{highest file descriptor}) \), while `poll()` is \( O(\text{number of file descriptors}) \).

`poll.register(fd[, eventmask])`

Register a file descriptor with the polling object. Future calls to the `poll()` method will then check whether the file descriptor has any pending I/O events. `fd` can be either an integer, or an object with a `fileno()` method that returns an integer. File objects implement `fileno()`, so they can also be used as the argument.

`eventmask` is an optional bitmask describing the type of events you want to check for, and can be a combination of the constants `POLLIN`, `POLLPRI`, and `POLLOUT`, described in the table below. If not specified, the default value used will check for all 3 types of events.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>POLLIN</td>
<td>There is data to read</td>
</tr>
<tr>
<td>POLLPRI</td>
<td>There is urgent data to read</td>
</tr>
<tr>
<td>POLLOUT</td>
<td>Ready for output: writing will not block</td>
</tr>
<tr>
<td>POLLERR</td>
<td>Error condition of some sort</td>
</tr>
<tr>
<td>POLLHUP</td>
<td>Hung up</td>
</tr>
<tr>
<td>-----------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>POLLRDHUP</td>
<td>Stream socket peer closed connection, or shut down writing half of connection</td>
</tr>
<tr>
<td>POLLNVAL</td>
<td>Invalid request: descriptor not open</td>
</tr>
</tbody>
</table>

Registering a file descriptor that’s already registered is not an error, and has the same effect as registering the descriptor exactly once.

**poll. modify(fd, eventmask)**

Modifies an already registered fd. This has the same effect as `register(fd, eventmask)`. Attempting to modify a file descriptor that was never registered causes an `OSError` exception with errno `ENOENT` to be raised.

**poll. unregister(fd)**

Remove a file descriptor being tracked by a polling object. Just like the `register()` method, `fd` can be an integer or an object with a `fileno()` method that returns an integer.

Attempting to remove a file descriptor that was never registered causes a `KeyError` exception to be raised.

**poll. poll([timeout])**

Polls the set of registered file descriptors, and returns a possibly-empty list containing `(fd, event)` 2-tuples for the descriptors that have events or errors to report. `fd` is the file descriptor, and `event` is a bitmask with bits set for the reported events for that descriptor — POLLIN for waiting input, POLLOUT to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If `timeout` is given, it specifies the length of time in milliseconds which the system will wait for events before returning.
If `timeout` is omitted, negative, or `None`, the call will block until there is an event for this poll object.

*Changed in version 3.5:* The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see PEP 475 for the rationale), instead of raising `InterruptedError`. 
18.3.4. Kqueue Objects

kqueue.**close**()
Close the control file descriptor of the kqueue object.

kqueue.**closed**
True if the kqueue object is closed.

kqueue.**fileno**()
Return the file descriptor number of the control fd.

kqueue.**fromfd**(fd)
Create a kqueue object from a given file descriptor.

kqueue.**control**(changelist, max_events[, timeout=None]) → eventlist
Low level interface to kevent

- changelist must be an iterable of kevent object or None
- max_events must be 0 or a positive integer
- timeout in seconds (floats possible)

*Changed in version 3.5:* The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see PEP 475 for the rationale), instead of raising InterruptedError.
18.3.5. Kevent Objects

kevent. **ident**
Value used to identify the event. The interpretation depends on the filter but it's usually the file descriptor. In the constructor ident can either be an int or an object with a `fileno()` method. kevent stores the integer internally.

kevent. **filter**
Name of the kernel filter.

`kevent.udata`

User defined value.
18.4. `selectors` — High-level I/O multiplexing

*New in version 3.4.*

**Source code:** `Lib/selectors.py`
18.4.1. Introduction

This module allows high-level and efficient I/O multiplexing, built upon the **select** module primitives. Users are encouraged to use this module instead, unless they want precise control over the OS-level primitives used.

It defines a **BaseSelector** abstract base class, along with several concrete implementations (**KqueueSelector**, **EpollSelector**…), that can be used to wait for I/O readiness notification on multiple file objects. In the following, “file object” refers to any object with a `fileno()` method, or a raw file descriptor. See **file object**.

**DefaultSelector** is an alias to the most efficient implementation available on the current platform: this should be the default choice for most users.

**Note:** The type of file objects supported depends on the platform: on Windows, sockets are supported, but not pipes, whereas on Unix, both are supported (some other types may be supported as well, such as fifos or special file devices).

**See also:**

**select**

Low-level I/O multiplexing module.
18.4.2. Classes

Classes hierarchy:

```
BaseSelector
 +-- SelectSelector
 +-- PollSelector
 +-- EpollSelector
 +-- DevpollSelector
 +-- KqueueSelector
```

In the following, `events` is a bitwise mask indicating which I/O events should be waited for on a given file object. It can be a combination of the modules constants below:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_READ</td>
<td>Available for read</td>
</tr>
<tr>
<td>EVENT_WRITE</td>
<td>Available for write</td>
</tr>
</tbody>
</table>

**class selectors.** `SelectorKey`

A `SelectorKey` is a `namedtuple` used to associate a file object to its underlying file descriptor, selected event mask and attached data. It is returned by several `BaseSelector` methods.

**fileobj**

File object registered.

**fd**

Underlying file descriptor.

**events**

Events that must be waited for on this file object.
data

Optional opaque data associated to this file object: for example, this could be used to store a per-client session ID.

class selectors. BaseSelector

A BaseSelector is used to wait for I/O event readiness on multiple file objects. It supports file stream registration, unregistration, and a method to wait for I/O events on those streams, with an optional timeout. It's an abstract base class, so cannot be instantiated. Use DefaultSelector instead, or one of SelectSelector, KqueueSelector etc. if you want to specifically use an implementation, and your platform supports it. BaseSelector and its concrete implementations support the context manager protocol.

abstractmethod register(fileobj, events, data=None)

Register a file object for selection, monitoring it for I/O events.

fileobj is the file object to monitor. It may either be an integer file descriptor or an object with a fileno() method. events is a bitwise mask of events to monitor. data is an opaque object.

This returns a new SelectorKey instance, or raises a ValueError in case of invalid event mask or file descriptor, or KeyError if the file object is already registered.

abstractmethod unregister(fileobj)

Unregister a file object from selection, removing it from monitoring. A file object shall be unregistered prior to being closed.

fileobj must be a file object previously registered.
This returns the associated `SelectorKey` instance, or raises a `KeyError` if `fileobj` is not registered. It will raise `ValueError` if `fileobj` is invalid (e.g. it has no `fileno()` method or its `fileno()` method has an invalid return value).

**modify**(fileobj, events, data=None)

Change a registered file object's monitored events or attached data.

This is equivalent to `BaseSelector.unregister(fileobj)()` followed by `BaseSelector.register(fileobj, events, data)()` except that it can be implemented more efficiently.

This returns a new `SelectorKey` instance, or raises a `ValueError` in case of invalid event mask or file descriptor, or `KeyError` if the file object is not registered.

**abstractmethod select**(timeout=None)

Wait until some registered file objects become ready, or the timeout expires.

If `timeout > 0`, this specifies the maximum wait time, in seconds. If `timeout <= 0`, the call won't block, and will report the currently ready file objects. If `timeout` is `None`, the call will block until a monitored file object becomes ready.

This returns a list of `(key, events)` tuples, one for each ready file object.

`key` is the `SelectorKey` instance corresponding to a ready file object. `events` is a bitmask of events ready on this file object.
**Note:** This method can return before any file object becomes ready or the timeout has elapsed if the current process receives a signal: in this case, an empty list will be returned.

*Changed in version 3.5:* The selector is now retried with a recomputed timeout when interrupted by a signal if the signal handler did not raise an exception (see [PEP 475](https://www.python.org/dev/peps/pep-0475/) for the rationale), instead of returning an empty list of events before the timeout.

**close()**

Close the selector.

This must be called to make sure that any underlying resource is freed. The selector shall not be used once it has been closed.

**get_key(fileobj)**

Return the key associated with a registered file object.

This returns the `SelectorKey` instance associated to this file object, or raises `KeyError` if the file object is not registered.

**abstractmethod get_map()**

Return a mapping of file objects to selector keys.

This returns a `Mapping` instance mapping registered file objects to their associated `SelectorKey` instance.

**class selectors.DefaultSelector**

The default selector class, using the most efficient implementation available on the current platform. This should be the default choice for most users.
class selectors. SelectSelector
select.select() - based selector.

class selectors. PollSelector
select.poll() - based selector.

class selectors. EpollSelector
select.epoll() - based selector.

fileno()
This returns the file descriptor used by the underlying
select.epoll() object.

class selectors. DevpollSelector
select.devpoll() - based selector.

fileno()
This returns the file descriptor used by the underlying
select.devpoll() object.

New in version 3.5.

class selectors. KqueueSelector
select.kqueue() - based selector.

fileno()
This returns the file descriptor used by the underlying
select.kqueue() object.
18.4.3. Examples

Here is a simple echo server implementation:

```python
import selectors
import socket

sel = selectors.DefaultSelector()

def accept(sock, mask):
    conn, addr = sock.accept()  # Should be ready
    print('accepted', conn, 'from', addr)
    conn.setblocking(False)
    sel.register(conn, selectors.EVENT_READ, read)

def read(conn, mask):
    data = conn.recv(1000)  # Should be ready
    if data:
        print('echoing', repr(data), 'to', conn)
        conn.send(data)  # Hope it won't block
    else:
        print('closing', conn)
        sel.unregister(conn)
        conn.close()

sock = socket.socket()
sock.bind(('localhost', 1234))
sock.listen(100)
sock.setblocking(False)
sel.register(sock, selectors.EVENT_READ, accept)

while True:
    events = sel.select()
    for key, mask in events:
        callback = key.data
```
callback(key.fileobj, mask)
18.5. asyncio — Asynchronous I/O, event loop, coroutines and tasks

New in version 3.4.

Source code: Lib/asyncio/

This module provides infrastructure for writing single-threaded concurrent code using coroutines, multiplexing I/O access over sockets and other resources, running network clients and servers, and other related primitives. Here is a more detailed list of the package contents:

- a pluggable event loop with various system-specific implementations;
- transport and protocol abstractions (similar to those in Twisted);
- concrete support for TCP, UDP, SSL, subprocess pipes, delayed calls, and others (some may be system-dependent);
- a Future class that mimics the one in the concurrent.futures module, but adapted for use with the event loop;
- coroutines and tasks based on yield from (PEP 380), to help write concurrent code in a sequential fashion;
- cancellation support for Futures and coroutines;
- synchronization primitives for use between coroutines in a single thread, mimicking those in the threading module;
- an interface for passing work off to a threadpool, for times when you absolutely, positively have to use a library that makes blocking I/O calls.
Asynchronous programming is more complex than classical “sequential” programming: see the Develop with asyncio page which lists common traps and explains how to avoid them. Enable the debug mode during development to detect common issues.

18. Interprocess Communication and Networking

18.5. asyncio — Asynchronous I/O, event loop, coroutines and tasks
18.5.1. Base Event Loop

**Source code:** Lib/asyncio/events.py

The event loop is the central execution device provided by `asyncio`. It provides multiple facilities, including:

- Registering, executing and cancelling delayed calls (timeouts).
- Creating client and server transports for various kinds of communication.
- Launching subprocesses and the associated transports for communication with an external program.
- Delegating costly function calls to a pool of threads.

*class asyncio.BaseEventLoop*

This class is an implementation detail. It is a subclass of `AbstractEventLoop` and may be a base class of concrete event loop implementations found in `asyncio`. It should not be used directly; use `AbstractEventLoop` instead. `BaseEventLoop` should not be subclassed by third-party code; the internal interface is not stable.

*class asyncio.AbstractEventLoop*

Abstract base class of event loops.

This class is *not thread safe.*
18.5.1.1. Run an event loop

AbstractEventLoop.run_forever()
Run until stop() is called. If stop() is called before run_forever() is called, this polls the I/O selector once with a timeout of zero, runs all callbacks scheduled in response to I/O events (and those that were already scheduled), and then exits. If stop() is called while run_forever() is running, this will run the current batch of callbacks and then exit. Note that callbacks scheduled by callbacks will not run in that case; they will run the next time run_forever() is called.

*Changed in version 3.5.1.*

AbstractEventLoop.run_until_complete(future)
Run until the Future is done.

If the argument is a coroutine object, it is wrapped by ensure_future().

Return the Future’s result, or raise its exception.

AbstractEventLoop.is_running()
Returns running status of event loop.

AbstractEventLoop.stop()
Stop running the event loop.

This causes run_forever() to exit at the next suitable opportunity (see there for more details).

*Changed in version 3.5.1.*
AbstractEventLoop.**is_closed()**

Returns *True* if the event loop was closed.

*New in version 3.4.2.*

AbstractEventLoop.**close()**

Close the event loop. The loop must not be running. Pending callbacks will be lost.

This clears the queues and shuts down the executor, but does not wait for the executor to finish.

This is idempotent and irreversible. No other methods should be called after this one.

coroutine AbstractEventLoop.**shutdown_asyncgens()**

Schedule all currently open asynchronous generator objects to close with an `aclose()` call. After calling this method, the event loop will issue a warning whenever a new asynchronous generator is iterated. Should be used to finalize all scheduled asynchronous generators reliably. Example:

```python
try:
    loop.run_forever()
finally:
    loop.run_until_complete(loop.shutdown_asyncgens()
    loop.close()
```

*New in version 3.6.*
18.5.1.2. Calls

Most asyncio functions don’t accept keywords. If you want to pass keywords to your callback, use `functools.partial()`. For example, `loop.call_soon(functools.partial(print, "Hello", flush=True))` will call `print("Hello", flush=True)`.

**Note:** `functools.partial()` is better than lambda functions, because asyncio can inspect `functools.partial()` object to display parameters in debug mode, whereas lambda functions have a poor representation.

AbstractEventLoop. **call_soon**(callback, *args)

Arrange for a callback to be called as soon as possible. The callback is called after `call_soon()` returns, when control returns to the event loop.

This operates as a FIFO queue, callbacks are called in the order in which they are registered. Each callback will be called exactly once.

Any positional arguments after the callback will be passed to the callback when it is called.

An instance of `asyncio.Handle` is returned, which can be used to cancel the callback.

Use `functools.partial` to pass keywords to the callback.

AbstractEventLoop. **call_soon_threadsafe**(callback,
*args)

Like `call_soon()`, but thread safe.

See the concurrency and multithreading section of the documentation.
18.5.1.3. Delayed calls

The event loop has its own internal clock for computing timeouts. Which clock is used depends on the (platform-specific) event loop implementation; ideally it is a monotonic clock. This will generally be a different clock than `time.time()`.

**Note:** Timeouts (relative *delay* or absolute *when*) should not exceed one day.

AbstractEventLoop. `call_later(delay, callback, *args)`

Arrange for the *callback* to be called after the given *delay* seconds (either an int or float).

An instance of `asyncio.Handle` is returned, which can be used to cancel the callback.

*callback* will be called exactly once per call to `call_later()`. If two callbacks are scheduled for exactly the same time, it is undefined which will be called first.

The optional positional *args* will be passed to the callback when it is called. If you want the callback to be called with some named arguments, use a closure or `functools.partial()`.

Use `functools.partial` to pass keywords to the callback.

AbstractEventLoop. `call_at(when, callback, *args)`

Arrange for the *callback* to be called at the given absolute timestamp *when* (an int or float), using the same time reference as AbstractEventLoop.time().
This method’s behavior is the same as `call_later()`.

An instance of `asyncio.Handle` is returned, which can be used to cancel the callback.

Use `functools.partial` to pass keywords to the callback.

AbstractEventLoop.`time()`
Return the current time, as a `float` value, according to the event loop’s internal clock.

**See also:** The `asyncio.sleep()` function.
18.5.1.4. Futures

AbstractEventLoop.\texttt{create\_future}()

Create an \texttt{asyncio.Future} object attached to the loop.

This is a preferred way to create futures in asyncio, as event loop implementations can provide alternative implementations of the Future class (with better performance or instrumentation).

\textit{New in version 3.5.2.}
18.5.1.5. Tasks

AbstractEventLoop.\texttt{create_task}(coro)
Schedule the execution of a coroutine object: wrap it in a future. Return a Task object.

Third-party event loops can use their own subclass of Task for interoperability. In this case, the result type is a subclass of Task.

This method was added in Python 3.4.2. Use the async() function to support also older Python versions.

\textit{New in version 3.4.2.}

AbstractEventLoop.\texttt{set_task_factory}(factory)
Set a task factory that will be used by AbstractEventLoop.create_task().

If \textit{factory} is \texttt{None} the default task factory will be set.

If \textit{factory} is a callable, it should have a signature matching \texttt{(loop, coro)}, where \textit{loop} will be a reference to the active event loop, \textit{coro} will be a coroutine object. The callable must return an asyncio.Future compatible object.

\textit{New in version 3.4.4.}

AbstractEventLoop.\texttt{get_task_factory}()
Return a task factory, or \texttt{None} if the default one is in use.

\textit{New in version 3.4.4.}
18.5.1.6. Creating connections

coroutine

AbstractEventLoop.create_connection(protocol_factory, host=None, port=None, *, ssl=None, family=0, proto=0, flags=0, sock=None, local_addr=None, server_hostname=None)

Create a streaming transport connection to a given Internet host and port: socket family AF_INET or AF_INET6 depending on host (or family if specified), socket type SOCK_STREAM. protocol_factory must be a callable returning a protocol instance.

This method is a coroutine which will try to establish the connection in the background. When successful, the coroutine returns a (transport, protocol) pair.

The chronological synopsis of the underlying operation is as follows:

1. The connection is established, and a transport is created to represent it.
2. protocol_factory is called without arguments and must return a protocol instance.
3. The protocol instance is tied to the transport, and its connection_made() method is called.
4. The coroutine returns successfully with the (transport, protocol) pair.

The created transport is an implementation-dependent bidirectional stream.

Note: protocol_factory can be any kind of callable, not necessarily a class. For example, if you want to use a pre-created protocol instance, you can pass lambda:
Options that change how the connection is created:

- **ssl**: if given and not false, a SSL/TLS transport is created (by default a plain TCP transport is created). If `ssl` is a `ssl.SSLContext` object, this context is used to create the transport; if `ssl` is `True`, a context with some unspecified default settings is used.

  **See also**: SSL/TLS security considerations

- **server_hostname**, is only for use together with `ssl`, and sets or overrides the hostname that the target server’s certificate will be matched against. By default the value of the `host` argument is used. If `host` is empty, there is no default and you must pass a value for `server_hostname`. If `server_hostname` is an empty string, hostname matching is disabled (which is a serious security risk, allowing for man-in-the-middle-attacks).

- **family**, **proto**, **flags** are the optional address family, protocol and flags to be passed through to `getaddrinfo()` for `host` resolution. If given, these should all be integers from the corresponding `socket` module constants.

- **sock**, if given, should be an existing, already connected `socket.socket` object to be used by the transport. If `sock` is given, none of `host`, `port`, `family`, `proto`, `flags` and `local_addr` should be specified.

- **local_addr**, if given, is a `local_host, local_port` tuple used to bind the socket to locally. The `local_host` and `local_port` are looked up using `getaddrinfo()`, similarly to `host`
and port.

*Changed in version 3.5:* On Windows with ProactorEventLoop, SSL/TLS is now supported.

**See also:** The open_connection() function can be used to get a pair of (StreamReader, StreamWriter) instead of a protocol.

**coroutine**
AbstractEventLoop.create_datagram_endpoint(protocol_factory, local_addr=None, remote_addr=None, *, family=0, proto=0, flags=0, reuse_address=None, reuse_port=None, allow_broadcast=None, sock=None)

Create datagram connection: socket family AF_INET or AF_INET6 depending on host (or family if specified), socket type SOCK_DGRAM. protocol_factory must be a callable returning a protocol instance.

This method is a coroutine which will try to establish the connection in the background. When successful, the coroutine returns a (transport, protocol) pair.

Options changing how the connection is created:

- **local_addr**, if given, is a (local_host, local_port) tuple used to bind the socket to locally. The local_host and local_port are looked up using getaddrinfo().
- **remote_addr**, if given, is a (remote_host, remote_port) tuple used to connect the socket to a remote address. The remote_host and remote_port are looked up up using getaddrinfo().
- **family**, **proto**, **flags** are the optional address family, protocol
and flags to be passed through to `getaddrinfo()` for host resolution. If given, these should all be integers from the corresponding `socket` module constants.

- `reuse_address` tells the kernel to reuse a local socket in TIME_WAIT state, without waiting for its natural timeout to expire. If not specified will automatically be set to `True` on UNIX.
- `reuse_port` tells the kernel to allow this endpoint to be bound to the same port as other existing endpoints are bound to, so long as they all set this flag when being created. This option is not supported on Windows and some UNIX's. If the SO_REUSEPORT constant is not defined then this capability is unsupported.
- `allow_broadcast` tells the kernel to allow this endpoint to send messages to the broadcast address.
- `sock` can optionally be specified in order to use a preexisting, already connected, `socket.socket` object to be used by the transport. If specified, `local_addr` and `remote_addr` should be omitted (must be `None`).

On Windows with `ProactorEventLoop`, this method is not supported.

See UDP echo client protocol and UDP echo server protocol examples.

```
coroutine
AbstractEventLoop.create_unix_connection(protocol_family, path, *, ssl=None, sock=None, server_hostname=None)
```

Create UNIX connection: socket family `AF_UNIX`, socket type `SOCK_STREAM`. The `AF_UNIX` socket family is used to communicate between processes on the same machine efficiently.

This method is a coroutine which will try to establish the connection
in the background. When successful, the coroutine returns a (transport, protocol) pair.

(path) is the name of a UNIX domain socket, and is required unless a sock parameter is specified. Abstract UNIX sockets, str, and bytes paths are supported.

See the AbstractEventLoop.create_connection() method for parameters.

Availability: UNIX.
18.5.1.7. Creating listening connections

coroutine
AbstractEventLoop.create_server(protocol_factory, host=None, port=None, *, family=socket.AF_UNSPEC, flags=socket.AI_PASSIVE, sock=None, backlog=100, ssl=None, reuse_address=None, reuse_port=None)

Create a TCP server (socket type **SOCK_STREAM**) bound to *host* and *port*.

Return a Server object, its sockets attribute contains created sockets. Use the Server.close() method to stop the server: close listening sockets.

Parameters:

- The *host* parameter can be a string, in that case the TCP server is bound to *host* and *port*. The *host* parameter can also be a sequence of strings and in that case the TCP server is bound to all hosts of the sequence. If *host* is an empty string or None, all interfaces are assumed and a list of multiple sockets will be returned (most likely one for IPv4 and another one for IPv6).
- *family* can be set to either socket.AF_INET or AF_INET6 to force the socket to use IPv4 or IPv6. If not set it will be determined from host (defaults to socket.AF_UNSPEC).
- *flags* is a bitmask for getaddrinfo().
- *sock* can optionally be specified in order to use a preexisting socket object. If specified, *host* and *port* should be omitted (must be None).
- *backlog* is the maximum number of queued connections passed to listen() (defaults to 100).
- *ssl* can be set to an SSLContext to enable SSL over the
accepted connections.

- `reuse_address` tells the kernel to reuse a local socket in TIME_WAIT state, without waiting for its natural timeout to expire. If not specified will automatically be set to True on UNIX.

- `reuse_port` tells the kernel to allow this endpoint to be bound to the same port as other existing endpoints are bound to, so long as they all set this flag when being created. This option is not supported on Windows.

This method is a coroutine.

*Changed in version 3.5:* On Windows with `ProactorEventLoop`, SSL/TLS is now supported.

**See also:** The function `start_server()` creates a `(StreamReader, StreamWriter)` pair and calls back a function with this pair.

*Changed in version 3.5.1:* The host parameter can now be a sequence of strings.

coroutine

AbstractEventLoop.

```
create_unix_server(protocol_factory, path=None, *, sock=None, backlog=100, ssl=None)
```

Similar to `AbstractEventLoop.create_server()`, but specific to the socket family `AF_UNIX`.

This method is a coroutine.

Availability: UNIX.

coroutine

BaseEventLoop.

```
connect_accepted_socket(protocol_factori
sock, *, ssl=None)
```
Handle an accepted connection.

This is used by servers that accept connections outside of asyncio but that use asyncio to handle them.

Parameters:

- *sock* is a preexisting socket object returned from an `accept` call.
- *ssl* can be set to an `SSLContext` to enable SSL over the accepted connections.

This method is a coroutine. When completed, the coroutine returns a `(transport, protocol)` pair.
18.5.1.8. Watch file descriptors

On Windows with `SelectorEventLoop`, only socket handles are supported (ex: pipe file descriptors are not supported).

On Windows with `ProactorEventLoop`, these methods are not supported.

`AbstractEventLoop.add_reader(fd, callback, *args)`
- Start watching the file descriptor for read availability and then call the `callback` with specified arguments.

  Use `functools.partial` to pass keywords to the callback.

`AbstractEventLoop.remove_reader(fd)`
- Stop watching the file descriptor for read availability.

`AbstractEventLoop.add_writer(fd, callback, *args)`
- Start watching the file descriptor for write availability and then call the `callback` with specified arguments.

  Use `functools.partial` to pass keywords to the callback.

`AbstractEventLoop.remove_writer(fd)`
- Stop watching the file descriptor for write availability.

The watch a file descriptor for read events example uses the low-level `AbstractEventLoop.add_reader()` method to register the file descriptor of a socket.
18.5.1.9. Low-level socket operations

**coroutine** AbstractEventLoop. **sock_recv**(sock, nbytes)

Receive data from the socket. Modeled after blocking `socket.socket.recv()` method.

The return value is a bytes object representing the data received. The maximum amount of data to be received at once is specified by `nbytes`.

With **SelectorEventLoop** event loop, the socket `sock` must be non-blocking.

This method is a **coroutine**.

**coroutine** AbstractEventLoop. **sock_sendall**(sock, data)

Send data to the socket. Modeled after blocking `socket.socket.sendall()` method.

The socket must be connected to a remote socket. This method continues to send data from `data` until either all data has been sent or an error occurs. **None** is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully processed by the receiving end of the connection.

With **SelectorEventLoop** event loop, the socket `sock` must be non-blocking.

This method is a **coroutine**.

**coroutine** AbstractEventLoop. **sock_connect**(sock, address)
Connect to a remote socket at address. Modeled after blocking `socket.socket.connect()` method.

With `SelectorEventLoop` event loop, the socket `sock` must be non-blocking.

This method is a coroutine.

*Changed in version 3.5.2:* address no longer needs to be resolved. `sock_connect` will try to check if the address is already resolved by calling `socket.inet_pton()`. If not, `AbstractEventLoop.getaddrinfo()` will be used to resolve the address.

See also: `AbstractEventLoop.create_connection()` and `asyncio.open_connection()`.

coroutine AbstractEventLoop. `sock_accept(sock)`

Accept a connection. Modeled after blocking `socket.socket.accept()`.

The socket must be bound to an address and listening for connections. The return value is a pair `(conn, address)` where `conn` is a new socket object usable to send and receive data on the connection, and `address` is the address bound to the socket on the other end of the connection.

The socket `sock` must be non-blocking.

This method is a coroutine.

See also: `AbstractEventLoop.create_server()` and
start_server().
18.5.1.10. Resolve host name

coroutine AbstractEventLoop.getaddrinfo(host, port, *,
family=0, type=0, proto=0, flags=0)

This method is a coroutine, similar to socket.getaddrinfo() function but non-blocking.

coroutine AbstractEventLoop.getnameinfo(sockaddr, flags=0)

This method is a coroutine, similar to socket.getnameinfo() function but non-blocking.
18.5.1.11. Connect pipes

On Windows with SelectorEventLoop, these methods are not supported. Use ProactorEventLoop to support pipes on Windows.

coroutine
AbstractEventLoop.connect_read_pipe(protocol_factory, pipe)

Register read pipe in eventloop.

protocol_factory should instantiate object with Protocol interface. pipe is a file-like object. Return pair (transport, protocol), where transport supports the ReadTransport interface.

With SelectorEventLoop event loop, the pipe is set to non-blocking mode.

This method is a coroutine.

coroutine
AbstractEventLoop.connect_write_pipe(protocol_factory, pipe)

Register write pipe in eventloop.

protocol_factory should instantiate object with BaseProtocol interface. pipe is file-like object. Return pair (transport, protocol), where transport supports WriteTransport interface.

With SelectorEventLoop event loop, the pipe is set to non-blocking mode.

This method is a coroutine.
See also: The AbstractEventLoop.subprocess_exec() and AbstractEventLoop.subprocess_shell() methods.
18.5.1.12. UNIX signals

Availability: UNIX only.

AbstractEventLoop. `add_signal_handler(signum, callback, *args)`

Add a handler for a signal.

Raise `ValueError` if the signal number is invalid or uncatchable. Raise `RuntimeError` if there is a problem setting up the handler.

Use `functools.partial` to pass keywords to the callback.

AbstractEventLoop. `remove_signal_handler(sig)`

Remove a handler for a signal.

Return `True` if a signal handler was removed, `False` if not.

See also: The `signal` module.
18.5.1.13. Executor

Call a function in an Executor (pool of threads or pool of processes). By default, an event loop uses a thread pool executor (ThreadPoolExecutor).

coroutine AbstractEventLoop.run_in_executor(executor, func, *args)

Arrange for a func to be called in the specified executor.

The executor argument should be an Executor instance. The default executor is used if executor is None.

Use functools.partial to pass keywords to the *func*.

This method is a coroutine.

Changed in version 3.5.3: BaseEventLoop.run_in_executor() no longer configures the max_workers of the thread pool executor it creates, instead leaving it up to the thread pool executor (ThreadPoolExecutor) to set the default.

AbstractEventLoop.set_default_executor(executor)

Set the default executor used by run_in_executor().
18.5.1.14. Error Handling API

 Allows customizing how exceptions are handled in the event loop.

 AbstractEventLoop. set_exception_handler(handler)
 Set handler as the new event loop exception handler.

 If handler is None, the default exception handler will be set.

 If handler is a callable object, it should have a matching signature to (loop, context), where loop will be a reference to the active event loop, context will be a dict object (see call_exception_handler() documentation for details about context).

 AbstractEventLoop. get_exception_handler()
 Return the exception handler, or None if the default one is in use.

 New in version 3.5.2.

 AbstractEventLoop. default_exception_handler(context)
 Default exception handler.

 This is called when an exception occurs and no exception handler is set, and can be called by a custom exception handler that wants to defer to the default behavior.

 context parameter has the same meaning as in call_exception_handler().

 AbstractEventLoop. call_exception_handler(context)
 Call the current event loop exception handler.
context is a dict object containing the following keys (new keys may be introduced later):

- ‘message’: Error message;
- ‘exception’ (optional): Exception object;
- ‘future’ (optional): asyncio.Future instance;
- ‘handle’ (optional): asyncio.Handle instance;
- ‘protocol’ (optional): Protocol instance;
- ‘transport’ (optional): Transport instance;
- ‘socket’ (optional): socket.socket instance.

Note: Note: this method should not be overloaded in subclassed event loops. For any custom exception handling, use set_exception_handler() method.
18.5.1.15. Debug mode

AbstractEventLoop.\texttt{get\_debug}(())

Get the debug mode (\texttt{bool}) of the event loop.

The default value is \texttt{True} if the environment variable \texttt{PYTHONASYNCIODEBUG} is set to a non-empty string, \texttt{False} otherwise.

\textit{New in version 3.4.2.}

AbstractEventLoop.\texttt{set\_debug}(\texttt{enabled: bool})

Set the debug mode of the event loop.

\textit{New in version 3.4.2.}

\textbf{See also:} The \texttt{debug mode of asyncio}. 
18.5.1.16. Server

```python
class asyncio.Server
    Server listening on sockets.
```

Object created by the `AbstractEventLoop.create_server()` method and the `start_server()` function. Don’t instantiate the class directly.

**close()**

Stop serving: close listening sockets and set the `sockets` attribute to `None`.

The sockets that represent existing incoming client connections are left open.

The server is closed asynchronously, use the `wait_closed()` coroutine to wait until the server is closed.

```python
coroutine def wait_closed()
    Wait until the `close()` method completes.
```

This method is a coroutine.

**sockets**

List of `socket.socket` objects the server is listening to, or `None` if the server is closed.
18.5.1.17. Handle

'class asyncio.Handle'

A callback wrapper object returned by 
AbstractEventLoop.call_soon(),
AbstractEventLoop.call_soon_threadsafe(),
AbstractEventLoop.call_later(), and
AbstractEventLoop.call_at().

cancel()

Cancel the call. If the callback is already canceled or executed, 
this method has no effect.
18.5.1.18. Event loop examples

18.5.1.18.1. Hello World with call_soon()

Example using the AbstractEventLoop.call_soon() method to schedule a callback. The callback displays "Hello World" and then stops the event loop:

```
import asyncio

def hello_world(loop):
    print('Hello World')
    loop.stop()

loop = asyncio.get_event_loop()

# Schedule a call to hello_world()
loop.call_soon(hello_world, loop)

# Blocking call interrupted by loop.stop()
loop.run_forever()
loop.close()
```

See also: The Hello World coroutine example uses a coroutine.

18.5.1.18.2. Display the current date with call_later()

Example of callback displaying the current date every second. The callback uses the AbstractEventLoop.call_later() method to reschedule itself during 5 seconds, and then stops the event loop:

```
import asyncio
```
import datetime

def display_date(end_time, loop):
    print(datetime.datetime.now())
    if (loop.time() + 1.0) < end_time:
        loop.callLater(1, display_date, end_time, loop)
    else:
        loop.stop()

loop = asyncio.get_event_loop()

# Schedule the first call to display_date()
end_time = loop.time() + 5.0
loop.call_soon(display_date, end_time, loop)

# Blocking call interrupted by loop.stop()
loop.run_forever()
loop.close()

See also: The coroutine displaying the current date example uses a coroutine.

18.5.1.18.3. Watch a file descriptor for read events

Wait until a file descriptor received some data using the AbstractEventLoop.add_reader() method and then close the event loop:

import asyncio
try:
    from socket import socketpair
except ImportError:
    from asyncio.windows_utils import socketpair
# Create a pair of connected file descriptors
rsock, wsock = socketpair()
loop = asyncio.get_event_loop()

def reader():
    data = rsock.recv(100)
    print("Received:", data.decode())
    # We are done: unregister the file descriptor
    loop.remove_reader(rsock)
    # Stop the event loop
    loop.stop()

    # Register the file descriptor for read event
    loop.add_reader(rsock, reader)

    # Simulate the reception of data from the network
    loop.call_soon(wsock.send, 'abc'.encode())

    # Run the event loop
    loop.run_forever()

    # We are done, close sockets and the event loop
    rsock.close()
wsock.close()
loop.close()

See also: The register an open socket to wait for data using a protocol example uses a low-level protocol created by the AbstractEventLoop.create_connection() method.

The register an open socket to wait for data using streams example uses high-level streams created by the open_connection() function in a coroutine.

18.5.1.18.4. Set signal handlers for SIGINT and
Register handlers for signals SIGINT and SIGTERM using the `AbstractEventLoop.add_signal_handler()` method:

```python
import asyncio
import functools
import os
import signal

def ask_exit(signame):
    print("got signal %s: exit" % signame)
    loop.stop()

loop = asyncio.get_event_loop()
for signame in ('SIGINT', 'SIGTERM'):
    loop.add_signal_handler(getattr(signal, signame),
        functools.partial(ask_exit))

print("Event loop running forever, press Ctrl+C to interrupt."
print("pid %s: send SIGINT or SIGTERM to exit." % os.pid)
try:
    loop.run_forever()
finally:
    loop.close()
```

This example only works on UNIX.
18.5.2. Event loops

Source code: Lib/asyncio/events.py
18.5.2.1. Event loop functions

The following functions are convenient shortcuts to accessing the methods of the global policy. Note that this provides access to the default policy, unless an alternative policy was set by calling `set_event_loop_policy()` earlier in the execution of the process.

**asyncio.** `get_event_loop()`

Equivalent to calling

```python
get_event_loop_policy().get_event_loop()
```

**asyncio.** `set_event_loop(loop)`

Equivalent to calling

```python
get_event_loop_policy().set_event_loop(loop)
```

**asyncio.** `new_event_loop()`

Equivalent to calling

```python
get_event_loop_policy().new_event_loop()
```
18.5.2.2. Available event loops

asyncio currently provides two implementations of event loops: `SelectorEventLoop` and `ProactorEventLoop`.

```python
class asyncio.SelectorEventLoop
    Event loop based on the selectors module. Subclass of AbstractEventLoop.

    Use the most efficient selector available on the platform.

    On Windows, only sockets are supported (ex: pipes are not supported): see the MSDN documentation of select.

class asyncio.ProactorEventLoop
    Proactor event loop for Windows using “I/O Completion Ports” aka IOCP. Subclass of AbstractEventLoop.

    Availability: Windows.
```

**See also:** MSDN documentation on I/O Completion Ports.

Example to use a `ProactorEventLoop` on Windows:

```python
import asyncio, sys

if sys.platform == 'win32':
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
```
18.5.2.3. Platform support

The asyncio module has been designed to be portable, but each platform still has subtle differences and may not support all asyncio features.

18.5.2.3.1. Windows

Common limits of Windows event loops:

- `create_unix_connection()` and `create_unix_server()` are not supported: the socket family `socket.AF_UNIX` is specific to UNIX
- `add_signal_handler()` and `remove_signal_handler()` are not supported
- `EventLoopPolicy.set_child_watcher()` is not supported.
  `ProactorEventLoop` supports subprocesses. It has only one implementation to watch child processes, there is no need to configure it.

`SelectorEventLoop` specific limits:

- `SelectSelector` is used which only supports sockets and is limited to 512 sockets.
- `add_reader()` and `add_writer()` only accept file descriptors of sockets
- Pipes are not supported (ex: `connect_read_pipe()`, `connect_write_pipe()`)  
- Subprocesses are not supported (ex: `subprocess_exec()`, `subprocess_shell()`)

`ProactorEventLoop` specific limits:

- `create_datagram_endpoint()` (UDP) is not supported
- `add_reader()` and `add_writer()` are not supported

The resolution of the monotonic clock on Windows is usually around 15.6 msec. The best resolution is 0.5 msec. The resolution depends on the hardware (availability of HPET) and on the Windows configuration. See asyncio delayed calls.

*Changed in version 3.5:* ProactorEventLoop now supports SSL.

### 18.5.2.3.2. Mac OS X

Character devices like PTY are only well supported since Mavericks (Mac OS 10.9). They are not supported at all on Mac OS 10.5 and older.

On Mac OS 10.6, 10.7 and 10.8, the default event loop is SelectorEventLoop which uses `selectors.KqueueSelector`. `selectors.KqueueSelector` does not support character devices on these versions. The SelectorEventLoop can be used with SelectSelector or PollSelector to support character devices on these versions of Mac OS X. Example:

```python
import asyncio
import selectors

selector = selectors.SelectSelector()
loop = asyncio.SelectorEventLoop(selector)
asyncio.set_event_loop(loop)
```
18.5.2.4. Event loop policies and the default policy

Event loop management is abstracted with a policy pattern, to provide maximal flexibility for custom platforms and frameworks. Throughout the execution of a process, a single global policy object manages the event loops available to the process based on the calling context. A policy is an object implementing the AbstractEventLoopPolicy interface.

For most users of asyncio, policies never have to be dealt with explicitly, since the default global policy is sufficient.

The default policy defines context as the current thread, and manages an event loop per thread that interacts with asyncio. The module-level functions get_event_loop() and set_event_loop() provide convenient access to event loops managed by the default policy.
18.5.2.5. Event loop policy interface

An event loop policy must implement the following interface:

```python
class asyncio.AbstractEventLoopPolicy
    Event loop policy.

    get_event_loop()
        Get the event loop for the current context.

        Returns an event loop object implementing the AbstractEventLoop interface.

        Raises an exception in case no event loop has been set for the current context and the current policy does not specify to create one. It must never return None.

    set_event_loop(loop)
        Set the event loop for the current context to loop.

    new_event_loop()
        Create and return a new event loop object according to this policy’s rules.

        If there’s need to set this loop as the event loop for the current context, set_event_loop() must be called explicitly.
```
18.5.2.6. Access to the global loop policy

asyncio.get_event_loop_policy()
Get the current event loop policy.

asyncio.set_event_loop_policy(policy)
Set the current event loop policy. If policy is None, the default policy is restored.
18.5.3. Tasks and coroutines

Source code: Lib/asyncio/tasks.py

Source code: Lib/asyncio/coroutines.py
18.5.3.1. Coroutines

Coroutines used with asyncio may be implemented using the async def statement, or by using generators. The async def type of coroutine was added in Python 3.5, and is recommended if there is no need to support older Python versions.

Generator-based coroutines should be decorated with @asyncio.coroutine, although this is not strictly enforced. The decorator enables compatibility with async def coroutines, and also serves as documentation. Generator-based coroutines use the yield from syntax introduced in PEP 380, instead of the original yield syntax.

The word “coroutine”, like the word “generator”, is used for two different (though related) concepts:

- The function that defines a coroutine (a function definition using async def or decorated with @asyncio.coroutine). If disambiguation is needed we will call this a coroutine function (iscoroutinefunction() returns True).
- The object obtained by calling a coroutine function. This object represents a computation or an I/O operation (usually a combination) that will complete eventually. If disambiguation is needed we will call it a coroutine object (iscoroutine() returns True).

Things a coroutine can do:

- result = await future or result = yield from future - suspends the coroutine until the future is done, then returns the future's result, or raises an exception, which will be
propagated. (If the future is cancelled, it will raise a `CancelledError` exception.) Note that tasks are futures, and everything said about futures also applies to tasks.

- `result = await coroutine` or `result = yield from coroutine` – wait for another coroutine to produce a result (or raise an exception, which will be propagated). The coroutine expression must be a `call` to another coroutine.

- `return expression` – produce a result to the coroutine that is waiting for this one using `await` or `yield from`.

- `raise exception` – raise an exception in the coroutine that is waiting for this one using `await` or `yield from`.

Calling a coroutine does not start its code running – the coroutine object returned by the call doesn’t do anything until you schedule its execution. There are two basic ways to start it running: call `await coroutine` or `yield from coroutine` from another coroutine (assuming the other coroutine is already running!), or schedule its execution using the `ensure_future()` function or the `AbstractEventLoop.create_task()` method.

Coroutines (and tasks) can only run when the event loop is running.

@asyncio.coroutine

Decorator to mark generator-based coroutines. This enables the generator use `yield from` to call `async def` coroutines, and also enables the generator to be called by `async def` coroutines, for instance using an `await` expression.

There is no need to decorate `async def` coroutines themselves.

If the generator is not yielded from before it is destroyed, an error message is logged. See Detect coroutines never scheduled.
18.5.3.1.1. Example: Hello World coroutine

Example of coroutine displaying "Hello World":

```python
import asyncio

async def hello_world():
    print("Hello World!")

loop = asyncio.get_event_loop()
# Blocking call which returns when the hello_world() coroutine
# is done
loop.run_until_complete(hello_world())
loop.close()
```

See also: The Hello World with call_soon() example uses the AbstractEventLoop.call_soon() method to schedule a callback.

18.5.3.1.2. Example: Coroutine displaying the current date

Example of coroutine displaying the current date every second during 5 seconds using the sleep() function:
import asyncio
import datetime

async def display_date(loop):
    end_time = loop.time() + 5.0
    while True:
        print(datetime.datetime.now())
        if (loop.time() + 1.0) >= end_time:
            break
        await asyncio.sleep(1)

loop = asyncio.get_event_loop()
# Blocking call which returns when the display_date()
loop.run_until_complete(display_date(loop))
loop.close()

See also: The display the current date with call_later() example uses a callback with the AbstractEventLoop.call_later() method.

18.5.3.1.3. Example: Chain coroutines

Example chaining coroutines:

import asyncio

async def compute(x, y):
    print("Compute %s + %s ..." % (x, y))
    await asyncio.sleep(1.0)
    return x + y

async def print_sum(x, y):
    result = await compute(x, y)
    print("%s + %s = %s" % (x, y, result))
loop = asyncio.get_event_loop()
loop.run_until_complete(print_sum(1, 2))
loop.close()

compute() is chained to print_sum(): print_sum() coroutine waits until compute() is completed before returning its result.

Sequence diagram of the example:

The “Task” is created by the AbstractEventLoop.run_until_complete() method when it gets a coroutine object instead of a task.

The diagram shows the control flow, it does not describe exactly how things work internally. For example, the sleep coroutine creates an internal future which uses AbstractEventLoop.call_later() to wake up the task in 1 second.
18.5.3.2. InvalidStateError

(exception asyncio.**InvalidStateError**

The operation is not allowed in this state.)
18.5.3.3. TimeoutError

_exception asyncio.TimeoutError_

The operation exceeded the given deadline.

**Note:** This exception is different from the builtin `TimeoutError` exception!
18.5.3.4. Future

```python
class asyncio.Future(*, loop=None)
```

This class is *almost* compatible with `concurrent.futures.Future`.

Differences:

- `result()` and `exception()` do not take a timeout argument and raise an exception when the future isn’t done yet.
- Callbacks registered with `add_done_callback()` are always called via the event loop’s `call_soon_threadsafe()`.
- This class is not compatible with the `wait()` and `as_completed()` functions in the `concurrent.futures` package.

This class is not thread safe.

`cancel()`

Cancel the future and schedule callbacks.

If the future is already done or cancelled, return `False`. Otherwise, change the future’s state to cancelled, schedule the callbacks and return `True`.

`cancelled()`

Return `True` if the future was cancelled.

`done()`

Return `True` if the future is done.
Done means either that a result / exception are available, or that the future was cancelled.

**result()**
Return the result this future represents.

If the future has been cancelled, raises `CancelledError`. If the future's result isn't yet available, raises `InvalidStateError`. If the future is done and has an exception set, this exception is raised.

**exception()**
Return the exception that was set on this future.

The exception (or `None` if no exception was set) is returned only if the future is done. If the future has been cancelled, raises `CancelledError`. If the future isn't done yet, raises `InvalidStateError`.

**add_done_callback(fn)**
Add a callback to be run when the future becomes done.

The callback is called with a single argument - the future object. If the future is already done when this is called, the callback is scheduled with `call_soon()`.

Use `functools.partial` to pass parameters to the callback. For example, `fut.add_done_callback(functools.partial(print, "Future: ", flush=True))` will call `print("Future:", fut, flush=True)`.

**remove_done_callback(fn)**
Remove all instances of a callback from the “call when done” list.

Returns the number of callbacks removed.

**set_result**(*result*)

Mark the future done and set its result.

If the future is already done when this method is called, raises `InvalidStateError`.

**set_exception**(*exception*)

Mark the future done and set an exception.

If the future is already done when this method is called, raises `InvalidStateError`.

18.5.3.4.1. Example: Future with `run_until_complete()`

Example combining a `Future` and a coroutine function:

```python
import asyncio

async def slow_operation(future):
    await asyncio.sleep(1)
    future.set_result('Future is done!')

loop = asyncio.get_event_loop()
future = asyncio.Future()
asyncio.ensure_future(slow_operation(future))
loop.run_until_complete(future)
print(future.result())
loop.close()
```
The coroutine function is responsible for the computation (which takes 1 second) and it stores the result into the future. The `run_until_complete()` method waits for the completion of the future.

**Note:** The `run_until_complete()` method uses internally the `add_done_callback()` method to be notified when the future is done.

### 18.5.3.4.2. Example: Future with `run_forever()`

The previous example can be written differently using the `Future.add_done_callback()` method to describe explicitly the control flow:

```python
import asyncio

async def slow_operation(future):
    await asyncio.sleep(1)
    future.set_result('Future is done!')

def got_result(future):
    print(future.result())
    loop.stop()

loop = asyncio.get_event_loop()
future = asyncio.Future()
asyncio.ensure_future(slow_operation(future))
future.add_done_callback(got_result)
try:
    loop.run_forever()
finally:
    loop.close()
```
In this example, the future is used to link `slow_operation()` to `got_result()`: when `slow_operation()` is done, `got_result()` is called with the result.
18.5.3.5. Task

```
class asyncio.Task(coro, *, loop=None)
```

Schedule the execution of a coroutine: wrap it in a future. A task is a subclass of Future.

A task is responsible for executing a coroutine object in an event loop. If the wrapped coroutine yields from a future, the task suspends the execution of the wrapped coroutine and waits for the completion of the future. When the future is done, the execution of the wrapped coroutine restarts with the result or the exception of the future.

Event loops use cooperative scheduling: an event loop only runs one task at a time. Other tasks may run in parallel if other event loops are running in different threads. While a task waits for the completion of a future, the event loop executes a new task.

The cancellation of a task is different from the cancelation of a future. Calling cancel() will throw a CancelledError to the wrapped coroutine. cancelled() only returns True if the wrapped coroutine did not catch the CancelledError exception, or raised a CancelledError exception.

If a pending task is destroyed, the execution of its wrapped coroutine did not complete. It is probably a bug and a warning is logged: see Pending task destroyed.

Don’t directly create Task instances: use the ensure_future() function or the AbstractEventLoop.create_task() method.

This class is not thread safe.
**classmethod all_tasks**(loop=\textit{None})

Return a set of all tasks for an event loop.

By default all tasks for the current event loop are returned.

**classmethod current_task**(loop=\textit{None})

Return the currently running task in an event loop or \texttt{None}.

By default the current task for the current event loop is returned.

\texttt{None} is returned when called not in the context of a \texttt{Task}.

**cancel()**

Request that this task cancel itself.

This arranges for a \texttt{CancelledError} to be thrown into the wrapped coroutine on the next cycle through the event loop. The coroutine then has a chance to clean up or even deny the request using try/except/finally.

Unlike \texttt{Future.cancel()}, this does not guarantee that the task will be cancelled: the exception might be caught and acted upon, delaying cancellation of the task or preventing cancellation completely. The task may also return a value or raise a different exception.

Immediately after this method is called, \texttt{cancelled()} will not return \texttt{True} (unless the task was already cancelled). A task will be marked as cancelled when the wrapped coroutine terminates with a \texttt{CancelledError} exception (even if \texttt{cancel()} was not called).

**get_stack**(\*, limit=\textit{None})
Return the list of stack frames for this task’s coroutine.

If the coroutine is not done, this returns the stack where it is suspended. If the coroutine has completed successfully or was cancelled, this returns an empty list. If the coroutine was terminated by an exception, this returns the list of traceback frames.

The frames are always ordered from oldest to newest.

The optional limit gives the maximum number of frames to return; by default all available frames are returned. Its meaning differs depending on whether a stack or a traceback is returned: the newest frames of a stack are returned, but the oldest frames of a traceback are returned. (This matches the behavior of the traceback module.)

For reasons beyond our control, only one stack frame is returned for a suspended coroutine.

**print_stack**(*, limit=None, file=None)

Print the stack or traceback for this task’s coroutine.

This produces output similar to that of the traceback module, for the frames retrieved by get_stack(). The limit argument is passed to get_stack(). The file argument is an I/O stream to which the output is written; by default output is written to sys.stderr.

18.5.3.5.1. Example: Parallel execution of tasks

Example executing 3 tasks (A, B, C) in parallel:
```python
import asyncio

async def factorial(name, number):
    f = 1
    for i in range(2, number+1):
        print("Task %s: Compute factorial(%s)...") % (name, number)
        await asyncio.sleep(1)
        f *= i
        print("Task %s: factorial(%s) = %s") % (name, number, f)

loop = asyncio.get_event_loop()
loop.run_until_complete(asyncio.gather(
    factorial("A", 2),
    factorial("B", 3),
    factorial("C", 4),
))
loop.close()
```

Output:

```
Task A: Compute factorial(2)...
Task B: Compute factorial(2)...
Task C: Compute factorial(2)...
Task A: factorial(2) = 2
Task B: Compute factorial(3)...
Task C: Compute factorial(3)...
Task B: factorial(3) = 6
Task C: Compute factorial(4)...
Task C: factorial(4) = 24
```

A task is automatically scheduled for execution when it is created. The event loop stops when all tasks are done.
18.5.3.6. Task functions

**Note:** In the functions below, the optional `loop` argument allows explicitly setting the event loop object used by the underlying task or coroutine. If it’s not provided, the default event loop is used.

```python
asyncio.as_completed(fs, *, loop=None, timeout=None)
```

Return an iterator whose values, when waited for, are `Future` instances.

Raises `asyncio.TimeoutError` if the timeout occurs before all Futures are done.

Example:

```python
for f in as_completed(fs):
    result = yield from f  # The 'yield from' may raise
    # Use result
```

**Note:** The futures `f` are not necessarily members of `fs`.

```python
asyncio.ensure_future(coro_or_future, *, loop=None)
```

Schedule the execution of a `coroutine object`: wrap it in a future. Return a `Task` object.

If the argument is a `Future`, it is returned directly.

*New in version 3.4.4.*

*Changed in version 3.5.1:* The function accepts any `awaitable` object.
See also: The AbstractEventLoop.create_task() method.

```python
asyncio.async(coro_or_future, *, loop=None)
```

A deprecated alias to ensure_future().

*Deprecated since version 3.4.4.*

```python
asyncio.wrap_future(future, *, loop=None)
```

Wrap a concurrent.futures.Future object in a Future object.

```python
asyncio.gather(*coros_or_futures, loop=None, return_exceptions=False)
```

Return a future aggregating results from the given coroutine objects or futures.

All futures must share the same event loop. If all the tasks are done successfully, the returned future's result is the list of results (in the order of the original sequence, not necessarily the order of results arrival). If return_exceptions is true, exceptions in the tasks are treated the same as successful results, and gathered in the result list; otherwise, the first raised exception will be immediately propagated to the returned future.

Cancellation: if the outer Future is cancelled, all children (that have not completed yet) are also cancelled. If any child is cancelled, this is treated as if it raised CancelledError – the outer Future is not cancelled in this case. (This is to prevent the cancellation of one child to cause other children to be cancelled.)

```python
asyncio.iscoroutine(obj)
```
Return **True** if `obj` is a coroutine **object**, which may be based on a generator or an `async def` coroutine.

*asyncio*. **iscoroutinefunction**(`func`)

Return **True** if `func` is determined to be a coroutine **function**, which may be a decorated generator function or an `async def` function.

*asyncio*. **run_coroutine_threadsafe**(`coro`, `loop`)

Submit a coroutine **object** to a given event loop.

Return a `concurrent.futures.Future` to access the result.

This function is meant to be called from a different thread than the one where the event loop is running. Usage:

```python
# Create a coroutine
coro = asyncio.sleep(1, result=3)
# Submit the coroutine to a given loop
future = asyncio.run_coroutine_threadsafe(coro, loop)
# Wait for the result with an optional timeout argument
assert future.result(timeout) == 3
```

If an exception is raised in the coroutine, the returned future will be notified. It can also be used to cancel the task in the event loop:

```python
try:
    result = future.result(timeout)
except asyncio.TimeoutError:
    print('The coroutine took too long, cancelling...')
    future.cancel()
except Exception as exc:
    print('The coroutine raised an exception: {!r}'.format(exc))
else:
    print('The coroutine returned: {!r}'.format(result))
```
See the concurrency and multithreading section of the documentation.

**Note:** Unlike other functions from the module, `run_coroutine_threadsafe()` requires the `loop` argument to be passed explicitly.

*New in version 3.5.1.*

coroutine `asyncio.sleep(delay, result=None, *, loop=None)`

Create a coroutine that completes after a given time (in seconds). If `result` is provided, it is produced to the caller when the coroutine completes.

The resolution of the sleep depends on the granularity of the event loop.

This function is a coroutine.

`asyncio.shield(arg, *, loop=None)`

Wait for a future, shielding it from cancellation.

The statement:

```
res = yield from shield(something())
```

is exactly equivalent to the statement:

```
res = yield from something()
```

except that if the coroutine containing it is cancelled, the task running in `something()` is not cancelled. From the point of view
of \texttt{something()}, the cancellation did not happen. But its caller is still cancelled, so the \texttt{yield-from} expression still raises \texttt{CancelledError}. Note: If \texttt{something()} is cancelled by other means this will still cancel \texttt{shield()}. If you want to completely ignore cancellation (not recommended) you can combine \texttt{shield()} with a try/except clause, as follows:

\begin{verbatim}
try:
    res = \texttt{yield from} \texttt{shield(something())}
except \texttt{CancelledError}:
    res = \texttt{None}
\end{verbatim}

\begin{verbatim}
\texttt{coroutine asyncio.wait(futures, *, loop=\texttt{None}, timeout=\texttt{None},}
\texttt{return\_when=\texttt{ALL\_COMPLETED})}
\end{verbatim}

Wait for the Futures and coroutine objects given by the sequence \texttt{futures} to complete. Coroutines will be wrapped in Tasks. Returns two sets of \texttt{Future}: (done, pending).

The sequence \texttt{futures} must not be empty.

\texttt{timeout} can be used to control the maximum number of seconds to wait before returning. \texttt{timeout} can be an int or float. If \texttt{timeout} is not specified or \texttt{None}, there is no limit to the wait time.

\texttt{return\_when} indicates when this function should return. It must be one of the following constants of the \texttt{concurrent.futures} module:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIRST_COMPLETED</td>
<td>The function will return when any future finishes or is cancelled.</td>
</tr>
<tr>
<td></td>
<td>The function will return when any</td>
</tr>
<tr>
<td>FIRST_EXCEPTION</td>
<td>future finishes by raising an exception. If no future raises an exception then it is equivalent to ALL_COMPLETED.</td>
</tr>
<tr>
<td>-----------------</td>
<td>------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ALL_COMPLETED</td>
<td>The function will return when all futures finish or are cancelled.</td>
</tr>
</tbody>
</table>

This function is a coroutine.

Usage:

```python
done, pending = yield from asyncio.wait(fs)
```

**Note:** This does not raise `asyncio.TimeoutError`! Futures that aren't done when the timeout occurs are returned in the second set.

```python
coroutine asyncio.wait_for(fut, timeout, *, loop=None)
```

Wait for the single Future or coroutine object to complete with timeout. If `timeout` is `None`, block until the future completes.

Coroutine will be wrapped in Task.

Returns result of the Future or coroutine. When a timeout occurs, it cancels the task and raises `asyncio.TimeoutError`. To avoid the task cancellation, wrap it in `shield()`.

If the wait is cancelled, the future `fut` is also cancelled.

This function is a coroutine, usage:

```python
result = yield from asyncio.wait_for(fut, 60.0)
```

*Changed in version 3.4.3:* If the wait is cancelled, the future `fut` is
now also cancelled.
18.5.4. Transports and protocols (callback based API)

Source code: Lib/asyncio/transports.py

Source code: Lib/asyncio/protocols.py
18.5.4.1. Transports

Transports are classes provided by asyncio in order to abstract various kinds of communication channels. You generally won’t instantiate a transport yourself; instead, you will call an AbstractEventLoop method which will create the transport and try to initiate the underlying communication channel, calling you back when it succeeds.

Once the communication channel is established, a transport is always paired with a protocol instance. The protocol can then call the transport’s methods for various purposes.

asyncio currently implements transports for TCP, UDP, SSL, and subprocess pipes. The methods available on a transport depend on the transport’s kind.

The transport classes are not thread safe.

*Changed in version 3.6:* The socket option TCP_NODELAY is now set by default.

18.5.4.1.1. BaseTransport

*class* asyncio.BaseTransport

Base class for transports.

*close()*

Close the transport. If the transport has a buffer for outgoing data, buffered data will be flushed asynchronously. No more data will be received. After all buffered data is flushed, the
protocol's `connection_lost()` method will be called with `None` as its argument.

**is_closing()**

Return `True` if the transport is closing or is closed.

*New in version 3.5.1.*

**get_extra_info**(name, default=None)

Return optional transport information. `name` is a string representing the piece of transport-specific information to get, `default` is the value to return if the information doesn't exist.

This method allows transport implementations to easily expose channel-specific information.

- **socket:**
  - 'peername': the remote address to which the socket is connected, result of `socket.socket.getpeername()` (None on error)
  - 'socket': `socket.socket` instance
  - 'sockname': the socket's own address, result of `socket.socket.getsockname()`

- **SSL socket:**
  - 'compression': the compression algorithm being used as a string, or `None` if the connection isn't compressed; result of `ssl.SSLSocket.compression()`
  - 'cipher': a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used; result of `ssl.SSLSocket.cipher()`
  - 'peercert': peer certificate; result of
ssl.SSLSocket.getpeercert()
- 'sslcontext': ssl.SSLContext instance
- 'ssl_object': ssl.SSLObject or ssl.SSLSocket instance

- pipe:
  - 'pipe': pipe object

- subprocess:
  - 'subprocess': subprocess.Popen instance

**set_protocol**(protocol)
Set a new protocol. Switching protocol should only be done when both protocols are documented to support the switch.

*New in version 3.5.3.*

**get_protocol()**
Return the current protocol.

*New in version 3.5.3.*

*Changed in version 3.5.1:* 'ssl_object' info was added to SSL sockets.

18.5.4.1.2. ReadTransport

*class* asyncio.ReadTransport
Interface for read-only transports.

**pause_reading()**
Pause the receiving end of the transport. No data will be passed to the protocol's data_received() method until **resume_reading()** is called.
resume_reading()
Resume the receiving end. The protocol's data_received() method will be called once again if some data is available for reading.

18.5.4.1.3. WriteTransport

class asyncio.WriteTransport
Interface for write-only transports.

abort()
Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's connection_lost() method will eventually be called with None as its argument.

can_write_eof()
Return True if the transport supports write_eof(), False if not.

get_write_buffer_size()
Return the current size of the output buffer used by the transport.

get_write_buffer_limits()
Get the high- and low-water limits for write flow control. Return a tuple (low, high) where low and high are positive number of bytes.

Use set_write_buffer_limits() to set the limits.

New in version 3.4.2.
set_write_buffer_limits(high=None, low=None)

Set the high- and low-water limits for write flow control.

These two values (measured in number of bytes) control when the protocol's pause_writing() and resume_writing() methods are called. If specified, the low-water limit must be less than or equal to the high-water limit. Neither high nor low can be negative.

pause_writing() is called when the buffer size becomes greater than or equal to the high value. If writing has been paused, resume_writing() is called when the buffer size becomes less than or equal to the low value.

The defaults are implementation-specific. If only the high-water limit is given, the low-water limit defaults to an implementation-specific value less than or equal to the high-water limit. Setting high to zero forces low to zero as well, and causes pause_writing() to be called whenever the buffer becomes non-empty. Setting low to zero causes resume_writing() to be called only once the buffer is empty. Use of zero for either limit is generally sub-optimal as it reduces opportunities for doing I/O and computation concurrently.

Use get_write_buffer_limits() to get the limits.

write(data)

Write some data bytes to the transport.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.

writelines(list_of_data)
Write a list (or any iterable) of data bytes to the transport. This is functionally equivalent to calling `write()` on each element yielded by the iterable, but may be implemented more efficiently.

**write_eof()**
Close the write end of the transport after flushing buffered data. Data may still be received.

This method can raise `NotImplementedError` if the transport (e.g. SSL) doesn’t support half-closes.

### 18.5.4.1.4. DatagramTransport

**DatagramTransport.** `sendto(data, addr=None)`
Send the `data` bytes to the remote peer given by `addr` (a transport-dependent target address). If `addr` is `None`, the data is sent to the target address given on transport creation.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.

**DatagramTransport.** `abort()`
Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's `connection_lost()` method will eventually be called with `None` as its argument.

### 18.5.4.1.5. BaseSubprocessTransport

```python
class asyncio.BaseSubprocessTransport
```
**get_pid()**

Return the subprocess process id as an integer.

**get_pipe_transport(fd)**

Return the transport for the communication pipe corresponding to the integer file descriptor *fd*:

- 0: readable streaming transport of the standard input (*stdin*), or *None* if the subprocess was not created with *stdin*={PIPE
- 1: writable streaming transport of the standard output (*stdout*), or *None* if the subprocess was not created with *stdout*={PIPE
- 2: writable streaming transport of the standard error (*stderr*), or *None* if the subprocess was not created with *stderr*={PIPE
- other *fd*: *None*

**get_returncode()**

Return the subprocess returncode as an integer or *None* if it hasn’t returned, similarly to the subprocess.Popen.returncode attribute.

**kill()**

Kill the subprocess, as in subprocess.Popen.kill().

On POSIX systems, the function sends SIGKILL to the subprocess. On Windows, this method is an alias for terminate().

**send_signal(signal)**

Send the *signal* number to the subprocess, as in
subprocess.Popen.send_signal().

**terminate()**
Ask the subprocess to stop, as in `subprocess.Popen.terminate()`. This method is an alias for the `close()` method.

On POSIX systems, this method sends SIGTERM to the subprocess. On Windows, the Windows API function TerminateProcess() is called to stop the subprocess.

**close()**
Ask the subprocess to stop by calling the `terminate()` method if the subprocess hasn’t returned yet, and close transports of all pipes (`stdin`, `stdout` and `stderr`).
18.5.4.2. Protocols

asyncio provides base classes that you can subclass to implement your network protocols. Those classes are used in conjunction with transports (see below): the protocol parses incoming data and asks for the writing of outgoing data, while the transport is responsible for the actual I/O and buffering.

When subclassing a protocol class, it is recommended you override certain methods. Those methods are callbacks: they will be called by the transport on certain events (for example when some data is received); you shouldn’t call them yourself, unless you are implementing a transport.

Note: All callbacks have default implementations, which are empty. Therefore, you only need to implement the callbacks for the events in which you are interested.

18.5.4.2.1. Protocol classes

class asyncio.Protocol
    The base class for implementing streaming protocols (for use with e.g. TCP and SSL transports).

class asyncio.DatagramProtocol
    The base class for implementing datagram protocols (for use with e.g. UDP transports).

class asyncio.SubprocessProtocol
    The base class for implementing protocols communicating with child processes (through a set of unidirectional pipes).
18.5.4.2.2. Connection callbacks

These callbacks may be called on `Protocol`, `DatagramProtocol` and `SubprocessProtocol` instances:

**BaseProtocol.** *connection_made*(transport)

Called when a connection is made.

The *transport* argument is the transport representing the connection. You are responsible for storing it somewhere (e.g. as an attribute) if you need to.

**BaseProtocol.** *connection_lost*(exc)

Called when the connection is lost or closed.

The argument is either an exception object or `None`. The latter means a regular EOF is received, or the connection was aborted or closed by this side of the connection.

`connection_made()` and `connection_lost()` are called exactly once per successful connection. All other callbacks will be called between those two methods, which allows for easier resource management in your protocol implementation.

The following callbacks may be called only on `SubprocessProtocol` instances:

**SubprocessProtocol.** *pipe_data_received*(fd, data)

Called when the child process writes data into its stdout or stderr pipe. *fd* is the integer file descriptor of the pipe. *data* is a non-empty bytes object containing the data.

**SubprocessProtocol.** *pipe_connection_lost*(fd, exc)
Called when one of the pipes communicating with the child process is closed. *fd* is the integer file descriptor that was closed.

SubprocessProtocol.`process_exited()`
Called when the child process has exited.

18.5.4.2.3. Streaming protocols

The following callbacks are called on `Protocol` instances:

Protocol.`data_received`(data)
Called when some data is received. *data* is a non-empty bytes object containing the incoming data.

**Note:** Whether the data is buffered, chunked or reassembled depends on the transport. In general, you shouldn’t rely on specific semantics and instead make your parsing generic and flexible enough. However, data is always received in the correct order.

Protocol.`eof_received()`
Called when the other end signals it won’t send any more data (for example by calling `write_eof()`, if the other end also uses asyncio).

This method may return a false value (including `None`), in which case the transport will close itself. Conversely, if this method returns a true value, closing the transport is up to the protocol. Since the default implementation returns `None`, it implicitly closes the connection.

**Note:** Some transports such as SSL don’t support half-closed
connections, in which case returning true from this method will not prevent closing the connection.

data_received() can be called an arbitrary number of times during a connection. However, eof_received() is called at most once and, if called, data_received() won't be called after it.

State machine:

```
start -> connection_made() [-] data_received() * [-] eof_received() ?] -> connection_lost() -> end
```

18.5.4.2.4. Datagram protocols

The following callbacks are called on `DatagramProtocol` instances.

`DatagramProtocol.datagram_received(data, addr)`

Called when a datagram is received. `data` is a bytes object containing the incoming data. `addr` is the address of the peer sending the data; the exact format depends on the transport.

`DatagramProtocol.error_received(exc)`

Called when a previous send or receive operation raises an `OSError`. `exc` is the `OSError` instance.

This method is called in rare conditions, when the transport (e.g. UDP) detects that a datagram couldn’t be delivered to its recipient. In many conditions though, undeliverable datagrams will be silently dropped.

18.5.4.2.5. Flow control callbacks
These callbacks may be called on `Protocol`, `DatagramProtocol` and `SubprocessProtocol` instances:

BaseProtocol.`pause_writing()`  
Called when the transport's buffer goes over the high-water mark.

BaseProtocol.`resume_writing()`  
Called when the transport's buffer drains below the low-water mark.

`pause_writing()` and `resume_writing()` calls are paired – `pause_writing()` is called once when the buffer goes strictly over the high-water mark (even if subsequent writes increases the buffer size even more), and eventually `resume_writing()` is called once when the buffer size reaches the low-water mark.

**Note:** If the buffer size equals the high-water mark, `pause_writing()` is not called – it must go strictly over. Conversely, `resume_writing()` is called when the buffer size is equal or lower than the low-water mark. These end conditions are important to ensure that things go as expected when either mark is zero.

**Note:** On BSD systems (OS X, FreeBSD, etc.) flow control is not supported for `DatagramProtocol`, because send failures caused by writing too many packets cannot be detected easily. The socket always appears ‘ready’ and excess packets are dropped; an `OSError` with `errno` set to `errno.ENOBUFS` may or may not be raised; if it is raised, it will be reported to `DatagramProtocol.error_received()` but otherwise ignored.

18.5.4.2.6. Coroutines and protocols
Coroutines can be scheduled in a protocol method using `ensure_future()`, but there is no guarantee made about the execution order. Protocols are not aware of coroutines created in protocol methods and so will not wait for them.

To have a reliable execution order, use stream objects in a coroutine with `yield from`. For example, the `StreamWriter.drain()` coroutine can be used to wait until the write buffer is flushed.
18.5.4.3. Protocol examples

18.5.4.3.1. TCP echo client protocol

TCP echo client using the AbstractEventLoop.create_connection() method, send data and wait until the connection is closed:

```python
import asyncio

class EchoClientProtocol(asyncio.Protocol):
    def __init__(self, message, loop):
        self.message = message
        self.loop = loop

    def connection_made(self, transport):
        transport.write(self.message.encode())
        print('Data sent: {!r}'.format(self.message))

    def data_received(self, data):
        print('Data received: {!r}'.format(data.decode()))

    def connection_lost(self, exc):
        print('The server closed the connection')
        print('Stop the event loop')
        self.loop.stop()

loop = asyncio.get_event_loop()
message = 'Hello World!'
coro = loop.create_connection(lambda: EchoClientProtocol(message), '127.0.0.1', 8888)
loop.run_until_complete(coro)
loop.run_forever()
loop.close()
```
The event loop is running twice. The `run_until_complete()` method is preferred in this short example to raise an exception if the server is not listening, instead of having to write a short coroutine to handle the exception and stop the running loop. At `run_until_complete()` exit, the loop is no longer running, so there is no need to stop the loop in case of an error.

See also: The TCP echo client using streams example uses the `asyncio.open_connection()` function.

### 18.5.4.3.2. TCP echo server protocol

TCP echo server using the `AbstractEventLoop.create_server()` method, send back received data and close the connection:

```python
import asyncio

class EchoServerClientProtocol(asyncio.Protocol):
    def connection_made(self, transport):
        peername = transport.get_extra_info('peername')
        print('Connection from {}'.format(peername))
        self.transport = transport

    def data_received(self, data):
        message = data.decode()
        print('Data received: {!r}'.format(message))

        print('Send: {!r}'.format(message))
        self.transport.write(data)

        print('Close the client socket')
        self.transport.close()
```
Transport.close() can be called immediately after WriteTransport.write() even if data are not sent yet on the socket: both methods are asynchronous. yield from is not needed because these transport methods are not coroutines.

See also: The TCP echo server using streams example uses the asyncio.start_server() function.

18.5.4.3.3. UDP echo client protocol

UDP echo client using the AbstractEventLoop.create_datagram_endpoint() method, send data and close the transport when we received the answer:

import asyncio
```python
class EchoClientProtocol:
    def __init__(self, message, loop):
        self.message = message
        self.loop = loop
        self.transport = None

    def connection_made(self, transport):
        self.transport = transport
        print('Send:', self.message)
        self.transport.sendto(self.message.encode())

    def datagram_received(self, data, addr):
        print("Received:", data.decode())
        print("Close the socket")
        self.transport.close()

    def error_received(self, exc):
        print('Error received:', exc)

    def connection_lost(self, exc):
        print("Socket closed, stop the event loop")
        loop = asyncio.get_event_loop()
        loop.stop()

loop = asyncio.get_event_loop()
message = "Hello World!"
connect = loop.create_datagram_endpoint(
    lambda: EchoClientProtocol(message, loop),
    remote_addr=(\'127.0.0.1', 9999))
transport, protocol = loop.run_until_complete(connect)
loop.run_forever()
transport.close()
loop.close()
```

18.5.4.3.4. UDP echo server protocol
UDP echo server using the AbstractEventLoop.create_datagram_endpoint() method, send back received data:

```python
import asyncio

class EchoServerProtocol:
    def connection_made(self, transport):
        self.transport = transport

    def datagram_received(self, data, addr):
        message = data.decode()
        print('Received %r from %s' % (message, addr))
        print('Send %r to %s' % (message, addr))
        self.transport.sendto(data, addr)

loop = asyncio.get_event_loop()
print("Starting UDP server")
# One protocol instance will be created to serve all
listen = loop.create_datagram_endpoint(
    EchoServerProtocol, local_addr=('127.0.0.1', 9999))
transport, protocol = loop.run_until_complete(listen)

try:
    loop.run_forever()
except KeyboardInterrupt:
    pass

transport.close()
loop.close()```

18.5.4.3.5. Register an open socket to wait for data using a protocol
Wait until a socket receives data using the `AbstractEventLoop.create_connection()` method with a protocol, and then close the event loop.

```python
import asyncio

try:
    from socket import socketpair
except ImportError:
    from asyncio.windows_utils import socketpair

# Create a pair of connected sockets
rsock, wsock = socketpair()
loop = asyncio.get_event_loop()

class MyProtocol(asyncio.Protocol):
    transport = None

    def connection_made(self, transport):
        self.transport = transport

    def data_received(self, data):
        print("Received:", data.decode())

        # We are done: close the transport (it will
        self.transport.close()

    def connection_lost(self, exc):
        # The socket has been closed, stop the event
        loop.stop()

# Register the socket to wait for data
connect_coro = loop.create_connection(MyProtocol, sock
transport, protocol = loop.run_until_complete(connect_coro)

# Simulate the reception of data from the network
loop.call_soon(wsock.send, 'abc'.encode())
```
# Run the event loop
```
loop.run_forever()
```

# We are done, close sockets and the event loop
```
rsock.close()
wsock.close()
loop.close()
```

See also: The [watch a file descriptor for read events](https://docs.python.org/3.6/library/asyncio-eventloop.html#watching-a-file-descriptor) example uses the low-level `AbstractEventLoop.add_reader()` method to register the file descriptor of a socket.

The [register an open socket to wait for data using streams](https://docs.python.org/3.6/library/asyncio-stream.html#example) example uses high-level streams created by the `open_connection()` function in a coroutine.
18.5. **asyncio** — Asynchronous I/O, event loop, coroutines and tasks
18.5.5. Streams (coroutine based API)

Source code: Lib/asyncio/streams.py
18.5.5.1. Stream functions

**Note:** The top-level functions in this module are meant as convenience wrappers only; there's really nothing special there, and if they don't do exactly what you want, feel free to copy their code.

coroutine asyncio.open_connection(host=None, port=None, *, loop=None, limit=None, **kwds)

A wrapper for create_connection() returning a (reader, writer) pair.

The reader returned is a StreamReader instance; the writer is a StreamWriter instance.

The arguments are all the usual arguments to AbstractEventLoop.create_connection() except protocol_factory; most common are positional host and port, with various optional keyword arguments following.

Additional optional keyword arguments are loop (to set the event loop instance to use) and limit (to set the buffer limit passed to the StreamReader).

This function is a coroutine.

coroutine asyncio.start_server(client_connected_cb, host=None, port=None, *, loop=None, limit=None, **kwds)

Start a socket server, with a callback for each client connected. The return value is the same as create_server().

The client_connected_cb parameter is called with two parameters: client_reader, client_writer. client_reader is a StreamReader
object, while client_writer is a StreamWriter object. The client_connected_cb parameter can either be a plain callback function or a coroutine function; if it is a coroutine function, it will be automatically converted into a Task.

The rest of the arguments are all the usual arguments to create_server() except protocol_factory; most common are positional host and port, with various optional keyword arguments following.

Additional optional keyword arguments are loop (to set the event loop instance to use) and limit (to set the buffer limit passed to the StreamReader).

This function is a coroutine.

coroutine asyncio.open_unix_connection(path=None, *, loop=None, limit=None, **kwds)

A wrapper for create_unix_connection() returning a (reader, writer) pair.

See open_connection() for information about return value and other details.

This function is a coroutine.

Availability: UNIX.

coroutine asyncio.start_unix_server(client_connected_cb, path=None, *, loop=None, limit=None, **kwds)

Start a UNIX Domain Socket server, with a callback for each client connected.

See start_server() for information about return value and
other details.

This function is a coroutine.

Availability: UNIX.
18.5.5.2. StreamReader

```python
class asyncio.StreamReader(limit=None, loop=None)
```
This class is not thread safe.

**exception()**
Get the exception.

**feed_eof()**
Acknowledge the EOF.

**feed_data(data)**
Feed `data` bytes in the internal buffer. Any operations waiting for the data will be resumed.

**set_exception(exc)**
Set the exception.

**set_transport(transport)**
Set the transport.

**coroutine read(n=-1)**
Read up to `n` bytes. If `n` is not provided, or set to `-1`, read until EOF and return all read bytes.

If the EOF was received and the internal buffer is empty, return an empty `bytes` object.

This method is a coroutine.

**coroutine readline()**
Read one line, where “line” is a sequence of bytes ending with
If EOF is received, and \n was not found, the method will return the partial read bytes.

If the EOF was received and the internal buffer is empty, return an empty `bytes` object.

This method is a coroutine.

**coroutine `readexactly(n)`**

Read exactly `n` bytes. Raise an `IncompleteReadError` if the end of the stream is reached before `n` can be read, the `IncompleteReadError.partial` attribute of the exception contains the partial read bytes.

This method is a coroutine.

**coroutine `readuntil(separator=b'\n')`**

Read data from the stream until `separator` is found.

On success, the data and separator will be removed from the internal buffer (consumed). Returned data will include the separator at the end.

Configured stream limit is used to check result. Limit sets the maximal length of data that can be returned, not counting the separator.

If an EOF occurs and the complete separator is still not found, an `IncompleteReadError` exception will be raised, and the internal buffer will be reset. The `IncompleteReadError.partial` attribute may contain the
separator partially.

If the data cannot be read because of over limit, a LimitOverrunError exception will be raised, and the data will be left in the internal buffer, so it can be read again.

*New in version 3.5.2.*

**at_eof()**

Return True if the buffer is empty and feed_eof() was called.
18.5.5.3. StreamWriter

```python
class asyncio.StreamWriter(transport, protocol, reader, loop)
```
Wraps a Transport.

This exposes `write()`, `writelines()`, `can_write_eof()`, `write_eof()`, `get_extra_info()` and `close()`. It adds `drain()` which returns an optional `Future` on which you can wait for flow control. It also adds a transport attribute which references the Transport directly.

This class is **not thread safe**.

**transport**

Transport.

**can_write_eof()**

Return `True` if the transport supports `write_eof()`, `False` if not. See `WriteTransport.can_write_eof()`.

**close()**

Close the transport: see `BaseTransport.close()`.

**coroutine drain()**

Let the write buffer of the underlying transport a chance to be flushed.

The intended use is to write:

```python
w.write(data)
yield from w.drain()
```
When the size of the transport buffer reaches the high-water limit (the protocol is paused), block until the size of the buffer is drained down to the low-water limit and the protocol is resumed. When there is nothing to wait for, the yield-from continues immediately.

Yielding from `drain()` gives the opportunity for the loop to schedule the write operation and flush the buffer. It should especially be used when a possibly large amount of data is written to the transport, and the coroutine does not yield-from between calls to `write()`.

This method is a coroutine.

`get_extra_info(name, default=None)`
Return optional transport information: see `BaseTransport.get_extra_info()`.

`write(data)`
Write some `data` bytes to the transport: see `WriteTransport.write()`.

`writelines(data)`
Write a list (or any iterable) of data bytes to the transport: see `WriteTransport.writelines()`.

`write_eof()`
Close the write end of the transport after flushing buffered data: see `WriteTransport.write_eof()`.
18.5.5.4. StreamReaderProtocol

class asyncio.StreamReaderProtocol(stream_reader, client_connected_cb=None, loop=None)

Trivial helper class to adapt between Protocol and StreamReader. Subclass of Protocol.

stream_reader is a StreamReader instance, client_connected_cb is an optional function called with (stream_reader, stream_writer) when a connection is made, loop is the event loop instance to use.

(This is a helper class instead of making StreamReader itself a Protocol subclass, because the StreamReader has other potential uses, and to prevent the user of the StreamReader from accidentally calling inappropriate methods of the protocol.)
18.5.5.5. IncompleteReadError

(exception asyncio.IncompleteReadError)

Incomplete read error, subclass of EOFError.

expected
Total number of expected bytes (int).

partial
Read bytes string before the end of stream was reached (bytes).
18.5.5.6. LimitOverrunError

*exception* asyncio.*LimitOverrunError*

Reached the buffer limit while looking for a separator.

*consumed*

Total number of to be consumed bytes.
18.5.5.7. Stream examples

18.5.5.7.1. TCP echo client using streams

TCP echo client using the `asyncio.open_connection()` function:

```python
import asyncio

@asyncio.coroutine
def tcp_echo_client(message, loop):
    reader, writer = yield from asyncio.open_connection()

    print('Send: %r' % message)
    writer.write(message.encode())

    data = yield from reader.read(100)
    print('Received: %r' % data.decode())

    print('Close the socket')
    writer.close()

message = 'Hello World!
loop = asyncio.get_event_loop()
loop.run_until_complete(tcp_echo_client(message, loop))
loop.close()
```

See also: The TCP echo client protocol example uses the AbstractEventLoop.create_connection() method.

18.5.5.7.2. TCP echo server using streams

TCP echo server using the `asyncio.start_server()` function:
import asyncio

@asyncio.coroutine
def handle_echo(reader, writer):
    data = yield from reader.read(100)
    message = data.decode()
    addr = writer.get_extra_info('peername')
    print("Received \%r from \%r" % (message, addr))

    print("Send: \%r" % message)
    writer.write(data)
    yield from writer.drain()

    print("Close the client socket")
    writer.close()

loop = asyncio.get_event_loop()
coro = asyncio.start_server(handle_echo, '127.0.0.1'
server = loop.run_until_complete(coro)

# Serve requests until Ctrl+C is pressed
try:
    loop.run_forever()
except KeyboardInterrupt:
    pass

# Close the server
server.close()
loop.run_until_complete(server.wait_closed())
loop.close()

See also: The TCP echo server protocol example uses the
AbstractEventLoop.create_server() method.
18.5.5.7.3. Get HTTP headers

Simple example querying HTTP headers of the URL passed on the command line:

```python
import asyncio
import urllib.parse
import sys

@asyncio.coroutine
def print_http_headers(url):
    url = urllib.parse.urlsplit(url)
    if url.scheme == 'https':
        connect = asyncio.open_connection(url.hostname)
    else:
        connect = asyncio.open_connection(url.hostname)
    reader, writer = yield from connect
    query = ('HEAD {path} HTTP/1.0\r\n' +
             'Host: {hostname}\r\n' +
             '\r\n').format(path=url.path or '/', hostname=url.hostname)
    writer.write(query.encode('latin-1'))
    while True:
        line = yield from reader.readline()
        if not line:
            break
        line = line.decode('latin1').rstrip()
        if line:
            print('HTTP header> %s' % line)

    # Ignore the body, close the socket
    writer.close()

url = sys.argv[1]
loop = asyncio.get_event_loop()
task = asyncio.ensure_future(print_http_headers(url))
loop.run_until_complete(task)
```
Usage:

```python example.py http://example.com/path/page.html```

or with HTTPS:

```python example.py https://example.com/path/page.html```

18.5.5.7.4. Register an open socket to wait for data using streams

Coroutine waiting until a socket receives data using the `open_connection()` function:

```python
import asyncio
try:
    from socket import socketpair
except ImportError:
    from asyncio.windows_utils import socketpair

@asyncio.coroutine
def wait_for_data(loop):
    # Create a pair of connected sockets
    rsock, wsock = socketpair()

    # Register the open socket to wait for data
    reader, writer = yield from asyncio.open_connection(rsock)

    # Simulate the reception of data from the network
    loop.call_soon(wsock.send, 'abc'.encode())
```
```python
# Wait for data
data = yield from reader.read(100)

# Got data, we are done: close the socket
print("Received:", data.decode())
writer.close()

# Close the second socket
wsock.close()

loop = asyncio.get_event_loop()
loop.run_until_complete(wait_for_data(loop))
loop.close()
```

See also: The register an open socket to wait for data using a protocol example uses a low-level protocol created by the `AbstractEventLoop.create_connection()` method.

The watch a file descriptor for read events example uses the low-level `AbstractEventLoop.add_reader()` method to register the file descriptor of a socket.
18.5.6. Subprocess

Source code: Lib/asyncio/subprocess.py
18.5.6.1. Windows event loop

On Windows, the default event loop is `SelectorEventLoop` which does not support subprocesses. `ProactorEventLoop` should be used instead. Example to use it on Windows:

```python
import asyncio, sys

if sys.platform == 'win32':
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
```

See also: Available event loops and Platform support.
18.5.6.2. Create a subprocess: high-level API using Process

coroutine asyncio.create_subprocess_exec(*args, stdin=None, stdout=None, stderr=None, loop=None, limit=None, **kwds)

Create a subprocess.

The limit parameter sets the buffer limit passed to the StreamReader. See AbstractEventLoop.subprocess_exec() for other parameters.

Return a Process instance.

This function is a coroutine.

coroutine asyncio.create_subprocess_shell(cmd, stdin=None, stdout=None, stderr=None, loop=None, limit=None, **kwds)

Run the shell command cmd.

The limit parameter sets the buffer limit passed to the StreamReader. See AbstractEventLoop.subprocess_shell() for other parameters.

Return a Process instance.

It is the application's responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid shell injection vulnerabilities. The shlex.quote() function can be
used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.

This function is a coroutine.

Use the `AbstractEventLoop.connect_read_pipe()` and `AbstractEventLoop.connect_write_pipe()` methods to connect pipes.
18.5.6.3. Create a subprocess: low-level API using subprocess.Popen

Run subprocesses asynchronously using the `subprocess` module.

coroutine
AbstractEventLoop. `subprocess_exec(protocol_factory, *args, stdin=subprocess.PIPE, stdout=subprocess.PIPE, stderr=subprocess.PIPE, **kwargs)`

Create a subprocess from one or more string arguments (character strings or bytes strings encoded to the filesystem encoding), where the first string specifies the program to execute, and the remaining strings specify the program’s arguments. (Thus, together the string arguments form the `sys.argv` value of the program, assuming it is a Python script.) This is similar to the standard library `subprocess.Popen` class called with shell=False and the list of strings passed as the first argument; however, where `Popen` takes a single argument which is list of strings, `subprocess_exec()` takes multiple string arguments.

The `protocol_factory` must instantiate a subclass of the `asyncio.SubprocessProtocol` class.

Other parameters:

- `stdin`: Either a file-like object representing the pipe to be connected to the subprocess’s standard input stream using `connect_write_pipe()`, or the constant `subprocess.PIPE` (the default). By default a new pipe will be created and connected.
- `stdout`: Either a file-like object representing the pipe to be connected to the subprocess’s standard output stream using
connect_read_pipe(), or the constant subprocess.PIPE (the default). By default a new pipe will be created and connected.

- stderr: Either a file-like object representing the pipe to be connected to the subprocess's standard error stream using connect_read_pipe(), or one of the constants subprocess.PIPE (the default) or subprocess.STDOUT. By default a new pipe will be created and connected. When subprocess.STDOUT is specified, the subprocess's standard error stream will be connected to the same pipe as the standard output stream.

- All other keyword arguments are passed to subprocess.Popen without interpretation, except for bufsize, universal_newlines and shell, which should not be specified at all.

Returns a pair of (transport, protocol), where transport is an instance of BaseSubprocessTransport.

This method is a coroutine.

See the constructor of the subprocess.Popen class for parameters.

coroutine

AbstractEventLoop.subprocess_shell(protocol_factory, cmd, *, stdin=subprocess.PIPE, stdout=subprocess.PIPE, stderr=subprocess.PIPE, **kwargs)

Create a subprocess from cmd, which is a character string or a bytes string encoded to the filesystem encoding, using the platform’s “shell” syntax. This is similar to the standard library subprocess.Popen class called with shell=True.

The protocol_factory must instantiate a subclass of the
asyncio.SubprocessProtocol class.

See subprocess_exec() for more details about the remaining arguments.

Returns a pair of (transport, protocol), where transport is an instance of BaseSubprocessTransport.

It is the application’s responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid shell injection vulnerabilities. The shlex.quote() function can be used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.

This method is a coroutine.

See also: The AbstractEventLoop.connect_read_pipe() and AbstractEventLoop.connect_write_pipe() methods.
18.5.6.4. Constants

asyncio.subprocess.PIPE

Special value that can be used as the stdin, stdout or stderr argument to create_subprocess_shell() and create_subprocess_exec() and indicates that a pipe to the standard stream should be opened.

asyncio.subprocess.STDOUT

Special value that can be used as the stderr argument to create_subprocess_shell() and create_subprocess_exec() and indicates that standard error should go into the same handle as standard output.

asyncio.subprocess.DEVNULL

Special value that can be used as the stdin, stdout or stderr argument to create_subprocess_shell() and create_subprocess_exec() and indicates that the special file os.devnull will be used.
18.5.6.5. Process

class asyncio.subprocess.Process

A subprocess created by the create_subprocess_exec() or the create_subprocess_shell() function.

The API of the Process class was designed to be close to the API of the subprocess.Popen class, but there are some differences:

- There is no explicit poll() method
- The communicate() and wait() methods don't take a timeout parameter: use the wait_for() function
- The universal_newlines parameter is not supported (only bytes strings are supported)
- The wait() method of the Process class is asynchronous whereas the wait() method of the Popen class is implemented as a busy loop.

This class is not thread safe. See also the Subprocess and threads section.

coroutine wait()

Wait for child process to terminate. Set and return returncode attribute.

This method is a coroutine.

Note: This will deadlock when using stdout=PIPE or stderr=PIPE and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use the communicate() method when using pipes to avoid that.
**coroutine** `communicate(input=None)`

Interact with process: Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate. The optional `input` argument should be data to be sent to the child process, or `None`, if no data should be sent to the child. The type of `input` must be bytes.

`communicate()` returns a tuple `(stdout_data, stderr_data)`.

If a `BrokenPipeError` or `ConnectionResetError` exception is raised when writing `input` into stdin, the exception is ignored. It occurs when the process exits before all data are written into stdin.

Note that if you want to send data to the process's stdin, you need to create the Process object with `stdin=PIPE`. Similarly, to get anything other than `None` in the result tuple, you need to give `stdout=PIPE` and/or `stderr=PIPE` too.

This method is a **coroutine**.

**Note:** The data read is buffered in memory, so do not use this method if the data size is large or unlimited.

*Changed in version 3.4.2:* The method now ignores `BrokenPipeError` and `ConnectionResetError`.

**send_signal**(*signal*)

Sends the signal `signal` to the child process.

**Note:** On Windows, SIGTERM is an alias for `terminate()`.
CTRL_C_EVENT and CTRL_BREAK_EVENT can be sent to processes started with a *creationflags* parameter which includes CREATE_NEW_PROCESS_GROUP.

**terminate()**
Stop the child. On Posix OSs the method sends `signal.SIGTERM` to the child. On Windows the Win32 API function `TerminateProcess()` is called to stop the child.

**kill()**
Kills the child. On Posix OSs the function sends `SIGKILL` to the child. On Windows `kill()` is an alias for `terminate()`.

**stdin**
Standard input stream (*StreamWriter*), `None` if the process was created with `stdin=None`.

**stdout**
Standard output stream (*StreamReader*), `None` if the process was created with `stdout=None`.

**stderr**
Standard error stream (*StreamReader*), `None` if the process was created with `stderr=None`.

**Warning**: Use the `communicate()` method rather than `.stdin.write`, `.stdout.read` or `.stderr.read` to avoid deadlocks due to streams pausing reading or writing and blocking the child process.

**pid**
The identifier of the process.
Note that for processes created by the `create_subprocess_shell()` function, this attribute is the process identifier of the spawned shell.

**returncode**

Return code of the process when it exited. A `None` value indicates that the process has not terminated yet.

A negative value `-N` indicates that the child was terminated by signal `N` (Unix only).
18.5.6.6. Subprocess and threads

asyncio supports running subprocesses from different threads, but there are limits:

- An event loop must run in the main thread
- The child watcher must be instantiated in the main thread, before executing subprocesses from other threads. Call the `get_child_watcher()` function in the main thread to instantiate the child watcher.

The `asyncio.subprocess.Process` class is not thread safe.

**See also:** The Concurrency and multithreading in asyncio section.
18.5.6.7. Subprocess examples

18.5.6.7.1. Subprocess using transport and protocol

Example of a subprocess protocol using to get the output of a subprocess and to wait for the subprocess exit. The subprocess is created by the `AbstractEventLoop.subprocess_exec()` method:

```python
import asyncio
import sys

class DateProtocol(asyncio.SubprocessProtocol):
    def __init__(self, exit_future):
        self.exit_future = exit_future
        self.output = bytearray()

    def pipe_data_received(self, fd, data):
        self.output.extend(data)

    def process_exited(self):
        self.exit_future.set_result(True)

@asyncio.coroutine
def get_date(loop):
    code = 'import datetime; print(datetime.datetime.now())'
    exit_future = asyncio.Future(loop=loop)

    # Create the subprocess controlled by the protocol
    # redirect the standard output into a pipe
    create = loop.subprocess_exec(llambda: DateProtocol(self),
                                 sys.executable, '-c',
                                 stdin=None, stderr=PIPE,
                                 stdout=PIPE)
```

```bash
import datetime; print(datetime.datetime.now())
```
transport, protocol = yield from create

# Wait for the subprocess exit using the process
# of the protocol
yield from exit_future

# Close the stdout pipe
transport.close()

# Read the output which was collected by the pipe
# method of the protocol
data = bytes(protocol.output)
return data.decode('ascii').rstrip()

if sys.platform == "win32":
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
else:
    loop = asyncio.get_event_loop()

date = loop.run_until_complete(get_date(loop))
print("Current date: %s" % date)
loop.close()

18.5.6.7.2. Subprocess using streams

Example using the Process class to control the subprocess and the StreamReader class to read from the standard output. The subprocess is created by the create_subprocess_exec() function:

import asyncio.subprocess
import sys
@asyncio.coroutine
def get_date():
    code = 'import datetime; print(datetime.datetime.now())'
    # Create the subprocess, redirect the standard output
    create = asyncio.create_subprocess_exec(sys.executable, stdout=asyncio.subprocess.PIPE)
    proc = yield from create

    # Read one line of output
    data = yield from proc.stdout.readline()
    line = data.decode('ascii').rstrip()

    # Wait for the subprocess exit
    yield from proc.wait()
    return line

if sys.platform == "win32":
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
else:
    loop = asyncio.get_event_loop()

date = loop.run_until_complete(get_date())
print("Current date: %s" % date)
loop.close()
asyncio — Asynchronous I/O, event loop, coroutines and tasks
18.5.7. Synchronization primitives

Source code: Lib/asyncio/locks.py

Locks:
- Lock
- Event
- Condition

Semaphores:
- Semaphore
- BoundedSemaphore

asyncio lock API was designed to be close to classes of the threading module (Lock, Event, Condition, Semaphore, BoundedSemaphore), but it has no timeout parameter. The asyncio.wait_for() function can be used to cancel a task after a timeout.
18.5.7.1. Locks

18.5.7.1.1. Lock

class asyncio.Lock(*, loop=None)

Primitive lock objects.

A primitive lock is a synchronization primitive that is not owned by a particular coroutine when locked. A primitive lock is in one of two states, ‘locked’ or ‘unlocked’.

It is created in the unlocked state. It has two basic methods, acquire() and release(). When the state is unlocked, acquire() changes the state to locked and returns immediately. When the state is locked, acquire() blocks until a call to release() in another coroutine changes it to unlocked, then the acquire() call resets it to locked and returns. The release() method should only be called in the locked state; it changes the state to unlocked and returns immediately. If an attempt is made to release an unlocked lock, a RuntimeError will be raised.

When more than one coroutine is blocked in acquire() waiting for the state to turn to unlocked, only one coroutine proceeds when a release() call resets the state to unlocked; first coroutine which is blocked in acquire() is being processed.

acquire() is a coroutine and should be called with yield from.

Locks also support the context management protocol. (yield from lock) should be used as the context manager expression.
This class is not thread safe.

Usage:

```python
lock = Lock()
...
yield from lock
try:
...
finally:
    lock.release()
```

Context manager usage:

```python
lock = Lock()
...
with (yield from lock):
    ...
```

Lock objects can be tested for locking state:

```python
if not lock.locked():
    yield from lock
else:
    # lock is acquired
    ...
```

**locked()**

Return `True` if the lock is acquired.

**coroutine acquire()**

Acquire a lock.

This method blocks until the lock is unlocked, then sets it to locked and returns `True`. 
This method is a coroutine.

**release()**
Release a lock.

When the lock is locked, reset it to unlocked, and return. If any other coroutines are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

When invoked on an unlocked lock, a `RuntimeError` is raised.

There is no return value.

### 18.5.7.1.2. Event

**class asyncio.Event(*, loop=None)**

An Event implementation, asynchronous equivalent to `threading.Event`.

Class implementing event objects. An event manages a flag that can be set to true with the `set()` method and reset to false with the `clear()` method. The `wait()` method blocks until the flag is true. The flag is initially false.

This class is not thread safe.

**clear()**
Reset the internal flag to false. Subsequently, coroutines calling `wait()` will block until `set()` is called to set the internal flag to true again.

**is_set()**
Return True if and only if the internal flag is true.

**set()**
Set the internal flag to true. All coroutines waiting for it to become true are awakened. Coroutine that call `wait()` once the flag is true will not block at all.

**coroutine wait()**
Block until the internal flag is true.

If the internal flag is true on entry, return True immediately. Otherwise, block until another coroutine calls set() to set the flag to true, then return True.

This method is a coroutine.

18.5.7.1.3. Condition

class asyncio.**Condition**(lock=None, *, loop=None)
A Condition implementation, asynchronous equivalent to `threading.Condition`.

This class implements condition variable objects. A condition variable allows one or more coroutines to wait until they are notified by another coroutine.

If the `lock` argument is given and not None, it must be a Lock object, and it is used as the underlying lock. Otherwise, a new Lock object is created and used as the underlying lock.

This class is not thread safe.

**coroutine acquire()**
Acquire the underlying lock.

This method blocks until the lock is unlocked, then sets it to locked and returns True.

This method is a coroutine.

**notify**\((n=1)\)

By default, wake up one coroutine waiting on this condition, if any. If the calling coroutine has not acquired the lock when this method is called, a `RuntimeError` is raised.

This method wakes up at most \(n\) of the coroutines waiting for the condition variable; it is a no-op if no coroutines are waiting.

**Note:** An awakened coroutine does not actually return from its `wait()` call until it can reacquire the lock. Since `notify()` does not release the lock, its caller should.

**locked()**

Return `True` if the underlying lock is acquired.

**notify_all()**

Wake up all coroutines waiting on this condition. This method acts like `notify()`, but wakes up all waiting coroutines instead of one. If the calling coroutine has not acquired the lock when this method is called, a `RuntimeError` is raised.

**release()**

Release the underlying lock.

When the lock is locked, reset it to unlocked, and return. If any other coroutines are blocked waiting for the lock to become
unlocked, allow exactly one of them to proceed.

When invoked on an unlocked lock, a RuntimeError is raised.

There is no return value.

coroutine wait()

Wait until notified.

If the calling coroutine has not acquired the lock when this method is called, a RuntimeError is raised.

This method releases the underlying lock, and then blocks until it is awakened by a notify() or notify_all() call for the same condition variable in another coroutine. Once awakened, it re-acquires the lock and returns True.

This method is a coroutine.

coroutine wait_for(predicate)

Wait until a predicate becomes true.

The predicate should be a callable which result will be interpreted as a boolean value. The final predicate value is the return value.

This method is a coroutine.
18.5.7.2. Semaphores

18.5.7.2.1. Semaphore

class asyncio.Semaphore(value=1, *, loop=None)

A Semaphore implementation.

A semaphore manages an internal counter which is decremented by each acquire() call and incremented by each release() call. The counter can never go below zero; when acquire() finds that it is zero, it blocks, waiting until some other coroutine calls release().

Semaphores also support the context management protocol.

The optional argument gives the initial value for the internal counter; it defaults to 1. If the value given is less than 0, ValueError is raised.

This class is not thread safe.

coroutine acquire()

Acquire a semaphore.

If the internal counter is larger than zero on entry, decrement it by one and return True immediately. If it is zero on entry, block, waiting until some other coroutine has called release() to make it larger than 0, and then return True.

This method is a coroutine.

locked()
Returns `True` if semaphore can not be acquired immediately.

**release()**
Release a semaphore, incrementing the internal counter by one. When it was zero on entry and another coroutine is waiting for it to become larger than zero again, wake up that coroutine.

### 18.5.7.2.2. BoundedSemaphore

```python
class asyncio.BoundedSemaphore(value=1, *, loop=None)
```
A bounded semaphore implementation. Inherit from `Semaphore`.

This raises `ValueError` in `release()` if it would increase the value above the initial value.
18.5. asyncio — Asynchronous I/O, event loop, coroutines and tasks
18.5.8. Queues

Source code: Lib/asyncio/queues.py

Queues:

- Queue
- PriorityQueue
- LifoQueue

asyncio queue API was designed to be close to classes of the queue module (Queue, PriorityQueue, LifoQueue), but it has no timeout parameter. The asyncio.wait_for() function can be used to cancel a task after a timeout.
18.5.8.1. Queue

class asyncio.Queue(maxsize=0, *, loop=None)

A queue, useful for coordinating producer and consumer coroutines.

If `maxsize` is less than or equal to zero, the queue size is infinite. If it is an integer greater than 0, then `yield from put()` will block when the queue reaches `maxsize`, until an item is removed by `get()`.

Unlike the standard library `queue`, you can reliably know this Queue's size with `qsize()`, since your single-threaded asyncio application won't be interrupted between calling `qsize()` and doing an operation on the Queue.

This class is not thread safe.

*Changed in version 3.4.4*: New `join()` and `task_done()` methods.

**empty()**

Return `True` if the queue is empty, `False` otherwise.

**full()**

Return `True` if there are `maxsize` items in the queue.

**Note:** If the Queue was initialized with `maxsize=0` (the default), then `full()` is never `True`.

**coroutine get()**
Remove and return an item from the queue. If queue is empty, wait until an item is available.

This method is a coroutine.

**See also:** The empty() method.

`get_nowait()`  
Remove and return an item from the queue.

Return an item if one is immediately available, else raise QueueEmpty.

**coroutine join()**  
Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls task_done() to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, join() unblocks.

This method is a coroutine.

*New in version 3.4.4.*

**coroutine put(item)**  
Put an item into the queue. If the queue is full, wait until a free slot is available before adding item.

This method is a coroutine.
See also: The `full()` method.

**put_nowait(item)**

Put an item into the queue without blocking.

If no free slot is immediately available, raise `QueueFull`.

**qsize()**

Number of items in the queue.

**task_done()**

Indicate that a formerly enqueued task is complete.

Used by queue consumers. For each `get()` used to fetch a task, a subsequent call to `task_done()` tells the queue that the processing on the task is complete.

If a `join()` is currently blocking, it will resume when all items have been processed (meaning that a `task_done()` call was received for every item that had been `put()` into the queue).

Raises `ValueError` if called more times than there were items placed in the queue.

_New in version 3.4.4._

**maxsize**

Number of items allowed in the queue.
18.5.8.2. PriorityQueue

class asyncio.PriorityQueue

A subclass of Queue; retrieves entries in priority order (lowest first).

Entries are typically tuples of the form: (priority number, data).
18.5.8.3. LifoQueue

_class asyncio.LifoQueue_

A subclass of Queue that retrieves most recently added entries first.

18.5.8.3.1. Exceptions

_exception asyncio.QueueEmpty_

Exception raised when the get_nowait() method is called on a Queue object which is empty.

_exception asyncio.QueueFull_

Exception raised when the put_nowait() method is called on a Queue object which is full.
18.5.9. Develop with asyncio

Asynchronous programming is different than classical "sequential" programming. This page lists common traps and explains how to avoid them.
18.5.9.1. Debug mode of asyncio

The implementation of asyncio has been written for performance. In order to ease the development of asynchronous code, you may wish to enable debug mode.

To enable all debug checks for an application:

- Enable the asyncio debug mode globally by setting the environment variable PYTHONASYNCIODEBUG to 1, or by calling AbstractEventLoop.set_debug().
- Set the log level of the asyncio logger to logging.DEBUG. For example, call logging.basicConfig(level=logging.DEBUG) at startup.
- Configure the warnings module to display ResourceWarning warnings. For example, use the -Wdefault command line option of Python to display them.

Examples debug checks:

- Log coroutines defined but never "yielded from"
- call_soon() and call_at() methods raise an exception if they are called from the wrong thread.
- Log the execution time of the selector
- Log callbacks taking more than 100 ms to be executed. The AbstractEventLoop.slow_callback_duration attribute is the minimum duration in seconds of "slow" callbacks.
- ResourceWarning warnings are emitted when transports and event loops are not closed explicitly.

See also: The AbstractEventLoop.set_debug() method and the asyncio logger.
Cancellation of tasks is not common in classic programming. In asynchronous programming, not only is it something common, but you have to prepare your code to handle it.

Futures and tasks can be cancelled explicitly with their `Future.cancel()` method. The `wait_for()` function cancels the waited task when the timeout occurs. There are many other cases where a task can be cancelled indirectly.

Don't call `set_result()` or `set_exception()` method of `Future` if the future is cancelled: it would fail with an exception. For example, write:

```python
if not fut.cancelled():
    fut.set_result('done')
```

Don't schedule directly a call to the `set_result()` or the `set_exception()` method of a future with `AbstractEventLoop.call_soon()`: the future can be cancelled before its method is called.

If you wait for a future, you should check early if the future was cancelled to avoid useless operations. Example:

```python
@coroutine
def slow_operation(fut):
    if fut.cancelled():
        return
    # ... slow computation ...
    yield from fut
    # ...
```
The `shield()` function can also be used to ignore cancellation.
18.5.9.3. Concurrency and multithreading

An event loop runs in a thread and executes all callbacks and tasks in the same thread. While a task is running in the event loop, no other task is running in the same thread. But when the task uses `yield from`, the task is suspended and the event loop executes the next task.

To schedule a callback from a different thread, the `AbstractEventLoop.call_soon_threadsafe()` method should be used. Example:

```
loop.call_soon_threadsafe(callback, *args)
```

Most asyncio objects are not thread safe. You should only worry if you access objects outside the event loop. For example, to cancel a future, don’t call directly its `Future.cancel()` method, but:

```
loop.call_soon_threadsafe(fut.cancel)
```

To handle signals and to execute subprocesses, the event loop must be run in the main thread.

To schedule a coroutine object from a different thread, the `run_coroutine_threadsafe()` function should be used. It returns a `concurrent.futures.Future` to access the result:

```
future = asyncio.run_coroutine_threadsafe(coro_func(), loop)
result = future.result(timeout)  # Wait for the result
```

The `AbstractEventLoop.run_in_executor()` method can be
used with a thread pool executor to execute a callback in different thread to not block the thread of the event loop.

**See also:** The *Synchronization primitives* section describes ways to synchronize tasks.

The *Subprocess and threads* section lists asyncio limitations to run subprocesses from different threads.
18.5.9.4. Handle blocking functions correctly

Blocking functions should not be called directly. For example, if a function blocks for 1 second, other tasks are delayed by 1 second which can have an important impact on reactivity.

For networking and subprocesses, the asyncio module provides high-level APIs like protocols.

An executor can be used to run a task in a different thread or even in a different process, to not block the thread of the event loop. See the AbstractEventLoop.run_in_executor() method.

See also: The Delayed calls section details how the event loop handles time.
18.5.9.5. Logging

The asyncio module logs information with the logging module in the logger 'asyncio'.

The default log level for the asyncio module is logging.INFO. For those not wanting such verbosity from asyncio the log level can be changed. For example, to change the level to logging.WARNING:

```
logging.getLogger('asyncio').setLevel(logging.WARNING)
```
18.5.9.6. Detect coroutine objects never scheduled

When a coroutine function is called and its result is not passed to `ensure_future()` or to the `AbstractEventLoop.create_task()` method, the execution of the coroutine object will never be scheduled which is probably a bug. Enable the debug mode of asyncio to log a warning to detect it.

Example with the bug:

```python
import asyncio
@asyncio.coroutine
def test():
    print("never scheduled")

test()
```

Output in debug mode:

```
Coroutine test() at test.py:3 was never yielded from Coroutine object created at (most recent call last):
 File "test.py", line 7, in <module>
    test()
```

The fix is to call the `ensure_future()` function or the `AbstractEventLoop.create_task()` method with the coroutine object.

*See also:* Pending task destroyed.
Detect exceptions never consumed

Python usually calls `sys.displayhook()` on unhandled exceptions. If `Future.set_exception()` is called, but the exception is never consumed, `sys.displayhook()` is not called. Instead, a log is emitted when the future is deleted by the garbage collector, with the traceback where the exception was raised.

Example of unhandled exception:

```python
import asyncio

@asyncio.coroutine
def bug():
    raise Exception("not consumed")

loop = asyncio.get_event_loop()
asyncio.ensure_future(bug())
loop.run_forever()
loop.close()
```

Output:

```
Task exception was never retrieved
future: <Task finished coro=<coro() done, defined at
Traceback (most recent call last):
  File "asyncio/tasks.py", line 237, in _step
    result = next(coro)
  File "asyncio/coroutines.py", line 141, in coro
    res = func(*args, **kw)
  File "test.py", line 5, in bug
    raise Exception("not consumed")
Exception: not consumed
```
Enable the debug mode of asyncio to get the traceback where the task was created. Output in debug mode:

```
Task exception was never retrieved
future: <Task finished coro=<bug() done, defined at source_traceback: Object created at (most recent call last):
    File "test.py", line 8, in <module>
        asyncio.ensure_future(bug())
Traceback (most recent call last):
    File "asyncio/tasks.py", line 237, in _step
        result = next(coro)
    File "asyncio/coroutines.py", line 79, in __next__
        return next(self.gen)
    File "asyncio/coroutines.py", line 141, in coro
        res = func(*args, **kw)
    File "test.py", line 5, in bug
        raise Exception("not consumed")
Exception: not consumed
```

There are different options to fix this issue. The first option is to chain the coroutine in another coroutine and use classic try/except:

```python
@asyncio.coroutine
def handle_exception():
    try:
        yield from bug()
    except Exception:
        print("exception consumed")

loop = asyncio.get_event_loop()
asyncio.ensure_future(handle_exception())
loop.run_forever()
loop.close()
```
Another option is to use the `AbstractEventLoop.run_until_complete()` function:

```python
task = asyncio.ensure_future(bug())
try:
    loop.run_until_complete(task)
except Exception:
    print("exception consumed")
```

**See also:** The `Future.exception()` method.
18.5.9.8. Chain coroutines correctly

When a coroutine function calls other coroutine functions and tasks, they should be chained explicitly with `yield from`. Otherwise, the execution is not guaranteed to be sequential.

Example with different bugs using `asyncio.sleep()` to simulate slow operations:

```python
import asyncio

@asyncio.coroutine
def create():
    yield from asyncio.sleep(3.0)
    print('(1) create file')

@asyncio.coroutine
def write():
    yield from asyncio.sleep(1.0)
    print('(2) write into file')

@asyncio.coroutine
def close():
    print('(3) close file')

@asyncio.coroutine
def test():
    asyncio.ensure_future(create())
    asyncio.ensure_future(write())
    asyncio.ensure_future(close())
    yield from asyncio.sleep(2.0)
    loop.stop()

loop = asyncio.get_event_loop()
asyncio.ensure_future(test())
```
loop.run_forever()

print("Pending tasks at exit: %s" % asyncio.Task.all_tasks)

loop.close()

Expected output:

(1) create file
(2) write into file
(3) close file

Pending tasks at exit: set()

Actual output:

(3) close file
(2) write into file

Pending tasks at exit: {<Task pending create() at test.py:7 wait_for=<Future pending cb=[Task._wakeup()]>}

Task was destroyed but it is pending!
task: <Task pending create() done at test.py:5 wait_for=<Future pending cb=[Task._wakeup()]>>

The loop stopped before the create() finished, close() has been called before write(), whereas coroutine functions were called in this order: create(), write(), close().

To fix the example, tasks must be marked with yield from:

```python
@asyncio.coroutine
def test():
    yield from asyncio.ensure_future(create())
    yield from asyncio.ensure_future(write())
    yield from asyncio.ensure_future(close())
    yield from asyncio.sleep(2.0)
    loop.stop()
```

Or without asyncio.ensure_future():

```python
@asyncio.coroutine
def test():
    create()  # Async function
    write()  # Async function
    close()  # Async function
    yield from asyncio.sleep(2.0)
    loop.stop()
```
@asyncio.coroutine
def test():
    yield from create()
    yield from write()
    yield from close()
    yield from asyncio.sleep(2.0)
    loop.stop()
18.5.9.9. Pending task destroyed

If a pending task is destroyed, the execution of its wrapped coroutine did not complete. It is probably a bug and so a warning is logged.

Example of log:

```python
Task was destroyed but it is pending!
task: <Task pending coro=<kill_me() done, defined at test.py:5>
wait_for=<Future pending cb=[Task._wakeup()]>>
```

Enable the debug mode of asyncio to get the traceback where the task was created. Example of log in debug mode:

```python
Task was destroyed but it is pending!
source_traceback: Object created at (most recent call last):
  File "test.py", line 15, in <module>
    task = asyncio.ensure_future(coro, loop=loop)
  task: <Task pending coro=<kill_me() done, defined at test.py:5>
```

See also: Detect coroutine objects never scheduled.
18.5.9.10. Close transports and event loops

When a transport is no more needed, call its `close()` method to release resources. Event loops must also be closed explicitly.

If a transport or an event loop is not closed explicitly, a `ResourceWarning` warning will be emitted in its destructor. By default, `ResourceWarning` warnings are ignored. The Debug mode of asyncio section explains how to display them.
18.6. **asyncore** — Asynchronous socket handler

**Source code:** Lib/asyncore.py

*Deprecated since version 3.6: Please use asyncio instead.*

---

**Note:** This module exists for backwards compatibility only. For new code we recommend using asyncio.

This module provides the basic infrastructure for writing asynchronous socket service clients and servers.

There are only two ways to have a program on a single processor do "more than one thing at a time." Multi-threaded programming is the simplest and most popular way to do it, but there is another very different technique, that lets you have nearly all the advantages of multi-threading, without actually using multiple threads. It's really only practical if your program is largely I/O bound. If your program is processor bound, then pre-emptive scheduled threads are probably what you really need. Network servers are rarely processor bound, however.

If your operating system supports the `select()` system call in its I/O library (and nearly all do), then you can use it to juggle multiple communication channels at once; doing other work while your I/O is taking place in the "background." Although this strategy can seem strange and complex, especially at first, it is in many ways easier to understand and control than multi-threaded programming. The **asyncore** module solves many of the difficult problems for you,
making the task of building sophisticated high-performance network servers and clients a snap. For “conversational” applications and protocols the companion `asynchat` module is invaluable.

The basic idea behind both modules is to create one or more network `channels`, instances of class `asyncore.dispatcher` and `asynchat.async_chat`. Creating the channels adds them to a global map, used by the `loop()` function if you do not provide it with your own `map`.

Once the initial channel(s) is(are) created, calling the `loop()` function activates channel service, which continues until the last channel (including any that have been added to the map during asynchronous service) is closed.

```python
asyncore.loop([timeout[, use_poll[, map[, count]]]])
```

Enter a polling loop that terminates after count passes or all open channels have been closed. All arguments are optional. The `count` parameter defaults to `None`, resulting in the loop terminating only when all channels have been closed. The `timeout` argument sets the timeout parameter for the appropriate `select()` or `poll()` call, measured in seconds; the default is 30 seconds. The `use_poll` parameter, if true, indicates that `poll()` should be used in preference to `select()` (the default is `False`).

The `map` parameter is a dictionary whose items are the channels to watch. As channels are closed they are deleted from their map. If `map` is omitted, a global map is used. Channels (instances of `asyncore.dispatcher`, `asynchat.async_chat` and subclasses thereof) can freely be mixed in the map.

```python
class asyncore.dispatcher
```
The **dispatcher** class is a thin wrapper around a low-level socket object. To make it more useful, it has a few methods for event-handling which are called from the asynchronous loop. Otherwise, it can be treated as a normal non-blocking socket object.

The firing of low-level events at certain times or in certain connection states tells the asynchronous loop that certain higher-level events have taken place. For example, if we have asked for a socket to connect to another host, we know that the connection has been made when the socket becomes writable for the first time (at this point you know that you may write to it with the expectation of success). The implied higher-level events are:

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle_connect()</td>
<td>Implied by the first read or write event</td>
</tr>
<tr>
<td>handle_close()</td>
<td>Implied by a read event with no data available</td>
</tr>
<tr>
<td>handle_accepted()</td>
<td>Implied by a read event on a listening socket</td>
</tr>
</tbody>
</table>

During asynchronous processing, each mapped channel's `readable()` and `writable()` methods are used to determine whether the channel's socket should be added to the list of channels `select()`ed or `poll()`ed for read and write events.

Thus, the set of channel events is larger than the basic socket events. The full set of methods that can be overridden in your subclass follows:

**handle_read()**

Called when the asynchronous loop detects that a `read()` call
on the channel's socket will succeed.

**handle_write()**
Called when the asynchronous loop detects that a writable socket can be written. Often this method will implement the necessary buffering for performance. For example:

```python
def handle_write(self):
    sent = self.send(self.buffer)
    self.buffer = self.buffer[sent:]
```

**handle_expt()**
Called when there is out of band (OOB) data for a socket connection. This will almost never happen, as OOB is tenuously supported and rarely used.

**handle_connect()**
Called when the active opener’s socket actually makes a connection. Might send a “welcome” banner, or initiate a protocol negotiation with the remote endpoint, for example.

**handle_close()**
Called when the socket is closed.

**handle_error()**
Called when an exception is raised and not otherwise handled. The default version prints a condensed traceback.

**handle_accept()**
Called on listening channels (passive openers) when a connection can be established with a new remote endpoint that has issued a `connect()` call for the local endpoint. Deprecated in version 3.2; use `handle_accepted()` instead.
**Deprecated since version 3.2.**

**handle_accepted**\(^{1}\)(\texttt{sock}, \texttt{addr})

Called on listening channels (passive openers) when a connection has been established with a new remote endpoint that has issued a \texttt{connect()} call for the local endpoint. \texttt{sock} is a new socket object usable to send and receive data on the connection, and \texttt{addr} is the address bound to the socket on the other end of the connection.

\emph{New in version 3.2.}

**readable()**

Called each time around the asynchronous loop to determine whether a channel’s socket should be added to the list on which read events can occur. The default method simply returns \texttt{True}, indicating that by default, all channels will be interested in read events.

**writable()**

Called each time around the asynchronous loop to determine whether a channel’s socket should be added to the list on which write events can occur. The default method simply returns \texttt{True}, indicating that by default, all channels will be interested in write events.

In addition, each channel delegates or extends many of the socket methods. Most of these are nearly identical to their socket partners.

**create_socket**\(^{1}\)(\texttt{family=socket.AF_INET}, \texttt{type=socket.SOCK_STREAM})

This is identical to the creation of a normal socket, and will use the same options for creation. Refer to the \texttt{socket \texttt{create_socket}}
documentation for information on creating sockets.

*Changed in version 3.3*: *family* and *type* arguments can be omitted.

**connect**(address)
As with the normal socket object, *address* is a tuple with the first element the host to connect to, and the second the port number.

**send**(data)
Send *data* to the remote end-point of the socket.

**recv**(buffer_size)
Read at most *buffer_size* bytes from the socket's remote end-point. An empty bytes object implies that the channel has been closed from the other end.

  Note that *recv()* may raise *BlockingIOError*, even though *select.select()* or *select.poll()* has reported the socket ready for reading.

**listen**(backlog)
Listen for connections made to the socket. The *backlog* argument specifies the maximum number of queued connections and should be at least 1; the maximum value is system-dependent (usually 5).

**bind**(address)
Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family — refer to the *socket* documentation for more information.) To mark the socket as re-usable (setting the SO_REUSEADDR
option), call the `dispatcher` object's `set_reuse_addr()` method.

**accept()**
Accept a connection. The socket must be bound to an address and listening for connections. The return value can be either `None` or a pair `(conn, address)` where `conn` is a new socket object usable to send and receive data on the connection, and `address` is the address bound to the socket on the other end of the connection. When `None` is returned it means the connection didn't take place, in which case the server should just ignore this event and keep listening for further incoming connections.

**close()**
Close the socket. All future operations on the socket object will fail. The remote end-point will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

**class asyncore.dispatcher_with_send**
A `dispatcher` subclass which adds simple buffered output capability, useful for simple clients. For more sophisticated usage use `asynchat.async_chat`.

**class asyncore.file_dispatcher**
A file_dispatcher takes a file descriptor or `file object` along with an optional map argument and wraps it for use with the `poll()` or `loop()` functions. If provided a file object or anything with a `fileno()` method, that method will be called and passed to the `file_wrapper` constructor. Availability: UNIX.
class asyncore.file_wrapper

A file_wrapper takes an integer file descriptor and calls os.dup() to duplicate the handle so that the original handle may be closed independently of the file_wrapper. This class implements sufficient methods to emulate a socket for use by the file_dispatcher class. Availability: UNIX.
Here is a very basic HTTP client that uses the `dispatcher` class to implement its socket handling:

```python
import asyncore

class HTTPClient(asyncore.dispatcher):
    def __init__(self, host, path):
        asyncore.dispatcher.__init__(self)
        self.create_socket()
        self.connect( (host, 80) )
        self.buffer = bytes('GET %s HTTP/1.0\r\nHost: (path, host), 'ascii')

    def handle_connect(self):
        pass

    def handle_close(self):
        self.close()

    def handle_read(self):
        print(self.recv(8192))

    def writable(self):
        return (len(self.buffer) > 0)

    def handle_write(self):
        sent = self.send(self.buffer)
        self.buffer = self.buffer[sent:]

client = HTTPClient('www.python.org', '/')
```
asyncore.loop()
Here is a basic echo server that uses the `dispatcher` class to accept connections and dispatches the incoming connections to a handler:

```python
import asyncore

class EchoHandler(asyncore.dispatcher_with_send):
    def handle_read(self):
        data = self.recv(8192)
        if data:
            self.send(data)

class EchoServer(asyncore.dispatcher):
    def __init__(self, host, port):
        asyncore.dispatcher.__init__(self)
        self.create_socket()
        self.set_reuse_addr()
        self.bind((host, port))
        self.listen(5)

    def handle_accepted(self, self, sock, addr):
        print('Incoming connection from %s' % repr(addr))
        handler = EchoHandler(sock)

server = EchoServer('localhost', 8080)
asyncore.loop()
```
18.7. **asynchat** — Asynchronous socket command/response handler

**Source code:** Lib/asynchat.py

*Deprecated since version 3.6:* Please use **asyncio** instead.

---

**Note:** This module exists for backwards compatibility only. For new code we recommend using **asyncio**.

This module builds on the **asyncore** infrastructure, simplifying asynchronous clients and servers and making it easier to handle protocols whose elements are terminated by arbitrary strings, or are of variable length. **asynchat** defines the abstract class **async_chat** that you subclass, providing implementations of the `collect_incoming_data()` and `found_terminator()` methods. It uses the same asynchronous loop as **asyncore**, and the two types of channel, **asyncore.dispatcher** and **asynchat.async_chat**, can freely be mixed in the channel map. Typically an **asyncore.dispatcher** server channel generates new **asynchat.async_chat** channel objects as it receives incoming connection requests.

**class asynchat.** **async_chat**

This class is an abstract subclass of **asyncore.dispatcher**. To make practical use of the code you must subclass **async_chat**, providing meaningful `collect_incoming_data()` and `found_terminator()` methods. The **asyncore.dispatcher** methods can be used, although not all make sense in a...
message/response context.

Like `asyncore.dispatcher`, `async_chat` defines a set of events that are generated by an analysis of socket conditions after a `select()` call. Once the polling loop has been started the `async_chat` object's methods are called by the event-processing framework with no action on the part of the programmer.

Two class attributes can be modified, to improve performance, or possibly even to conserve memory.

**ac_in_buffer_size**

The asynchronous input buffer size (default 4096).

**ac_out_buffer_size**

The asynchronous output buffer size (default 4096).

Unlike `asynccore.dispatcher`, `async_chat` allows you to define a FIFO queue of producers. A producer need have only one method, `more()`, which should return data to be transmitted on the channel. The producer indicates exhaustion (i.e. that it contains no more data) by having its `more()` method return the empty bytes object. At this point the `async_chat` object removes the producer from the queue and starts using the next producer, if any. When the producer queue is empty the `handle_write()` method does nothing. You use the channel object's `set_terminator()` method to describe how to recognize the end of, or an important breakpoint in, an incoming transmission from the remote endpoint.

To build a functioning `async_chat` subclass your input methods `collect_incoming_data()` and `found_terminator()` must handle the data that the channel receives asynchronously. The
methods are described below.

async_chat.**close_when_done()**

Pushes a `None` on to the producer queue. When this producer is popped off the queue it causes the channel to be closed.

async_chat.**collect_incoming_data**(data)

Called with `data` holding an arbitrary amount of received data. The default method, which must be overridden, raises a `NotImplementedError` exception.

async_chat.**discard_buffers()**

In emergencies this method will discard any data held in the input and/or output buffers and the producer queue.

async_chat.**found_terminator()**

Called when the incoming data stream matches the termination condition set by `set_terminator()`. The default method, which must be overridden, raises a `NotImplementedError` exception. The buffered input data should be available via an instance attribute.

async_chat.**get_terminator()**

Returns the current terminator for the channel.

async_chat.**push**(data)

Pushes data on to the channel’s queue to ensure its transmission. This is all you need to do to have the channel write the data out to the network, although it is possible to use your own producers in more complex schemes to implement encryption and chunking, for example.
async_chat.push_with_producer(producer)

Takes a producer object and adds it to the producer queue associated with the channel. When all currently-pushed producers have been exhausted the channel will consume this producer’s data by calling its more() method and send the data to the remote endpoint.

async_chat.set_terminator(term)

Sets the terminating condition to be recognized on the channel. term may be any of three types of value, corresponding to three different ways to handle incoming protocol data.

<table>
<thead>
<tr>
<th>term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>Will call found_terminator() when the string is found in the input stream</td>
</tr>
<tr>
<td>integer</td>
<td>Will call found_terminator() when the indicated number of characters have been received</td>
</tr>
<tr>
<td>None</td>
<td>The channel continues to collect data forever</td>
</tr>
</tbody>
</table>

Note that any data following the terminator will be available for reading by the channel after found_terminator() is called.
18.7.1. asynchat Example

The following partial example shows how HTTP requests can be read with `async_chat`. A web server might create an `http_request_handler` object for each incoming client connection. Notice that initially the channel terminator is set to match the blank line at the end of the HTTP headers, and a flag indicates that the headers are being read.

Once the headers have been read, if the request is of type POST (indicating that further data are present in the input stream) then the `Content-Length:` header is used to set a numeric terminator to read the right amount of data from the channel.

The `handle_request()` method is called once all relevant input has been marshalled, after setting the channel terminator to `None` to ensure that any extraneous data sent by the web client are ignored.

```python
import asynchat

class http_request_handler(asynchat.async_chat):
    def __init__(self, sock, addr, sessions, log):
        asynchat.async_chat.__init__(self, sock=sock)
        self.addr = addr
        self.sessions = sessions
        self.ibuffer = []
        self.obuffer = b''
        self.set_terminator(b'

')
        self.reading_headers = True
        self.handling = False
        self.cgi_data = None
        self.log = log
```
```python
def collect_incoming_data(self, data):
    """Buffer the data""
    self.ibuffer.append(data)

def found_terminator(self):
    if self.reading_headers:
        self.reading_headers = False
        self.parse_headers(b"".join(self.ibuffer)
        self.ibuffer = []
    if self.op.upper() == b"POST":
        clen = self.headers.getheader("content-length")
        self.set_terminator(int(clen))
    else:
        self.handling = True
        self.set_terminator(None)
        self.handle_request()
    elif not self.handling:
        self.set_terminator(None)  # browsers sometimes over-send
        self.cgi_data = parse(self.headers, b"
        self.handling = True
        self.ibuffer = []
        self.handle_request()
```

18.8. `signal` — Set handlers for asynchronous events

This module provides mechanisms to use signal handlers in Python.
18.8.1. General rules

The `signal.signal()` function allows defining custom handlers to be executed when a signal is received. A small number of default handlers are installed: SIGPIPE is ignored (so write errors on pipes and sockets can be reported as ordinary Python exceptions) and SIGINT is translated into a `KeyboardInterrupt` exception.

A handler for a particular signal, once set, remains installed until it is explicitly reset (Python emulates the BSD style interface regardless of the underlying implementation), with the exception of the handler for SIGCHLD, which follows the underlying implementation.

18.8.1.1. Execution of Python signal handlers

A Python signal handler does not get executed inside the low-level (C) signal handler. Instead, the low-level signal handler sets a flag which tells the virtual machine to execute the corresponding Python signal handler at a later point (for example at the next bytecode instruction). This has consequences:

- It makes little sense to catch synchronous errors like SIGFPE or SIGSEGV that are caused by an invalid operation in C code. Python will return from the signal handler to the C code, which is likely to raise the same signal again, causing Python to apparently hang. From Python 3.3 onwards, you can use the `faulthandler` module to report on synchronous errors.
- A long-running calculation implemented purely in C (such as regular expression matching on a large body of text) may run uninterrupted for an arbitrary amount of time, regardless of any signals received. The Python signal handlers will be called when
the calculation finishes.

18.8.1.2. Signals and threads

Python signal handlers are always executed in the main Python thread, even if the signal was received in another thread. This means that signals can’t be used as a means of inter-thread communication. You can use the synchronization primitives from the `threading` module instead.

Besides, only the main thread is allowed to set a new signal handler.
18.8.2. Module contents

*Changed in version 3.5:* signal (SIG*), handler (SIG_DFL, SIG_IGN) and sigmask (SIG_BLOCK, SIG_UNBLOCK, SIG_SETMASK) related constants listed below were turned into enums. `getsignal()`, `pthread_sigmask()`, `sigpending()` and `sigwait()` functions return human-readable enums.

The variables defined in the `signal` module are:

**signal.SIG_DFL**
- This is one of two standard signal handling options; it will simply perform the default function for the signal. For example, on most systems the default action for SIGQUIT is to dump core and exit, while the default action for SIGCHLD is to simply ignore it.

**signal.SIG_IGN**
- This is another standard signal handler, which will simply ignore the given signal.

**SIG* 
- All the signal numbers are defined symbolically. For example, the hangup signal is defined as `signal.SIGHUP`; the variable names are identical to the names used in C programs, as found in `<signal.h>`. The Unix man page for `signal()` lists the existing signals (on some systems this is `signal(2)`, on others the list is in `signal(7)`). Note that not all systems define the same set of signal names; only those names defined by the system are defined by this module.

**signal.CTRL_C_EVENT**
The signal corresponding to the Ctrl+C keystroke event. This signal can only be used with `os.kill()`.

Availability: Windows.

*New in version 3.2.*

**signal.** **CTRL_BREAK_EVENT**

The signal corresponding to the Ctrl+Break keystroke event. This signal can only be used with `os.kill()`.

Availability: Windows.

*New in version 3.2.*

**signal.** **NSIG**

One more than the number of the highest signal number.

**signal.** **ITIMER_REAL**

Decrements interval timer in real time, and delivers SIGALRM upon expiration.

**signal.** **ITIMER_VIRTUAL**

Decrements interval timer only when the process is executing, and delivers SIGVTALRM upon expiration.

**signal.** **ITIMER_PROF**

Decrements interval timer both when the process executes and when the system is executing on behalf of the process. Coupled with ITIMER_VIRTUAL, this timer is usually used to profile the time spent by the application in user and kernel space. SIGPROF is delivered upon expiration.

**signal.** **SIG_BLOCK**
A possible value for the `how` parameter to `pthread_sigmask()` indicating that signals are to be blocked.

*New in version 3.3.*

`signal.SIG_UNBLOCK`
A possible value for the `how` parameter to `pthread_sigmask()` indicating that signals are to be unblocked.

*New in version 3.3.*

`signal.SIG_SETMASK`
A possible value for the `how` parameter to `pthread_sigmask()` indicating that the signal mask is to be replaced.

*New in version 3.3.*

The `signal` module defines one exception:

**exception** `signal.ItimerError`
Raised to signal an error from the underlying `setitimer()` or `getitimer()` implementation. Expect this error if an invalid interval timer or a negative time is passed to `setitimer()`. This error is a subtype of `OSError`.

*New in version 3.3:* This error used to be a subtype of `IOError`, which is now an alias of `OSError`.

The `signal` module defines the following functions:

`signal.alarm(time)`
If `time` is non-zero, this function requests that a SIGALRM signal be sent to the process in `time` seconds. Any previously scheduled
alarm is canceled (only one alarm can be scheduled at any time). The returned value is then the number of seconds before any previously set alarm was to have been delivered. If `time` is zero, no alarm is scheduled, and any scheduled alarm is canceled. If the return value is zero, no alarm is currently scheduled. (See the Unix man page `alarm(2)`.) Availability: Unix.

**signal.getsignal**(`signalnum`)

Return the current signal handler for the signal `signalnum`. The returned value may be a callable Python object, or one of the special values `signal.SIG_IGN`, `signal.SIG_DFL` or `None`. Here, `signal.SIG_IGN` means that the signal was previously ignored, `signal.SIG_DFL` means that the default way of handling the signal was previously in use, and `None` means that the previous signal handler was not installed from Python.

**signal.pause**()

Cause the process to sleep until a signal is received; the appropriate handler will then be called. Returns nothing. Not on Windows. (See the Unix man page `signal(2)`.)

See also `sigwait()`, `sigwaitinfo()`, `sigtimedwait()` and `sigpending()`.

**signal.pthread_kill**(`thread_id`, `signalnum`)

Send the signal `signalnum` to the thread `thread_id`, another thread in the same process as the caller. The target thread can be executing any code (Python or not). However, if the target thread is executing the Python interpreter, the Python signal handlers will be **executed by the main thread**. Therefore, the only point of sending a signal to a particular Python thread would be to force a running system call to fail with `InterruptedError`. 
Use `threading.get_ident()` or the `ident` attribute of `threading.Thread` objects to get a suitable value for `thread_id`.

If `signalnum` is 0, then no signal is sent, but error checking is still performed; this can be used to check if the target thread is still running.

Availability: Unix (see the man page `pthread_kill(3)` for further information).

See also `os.kill()`.

*New in version 3.3.*

**signal.pthread_sigmask**(how, mask)**

Fetch and/or change the signal mask of the calling thread. The signal mask is the set of signals whose delivery is currently blocked for the caller. Return the old signal mask as a set of signals.

The behavior of the call is dependent on the value of `how`, as follows.

- **SIG_BLOCK**: The set of blocked signals is the union of the current set and the `mask` argument.
- **SIG_UNBLOCK**: The signals in `mask` are removed from the current set of blocked signals. It is permissible to attempt to unblock a signal which is not blocked.
- **SIG_SETMASK**: The set of blocked signals is set to the `mask` argument.

`mask` is a set of signal numbers (e.g. `{signal.SIGINT, signal.SIGTERM}`). Use `range(1, signal.NSIG)` for a full mask including all signals.
For example, `signal.pthread_sigmask(signal.SIG_BLOCK, [])` reads the signal mask of the calling thread.

Availability: Unix. See the man page `sigprocmask(3)` and `pthread_sigmask(3)` for further information.

See also `pause()`, `sigpending()` and `sigwait()`.

*New in version 3.3.*

`signal.setitimer(which, seconds[, interval])`

Sets given interval timer (one of `signal.ITIMER_REAL`, `signal.ITIMER_VIRTUAL` or `signal.ITIMER_PROF`) specified by `which` to fire after `seconds` (float is accepted, different from `alarm()`) and after that every `interval` seconds. The interval timer specified by `which` can be cleared by setting `seconds` to zero.

When an interval timer fires, a signal is sent to the process. The signal sent is dependent on the timer being used; `signal.ITIMER_REAL` will deliver `SIGALRM`, `signal.ITIMER_VIRTUAL` sends `SIGVTALRM`, and `signal.ITIMER_PROF` will deliver `SIGPROF`.

The old values are returned as a tuple: (delay, interval).

Attempting to pass an invalid interval timer will cause an `ItimerError`. Availability: Unix.

`signal.getitimer(which)`

Returns current value of a given interval timer specified by `which`. Availability: Unix.
**signal.set_wakeup_fd(fd)**

Set the wakeup file descriptor to *fd*. When a signal is received, the signal number is written as a single byte into the fd. This can be used by a library to wakeup a poll or select call, allowing the signal to be fully processed.

The old wakeup fd is returned (or -1 if file descriptor wakeup was not enabled). If *fd* is -1, file descriptor wakeup is disabled. If not -1, *fd* must be non-blocking. It is up to the library to remove any bytes from *fd* before calling poll or select again.

Use for example `struct.unpack('%uB' % len(data), data)` to decode the signal numbers list.

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a `ValueError` exception to be raised.

*Changed in version 3.5:* On Windows, the function now also supports socket handles.

**signal.siginterrupt(signalnum, flag)**

Change system call restart behaviour: if *flag* is `False`, system calls will be restarted when interrupted by signal *signalnum*, otherwise system calls will be interrupted. Returns nothing. Availability: Unix (see the man page `siginterrupt(3)` for further information).

Note that installing a signal handler with `signal()` will reset the restart behaviour to interruptible by implicitly calling `siginterrupt()` with a true *flag* value for the given signal.

**signal.signal(signalnum, handler)**
Set the handler for signal *signalnum* to the function *handler*. *handler* can be a callable Python object taking two arguments (see below), or one of the special values *signal.SIG_IGN* or *signal.SIG_DFL*. The previous signal handler will be returned (see the description of *getsignal()* above). (See the Unix man page *signal(2)*.)

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a *ValueError* exception to be raised.

The *handler* is called with two arguments: the signal number and the current stack frame (None or a frame object; for a description of frame objects, see the description in the type hierarchy or see the attribute descriptions in the *inspect* module).

On Windows, *signal()* can only be called with SIGABRT, SIGFPE, SIGILL, SIGINT, SIGSEGV, SIGTERM, or SIGBREAK. A *ValueError* will be raised in any other case. Note that not all systems define the same set of signal names; an *AttributeError* will be raised if a signal name is not defined as SIG* module level constant.

**signal.*sigpending*(*)**

Examine the set of signals that are pending for delivery to the calling thread (i.e., the signals which have been raised while blocked). Return the set of the pending signals.

Availability: Unix (see the man page *sigpending(2)* for further information).

See also *pause()*,*pthread_sigmask()* and *sigwait()*.
signal. **sigwait**(*sigset*)

Suspend execution of the calling thread until the delivery of one of the signals specified in the signal set *sigset*. The function accepts the signal (removes it from the pending list of signals), and returns the signal number.

Availability: Unix (see the man page `sigwait(3)` for further information).

See also `pause()`, `pthread_sigmask()`, `sigpending()`, `sigwaitinfo()` and `sigtimedwait()`.

signal. **sigwaitinfo**(*sigset*)

Suspend execution of the calling thread until the delivery of one of the signals specified in the signal set *sigset*. The function accepts the signal and removes it from the pending list of signals. If one of the signals in *sigset* is already pending for the calling thread, the function will return immediately with information about that signal. The signal handler is not called for the delivered signal. The function raises an ` InterruptedError` if it is interrupted by a signal that is not in *sigset*.

The return value is an object representing the data contained in the **siginfo_t** structure, namely: *si_signo*, *si_code*, *si_errno*, *si_pid*, *si_uid*, *si_status*, *si_band*.

Availability: Unix (see the man page `sigwaitinfo(2)` for further information).
See also `pause()`, `sigwait()` and `sigtimedwait()`.

New in version 3.3.

Changed in version 3.5: The function is now retried if interrupted by a signal not in `sigset` and the signal handler does not raise an exception (see PEP 475 for the rationale).

```
signal.sigtimedwait(sigset, timeout)
```

Like `sigwaitinfo()`, but takes an additional `timeout` argument specifying a timeout. If `timeout` is specified as 0, a poll is performed. Returns `None` if a timeout occurs.

Availability: Unix (see the man page `sigtimedwait(2)` for further information).

See also `pause()`, `sigwait()` and `sigwaitinfo()`.

New in version 3.3.

Changed in version 3.5: The function is now retried with the recomputed `timeout` if interrupted by a signal not in `sigset` and the signal handler does not raise an exception (see PEP 475 for the rationale).
18.8.3. Example

Here is a minimal example program. It uses the `alarm()` function to limit the time spent waiting to open a file; this is useful if the file is for a serial device that may not be turned on, which would normally cause the `os.open()` to hang indefinitely. The solution is to set a 5-second alarm before opening the file; if the operation takes too long, the alarm signal will be sent, and the handler raises an exception.

```python
import signal, os

def handler(signum, frame):
    print('Signal handler called with signal', signum)
    raise OSError("Couldn't open device!")

# Set the signal handler and a 5-second alarm
signal.signal(signal.SIGALRM, handler)
signal.alarm(5)

# This open() may hang indefinitely
fd = os.open('/dev/ttyS0', os.O_RDWR)

signal.alarm(0)  # Disable the alarm
```

18.9. `mmap` — Memory-mapped file support

Memory-mapped file objects behave like both `bytearray` and like file objects. You can use mmap objects in most places where `bytearray` are expected; for example, you can use the `re` module to search through a memory-mapped file. You can also change a single byte by doing `obj[index] = 97`, or change a subsequence by assigning to a slice: `obj[i1:i2] = b'...'`. You can also read and write data starting at the current file position, and `seek()` through the file to different positions.

A memory-mapped file is created by the `mmap` constructor, which is different on Unix and on Windows. In either case you must provide a file descriptor for a file opened for update. If you wish to map an existing Python file object, use its `fileno()` method to obtain the correct value for the `fileno` parameter. Otherwise, you can open the file using the `os.open()` function, which returns a file descriptor directly (the file still needs to be closed when done).

**Note:** If you want to create a memory-mapping for a writable, buffered file, you should `flush()` the file first. This is necessary to ensure that local modifications to the buffers are actually available to the mapping.

For both the Unix and Windows versions of the constructor, `access` may be specified as an optional keyword parameter. `access` accepts one of three values: `ACCESS_READ`, `ACCESS_WRITE`, or `ACCESS_COPY` to specify read-only, write-through or copy-on-write
memory respectively. access can be used on both Unix and Windows. If access is not specified, Windows mmap returns a write-through mapping. The initial memory values for all three access types are taken from the specified file. Assignment to an ACCESS_READ memory map raises a TypeError exception. Assignment to an ACCESS_WRITE memory map affects both memory and the underlying file. Assignment to an ACCESS_COPY memory map affects memory but does not update the underlying file.

To map anonymous memory, -1 should be passed as the fileno along with the length.

class mmap.mmap(fileno, length, tagname=None, access=ACCESS_DEFAULT[, offset])

(Windows version) Maps length bytes from the file specified by the file handle fileno, and creates a mmap object. If length is larger than the current size of the file, the file is extended to contain length bytes. If length is 0, the maximum length of the map is the current size of the file, except that if the file is empty Windows raises an exception (you cannot create an empty mapping on Windows).

tagname, if specified and not None, is a string giving a tag name for the mapping. Windows allows you to have many different mappings against the same file. If you specify the name of an existing tag, that tag is opened, otherwise a new tag of this name is created. If this parameter is omitted or None, the mapping is created without a name. Avoiding the use of the tag parameter will assist in keeping your code portable between Unix and Windows.

offset may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the
file. `offset` defaults to 0. `offset` must be a multiple of the ALLOCATIONGRANULARITY.

```python
class mmap:
    mmap(fileno, length, flags=MAP_SHARED,
          prot=PROT_WRITE|PROT_READ, access=ACCESS_DEFAULT[, offset])
```

*(Unix version)* Maps `length` bytes from the file specified by the file descriptor `fileno`, and returns a mmap object. If `length` is 0, the maximum length of the map will be the current size of the file when `mmap` is called.

`flags` specifies the nature of the mapping. MAP_PRIVATE creates a private copy-on-write mapping, so changes to the contents of the `mmap` object will be private to this process, and MAP_SHARED creates a mapping that's shared with all other processes mapping the same areas of the file. The default value is MAP_SHARED.

`prot`, if specified, gives the desired memory protection; the two most useful values are PROT_READ and PROT_WRITE, to specify that the pages may be read or written. `prot` defaults to PROT_READ | PROT_WRITE.

`access` may be specified in lieu of `flags` and `prot` as an optional keyword parameter. It is an error to specify both `flags`, `prot` and `access`. See the description of `access` above for information on how to use this parameter.

`offset` may be specified as a non-negative integer offset. `mmap` references will be relative to the offset from the beginning of the file. `offset` defaults to 0. `offset` must be a multiple of the PAGESIZE or ALLOCATIONGRANULARITY.
To ensure validity of the created memory mapping the file specified by the descriptor `fileno` is internally automatically synchronized with physical backing store on Mac OS X and OpenVMS.

This example shows a simple way of using `mmap`:

```python
import mmap

# write a simple example file
with open("hello.txt", "wb") as f:
    f.write(b"Hello Python!
")

with open("hello.txt", "r+b") as f:
    # memory-map the file, size 0 means whole file
    mm = mmap.mmap(f.fileno(), 0)
    # read content via standard file methods
    print(mm.readline())  # prints b"Hello Python"
    # read content via slice notation
    print(mm[5:])  # prints b"Hello"
    # update content using slice notation;
    # note that new content must have same size
    mm[6:] = b" world!\n"
    # ... and read again using standard file methods
    mm.seek(0)
    print(mm.readline())  # prints b"Hello world"
    # close the map
    mm.close()
```

`mmap` can also be used as a context manager in a `with` statement:

```python
import mmap

with mmap.mmap(-1, 13) as mm:
    mm.write(b"Hello world!"
```
New in version 3.2: Context manager support.

The next example demonstrates how to create an anonymous map and exchange data between the parent and child processes:

```python
import mmap
import os

mm = mmap.mmap(-1, 13)
mm.write(b"Hello world!"

pid = os.fork()

if pid == 0:  # In a child process
    mm.seek(0)
    print(mm.readline())
    mm.close()
```

Memory-mapped file objects support the following methods:

**close()**

Closes the mmap. Subsequent calls to other methods of the object will result in a ValueError exception being raised. This will not close the open file.

**closed**

True if the file is closed.

New in version 3.2.

**find(sub[, start[, end]])**

Returns the lowest index in the object where the subsequence `sub` is found, such that `sub` is contained in the range [start,
Optional arguments start and end are interpreted as in slice notation. Returns -1 on failure.

Changed in version 3.5: Writable bytes-like object is now accepted.

flush([offset[, size]])
Flushes changes made to the in-memory copy of a file back to disk. Without use of this call there is no guarantee that changes are written back before the object is destroyed. If offset and size are specified, only changes to the given range of bytes will be flushed to disk; otherwise, the whole extent of the mapping is flushed.

(Windows version) A nonzero value returned indicates success; zero indicates failure.

(Unix version) A zero value is returned to indicate success. An exception is raised when the call failed.

move(dest, src, count)
Copy the count bytes starting at offset src to the destination index dest. If the mmap was created with ACCESS_READ, then calls to move will raise a TypeError exception.

read([n])
Return a bytes containing up to n bytes starting from the current file position. If the argument is omitted, None or negative, return all bytes from the current file position to the end of the mapping. The file position is updated to point after the bytes that were returned.
Changed in version 3.3: Argument can be omitted or None.

**read_byte()**
Returns a byte at the current file position as an integer, and advances the file position by 1.

**readline()**
Returns a single line, starting at the current file position and up to the next newline.

**resize(newsize)**
Resizes the map and the underlying file, if any. If the mmap was created with ACCESS_READ or ACCESS_COPY, resizing the map will raise a *TypeError* exception.

**rfind(sub[, start[, end]])**
Returns the highest index in the object where the subsequence `sub` is found, such that `sub` is contained in the range `[start, end]`. Optional arguments `start` and `end` are interpreted as in slice notation. Returns -1 on failure.

*Changed in version 3.5:* Writable *bytes-like object* is now accepted.

**seek(pos[, whence])**
Set the file's current position. `whence` argument is optional and defaults to `os.SEEK_SET` or 0 (absolute file positioning); other values are `os.SEEK_CUR` or 1 (seek relative to the current position) and `os.SEEK_END` or 2 (seek relative to the file's end).

**size()**
Return the length of the file, which can be larger than the size of the memory-mapped area.

**tell()**

Returns the current position of the file pointer.

**write(bytes)**

Write the bytes in `bytes` into memory at the current position of the file pointer and return the number of bytes written (never less than `len(bytes)`), since if the write fails, a `ValueError` will be raised). The file position is updated to point after the bytes that were written. If the mmap was created with `ACCESS_READ`, then writing to it will raise a `TypeError` exception.

*Changed in version 3.5:* Writable bytes-like object is now accepted.

*Changed in version 3.6:* The number of bytes written is now returned.

**write_byte(byte)**

Write the integer `byte` into memory at the current position of the file pointer; the file position is advanced by 1. If the mmap was created with `ACCESS_READ`, then writing to it will raise a `TypeError` exception.
19. Internet Data Handling

This chapter describes modules which support handling data formats commonly used on the Internet.

- 19.1. email — An email and MIME handling package
  - 19.1.1. email.message: Representing an email message
  - 19.1.2. email.parser: Parsing email messages
    - 19.1.2.1. FeedParser API
    - 19.1.2.2. Parser API
    - 19.1.2.3. Additional notes
  - 19.1.3. email.generator: Generating MIME documents
  - 19.1.4. email.policy: Policy Objects
  - 19.1.5. email.errors: Exception and Defect classes
  - 19.1.6. email.headerregistry: Custom Header Objects
  - 19.1.7. email.contentmanager: Managing MIME Content
    - 19.1.7.1. Content Manager Instances
  - 19.1.8. email: Examples
  - 19.1.9. email.message.Message: Representing an email message using the compat32 API
  - 19.1.10. email.mime: Creating email and MIME objects from scratch
  - 19.1.11. email.header: Internationalized headers
  - 19.1.12. email.charset: Representing character sets
  - 19.1.13. email.encoders: Encoders
  - 19.1.14. email.utils: Miscellaneous utilities
  - 19.1.15. email.iterators: Iterators

- 19.2. json — JSON encoder and decoder
  - 19.2.1. Basic Usage
  - 19.2.2. Encoders and Decoders
  - 19.2.3. Exceptions
- 19.2.4. Standard Compliance and Interoperability
  - 19.2.4.1. Character Encodings
  - 19.2.4.2. Infinite and NaN Number Values
  - 19.2.4.3. Repeated Names Within an Object
  - 19.2.4.4. Top-level Non-Object, Non-Array Values
  - 19.2.4.5. Implementation Limitations
- 19.2.5. Command Line Interface
  - 19.2.5.1. Command line options
- 19.3. mailcap — Mailcap file handling
- 19.4. mailbox — Manipulate mailboxes in various formats
  - 19.4.1. Mailbox objects
    - 19.4.1.1. Maildir
    - 19.4.1.2. mbox
    - 19.4.1.3. MH
    - 19.4.1.4. Babyl
    - 19.4.1.5. MMDF
  - 19.4.2. Message objects
    - 19.4.2.1. MaildirMessage
    - 19.4.2.2. mboxMessage
    - 19.4.2.3. MHMessage
    - 19.4.2.4. BabylMessage
    - 19.4.2.5. MMDFMessage
  - 19.4.3. Exceptions
  - 19.4.4. Examples
- 19.5. mimetypes — Map filenames to MIME types
  - 19.5.1. MimeTypes Objects
- 19.6. base64 — Base16, Base32, Base64, Base85 Data Encodings
- 19.7. binhex — Encode and decode binhex4 files
  - 19.7.1. Notes
- 19.8. binascii — Convert between binary and ASCII
- 19.9. quopri — Encode and decode MIME quoted-printable data
- 19.10. uu — Encode and decode uuencode files
19.1. `email` — An email and MIME handling package

**Source code:** `Lib/email/__init__.py`

The `email` package is a library for managing email messages. It is specifically *not* designed to do any sending of email messages to SMTP (RFC 2821), NNTP, or other servers; those are functions of modules such as `smtplib` and `nntplib`. The `email` package attempts to be as RFC-compliant as possible, supporting RFC 5233 and RFC 6532, as well as such MIME-related RFCs as RFC 2045, RFC 2046, RFC 2047, RFC 2183, and RFC 2231.

The overall structure of the email package can be divided into three major components, plus a fourth component that controls the behavior of the other components.

The central component of the package is an “object model” that represents email messages. An application interacts with the package primarily through the object model interface defined in the `message` sub-module. The application can use this API to ask questions about an existing email, to construct a new email, or to add or remove email subcomponents that themselves use the same object model interface. That is, following the nature of email messages and their MIME subcomponents, the email object model is a tree structure of objects that all provide the `EmailMessage` API.

The other two major components of the package are the `parser` and the `generator`. The parser takes the serialized version of an email
message (a stream of bytes) and converts it into a tree of EmailMessage objects. The generator takes an EmailMessage and turns it back into a serialized byte stream. (The parser and generator also handle streams of text characters, but this usage is discouraged as it is too easy to end up with messages that are not valid in one way or another.)

The control component is the policy module. Every EmailMessage, every generator, and every parser has an associated policy object that controls its behavior. Usually an application only needs to specify the policy when an EmailMessage is created, either by directly instantiating an EmailMessage to create a new email, or by parsing an input stream using a parser. But the policy can be changed when the message is serialized using a generator. This allows, for example, a generic email message to be parsed from disk, but to serialize it using standard SMTP settings when sending it to an email server.

The email package does its best to hide the details of the various governing RFCs from the application. Conceptually the application should be able to treat the email message as a structured tree of unicode text and binary attachments, without having to worry about how these are represented when serialized. In practice, however, it is often necessary to be aware of at least some of the rules governing MIME messages and their structure, specifically the names and nature of the MIME “content types” and how they identify multipart documents. For the most part this knowledge should only be required for more complex applications, and even then it should only be the high level structure in question, and not the details of how those structures are represented. Since MIME content types are used widely in modern internet software (not just email), this will be a familiar concept to many programmers.
The following sections describe the functionality of the email package. We start with the message object model, which is the primary interface an application will use, and follow that with the parser and generator components. Then we cover the policy controls, which completes the treatment of the main components of the library.

The next three sections cover the exceptions the package may raise and the defects (non-compliance with the RFCs) that the parser may detect. Then we cover the headerregistry and the contentmanager sub-components, which provide tools for doing more detailed manipulation of headers and payloads, respectively. Both of these components contain features relevant to consuming and producing non-trivial messages, but also document their extensibility APIs, which will be of interest to advanced applications.

Following those is a set of examples of using the fundamental parts of the APIs covered in the preceding sections.

The forgoing represent the modern (unicode friendly) API of the email package. The remaining sections, starting with the Message class, cover the legacy compat32 API that deals much more directly with the details of how email messages are represented. The compat32 API does not hide the details of the RFCs from the application, but for applications that need to operate at that level, they can be useful tools. This documentation is also relevant for applications that are still using the compat32 API for backward compatibility reasons.

Changed in version 3.6: Docs reorganized and rewritten to promote the new EmailMessage/EmailPolicy API.

Contents of the email package documentation:
19.1.1. email.message: Representing an email message
19.1.2. email.parser: Parsing email messages
  - 19.1.2.1. FeedParser API
  - 19.1.2.2. Parser API
  - 19.1.2.3. Additional notes
19.1.3. email.generator: Generating MIME documents
19.1.4. email.policy: Policy Objects
19.1.5. email.errors: Exception and Defect classes
19.1.6. email.headerregistry: Custom Header Objects
19.1.7. email.contentmanager: Managing MIME Content
  - 19.1.7.1. Content Manager Instances
19.1.8. email: Examples

Legacy API:

19.1.9. email.message.Message: Representing an email message using the compat32 API
19.1.10. email.mime: Creating email and MIME objects from scratch
19.1.11. email.header: Internationalized headers
19.1.12. email.charset: Representing character sets
19.1.13. email.encoders: Encoders
19.1.14. email.utils: Miscellaneous utilities
19.1.15. email.iterators: Iterators

**Module mailbox**
Tools for creating, reading, and managing collections of messages on disk using a variety standard formats.

**Module smtpd**
SMTP server framework (primarily useful for testing)
19.1. **email** — An email and MIME handling package

…
19.1.1. **email.message**: Representing an email message

**Source code:** Lib/email/message.py

*New in version 3.6:* [1]

The central class in the `email` package is the `EmailMessage` class, imported from the `email.message` module. It is the base class for the `email` object model. `EmailMessage` provides the core functionality for setting and querying header fields, for accessing message bodies, and for creating or modifying structured messages.

An email message consists of *headers* and a *payload* (which is also referred to as the *content*). Headers are **RFC 5322** or **RFC 6532** style field names and values, where the field name and value are separated by a colon. The colon is not part of either the field name or the field value. The payload may be a simple text message, or a binary object, or a structured sequence of sub-messages each with their own set of headers and their own payload. The latter type of payload is indicated by the message having a MIME type such as `multipart/*` or `message/rfc822`.

The conceptual model provided by an `EmailMessage` object is that of an ordered dictionary of headers coupled with a *payload* that represents the **RFC 5322** body of the message, which might be a list of sub-`EmailMessage` objects. In addition to the normal dictionary methods for accessing the header names and values, there are methods for accessing specialized information from the headers (for example the MIME content type), for operating on the payload, for
generating a serialized version of the message, and for recursively walking over the object tree.

The `EmailMessage` dictionary-like interface is indexed by the header names, which must be ASCII values. The values of the dictionary are strings with some extra methods. Headers are stored and returned in case-preserving form, but field names are matched case-insensitively. Unlike a real dict, there is an ordering to the keys, and there can be duplicate keys. Additional methods are provided for working with headers that have duplicate keys.

The `payload` is either a string or bytes object, in the case of simple message objects, or a list of `EmailMessage` objects, for MIME container documents such as `multipart/*` and `message/rfc822` message objects.

class email.message.EmailMessage(policy=default)

If `policy` is specified use the rules it specifies to update and serialize the representation of the message. If `policy` is not set, use the `default` policy, which follows the rules of the email RFCs except for line endings (instead of the RFC mandated `\r\n`, it uses the Python standard `\n` line endings). For more information see the `policy` documentation.

as_string(unixfrom=False, maxheaderlen=None, policy=None)

Return the entire message flattened as a string. When optional `unixfrom` is true, the envelope header is included in the returned string. `unixfrom` defaults to `False`. For backward compatibility with the base `Message` class `maxheaderlen` is accepted, but defaults to `None`, which means that by default the line length is controlled by the `max_line_length` of the policy. The `policy`
argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified policy will be passed to the Generator.

Flattening the message may trigger changes to the EmailMessage if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not be the most useful way to serialize messages in your application, especially if you are dealing with multiple messages. See email.generator.Generator for a more flexible API for serializing messages. Note also that this method is restricted to producing messages serialized as “7 bit clean” when utf8 is False, which is the default.

*Changed in version 3.6:* the default behavior when maxheaderlen is not specified was changed from defaulting to 0 to defaulting to the value of max_line_length from the policy.

__str__()
Equivalent to as_string(policy=self.policy.clone(utf8=True)). Allows str(msg) to produce a string containing the serialized message in a readable format.

*Changed in version 3.4:* the method was changed to use utf8=True, thus producing an RFC 6531-like message representation, instead of being a direct alias for as_string().

as_bytes(unixfrom=False, policy=None)
Return the entire message flattened as a bytes object. When optional `unixfrom` is true, the envelope header is included in the returned string. `unixfrom` defaults to `False`. The `policy` argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified `policy` will be passed to the `BytesGenerator`.

Flattening the message may trigger changes to the `EmailMessage` if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not be the most useful way to serialize messages in your application, especially if you are dealing with multiple messages. See `email.generator.BytesGenerator` for a more flexible API for serializing messages.

```python
__bytes__()
```
Equivalent to `as_bytes()`. Allows `bytes(msg)` to produce a bytes object containing the serialized message.

```python
is_multipart()
```
Return `True` if the message's payload is a list of sub- `EmailMessage` objects, otherwise return `False`. When `is_multipart()` returns `False`, the payload should be a string object (which might be a CTE encoded binary payload). Note that `is_multipart()` returning `True` does not necessarily mean that “`msg.get_content_maintype() == 'multipart'`” will return the `True`. For example, `is_multipart` will return `True` when the `EmailMessage` is of type
message/rfc822.

**set_unixfrom**(unixfrom)

Set the message's envelope header to `unixfrom`, which should be a string. (See `mboxMessage` for a brief description of this header.)

**get_unixfrom**()

Return the message's envelope header. Defaults to `None` if the envelope header was never set.

The following methods implement the mapping-like interface for accessing the message's headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by `keys()`, but in an `EmailMessage` object, headers are always returned in the order they appeared in the original message, or in which they were added to the message later. Any header deleted and then re-added is always appended to the end of the header list.

These semantic differences are intentional and are biased toward convenience in the most common use cases.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

**__len__**()

Return the total number of headers, including duplicates.

**__contains__**(name)
Return true if the message object has a field named *name*. Matching is done without regard to case and *name* does not include the trailing colon. Used for the `in` operator. For example:

```python
if 'message-id' in myMessage:
    print('Message-ID:', myMessage['message-id'])
```

**__getitem__(name)__**

Return the value of the named header field. *name* does not include the colon field separator. If the header is missing, `None` is returned; a `KeyError` is never raised.

Note that if the named field appears more than once in the message's headers, exactly which of those field values will be returned is undefined. Use the `get_all()` method to get the values of all the extant headers named *name*.

Using the standard (non-`compat32`) policies, the returned value is an instance of a subclass of `email.headerregistry.BaseHeader`.

**__setitem__(name, val)__**

Add a header to the message with field name *name* and value *val*. The field is appended to the end of the message's existing headers.

Note that this does *not* overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name *name*, delete the field first, e.g.:
If the policy defines certain headers to be unique (as the standard policies do), this method may raise a `ValueError` when an attempt is made to assign a value to such a header when one already exists. This behavior is intentional for consistency's sake, but do not depend on it as we may choose to make such assignments do an automatic deletion of the existing header in the future.

```
msg['subject'] = 'Python roolz!
```

**__delitem__(name)**

Delete all occurrences of the field with name `name` from the message's headers. No exception is raised if the named field isn't present in the headers.

**keys()**

Return a list of all the message's header field names.

**values()**

Return a list of all the message's field values.

**items()**

Return a list of 2-tuples containing all the message's field headers and values.

**get(name, failobj=None)**

Return the value of the named header field. This is identical to **__getitem__()** except that optional `failobj` is returned if the named header is missing (`failobj` defaults to None).

Here are some additional useful header related methods:
get_all(name, failobj=None)

Return a list of all the values for the field named name. If there are no such named headers in the message, failobj is returned (defaults to None).

add_header(_name, _value, **_params)

Extended header setting. This method is similar to __setitem__() except that additional header parameters can be provided as keyword arguments. _name is the header field to add and _value is the primary value for the header.

For each item in the keyword argument dictionary _params, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as key="value" unless the value is None, in which case only the key will be added.

If the value contains non-ASCII characters, the charset and language may be explicitly controlled by specifying the value as a three tuple in the format (CHARSET, LANGUAGE, VALUE), where CHARSET is a string naming the charset to be used to encode the value, LANGUAGE can usually be set to None or the empty string (see RFC 2231 for other possibilities), and VALUE is the string value containing non-ASCII code points. If a three tuple is not passed and the value contains non-ASCII characters, it is automatically encoded in RFC 2231 format using a CHARSET of utf-8 and a LANGUAGE of None.

Here is an example:

```python
msg.add_header('Content-Disposition', 'attachment'
```
This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.gif"
```

An example of the extended interface with non-ASCII characters:

```
msg.add_header('Content-Disposition', 'attachment;
               filename=('iso-8859-1', '', 'Fußballer.ppt'))
```

`replace_header(_name, _value)`
Replace a header. Replace the first header found in the message that matches `_name`, retaining header order and field name case of the original header. If no matching header is found, raise a `KeyError`.

`get_content_type()`
Return the message’s content type, coerced to lower case of the form `maintype/subtype`. If there is no `Content-Type` header in the message return the value returned by `get_default_type()`. If the `Content-Type` header is invalid, return `text/plain`.

(According to [RFC 2045](https://tools.ietf.org/html/rfc2045), messages always have a default type, `get_content_type()` will always return a value. [RFC 2045](https://tools.ietf.org/html/rfc2045) defines a message’s default type to be `text/plain` unless it appears inside a `multipart/digest` container, in which case it would be `message/rfc822`. If the `Content-Type` header has an invalid type specification, [RFC 2045](https://tools.ietf.org/html/rfc2045) mandates that the default type be `text/plain`.)
get_content_maintype()

Return the message’s main content type. This is the *maintype* part of the string returned by `get_content_type()`.

get_content_subtype()

Return the message’s sub-content type. This is the * subtype* part of the string returned by `get_content_type()`.

get_default_type()

Return the default content type. Most messages have a default content type of *text/plain*, except for messages that are subparts of *multipart/digest* containers. Such subparts have a default content type of *message/rfc822*.

set_default_type(ctype)

Set the default content type. *ctype* should either be *text/plain* or *message/rfc822*, although this is not enforced. The default content type is not stored in the *Content-Type* header, so it only affects the return value of the `get_content_type` methods when no *Content-Type* header is present in the message.

set_param(param, value, header='Content-Type', requote=True, charset=None, language='', replace=False)

Set a parameter in the *Content-Type* header. If the parameter already exists in the header, replace its value with *value*. When *header* is *Content-Type* (the default) and the header does not yet exist in the message, add it, set its value to *text/plain*, and append the new parameter value. Optional *header* specifies an alternative header to *Content-Type*.

If the value contains non-ASCII characters, the charset and language may be explicitly specified using the optional *charset*
and `language` parameters. Optional `language` specifies the RFC 2231 language, defaulting to the empty string. Both `charset` and `language` should be strings. The default is to use the `utf8` `charset` and `None` for the `language`.

If `replace` is `False` (the default) the header is moved to the end of the list of headers. If `replace` is `True`, the header will be updated in place.

Use of the `requote` parameter with `EmailMessage` objects is deprecated.

Note that existing parameter values of headers may be accessed through the `params` attribute of the header value (for example, `msg['Content-Type'].params['charset']`).

*Changed in version 3.4*: `replace` keyword was added.

```
def del_param(param, header='content-type', requote=True)
```

Remove the given parameter completely from the `Content-Type` header. The header will be re-written in place without the parameter or its value. Optional `header` specifies an alternative to `Content-Type`.

Use of the `requote` parameter with `EmailMessage` objects is deprecated.

```
def get_filename(failobj=None)
```

Return the value of the `filename` parameter of the `Content-Disposition` header of the message. If the header does not have a `filename` parameter, this method falls back to looking for the `name` parameter on the `Content-Type` header. If neither is found, or the header is missing, then `failobj` is returned. The
returned string will always be unquoted as per \texttt{email.utils.unquote()}.

\textbf{get\_boundary}(\texttt{failobj=None})

Return the value of the \texttt{boundary} parameter of the \texttt{Content-Type} header of the message, or \texttt{failobj} if either the header is missing, or has no \texttt{boundary} parameter. The returned string will always be unquoted as per \texttt{email.utils.unquote()}.

\textbf{set\_boundary}(\texttt{boundary})

Set the \texttt{boundary} parameter of the \texttt{Content-Type} header to \texttt{boundary}. \texttt{set\_boundary()} will always quote \texttt{boundary} if necessary. A \texttt{HeaderParseError} is raised if the message object has no \texttt{Content-Type} header.

Note that using this method is subtly different from deleting the old \texttt{Content-Type} header and adding a new one with the new boundary via \texttt{add\_header()}, because \texttt{set\_boundary()} preserves the order of the \texttt{Content-Type} header in the list of headers.

\textbf{get\_content\_charset}(\texttt{failobj=None})

Return the \texttt{charset} parameter of the \texttt{Content-Type} header, coerced to lower case. If there is no \texttt{Content-Type} header, or if that header has no \texttt{charset} parameter, \texttt{failobj} is returned.

\textbf{get\_charsets}(\texttt{failobj=None})

Return a list containing the character set names in the message. If the message is a \texttt{multipart}, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.
Each item in the list will be a string which is the value of the charset parameter in the Content-Type header for the represented subpart. If the subpart has no Content-Type header, no charset parameter, or is not of the text main MIME type, then that item in the returned list will be failobj.

**is_attachment()**

Return True if there is a Content-Disposition header and its (case insensitive) value is attachment, False otherwise.

*Changed in version 3.4.2: is_attachment is now a method instead of a property, for consistency with is_multipart().*

**get_content_disposition()**

Return the lowercased value (without parameters) of the message’s Content-Disposition header if it has one, or None. The possible values for this method are inline, attachment or None if the message follows RFC 2183.

*New in version 3.5.*

The following methods relate to interrogating and manipulating the content (payload) of the message.

**walk()**

The walk() method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use walk() as the iterator in a for loop; each iteration returns the next subpart.

Here’s an example that prints the MIME type of every part of a multipart message structure:
walk iterates over the subparts of any part where is_multipart() returns True, even though msg.get_content_maintype() == 'multipart' may return False. We can see this in our example by making use of the _structure debug helper function:

```python
>>> for part in msg.walk():
...     print(part.get_content_type())
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
text/plain
```
Here the message parts are not multiparts, but they do contain subparts. `is_multipart()` returns `True` and `walk` descends into the subparts.

**get_body**(preferencelist=('related', 'html', 'plain'))

Return the MIME part that is the best candidate to be the “body” of the message.

`preferencelist` must be a sequence of strings from the set `related`, `html`, and `plain`, and indicates the order of preference for the content type of the part returned.

Start looking for candidate matches with the object on which the `get_body` method is called.

If `related` is not included in `preferencelist`, consider the root part (or subpart of the root part) of any related encountered as a candidate if the (sub-)part matches a preference.

When encountering a `multipart/related`, check the `start` parameter and if a part with a matching `Content-ID` is found, consider only it when looking for candidate matches. Otherwise consider only the first (default root) part of the `multipart/related`.

If a part has a `Content-Disposition` header, only consider the part a candidate match if the value of the header is `inline`.

If none of the candidates matches any of the preferences in `preferencelist`, return `None`.

Notes: (1) For most applications the only `preferencelist` combinations that really make sense are (`'plain'`,),
('html', 'plain'), and the default ('related', 'html', 'plain').

(2) Because matching starts with the object on which \texttt{get\_body} is called, calling \texttt{get\_body} on a \texttt{multipart/related} will return the object itself unless \texttt{preferencelist} has a non-default value. (3) Messages (or message parts) that do not specify a \textit{Content-Type} or whose \textit{Content-Type} header is invalid will be treated as if they are of type \texttt{text/plain}, which may occasionally cause \texttt{get\_body} to return unexpected results.

\textbf{iter\_attachments()}

Return an iterator over all of the immediate sub-parts of the message that are not candidate “body” parts. That is, skip the first occurrence of each of \texttt{text/plain}, \texttt{text/html}, \texttt{multipart/related}, or \texttt{multipart/alternative} (unless they are explicitly marked as attachments via \textit{Content-Disposition: attachment}), and return all remaining parts. When applied directly to a \texttt{multipart/related}, return an iterator over the all the related parts except the root part (ie: the part pointed to by the \texttt{start} parameter, or the first part if there is no \texttt{start} parameter or the \texttt{start} parameter doesn’t match the \textit{Content-ID} of any of the parts). When applied directly to a \texttt{multipart/alternative} or a non-\texttt{multipart}, return an empty iterator.

\textbf{iter\_parts()}

Return an iterator over all of the immediate sub-parts of the message, which will be empty for a non-\texttt{multipart}. (See also \texttt{walk()}).

\textbf{get\_content(*args, content\_manager=None, **kw)}
Call the `get_content()` method of the `content_manager`, passing `self` as the message object, and passing along any other arguments or keywords as additional arguments. If `content_manager` is not specified, use the `content_manager` specified by the current `policy`.

```python
set_content(*args, content_manager=None, **kw)
```

Call the `set_content()` method of the `content_manager`, passing `self` as the message object, and passing along any other arguments or keywords as additional arguments. If `content_manager` is not specified, use the `content_manager` specified by the current `policy`.

```python
make_related(boundary=None)
```

Convert a non-multipart message into a multipart/related message, moving any existing Content-headers and payload into a (new) first part of the multipart. If `boundary` is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

```python
make_alternative(boundary=None)
```

Convert a non-multipart or a multipart/related into a multipart/alternative, moving any existing Content-headers and payload into a (new) first part of the multipart. If `boundary` is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).
**make_mixed**(boundary=None)

Convert a non-multipart, a multipart/related, or a multipart-alternative into a multipart/mixed, moving any existing *Content-* headers and payload into a (new) first part of the multipart. If *boundary* is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

**add_related**(args, content_manager=None, **kw)

If the message is a multipart/related, create a new message object, pass all of the arguments to its *set_content()* method, and *attach()* it to the multipart. If the message is a non-multipart, call *make_related()* and then proceed as above. If the message is any other type of multipart, raise a *TypeError*. If *content_manager* is not specified, use the *content_manager* specified by the current *policy*. If the added part has no *Content-Disposition* header, add one with the value *inline*.

**add_alternative**(args, content_manager=None, **kw)

If the message is a multipart/alternative, create a new message object, pass all of the arguments to its *set_content()* method, and *attach()* it to the multipart. If the message is a non-multipart or multipart/related, call *make_alternative()* and then proceed as above. If the message is any other type of multipart, raise a *TypeError*. If *content_manager* is not specified, use the *content_manager* specified by the current *policy*. 
add_attachment(*args, content_manager=None, **kw)

If the message is a multipart/mixed, create a new message object, pass all of the arguments to its set_content() method, and attach() it to the multipart. If the message is a non-multipart, multipart/related, or multipart/alternative, call make_mixed() and then proceed as above. If content_manager is not specified, use the content_manager specified by the current policy. If the added part has no Content-Disposition header, add one with the value attachment. This method can be used both for explicit attachments (Content-Disposition: attachment and inline attachments (Content-Disposition: inline), by passing appropriate options to the content_manager.

clear()

Remove the payload and all of the headers.

clear_content()

Remove the payload and all of the Content- headers, leaving all other headers intact and in their original order.

EmailMessage objects have the following instance attributes:

preamble

The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this
text can become visible.

The *preamble* attribute contains this leading extra-armor text for MIME documents. When the *Parser* discovers some text after the headers but before the first boundary string, it assigns this text to the message’s *preamble* attribute. When the *Generator* is writing out the plain text representation of a MIME message, and it finds the message has a *preamble* attribute, it will write this text in the area between the headers and the first boundary. See *email.parser* and *email.generator* for details.

Note that if the message object has no preamble, the *preamble* attribute will be `None`.

**epilogue**

The *epilogue* attribute acts the same way as the *preamble* attribute, except that it contains text that appears between the last boundary and the end of the message. As with the *preamble*, if there is no epilog text this attribute will be `None`.

**defects**

The *defects* attribute contains a list of all the problems found when parsing this message. See *email.errors* for a detailed description of the possible parsing defects.

**class** `email.message.MIMEPart(policy=default)`

This class represents a subpart of a MIME message. It is identical to *EmailMessage*, except that no *MIME-Version* headers are added when `set_content()` is called, since sub-parts do not need their own *MIME-Version* headers.
Footnotes

Originally added in 3.4 as a provisional module. Docs for legacy message class moved to email.message.Message: Representing an email message using the compat32 API.

[1]
19.1.2. `email.parser`: Parsing email messages

**Source code:** [Lib/email/parser.py](https://docs.python.org/3/library/email.parser.html)

Message object structures can be created in one of two ways: they can be created from whole cloth by creating an `EmailMessage` object, adding headers using the dictionary interface, and adding payload(s) using `set_content()` and related methods, or they can be created by parsing a serialized representation of the email message.

The `email` package provides a standard parser that understands most email document structures, including MIME documents. You can pass the parser a bytes, string or file object, and the parser will return to you the root `EmailMessage` instance of the object structure. For simple, non-MIME messages the payload of this root object will likely be a string containing the text of the message. For MIME messages, the root object will return `True` from its `is_multipart()` method, and the subparts can be accessed via the payload manipulation methods, such as `get_body()`, `iter_parts()`, and `walk()`.

There are actually two parser interfaces available for use, the `Parser` API and the incremental `FeedParser` API. The `Parser` API is most useful if you have the entire text of the message in memory, or if the entire message lives in a file on the file system. `FeedParser` is more appropriate when you are reading the message from a stream which might block waiting for more input (such as reading an email message from a socket). The `FeedParser` can consume and parse the
message incrementally, and only returns the root object when you close the parser.

Note that the parser can be extended in limited ways, and of course you can implement your own parser completely from scratch. All of the logic that connects the email package's bundled parser and the EmailMessage class is embodied in the policy class, so a custom parser can create message object trees any way it finds necessary by implementing custom versions of the appropriate policy methods.
19.1.2.1. FeedParser API

The BytesFeedParser, imported from the email.feedparser module, provides an API that is conducive to incremental parsing of email messages, such as would be necessary when reading the text of an email message from a source that can block (such as a socket). The BytesFeedParser can of course be used to parse an email message fully contained in a bytes-like object, string, or file, but the BytesParser API may be more convenient for such use cases. The semantics and results of the two parser APIs are identical.

The BytesFeedParser’s API is simple; you create an instance, feed it a bunch of bytes until there’s no more to feed it, then close the parser to retrieve the root message object. The BytesFeedParser is extremely accurate when parsing standards-compliant messages, and it does a very good job of parsing non-compliant messages, providing information about how a message was deemed broken. It will populate a message object’s defects attribute with a list of any problems it found in a message. See the email.errors module for the list of defects that it can find.

Here is the API for the BytesFeedParser:

class email.parser.BytesFeedParser(_factory=None, *, policy=policy.compat32)

Create a BytesFeedParser instance. Optional _factory is a no-argument callable; if not specified use the message_factory from the policy. Call _factory whenever a new message object is needed.

If policy is specified use the rules it specifies to update the
representation of the message. If \textit{policy} is not set, use the \texttt{compat32} policy, which maintains backward compatibility with the Python 3.2 version of the email package and provides \texttt{Message} as the default factory. All other policies provide \texttt{EmailMessage} as the default \_\texttt{factory}. For more information on what else \textit{policy} controls, see the \texttt{policy} documentation.

Note: \textbf{The policy keyword should always be specified;} The default will change to \texttt{email.policy.default} in a future version of Python.

\textit{New in version 3.2.}

\textit{Changed in version 3.3:} Added the \texttt{policy} keyword.

\textit{Changed in version 3.6:} \_\texttt{factory} defaults to the policy \texttt{message_factory}.

\texttt{feed(data)}

Feed the parser some more data. \texttt{data} should be a \texttt{bytes-like object} containing one or more lines. The lines can be partial and the parser will stitch such partial lines together properly. The lines can have any of the three common line endings: carriage return, newline, or carriage return and newline (they can even be mixed).

\texttt{close()}  
Complete the parsing of all previously fed data and return the root message object. It is undefined what happens if \texttt{feed()} is called after this method has been called.

\texttt{class email.parser.FeedParser(_factory=None, *, policy=policy.compat32)}
Works like `BytesFeedParser` except that the input to the `feed()` method must be a string. This is of limited utility, since the only way for such a message to be valid is for it to contain only ASCII text or, if `utf8` is `True`, no binary attachments.

*Changed in version 3.3:* Added the `policy` keyword.
19.1.2.2. Parser API

The `BytesParser` class, imported from the `email.parser` module, provides an API that can be used to parse a message when the complete contents of the message are available in a bytes-like object or file. The `email.parser` module also provides `Parser` for parsing strings, and header-only parsers, `BytesHeaderParser` and `HeaderParser`, which can be used if you're only interested in the headers of the message. `BytesHeaderParser` and `HeaderParser` can be much faster in these situations, since they do not attempt to parse the message body, instead setting the payload to the raw body.

```python
class email.parser.BytesParser(_class=None, *, policy=policy.compat32)

Create a `BytesParser` instance. The `_class` and `policy` arguments have the same meaning and semantics as the `_factory` and `policy` arguments of `BytesFeedParser`.

Note: The policy keyword should always be specified; The default will change to `email.policy.default` in a future version of Python.

Changed in version 3.3: Removed the strict argument that was deprecated in 2.4. Added the `policy` keyword.

Changed in version 3.6: `_class` defaults to the policy `message_factory`.
```

```python
parse(fp, headersonly=False)

Read all the data from the binary file-like object `fp`, parse the resulting bytes, and return the message object. `fp` must support
both the `readline()` and the `read()` methods.

The bytes contained in `fp` must be formatted as a block of RFC 5322 (or, if `utf8` is True, RFC 6532) style headers and header continuation lines, optionally preceded by an envelope header. The header block is terminated either by the end of the data or by a blank line. Following the header block is the body of the message (which may contain MIME-encoded subparts, including subparts with a `Content-Transfer-Encoding` of 8bit).

Optional `headersonly` is a flag specifying whether to stop parsing after reading the headers or not. The default is `False`, meaning it parses the entire contents of the file.

`parsebytes`(*`bytes`, `headersonly=False`*)

Similar to the `parse()` method, except it takes a bytes-like object instead of a file-like object. Calling this method on a bytes-like object is equivalent to wrapping `bytes` in a `BytesIO` instance first and calling `parse()`.

Optional `headersonly` is as with the `parse()` method.

*New in version 3.2.*

class `email.parser.BytesHeaderParser`(_`class=None`, `*`, `policy=policy.compat32`)

Exactly like `BytesParser`, except that `headersonly` defaults to `True`.

*New in version 3.3.*

class `email.parser.Parser`(_`class=None`, `*`, `policy=policy.compat32`)

This class is parallel to BytesParser, but handles string input.

*Changed in version 3.3:* Removed the strict argument. Added the policy keyword.

*Changed in version 3.6:* _class defaults to the policy message_factory.

**parse**(fp, headersonly=False)

Read all the data from the text-mode file-like object fp, parse the resulting text, and return the root message object. fp must support both the readline() and the read() methods on file-like objects.

Other than the text mode requirement, this method operates like BytesParser.parse().

**parsestr**(text, headersonly=False)

Similar to the parse() method, except it takes a string object instead of a file-like object. Calling this method on a string is equivalent to wrapping text in a StringIO instance first and calling parse().

Optional headersonly is as with the parse() method.

```python
class email.parser.HeaderParser(_class=None, *, policy=policy.compat32)
```

Exactly like Parser, except that headersonly defaults to True.

Since creating a message object structure from a string or a file object is such a common task, four functions are provided as a convenience. They are available in the top-level email package namespace.
email.message_from_bytes(s, _class=None, *, policy=policy.compat32)

Return a message object structure from a bytes-like object. This is equivalent to BytesParser().parsebytes(s). Optional _class and strict are interpreted as with the BytesParser class constructor.

New in version 3.2.

Changed in version 3.3: Removed the strict argument. Added the policy keyword.

message_from_binary_file(fp, _class=None, *, policy=policy.compat32)

Return a message object structure tree from an open binary file object. This is equivalent to BytesParser().parse(fp). _class and policy are interpreted as with the BytesParser class constructor.

New in version 3.2.

Changed in version 3.3: Removed the strict argument. Added the policy keyword.

eemail.message_from_string(s, _class=None, *, policy=policy.compat32)

Return a message object structure from a string. This is equivalent to Parser().parsestr(s). _class and policy are interpreted as with the Parser class constructor.

Changed in version 3.3: Removed the strict argument. Added the policy keyword.
email.message_from_file(fp, _class=None, *, policy=policy.compat32)

Return a message object structure tree from an open file object. This is equivalent to Parser().parse(fp). _class and policy are interpreted as with the Parser class constructor.

Changed in version 3.3: Removed the strict argument. Added the policy keyword.

Changed in version 3.6: _class defaults to the policy message_factory.

Here's an example of how you might use message_from_bytes() at an interactive Python prompt:

```python
>>> import email
>>> msg = email.message_from_bytes(myBytes)
```
19.1.2.3. Additional notes

Here are some notes on the parsing semantics:

- Most non-
  *multipart* type messages are parsed as a single message object with a string payload. These objects will return `False` for `is_multipart()`, and `iter_parts()` will yield an empty list.

- All `multipart` type messages will be parsed as a container message object with a list of sub-message objects for their payload. The outer container message will return `True` for `is_multipart()`, and `iter_parts()` will yield a list of subparts.

- Most messages with a content type of `message/*` (such as `message/delivery-status` and `message/rfc822`) will also be parsed as container object containing a list payload of length 1. Their `is_multipart()` method will return `True`. The single element yielded by `iter_parts()` will be a sub-message object.

- Some non-standards-compliant messages may not be internally consistent about their `multipart`-edness. Such messages may have a `Content-Type` header of type `multipart`, but their `is_multipart()` method may return `False`. If such messages were parsed with the `FeedParser`, they will have an instance of the `MultipartInvariantViolationDefect` class in their `defects` attribute list. See `email.errors` for details.
19.1. `email` — An email and MIME handling package
One of the most common tasks is to generate the flat (serialized) version of the email message represented by a message object structure. You will need to do this if you want to send your message via `smtplib.SMTP.sendmail()` or the `nntplib` module, or print the message on the console. Taking a message object structure and producing a serialized representation is the job of the generator classes.

As with the `email.parser` module, you aren’t limited to the functionality of the bundled generator; you could write one from scratch yourself. However the bundled generator knows how to generate most email in a standards-compliant way, should handle MIME and non-MIME email messages just fine, and is designed so that the bytes-oriented parsing and generation operations are inverses, assuming the same non-transforming policy is used for both. That is, parsing the serialized byte stream via the `BytesParser` class and then regenerating the serialized byte stream using `BytesGenerator` should produce output identical to the input [1]. (On the other hand, using the generator on an `EmailMessage` constructed by program may result in changes to the `EmailMessage` object as defaults are filled in.)

The `Generator` class can be used to flatten a message into a text (as opposed to binary) serialized representation, but since Unicode
cannot represent binary data directly, the message is of necessity transformed into something that contains only ASCII characters, using the standard email RFC Content Transfer Encoding techniques for encoding email messages for transport over channels that are not “8 bit clean”.

```python
class email.generator.BytesGenerator(outfp, mangle_from_=None, maxheaderlen=None, *, policy=None)
```

Return a `BytesGenerator` object that will write any message provided to the `flatten()` method, or any surrogateescape encoded text provided to the `write()` method, to the file-like object `outfp`. `outfp` must support a `write` method that accepts binary data.

If optional `mangle_from_` is True, put a `>` character in front of any line in the body that starts with the exact string "From ", that is From followed by a space at the beginning of a line. `mangle_from_` defaults to the value of the `mangle_from_` setting of the `policy` (which is True for the `compat32` policy and False for all others). `mangle_from_` is intended for use when messages are stored in unix mbox format (see `mailbox` and WHY THE CONTENT-LENGTH FORMAT IS BAD).

If `maxheaderlen` is not None, refold any header lines that are longer than `maxheaderlen`, or if 0, do not rewrap any headers. If `maxheaderlen` is None (the default), wrap headers and other message lines according to the `policy` settings.

If `policy` is specified, use that policy to control message generation. If `policy` is None (the default), use the policy associated with the `Message` or `EmailMessage` object passed to `flatten` to control the message generation. See `email.policy` for details on what
policy controls.

New in version 3.2.

Changed in version 3.3: Added the policy keyword.

Changed in version 3.6: The default behavior of the mangle_from_ and maxheaderlen parameters is to follow the policy.

\textbf{flatten}(\texttt{msg, unixfrom=False, linesep=None})

Print the textual representation of the message object structure rooted at \texttt{msg} to the output file specified when the \texttt{BytesGenerator} instance was created.

If the \texttt{policy} option \texttt{cte_type} is 8bit (the default), copy any headers in the original parsed message that have not been modified to the output with any bytes with the high bit set reproduced as in the original, and preserve the non-ASCII Content-Transfer-Encoding of any body parts that have them. If \texttt{cte_type} is 7bit, convert the bytes with the high bit set as needed using an ASCII-compatible Content-Transfer-Encoding. That is, transform parts with non-ASCII Content-Transfer-Encoding (Content-Transfer-Encoding: 8bit) to an ASCII compatible Content-Transfer-Encoding, and encode RFC-invalid non-ASCII bytes in headers using the MIME unknown-8bit character set, thus rendering them RFC-compliant.

If \texttt{unixfrom} is True, print the envelope header delimiter used by the Unix mailbox format (see \texttt{mailbox}) before the first of the RFC 5322 headers of the root message object. If the root object has no envelope header, craft a standard one. The default is False. Note that for subparts, no envelope header is ever printed.
If `linesep` is not `None`, use it as the separator character between all the lines of the flattened message. If `linesep` is `None` (the default), use the value specified in the `policy`.

**clone**(fp)

Return an independent clone of this `BytesGenerator` instance with the exact same option settings, and `fp` as the new `outfp`.

**write**(s)

Encode `s` using the ASCII codec and the surrogateescape error handler, and pass it to the `write` method of the `outfp` passed to the `BytesGenerator`'s constructor.

As a convenience, `EmailMessage` provides the methods `as_bytes()` and `bytes(aMessage)` (a.k.a. `__bytes__()`), which simplify the generation of a serialized binary representation of a message object. For more detail, see `email.message`.

Because strings cannot represent binary data, the `Generator` class must convert any binary data in any message it flattens to an ASCII compatible format, by converting them to an ASCII compatible `Content-Transfer_Encoding`. Using the terminology of the email RFCs, you can think of this as `Generator` serializing to an I/O stream that is not “8 bit clean”. In other words, most applications will want to be using `BytesGenerator`, and not `Generator`.

**class** `email.generator.Generator`(outfp, mangle_from_=None, maxheaderlen=None, *, policy=None)

Return a `Generator` object that will write any message provided to the `flatten()` method, or any text provided to the `write()` method, to the file-like object `outfp`. `outfp` must support a write
method that accepts string data.

If optional `mangle_from_` is True, put a > character in front of any line in the body that starts with the exact string "From ", that is From followed by a space at the beginning of a line. `mangle_from_` defaults to the value of the `mangle_from_` setting of the policy (which is True for the compat32 policy and False for all others). `mangle_from_` is intended for use when messages are stored in unix mbox format (see mailbox and WHY THE CONTENT-LENGTH FORMAT IS BAD).

If `maxheaderlen` is not None, refold any header lines that are longer than `maxheaderlen`, or if 0, do not rewrap any headers. If `manheaderlen` is None (the default), wrap headers and other message lines according to the policy settings.

If `policy` is specified, use that policy to control message generation. If `policy` is None (the default), use the policy associated with the Message or EmailMessage object passed to flatten to control the message generation. See email.policy for details on what policy controls.

*Changed in version 3.3:* Added the `policy` keyword.

*Changed in version 3.6:* The default behavior of the `mangle_from_` and `maxheaderlen` parameters is to follow the policy.

**flatten**(msg, unixfrom=False, linesep=None)

Print the textual representation of the message object structure rooted at `msg` to the output file specified when the Generator instance was created.

If the `policy` option cte_type is 8bit, generate the
message as if the option were set to 7bit. (This is required because strings cannot represent non-ASCII bytes.) Convert any bytes with the high bit set as needed using an ASCII-compatible Content-Transfer-Encoding. That is, transform parts with non-ASCII Content-Transfer-Encoding (Content-Transfer-Encoding: 8bit) to an ASCII compatible Content-Transfer-Encoding, and encode RFC-invalid non-ASCII bytes in headers using the MIME unknown-8bit character set, thus rendering them RFC-compliant.

If unixfrom is True, print the envelope header delimiter used by the Unix mailbox format (see mailbox) before the first of the RFC 5322 headers of the root message object. If the root object has no envelope header, craft a standard one. The default is False. Note that for subparts, no envelope header is ever printed.

If linesep is not None, use it as the separator character between all the lines of the flattened message. If linesep is None (the default), use the value specified in the policy.

*Changed in version 3.2:* Added support for re-encoding 8bit message bodies, and the linesep argument.

**clone**(fp)

Return an independent clone of this Generator instance with the exact same options, and fp as the new outfp.

**write**(s)

Write s to the write method of the outfp passed to the Generator's constructor. This provides just enough file-like API for Generator instances to be used in the print()
function.

As a convenience, EmailMessage provides the methods as_string() and str(aMessage) (a.k.a. __str__()), which simplify the generation of a formatted string representation of a message object. For more detail, see email.message.

The email.generator module also provides a derived class, DecodedGenerator, which is like the Generator base class, except that non-text parts are not serialized, but are instead represented in the output stream by a string derived from a template filled in with information about the part.

class email.generator. **DecodedGenerator** (outfp, mangle_from_=None, maxheaderlen=None, fmt=None, *, policy=None)

Act like Generator, except that for any subpart of the message passed to Generator.flatten(), if the subpart is of main type text, print the decoded payload of the subpart, and if the main type is not text, instead of printing it fill in the string fmt using information from the part and print the resulting filled-in string.

To fill in fmt, execute fmt % part_info, where part_info is a dictionary composed of the following keys and values:

- type – Full MIME type of the non-text part
- maintype – Main MIME type of the non-text part
- subtype – Sub-MIME type of the non-text part
- filename – Filename of the non-text part
- description – Description associated with the non-text part
- encoding – Content transfer encoding of the non-text part

If fmt is None, use the following default fmt:
“[Non-text (%(type)s) part of message omitted, filename % (filename)s]”

Optional _mangle_from_ and maxheaderlen are as with the Generator base class.

Footnotes

This statement assumes that you use the appropriate setting for unixfrom, and that there are no policy settings calling for automatic adjustments (for example, refold_source must be none, which is not the default). It is also not 100% true, since if the message does not conform to the RFC standards occasionally information about the exact original text is lost during parsing error recovery. It is a goal to fix these latter edge cases when possible.

[1]
19.1. **email** — An email and MIME handling package
19.1.4. **email.policy**: Policy Objects

*New in version 3.3.*

**Source code:** `Lib/email/policy.py`

The `email` package's prime focus is the handling of email messages as described by the various email and MIME RFCs. However, the general format of email messages (a block of header fields each consisting of a name followed by a colon followed by a value, the whole block followed by a blank line and an arbitrary ‘body’), is a format that has found utility outside of the realm of email. Some of these uses conform fairly closely to the main email RFCs, some do not. Even when working with email, there are times when it is desirable to break strict compliance with the RFCs, such as generating emails that interoperate with email servers that do not themselves follow the standards, or that implement extensions you want to use in ways that violate the standards.

Policy objects give the email package the flexibility to handle all these disparate use cases.

A **Policy** object encapsulates a set of attributes and methods that control the behavior of various components of the email package during use. Policy instances can be passed to various classes and methods in the email package to alter the default behavior. The settable values and their defaults are described below.

There is a default policy used by all classes in the email package. For
all of the `parser` classes and the related convenience functions, and for the `Message` class, this is the `Compat32` policy, via its corresponding pre-defined instance `compat32`. This policy provides for complete backward compatibility (in some cases, including bug compatibility) with the pre-Python3.3 version of the email package.

This default value for the `policy` keyword to `EmailMessage` is the `EmailPolicy` policy, via its pre-defined instance `default`.

When a `Message` or `EmailMessage` object is created, it acquires a policy. If the message is created by a `parser`, a policy passed to the parser will be the policy used by the message it creates. If the message is created by the program, then the policy can be specified when it is created. When a message is passed to a `generator`, the generator uses the policy from the message by default, but you can also pass a specific policy to the generator that will override the one stored on the message object.

The default value for the `policy` keyword for the `email.parser` classes and the parser convenience functions will be changing in a future version of Python. Therefore you should always specify explicitly which policy you want to use when calling any of the classes and functions described in the `parser` module.

The first part of this documentation covers the features of `Policy`, an abstract base class that defines the features that are common to all policy objects, including `compat32`. This includes certain hook methods that are called internally by the email package, which a custom policy could override to obtain different behavior. The second part describes the concrete classes `EmailPolicy` and `Compat32`, which implement the hooks that provide the standard behavior and the backward compatible behavior and features, respectively.
Policy instances are immutable, but they can be cloned, accepting
the same keyword arguments as the class constructor and returning a
new Policy instance that is a copy of the original but with the
specified attributes values changed.

As an example, the following code could be used to read an email
message from a file on disk and pass it to the system `sendmail`
program on a Unix system:

```python
>>> from email import message_from_binary_file
>>> from email.generator import BytesGenerator
>>> from email import policy
>>> from subprocess import Popen, PIPE
>>> with open('mymsg.txt', 'rb') as f:
...     msg = message_from_binary_file(f, policy=p)
>>> p = Popen(['sendmail', msg['To'].addresses[0]],
>>>            stdin=PIPE)
>>> g = BytesGenerator(p.stdin, policy=msg.policy.clone)
>>> g.flatten(msg)
>>> p.stdin.close()
>>> rc = p.wait()
```

Here we are telling BytesGenerator to use the RFC correct line
separator characters when creating the binary string to feed into
sendmail's stdin, where the default policy would use \n line
separators.

Some email package methods accept a policy keyword argument,
allowing the policy to be overridden for that method. For example, the
following code uses the as_bytes() method of the msg object from
the previous example and writes the message to a file using the native
line separators for the platform on which it is running:

```python
>>> import os
```
Policy objects can also be combined using the addition operator, producing a policy object whose settings are a combination of the non-default values of the summed objects:

```python
>>> compat_SMTP = policy.compat32.clone(linesep='
')
>>> compat_strict = policy.compat32.clone(raise_on_defect)
>>> compat_strict_SMTP = compat_SMTP + compat_strict
```

This operation is not commutative; that is, the order in which the objects are added matters. To illustrate:

```python
>>> policy100 = policy.compat32.clone(max_line_length=100)
>>> policy80 = policy.compat32.clone(max_line_length=80)
>>> apolicy = policy100 + policy80
>>> apolicy.max_line_length
80
>>> apolicy = policy80 + policy100
>>> apolicy.max_line_length
100
```

```python
class email.policy.Policy(**kw)
```

This is the abstract base class for all policy classes. It provides default implementations for a couple of trivial methods, as well as the implementation of the immutability property, the clone() method, and the constructor semantics.

The constructor of a policy class can be passed various keyword arguments. The arguments that may be specified are any non-
method properties on this class, plus any additional non-method properties on the concrete class. A value specified in the constructor will override the default value for the corresponding attribute.

This class defines the following properties, and thus values for the following may be passed in the constructor of any policy class:

- **max_line_length**
  The maximum length of any line in the serialized output, not counting the end of line character(s). Default is 78, per RFC 5322. A value of 0 or None indicates that no line wrapping should be done at all.

- **linesep**
  The string to be used to terminate lines in serialized output. The default is \n because that's the internal end-of-line discipline used by Python, though \r\n is required by the RFCs.

- **cte_type**
  Controls the type of Content Transfer Encodings that may be or are required to be used. The possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>7bit</td>
<td>all data must be “7 bit clean” (ASCII-only). This means that where necessary data will be encoded using either quoted-printable or base64 encoding.</td>
</tr>
<tr>
<td>8bit</td>
<td>data is not constrained to be 7 bit clean. Data in headers is still required to be ASCII-only and so will be encoded (see fold_binary() and utf8 below for exceptions), but body parts may use the 8bit CTE.</td>
</tr>
</tbody>
</table>

A cte_type value of 8bit only works with BytesGenerator, not Generator, because strings cannot
contain binary data. If a Generator is operating under a policy that specifies `cte_type=8bit`, it will act as if `cte_type` is `7bit`.

**raise_on_defect**
If `True`, any defects encountered will be raised as errors. If `False` (the default), defects will be passed to the `register_defect()` method.

**mangle_from_**
If `True`, lines starting with “From “ in the body are escaped by putting a `>` in front of them. This parameter is used when the message is being serialized by a generator. Default: `False`.

*New in version 3.5:* The `mangle_from_` parameter.

**message_factory**
A factory function for constructing a new empty message object. Used by the parser when building messages. Defaults to `None`, in which case `Message` is used.

*New in version 3.6.*

The following `Policy` method is intended to be called by code using the email library to create policy instances with custom settings:

**clone(**kw)**
Return a new `Policy` instance whose attributes have the same values as the current instance, except where those attributes are given new values by the keyword arguments.

The remaining `Policy` methods are called by the email package
code, and are not intended to be called by an application using the email package. A custom policy must implement all of these methods.

**handle_defect** *(obj, defect)*

Handle a *defect* found on *obj*. When the email package calls this method, *defect* will always be a subclass of Defect.

The default implementation checks the `raise_on_defect` flag. If it is `True`, *defect* is raised as an exception. If it is `False` (the default), *obj* and *defect* are passed to `register_defect()`.

**register_defect** *(obj, defect)*

Register a *defect* on *obj*. In the email package, *defect* will always be a subclass of Defect.

The default implementation calls the `append` method of the *defects* attribute of *obj*. When the email package calls `handle_defect`, *obj* will normally have a *defects* attribute that has an `append` method. Custom object types used with the email package (for example, custom *Message* objects) should also provide such an attribute, otherwise defects in parsed messages will raise unexpected errors.

**header_max_count** *(name)*

Return the maximum allowed number of headers named *name*.

Called when a header is added to an *EmailMessage* or *Message* object. If the returned value is not `0` or `None`, and there are already a number of headers with the name *name* greater than or equal to the value returned, a `ValueError` is
Because the default behavior of Message.__setitem__ is to append the value to the list of headers, it is easy to create duplicate headers without realizing it. This method allows certain headers to be limited in the number of instances of that header that may be added to a Message programmatically. (The limit is not observed by the parser, which will faithfully produce as many headers as exist in the message being parsed.)

The default implementation returns None for all header names.

**header_source_parse(sourcelines)**

The email package calls this method with a list of strings, each string ending with the line separation characters found in the source being parsed. The first line includes the field header name and separator. All whitespace in the source is preserved. The method should return the (name, value) tuple that is to be stored in the Message to represent the parsed header.

If an implementation wishes to retain compatibility with the existing email package policies, name should be the case preserved name (all characters up to the ':' separator), while value should be the unfolded value (all line separator characters removed, but whitespace kept intact), stripped of leading whitespace.

sourcelines may contain surrogateescaped binary data.

There is no default implementation

**header_store_parse(name, value)**
The email package calls this method with the name and value provided by the application program when the application program is modifying a Message programmatically (as opposed to a Message created by a parser). The method should return the (name, value) tuple that is to be stored in the Message to represent the header.

If an implementation wishes to retain compatibility with the existing email package policies, the name and value should be strings or string subclasses that do not change the content of the passed in arguments.

There is no default implementation

header_fetch_parse(name, value)

The email package calls this method with the name and value currently stored in the Message when that header is requested by the application program, and whatever the method returns is what is passed back to the application as the value of the header being retrieved. Note that there may be more than one header with the same name stored in the Message; the method is passed the specific name and value of the header destined to be returned to the application.

value may contain surrogateescaped binary data. There should be no surrogateescaped binary data in the value returned by the method.

There is no default implementation

fold(name, value)

The email package calls this method with the name and value currently stored in the Message for a given header. The
method should return a string that represents that header “folded” correctly (according to the policy settings) by composing the \textit{name} with the \textit{value} and inserting \texttt{linesep} characters at the appropriate places. See \texttt{RFC 5322} for a discussion of the rules for folding email headers.

\textit{value} may contain surrogateescaped binary data. There should be no surrogateescaped binary data in the string returned by the method.

\texttt{fold\_binary}(\textit{name}, \textit{value})

The same as \texttt{fold()}, except that the returned value should be a bytes object rather than a string.

\textit{value} may contain surrogateescaped binary data. These could be converted back into binary data in the returned bytes object.

\texttt{class email.policy.\texttt{EmailPolicy}(**kw)}

This concrete \texttt{Policy} provides behavior that is intended to be fully compliant with the current email RFCs. These include (but are not limited to) \texttt{RFC 5322}, \texttt{RFC 2047}, and the current MIME RFCs.

This policy adds new header parsing and folding algorithms. Instead of simple strings, headers are \texttt{str} subclasses with attributes that depend on the type of the field. The parsing and folding algorithm fully implement \texttt{RFC 2047} and \texttt{RFC 5322}.

The default value for the \texttt{message\_factory} attribute is \texttt{EmailMessage}.

In addition to the settable attributes listed above that apply to all policies, this policy adds the following additional attributes:
utf8

If False, follow **RFC 5322**, supporting non-ASCII characters in headers by encoding them as “encoded words”. If True, follow **RFC 6532** and use utf-8 encoding for headers. Messages formatted in this way may be passed to SMTP servers that support the SMTPUTF8 extension (**RFC 6531**).

refold_source

If the value for a header in the `Message` object originated from a parser (as opposed to being set by a program), this attribute indicates whether or not a generator should refold that value when transforming the message back into serialized form. The possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>all source values use original folding</td>
</tr>
<tr>
<td>long</td>
<td>source values that have any line that is longer than <code>max_line_length</code> will be refolded</td>
</tr>
<tr>
<td>all</td>
<td>all values are refolded.</td>
</tr>
</tbody>
</table>

The default is `long`.

header_factory

A callable that takes two arguments, `name` and `value`, where `name` is a header field name and `value` is an unfolded header field value, and returns a string subclass that represents that header. A default `header_factory` (see `headerregistry`) is provided that supports custom parsing for the various address and date **RFC 5322** header field types, and the major MIME header field stypes. Support for additional custom parsing will be added in the future.
**content_manager**

An object with at least two methods: get_content and set_content. When the `get_content()` or `set_content()` method of an `EmailMessage` object is called, it calls the corresponding method of this object, passing it the message object as its first argument, and any arguments or keywords that were passed to it as additional arguments. By default `content_manager` is set to `raw_data_manager`.

*New in version 3.4.*

The class provides the following concrete implementations of the abstract methods of `Policy`:

**header_max_count** *(name)*

Returns the value of the `max_count` attribute of the specialized class used to represent the header with the given name.

**header_source_parse** *(sourcelines)*

The name is parsed as everything up to the `:`, and returned unmodified. The value is determined by stripping leading whitespace off the remainder of the first line, joining all subsequent lines together, and stripping any trailing carriage return or linefeed characters.

**header_store_parse** *(name, value)*

The name is returned unchanged. If the input value has a `name` attribute and it matches `name` ignoring case, the value is returned unchanged. Otherwise the `name` and `value` are passed to `header_factory`, and the resulting header object is returned as the value. In this case a `ValueError` is raised if the input value contains CR or LF characters.
**header_fetch_parse**(*name, value*)

If the value has a `name` attribute, it is returned to unmodified. Otherwise the `name`, and the `value` with any CR or LF characters removed, are passed to the `header_factory`, and the resulting header object is returned. Any surrogateescaped bytes get turned into the unicode unknown-character glyph.

**fold**(*name, value*)

Header folding is controlled by the `refold_source` policy setting. A value is considered to be a ‘source value’ if and only if it does not have a `name` attribute (having a `name` attribute means it is a header object of some sort). If a source value needs to be refolded according to the policy, it is converted into a header object by passing the `name` and the `value` with any CR and LF characters removed to the `header_factory`. Folding of a header object is done by calling its `fold` method with the current policy.

Source values are split into lines using `splitlines()`. If the value is not to be refolded, the lines are rejoined using the `linesep` from the policy and returned. The exception is lines containing non-ascii binary data. In that case the value is refolded regardless of the `refold_source` setting, which causes the binary data to be CTE encoded using the unknown-8bit charset.

**fold_binary**(*name, value*)

The same as `fold()` if `cte_type` is 7bit, except that the returned value is bytes.

If `cte_type` is 8bit, non-ASCII binary data is converted back into bytes. Headers with binary data are not refolded,
regardless of the refold_header setting, since there is no way to know whether the binary data consists of single byte characters or multibyte characters.

The following instances of EmailPolicy provide defaults suitable for specific application domains. Note that in the future the behavior of these instances (in particular the HTTP instance) may be adjusted to conform even more closely to the RFCs relevant to their domains.

email.policy.default
An instance of EmailPolicy with all defaults unchanged. This policy uses the standard Python \n line endings rather than the RFC-correct \r\n.

e-mail.policy.SMTP
Suitable for serializing messages in conformance with the email RFCs. Like default, but with linesep set to \r\n, which is RFC compliant.

e-mail.policy.SMTPUTF8
The same as SMTP except that utf8 is True. Useful for serializing messages to a message store without using encoded words in the headers. Should only be used for SMTP transmission if the sender or recipient addresses have non-ASCII characters (the smtplib.SMTP.send_message() method handles this automatically).

e-mail.policy.HTTP
Suitable for serializing headers with for use in HTTP traffic. Like SMTP except that max_line_length is set to None (unlimited).

e-mail.policy.strict
Convenience instance. The same as `default` except that `raise_on_defect` is set to `True`. This allows any policy to be made strict by writing:

```python
somepolicy + policy.strict
```

With all of these `EmailPolicies`, the effective API of the email package is changed from the Python 3.2 API in the following ways:

- Setting a header on a `Message` results in that header being parsed and a header object created.
- Fetching a header value from a `Message` results in that header being parsed and a header object created and returned.
- Any header object, or any header that is refolded due to the policy settings, is folded using an algorithm that fully implements the RFC folding algorithms, including knowing where encoded words are required and allowed.

From the application view, this means that any header obtained through the `EmailMessage` is a header object with extra attributes, whose string value is the fully decoded unicode value of the header. Likewise, a header may be assigned a new value, or a new header created, using a unicode string, and the policy will take care of converting the unicode string into the correct RFC encoded form.

The header objects and their attributes are described in `headerregistry`.

```python
class email.policy.Compat32(**kw)
```

This concrete `Policy` is the backward compatibility policy. It replicates the behavior of the email package in Python 3.2. The `policy` module also defines an instance of this class, `compat32`,
that is used as the default policy. Thus the default behavior of the
email package is to maintain compatibility with Python 3.2.

The following attributes have values that are different from the
Policy default:

**mangle_from_**

The default is True.

The class provides the following concrete implementations of the
abstract methods of Policy:

**header_source_parse**(sourcelines)

The name is parsed as everything up to the `:` and returned
unmodified. The value is determined by stripping leading
whitespace off the remainder of the first line, joining all
subsequent lines together, and stripping any trailing carriage
return or linefeed characters.

**header_store_parse**(name, value)

The name and value are returned unmodified.

**header_fetch_parse**(name, value)

If the value contains binary data, it is converted into a Header
object using the **unknown-8bit** charset. Otherwise it is
returned unmodified.

**fold**(name, value)

Headers are folded using the Header folding algorithm, which
preserves existing line breaks in the value, and wraps each
resulting line to the **max_line_length**. Non-ASCII binary
data are CTE encoded using the **unknown-8bit** charset.
**fold_binary**(name, value)

Headers are folded using the Header folding algorithm, which preserves existing line breaks in the value, and wraps each resulting line to the max_line_length. If cte_type is 7bit, non-ascii binary data is CTE encoded using the unknown-8bit charset. Otherwise the original source header is used, with its existing line breaks and any (RFC invalid) binary data it may contain.

email.policy.**compat32**

An instance of Compat32, providing backward compatibility with the behavior of the email package in Python 3.2.

**Footnotes**

[1] Originally added in 3.3 as a provisional feature.
19.1.5. **email.errors**: Exception and Defect classes

**Source code**: Lib/email/errors.py

The following exception classes are defined in the `email.errors` module:

*exception* `email.errors.MessageError`

This is the base class for all exceptions that the `email` package can raise. It is derived from the standard `Exception` class and defines no additional methods.

*exception* `email.errors.MessageParseError`

This is the base class for exceptions raised by the `Parser` class. It is derived from `MessageError`. This class is also used internally by the parser used by `headerregistry`.

*exception* `email.errors.HeaderParseError`

Raised under some error conditions when parsing the RFC 5322 headers of a message, this class is derived from `MessageParseError`. The `set_boundary()` method will raise this error if the content type is unknown when the method is called. `Header` may raise this error for certain base64 decoding errors, and when an attempt is made to create a header that appears to contain an embedded header (that is, there is what is supposed to be a continuation line that has no leading whitespace and looks like a header).
exception email.errors.BoundaryError

Deprecated and no longer used.

exception email.errors.MultipartConversionError

Raised when a payload is added to a Message object using add_payload(), but the payload is already a scalar and the message’s Content-Type main type is not either multipart or missing. MultipartConversionError multiply inherits from MessageError and the built-in TypeError.

Since Message.add_payload() is deprecated, this exception is rarely raised in practice. However the exception may also be raised if the attach() method is called on an instance of a class derived from MIMENonMultipart (e.g. MIMEImage).

Here is the list of the defects that the FeedParser can find while parsing messages. Note that the defects are added to the message where the problem was found, so for example, if a message nested inside a multipart/alternative had a malformed header, that nested message object would have a defect, but the containing messages would not.

All defect classes are subclassed from email.errors.MessageDefect.

- NoBoundaryInMultipartDefect – A message claimed to be a multipart, but had no boundary parameter.

- StartBoundaryNotFoundDefect – The start boundary claimed in the Content-Type header was never found.

- CloseBoundaryNotFoundDefect – A start boundary was found, but no corresponding close boundary was ever found.
New in version 3.3.

- FirstHeaderLineIsContinuationDefect – The message had a continuation line as its first header line.

- MisplacedEnvelopeHeaderDefect - A “Unix From” header was found in the middle of a header block.

- MissingHeaderBodySeparatorDefect - A line was found while parsing headers that had no leading white space but contained no ‘:’. Parsing continues assuming that the line represents the first line of the body.

New in version 3.3.

- MalformedHeaderDefect – A header was found that was missing a colon, or was otherwise malformed.

  Deprecated since version 3.3: This defect has not been used for several Python versions.

- MultipartInvariantViolationDefect – A message claimed to be a multipart, but no subparts were found. Note that when a message has this defect, its is_multipart() method may return false even though its content type claims to be multipart.

- InvalidBase64PaddingDefect – When decoding a block of base64 encoded bytes, the padding was not correct. Enough padding is added to perform the decode, but the resulting decoded bytes may be invalid.

- InvalidBase64CharactersDefect – When decoding a block of base64 encoded bytes, characters outside the base64 alphabet
were encountered. The characters are ignored, but the resulting decoded bytes may be invalid.
19.1. `email` — An email and MIME handling package
19.1.6. 

**email.headerregistry**: Custom Header Objects

**Source code**: Lib/email/headerregistry.py

*New in version 3.6: [1]*

Headers are represented by customized subclasses of `str`. The particular class used to represent a given header is determined by the `header_factory` of the `policy` in effect when the headers are created. This section documents the particular `header_factory` implemented by the email package for handling [RFC 5322](https://tools.ietf.org/html/rfc5322) compliant email messages, which not only provides customized header objects for various header types, but also provides an extension mechanism for applications to add their own custom header types.

When using any of the policy objects derived from `EmailPolicy`, all headers are produced by `HeaderRegistry` and have `BaseHeader` as their last base class. Each header class has an additional base class that is determined by the type of the header. For example, many headers have the class `UnstructuredHeader` as their other base class. The specialized second class for a header is determined by the name of the header, using a lookup table stored in the `HeaderRegistry`. All of this is managed transparently for the typical application program, but interfaces are provided for modifying the default behavior for use by more complex applications.

The sections below first document the header base classes and their
attributes, followed by the API for modifying the behavior of `HeaderRegistry`, and finally the support classes used to represent the data parsed from structured headers.

```python
class email.headerregistry.BaseHeader(name, value)
    name and value are passed to BaseHeader from the header_factory call. The string value of any header object is the value fully decoded to unicode.
```

This base class defines the following read-only properties:

**name**

The name of the header (the portion of the field before the `:`). This is exactly the value passed in the header_factory call for name; that is, case is preserved.

**defects**

A tuple of HeaderDefect instances reporting any RFC compliance problems found during parsing. The email package tries to be complete about detecting compliance issues. See the errors module for a discussion of the types of defects that may be reported.

**max_count**

The maximum number of headers of this type that can have the same name. A value of `None` means unlimited. The BaseHeader value for this attribute is `None`; it is expected that specialized header classes will override this value as needed.

BaseHeader also provides the following method, which is called by the email library code and should not in general be called by application programs:
fold(*, policy)

Return a string containing linesep characters as required to correctly fold the header according to policy. A cte_type of 8bit will be treated as if it were 7bit, since headers may not contain arbitrary binary data. If utf8 is False, non-ASCII data will be RFC 2047 encoded.

BaseHeader by itself cannot be used to create a header object. It defines a protocol that each specialized header cooperates with in order to produce the header object. Specifically, BaseHeader requires that the specialized class provide a classmethod() named parse. This method is called as follows:

```python
def parse(string, kwds):
    kwds is a dictionary containing one pre-initialized key, defects. defects is an empty list. The parse method should append any detected defects to this list. On return, the kwds dictionary must contain values for at least the keys decoded and defects. decoded should be the string value for the header (that is, the header value fully decoded to unicode). The parse method should assume that string may contain content-transfer-encoded parts, but should correctly handle all valid unicode characters as well so that it can parse un-encoded header values.
```

BaseHeader's __new__ then creates the header instance, and calls its init method. The specialized class only needs to provide an init method if it wishes to set additional attributes beyond those provided by BaseHeader itself. Such an init method should look like this:
```python
def init(self, *args, **kw):
    self._myattr = kw.pop('myattr')
    super().init(*args, **kw)
```

That is, anything extra that the specialized class puts in to the `kwds` dictionary should be removed and handled, and the remaining contents of `kw` (and `args`) passed to the `BaseHeader init` method.

```python
class email.headerregistry.UnstructuredHeader
```

An “unstructured” header is the default type of header in RFC 5322. Any header that does not have a specified syntax is treated as unstructured. The classic example of an unstructured header is the `Subject` header.

In RFC 5322, an unstructured header is a run of arbitrary text in the ASCII character set. RFC 2047, however, has an RFC 5322 compatible mechanism for encoding non-ASCII text as ASCII characters within a header value. When a `value` containing encoded words is passed to the constructor, the `UnstructuredHeader` parser converts such encoded words into unicode, following the RFC 2047 rules for unstructured text. The parser uses heuristics to attempt to decode certain non-compliant encoded words. Defects are registered in such cases, as well as defects for issues such as invalid characters within the encoded words or the non-encoded text.

This header type provides no additional attributes.

```python
class email.headerregistry.DateHeader
```

RFC 5322 specifies a very specific format for dates within email headers. The `DateHeader` parser recognizes that date format, as well as recognizing a number of variant forms that are sometimes
found “in the wild”.

This header type provides the following additional attributes:

**datetime**

If the header value can be recognized as a valid date of one form or another, this attribute will contain a `datetime` instance representing that date. If the timezone of the input date is specified as `-0000` (indicating it is in UTC but contains no information about the source timezone), then `datetime` will be a naive `datetime`. If a specific timezone offset is found (including `+0000`), then `datetime` will contain an aware `datetime` that uses `datetime.timezone` to record the timezone offset.

The decoded value of the header is determined by formatting the `datetime` according to the RFC 5322 rules; that is, it is set to:

```python
email.utils.format_datetime(self.datetime)
```

When creating a `DateHeader`, `value` may be `datetime` instance. This means, for example, that the following code is valid and does what one would expect:

```python
msg['Date'] = datetime(2011, 7, 15, 21)
```

Because this is a naive `datetime` it will be interpreted as a UTC timestamp, and the resulting value will have a timezone of `-0000`. Much more useful is to use the `localtime()` function from the `utils` module:

```python
msg['Date'] = utils.localtime()
```
This example sets the date header to the current time and date using the current timezone offset.

```python
class email.headerregistry.AddressHeader
```
Address headers are one of the most complex structured header types. The `AddressHeader` class provides a generic interface to any address header.

This header type provides the following additional attributes:

**groups**
A tuple of `Group` objects encoding the addresses and groups found in the header value. Addresses that are not part of a group are represented in this list as single-address `Groups` whose `display_name` is `None`.

**addresses**
A tuple of `Address` objects encoding all of the individual addresses from the header value. If the header value contains any groups, the individual addresses from the group are included in the list at the point where the group occurs in the value (that is, the list of addresses is “flattened” into a one dimensional list).

The decoded value of the header will have all encoded words decoded to unicode. `idna` encoded domain names are also decoded to unicode. The decoded value is set by `joining` the `str` value of the elements of the `groups` attribute with ",".

A list of `Address` and `Group` objects in any combination may be used to set the value of an address header. `Group` objects whose `display_name` is `None` will be interpreted as single addresses,
which allows an address list to be copied with groups intact by using the list obtained from the `groups` attribute of the source header.

class email.headerregistry.SingleAddressHeader
  A subclass of `AddressHeader` that adds one additional attribute:

  **address**
  The single address encoded by the header value. If the header value actually contains more than one address (which would be a violation of the RFC under the default `policy`), accessing this attribute will result in a `ValueError`.

Many of the above classes also have a `Unique` variant (for example, `UniqueUnstructuredHeader`). The only difference is that in the `Unique` variant, `max_count` is set to 1.

class email.headerregistry.MIMEVersionHeader
  There is really only one valid value for the `MIME-Version` header, and that is `1.0`. For future proofing, this header class supports other valid version numbers. If a version number has a valid value per `RFC 2045`, then the header object will have non-None values for the following attributes:

  **version**
  The version number as a string, with any whitespace and/or comments removed.

  **major**
  The major version number as an integer

  **minor**
  The minor version number as an integer
class email.headerregistry.ParameterizedMIMEHeader

MIME headers all start with the prefix 'Content-'. Each specific header has a certain value, described under the class for that header. Some can also take a list of supplemental parameters, which have a common format. This class serves as a base for all the MIME headers that take parameters.

params

A dictionary mapping parameter names to parameter values.

class email.headerregistry.ContentTypeHeader

A ParameterizedMIMEHeader class that handles the Content-Type header.

content_type

The content type string, in the form maintype/subtype.

maintype

subtype

class email.headerregistry.ContentDispositionHeader

A ParameterizedMIMEHeader class that handles the Content-Disposition header.

content-disposition

inline and attachment are the only valid values in common use.

class email.headerregistry.ContentTransferEncoding

Handles the Content-Transfer-Encoding header.

cte
Valid values are 7bit, 8bit, base64, and quoted-printable. See RFC 2045 for more information.

class
effects.headerregistry.HeaderRegistry(base_class=BaseHeader,
default_class=UnstructuredHeader, use_default_map=True)

This is the factory used by EmailPolicy by default. HeaderRegistry builds the class used to create a header instance dynamically, using base_class and a specialized class retrieved from a registry that it holds. When a given header name does not appear in the registry, the class specified by default_class is used as the specialized class. When use_default_map is True (the default), the standard mapping of header names to classes is copied in to the registry during initialization. base_class is always the last class in the generated class's __bases__ list.

The default mappings are:

<table>
<thead>
<tr>
<th>header</th>
<th>class</th>
</tr>
</thead>
<tbody>
<tr>
<td>subject</td>
<td>UniqueUnstructuredHeader</td>
</tr>
<tr>
<td>date</td>
<td>UniqueDateHeader</td>
</tr>
<tr>
<td>resent-date</td>
<td>DateHeader</td>
</tr>
<tr>
<td>orig-date</td>
<td>UniqueDateHeader</td>
</tr>
<tr>
<td>sender</td>
<td>UniqueSingleAddressHeader</td>
</tr>
<tr>
<td>resent-sender</td>
<td>SingleAddressHeader</td>
</tr>
<tr>
<td>to</td>
<td>UniqueAddressHeader</td>
</tr>
<tr>
<td>resent-to</td>
<td>AddressHeader</td>
</tr>
<tr>
<td>cc</td>
<td>UniqueAddressHeader</td>
</tr>
<tr>
<td>resent-cc</td>
<td>AddressHeader</td>
</tr>
<tr>
<td>from</td>
<td>UniqueAddressHeader</td>
</tr>
</tbody>
</table>
HeaderRegistry has the following methods:

**map_to_type**(self, name, cls)

`name` is the name of the header to be mapped. It will be converted to lower case in the registry. `cls` is the specialized class to be used, along with `base_class`, to create the class used to instantiate headers that match `name`.

**__getitem__**(name)

Construct and return a class to handle creating a `name` header.

**__call__**(name, value)

Retrieves the specialized header associated with `name` from the registry (using `default_class` if `name` does not appear in the registry) and composes it with `base_class` to produce a class, calls the constructed class’s constructor, passing it the same argument list, and finally returns the class instance created thereby.

The following classes are the classes used to represent data parsed from structured headers and can, in general, be used by an application program to construct structured values to assign to specific headers.

```python
class email.headerregistry.Address(display_name='', username='', domain='', addr_spec=None)
```

The class used to represent an email address. The general form of an address is:

```
[display_name] <username@domain>
```
or:

```
username@domain
```

where each part must conform to specific syntax rules spelled out in RFC 5322.

As a convenience `addr_spec` can be specified instead of `username` and `domain`, in which case `username` and `domain` will be parsed from the `addr_spec`. An `addr_spec` must be a properly RFC quoted string; if it is not `Address` will raise an error. Unicode characters are allowed and will be properly encoded when serialized. However, per the RFCs, unicode is not allowed in the username portion of the address.

**display_name**

The display name portion of the address, if any, with all quoting removed. If the address does not have a display name, this attribute will be an empty string.

**username**

The `username` portion of the address, with all quoting removed.

**domain**

The `domain` portion of the address.

**addr_spec**

The `username@domain` portion of the address, correctly quoted for use as a bare address (the second form shown above). This attribute is not mutable.

```
__str__()
```
The `str` value of the object is the address quoted according to RFC 5322 rules, but with no Content Transfer Encoding of any non-ASCII characters.

To support SMTP (RFC 5321), Address handles one special case: if username and domain are both the empty string (or None), then the string value of the Address is `<>`.

```python
class email.headerregistry.Group(display_name=None, addresses=None)
```

The class used to represent an address group. The general form of an address group is:

```plaintext
display_name: [address-list];
```

As a convenience for processing lists of addresses that consist of a mixture of groups and single addresses, a Group may also be used to represent single addresses that are not part of a group by setting `display_name` to `None` and providing a list of the single address as `addresses`.

**display_name**

The `display_name` of the group. If it is `None` and there is exactly one Address in `addresses`, then the Group represents a single address that is not in a group.

**addresses**

A possibly empty tuple of `Address` objects representing the addresses in the group.

```python
__str__()
```

The `str` value of a Group is formatted according to RFC 5322,
but with no Content Transfer Encoding of any non-ASCII characters. If display_name is none and there is a single Address in the addresses list, the str value will be the same as the str of that single Address.

Footnotes

[1] Originally added in 3.3 as a provisional module
19.1.7. **email.contentmanager:** Managing MIME Content

**Source code:** Lib/email/contentmanager.py

*New in version 3.6:* [1]

```python
class email.contentmanager.ContentManager
    Base class for content managers. Provides the standard registry mechanisms to register converters between MIME content and other representations, as well as the `get_content` and `set_content` dispatch methods.

    `get_content(msg, *args, **kw)`
    Look up a handler function based on the `mimetype` of `msg` (see next paragraph), call it, passing through all arguments, and return the result of the call. The expectation is that the handler will extract the payload from `msg` and return an object that encodes information about the extracted data.

    To find the handler, look for the following keys in the registry, stopping with the first one found:

    - the string representing the full MIME type (`maintype/subtype`)
    - the string representing the `maintype`
    - the empty string
```
If none of these keys produce a handler, raise a **KeyError** for the full MIME type.

```
set_content(msg, obj, *args, **kw)
```

If the maintype is **multipart**, raise a **TypeError**; otherwise look up a handler function based on the type of `obj` (see next paragraph), call `clear_content()` on the `msg`, and call the handler function, passing through all arguments. The expectation is that the handler will transform and store `obj` into `msg`, possibly making other changes to `msg` as well, such as adding various MIME headers to encode information needed to interpret the stored data.

To find the handler, obtain the type of `obj` (`typ = type(obj)`), and look for the following keys in the registry, stopping with the first one found:

- the type itself (`typ`)
- the type's fully qualified name (`typ.__module__ + '.' + typ.__qualname__`).
- the type's qualname (`typ.__qualname__`)
- the type's name (`typ.__name__`).

If none of the above match, repeat all of the checks above for each of the types in the **MRO** (`typ.__mro__`). Finally, if no other key yields a handler, check for a handler for the key `None`. If there is no handler for `None`, raise a **KeyError** for the fully qualified name of the type.

Also add a **MIME-Version** header if one is not present (see also **MIMEPart**).

```
add_get_handler(key, handler)
```
Record the function \textit{handler} as the handler for \textit{key}. For the possible values of \textit{key}, see \textit{get\_content()}.\\

\texttt{add\_set\_handler}(\textit{typekey}, \textit{handler})\\
Record \textit{handler} as the function to call when an object of a type matching \textit{typekey} is passed to \textit{set\_content()}. For the possible values of \textit{typekey}, see \textit{set\_content()}.\"
19.1.7.1. Content Manager Instances

Currently the email package provides only one concrete content manager, `raw_data_manager`, although more may be added in the future. `raw_data_manager` is the `content_manager` provided by `EmailPolicy` and its derivatives.

This content manager provides only a minimum interface beyond that provided by `Message` itself: it deals only with text, raw byte strings, and `Message` objects. Nevertheless, it provides significant advantages compared to the base API: `get_content` on a text part will return a unicode string without the application needing to manually decode it, `set_content` provides a rich set of options for controlling the headers added to a part and controlling the content transfer encoding, and it enables the use of the various `add_` methods, thereby simplifying the creation of multipart messages.

```python
email.contentmanager.get_content(msg, errors='replace')
```

Return the payload of the part as either a string (for text parts), an `EmailMessage` object (for `message/rfc822` parts), or a bytes object (for all other non-multipart types). Raise a `KeyError` if called on a multipart. If the part is a text part and `errors` is specified, use it as the error handler when decoding the payload to unicode. The default error handler is `replace`.

```python
email.contentmanager.set_content(msg, subtype="plain", charset='utf-8', cte=None, disposition=None,
```
Add the headers and payload to `msg`:

Add a `Content-Type` header with a `maintype/subtype` value.

- For `str`, set the MIME maintype to `text`, and set the subtype to `subtype` if it is specified, or `plain` if it is not.
- For `bytes`, use the specified `maintype` and `subtype`, or raise a `TypeError` if they are not specified.
- For `EmailMessage` objects, set the maintype to `message`, and set the subtype to `subtype` if it is specified or `rfc822` if it is not. If `subtype` is partial, raise an error (bytes objects must be used to construct `message/partial` parts).
- For `<list>`, which should be a list of `EmailMessage` objects, set the maintype to `multipart`, and the subtype to `subtype` if it is specified, and `mixed` if it is not. If the message parts in the `<list>` have `MIME-Version` headers, remove them.

If `charset` is provided (which is valid only for `str`), encode the string to bytes using the specified character set. The default is `utf-8`. If the specified `charset` is a known alias for a standard
MIME charset name, use the standard charset instead.

If `cte` is set, encode the payload using the specified content transfer encoding, and set the `Content-Transfer-Encoding` header to that value. Possible values for `cte` are quoted-printable, base64, 7bit, 8bit, and binary. If the input cannot be encoded in the specified encoding (for example, specifying a `cte` of 7bit for an input that contains non-ASCII values), raise a `ValueError`.

- For `str` objects, if `cte` is not set use heuristics to determine the most compact encoding.
- For `EmailMessage`, per RFC 2046, raise an error if a `cte` of quoted-printable or base64 is requested for subtype rfc822, and for any `cte` other than 7bit for subtype external-body. For message/rfc822, use 8bit if `cte` is not specified. For all other values of subtype, use 7bit.

**Note:** A `cte` of binary does not actually work correctly yet. The EmailMessage object as modified by `set_content` is correct, but `BytesGenerator` does not serialize it correctly.

If `disposition` is set, use it as the value of the `Content-Disposition` header. If not specified, and `filename` is specified, add the header with the value attachment. If `disposition` is not specified and `filename` is also not specified, do not add the header. The only valid values for `disposition` are attachment and inline.

If `filename` is specified, use it as the value of the `filename` parameter of the `Content-Disposition` header.
If `cid` is specified, add a `Content-ID` header with `cid` as its value.

If `params` is specified, iterate its `items` method and use the resulting `(key, value)` pairs to set additional parameters on the `Content-Type` header.

If `headers` is specified and is a list of strings of the form `headername: headervalue` or a list of header objects (distinguished from strings by having a `name` attribute), add the headers to `msg`.

[1] Originally added in 3.4 as a provisional module
19.1.8. **email**: Examples

Here are a few examples of how to use the `email` package to read, write, and send simple email messages, as well as more complex MIME messages.

First, let's see how to create and send a simple text message (both the text content and the addresses may contain unicode characters):

```python
# Import smtplib for the actual sending function
import smtplib

# Import the email modules we'll need
from email.message import EmailMessage

# Open the plain text file whose name is in textfile
with open(textfile) as fp:
    # Create a text/plain message
    msg = EmailMessage()
    msg.set_content(fp.read())

    # me == the sender's email address
    # you == the recipient's email address
    msg['Subject'] = 'The contents of %s' % textfile
    msg['From'] = me
    msg['To'] = you

    # Send the message via our own SMTP server.
    s = smtplib.SMTP('localhost')
    s.send_message(msg)
    s.quit()
```

Parsing RFC822 headers can easily be done by the using the classes
from the `parser` module:

```python
# Import the email modules we'll need
from email.parser import BytesParser, Parser
from email.policy import default

# If the e-mail headers are in a file, uncomment these two lines:
# with open(messagefile, 'rb') as fp:
#     headers = BytesParser(policy=default).parse(fp)

# Or for parsing headers in a string (this is an uncommon operation), use:
headers = Parser(policy=default).parsestr(
    'From: Foo Bar <user@example.com>
    To: <someone_else@example.com>
    Subject: Test message
    
    'Body would go here')

# Now the header items can be accessed as a dictionary:
print('To: {}'.format(headers['to']))
print('From: {}'.format(headers['from']))
print('Subject: {}'.format(headers['subject']))

# You can also access the parts of the addresses:
print('Recipient username: {}'.format(headers['to']_ADDRESS))
print('Sender name: {}'.format(headers['from'].address))
```

Here's an example of how to send a MIME message containing a bunch of family pictures that may be residing in a directory:

```python
# Import smtplib for the actual sending function
import smtplib

# And imghdr to find the types of our images
import imghdr
```
# Here are the email package modules we'll need
from email.message import EmailMessage

# Create the container email message.
msg = EmailMessage()
msg['Subject'] = 'Our family reunion'
# me == the sender's email address
# family = the list of all recipients' email addresses
msg['From'] = me
msg['To'] = ', '.join(family)
msg.preamble = 'Our family reunion'

# Open the files in binary mode. Use imghdr to figure # MIME subtype for each specific image.
for file in pngfiles:
    with open(file, 'rb') as fp:
        img_data = fp.read()
        msg.add_attachment(img_data, maintype='image', subtype=imghdr.what)

# Send the email via our own SMTP server.
with smtplib.SMTP('localhost') as s:
    s.send_message(msg)

Here's an example of how to send the entire contents of a directory as an email message: [1]

#!/usr/bin/env python3

"""Send the contents of a directory as a MIME message"

import os
import smtplib
# For guessing MIME type based on file name extension
import mimetypes
from argparse import ArgumentParser
from email.message import EmailMessage
from email.policy import SMTP

def main():
    parser = ArgumentParser(description="""Send the contents of a directory as a MIME message. Unless the \-o option is given, the email is sent by a SMTP server, which then does the normal delivery process. Your local machine must be running an SMTP server. """")
    parser.add_argument('\-d', '--directory',
                        help="""Mail the contents of the specified directory, otherwise use the current directory. Only the regular files in the directory are sent, and we don't recurse to subdirectories."""")
    parser.add_argument('\-o', '--output',
                        metavar='FILE',
                        help="""Print the composed message to FILE instead of sending the message to the SMTP server."")
    parser.add_argument('\-s', '--sender', required=True,
                        help='The value of the From: header (required)')
    parser.add_argument('\-r', '--recipient', required=True,
                        action='append', metavar='RECIPIENT',
                        default=[], dest='recipients',
                        help='A To: header value (at least one required)')

    args = parser.parse_args()
    directory = args.directory
    if not directory:
        directory = '.
    # Create the message
    msg = EmailMessage()
    msg['Subject'] = 'Contents of directory %s' % os
    msg['To'] = ', '.join(args.recipients)
    msg['From'] = args.sender
msg.preamble = 'You will not see this in a MIME-aware

for filename in os.listdir(directory):
    path = os.path.join(directory, filename)
    if not os.path.isfile(path):
        continue
    # Guess the content type based on the file's
    # will be ignored, although we should check
    # gzip'd or compressed files.
    ctype, encoding = mimetypes.guess_type(path)
    if ctype is None or encoding is not None:
        # No guess could be made, or the file is
        # use a generic bag-of-bits type.
        ctype = 'application/octet-stream'
    maintype, subtype = ctype.split('/', 1)
    with open(path, 'rb') as fp:
        msg.add_attachment(fp.read(),
            maintype=maintype,
            subtype=subtype,
            filename=filename)

    # Now send or store the message
    if args.output:
        with open(args.output, 'wb') as fp:
            fp.write(msg.as_bytes(policy=SMTP))
    else:
        with smtplib.SMTP('localhost') as s:
            s.send_message(msg)

if __name__ == '__main__':
    main()

Here's an example of how to unpack a MIME message like the one above, into a directory of files:

#!/usr/bin/env python3
Unpack a MIME message into a directory of files.

```python
import os
import email
import mimetypes

from email.policy import default
from argparse import ArgumentParser

def main():
    parser = ArgumentParser(description="""Unpack a MIME message into a directory of files."
    parser.add_argument('-d', '--directory', required=False,
                        help="""Unpack the MIME message into the named directory, which will be created if it doesn't already exist."""
    parser.add_argument('msgfile')
    args = parser.parse_args()

    with open(args.msgfile, 'rb') as fp:
        msg = email.message_from_binary_file(fp, policy=default)

    try:
        os.mkdir(args.directory)
    except FileExistsError:
        pass

    counter = 1
    for part in msg.walk():
        # multipart/* are just containers
        if part.get_content_maintype() == 'multipart':
            continue
        # Applications should really sanitize the given
```
Here's an example of how to create an HTML message with an alternative plain text version. To make things a bit more interesting, we include a related image in the html part, and we save a copy of what we are going to send to disk, as well as sending it.

```python
#!/usr/bin/env python3

import smtplib
from email.message import EmailMessage
from email.headerregistry import Address
from email.utils import make_msgid

# Create the base text message.
msg = EmailMessage()
msg['Subject'] = "Ayons asperges pour le déjeuner"
msg['From'] = Address("Pepé Le Pew", "pepe", "example.com")
msg['To'] = (Address("Penelope Pussycat", "penelope")
            Address("Fabrette Pussycat", "fabrette")
msg.set_content(""")
```

```python
# email message can't be used to overwrite important files
filename = part.get_filename()
if not filename:
    ext = mimetypes.guess_extension(part.get_content_type())
if not ext:
    # Use a generic bag-of-bits extension
    ext = ".bin"
filename = 'part-%03d%s' % (counter, ext)
counter += 1
with open(os.path.join(args.directory, filename), 'wb') as fp:
    fp.write(part.get_payload(decode=True))

if __name__ == '__main__':
    main()
```
Salut!

--Pepé
""

# Add the html version. This converts the message into a multipart/alternative container, with the original text message as the first part and the html message as the second part.

asparagus_cid = make_msgid()
msg.add_alternative("""\n<html>
  <head></head>
  <body>
    <p>Salut!</p>
    <p>Cela ressemble à un excellent recipie</p>
    </body>
</html>""".

# note that we needed to peel the <> off the msgid for use in the html.

# Now add the related image to the html part.

with open("roasted-asparagus.jpg", 'rb') as img:
    msg.get_payload()[1].add_related(img.read(), 'image', cid=asparagus_cid)

# Make a local copy of what we are going to send.

with open('outgoing.msg', 'wb') as f:
    f.write(bytes(msg))
# Send the message via local SMTP server.
with smtplib.SMTP('localhost') as s:
    s.send_message(msg)

If we were sent the message from the last example, here is one way we could process it:

```python
import os
import sys
import tempfile
import mimetypes
import webbrowser

# Import the email modules we'll need
from email import policy
from email.parser import BytesParser

# An imaginary module that would make this work and
from imaginary import magic_html_parser

# In a real program you'd get the filename from the
with open('outgoing.msg', 'rb') as fp:
    msg = BytesParser(policy=policy.default).parse(fp)

# Now the header items can be accessed as a dictionary,
# be converted to unicode:
print('To:', msg['to'])
print('From:', msg['from'])
print('Subject:', msg['subject'])

# If we want to print a preview of the message content
# the least formatted payload is and print the first
# if the message has no plain text part printing the
# is probably useless, but this is just a conceptual
simplest = msg.get_body(preferencelist=('plain', 'ht
print()
print(''.join(simplest.get_content().splitlines(keepends=True))

ans = input("View full message?")
if ans.lower()[0] == 'n':
    sys.exit()

# We can extract the richest alternative in order to display
richest = msg.get_body()
partfiles = {}
if richest['content-type'].maintype == 'text':
    if richest['content-type'].subtype == 'plain':
        for line in richest.get_content().splitlines():
            print(line)
        sys.exit()
    elif richest['content-type'].subtype == 'html':
        body = richest
else:
    print("Don't know how to display {}".format(richest))
    sys.exit()

elif richest['content-type'].content_type == 'multipart/related':
    body = richest.get_body(preferencelist=('html'))
    for part in richest.iter_attachments():
        fn = part.get_filename()
        if fn:
            extension = os.path.splitext(part.get_filename())
        else:
            extension = mimetypes.guess_extension(part)
            with tempfile.NamedTemporaryFile(suffix=extension) as f:
                f.write(part.get_content())
                # again strip the <> to go from email for
                partfiles[part['content-id'][1:-1]] = f

else:
    print("Don't know how to display {}".format(richest))
    sys.exit()

with tempfile.NamedTemporaryFile(mode='w', delete=False) as f:
    # The magic_html_parser has to rewrite the href=...
# point to the filenames in partfiles. It also
# of the html. It could be written using html.parser.
f.write(magic_html_parser(body.get_content(), partfiles))
webbrowser.open(f.name)
for fn in partfiles.values():
    os.remove(fn)

# Of course, there are lots of email messages that can't
# minded program, but it will handle the most common.

Up to the prompt, the output from the above is:

To: Penelope Pussycat <penelope@example.com>, Fabrette Pussycat <fabrette@example.com>
From: Pepé Le Pew <pepe@example.com>
Subject: Ayons asperges pour le déjeuner

Salut!

Footnotes

[1] Thanks to Matthew Dixon Cowles for the original inspiration and examples.
19.1.9. `email.message.Message`: Representing an email message using the `compat32` API

The `Message` class is very similar to the `EmailMessage` class, without the methods added by that class, and with the default behavior of certain other methods being slightly different. We also document here some methods that, while supported by the `EmailMessage` class, are not recommended unless you are dealing with legacy code.

The philosophy and structure of the two classes is otherwise the same.

This document describes the behavior under the default (for `Message`) policy `Compat32`. If you are going to use another policy, you should be using the `EmailMessage` class instead.

An email message consists of *headers* and a *payload*. Headers must be `RFC 5233` style names and values, where the field name and value are separated by a colon. The colon is not part of either the field name or the field value. The payload may be a simple text message, or a binary object, or a structured sequence of sub-messages each with their own set of headers and their own payload. The latter type of payload is indicated by the message having a MIME type such as `multipart/*` or `message/rfc822`.

The conceptual model provided by a `Message` object is that of an ordered dictionary of headers with additional methods for accessing
both specialized information from the headers, for accessing the payload, for generating a serialized version of the message, and for recursively walking over the object tree. Note that duplicate headers are supported but special methods must be used to access them.

The `Message` pseudo-dictionary is indexed by the header names, which must be ASCII values. The values of the dictionary are strings that are supposed to contain only ASCII characters; there is some special handling for non-ASCII input, but it doesn't always produce the correct results. Headers are stored and returned in case-preserving form, but field names are matched case-insensitively. There may also be a single envelope header, also known as the `Unix-From` header or the `From_` header. The payload is either a string or bytes, in the case of simple message objects, or a list of `Message` objects, for MIME container documents (e.g. `multipart/*` and `message/rfc822`).

Here are the methods of the `Message` class:

```python
class email.message.Message(policy=compat32)
```

If `policy` is specified (it must be an instance of a `policy` class) use the rules it specifies to update and serialize the representation of the message. If `policy` is not set, use the `compat32` policy, which maintains backward compatibility with the Python 3.2 version of the email package. For more information see the `policy` documentation.

*Changed in version 3.3:* The `policy` keyword argument was added.

```python
as_string(unixfrom=False, maxheaderlen=0, policy=None)
```

Return the entire message flattened as a string. When optional `unixfrom` is true, the envelope header is included in the returned string. `unixfrom` defaults to `False`. For backward compatibility
reasons, \textit{maxheaderlen} defaults to 0, so if you want a different value you must override it explicitly (the value specified for \textit{max_line_length} in the policy will be ignored by this method). The \textit{policy} argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified \textit{policy} will be passed to the \texttt{Generator}.

Flattening the message may trigger changes to the \texttt{Message} if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it does not do the mangling of lines that begin with \texttt{From} that is required by the unix mbox format. For more flexibility, instantiate a \texttt{Generator} instance and use its \texttt{flatten()} method directly. For example:

```python
from io import StringIO
from email.generator import Generator
fp = StringIO()
g = Generator(fp, mangle_from_=\texttt{True}, maxheaderlen)
g.flatten(msg)
text = fp.getvalue()
```

If the message object contains binary data that is not encoded according to RFC standards, the non-compliant data will be replaced by unicode “unknown character” code points. (See also \texttt{as_bytes()} and \texttt{BytesGenerator}.)
*Changed in version 3.4:* the `policy` keyword argument was added.

```
__str__()
```

Equivalent to `as_string()`. Allows `str(msg)` to produce a string containing the formatted message.

```
as_bytes(unixfrom=False, policy=None)
```

Return the entire message flattened as a bytes object. When optional `unixfrom` is true, the envelope header is included in the returned string. `unixfrom` defaults to `False`. The `policy` argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified `policy` will be passed to the `BytesGenerator`.

Flattening the message may trigger changes to the `Message` if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it does not do the mangling of lines that begin with `From` that is required by the unix mbox format. For more flexibility, instantiate a `BytesGenerator` instance and use its `flatten()` method directly. For example:

```python
from io import BytesIO
from email.generator import BytesGenerator
fp = BytesIO()
g = BytesGenerator(fp, mangle_from_=True, maxheaderlen=
```
New in version 3.4.

`__bytes__()`
Equivalent to `as_bytes()`. Allows `bytes(msg)` to produce a bytes object containing the formatted message.

New in version 3.4.

`is_multipart()`
Return `True` if the message's payload is a list of sub-`Message` objects, otherwise return `False`. When `is_multipart()` returns `False`, the payload should be a string object (which might be a CTE encoded binary payload. (Note that `is_multipart()` returning `True` does not necessarily mean that “msg.get_content_maintype() == ‘multipart’” will return the `True`. For example, `is_multipart` will return `True` when the `Message` is of type `message/rfc822`.)

`set_unixfrom(unixfrom)`
Set the message's envelope header to `unixfrom`, which should be a string.

`get_unixfrom()`
Return the message's envelope header. Defaults to `None` if the envelope header was never set.

`attach(payload)`
Add the given `payload` to the current payload, which must be `None` or a list of `Message` objects before the call. After the call, the payload will always be a list of `Message` objects. If you
want to set the payload to a scalar object (e.g. a string), use `set_payload()` instead.

This is a legacy method. On the EmailMessage class its functionality is replaced by `set_content()` and the related `make` and `add` methods.

**get_payload(i=None, decode=False)**

Return the current payload, which will be a list of `Message` objects when `is_multipart()` is `True`, or a string when `is_multipart()` is `False`. If the payload is a list and you mutate the list object, you modify the message's payload in place.

With optional argument `i`, `get_payload()` will return the `i`-th element of the payload, counting from zero, if `is_multipart()` is `True`. An `IndexError` will be raised if `i` is less than 0 or greater than or equal to the number of items in the payload. If the payload is a string (i.e. `is_multipart()` is `False`) and `i` is given, a `TypeError` is raised.

Optional `decode` is a flag indicating whether the payload should be decoded or not, according to the `Content-Transfer-Encoding` header. When `True` and the message is not a multipart, the payload will be decoded if this header's value is `quoted-printable` or `base64`. If some other encoding is used, or `Content-Transfer-Encoding` header is missing, the payload is returned as-is (undecoded). In all cases the returned value is binary data. If the message is a multipart and the `decode` flag is `True`, then `None` is returned. If the payload is base64 and it was not perfectly formed (missing padding, characters outside the base64 alphabet), then an appropriate defect will be added
to the message's defect property (InvalidBase64PaddingDefect or InvalidBase64CharactersDefect, respectively).

When decode is False (the default) the body is returned as a string without decoding the Content-Transfer-Encoding. However, for a Content-Transfer-Encoding of 8bit, an attempt is made to decode the original bytes using the charset specified by the Content-Type header, using the replace error handler. If no charset is specified, or if the charset given is not recognized by the email package, the body is decoded using the default ASCII charset.

This is a legacy method. On the EmailMessage class its functionality is replaced by get_content() and iter_parts().

set_payload(payload, charset=None)
Set the entire message object's payload to payload. It is the client's responsibility to ensure the payload invariants. Optional charset sets the message's default character set; see set_charset() for details.

This is a legacy method. On the EmailMessage class its functionality is replaced by set_content().

set_charset(charset)
Set the character set of the payload to charset, which can either be a Charset instance (see email.charset), a string naming a character set, or None. If it is a string, it will be converted to a Charset instance. If charset is None, the charset parameter will be removed from the Content-Type
header (the message will not be otherwise modified). Anything else will generate a `TypeError`.

If there is no existing `MIME-Version` header one will be added. If there is no existing `Content-Type` header, one will be added with a value of `text/plain`. Whether the `Content-Type` header already exists or not, its `charset` parameter will be set to `charset.output_charset`. If `charset.input_charset` and `charset.output_charset` differ, the payload will be re-encoded to the `output_charset`. If there is no existing `Content-Transfer-Encoding` header, then the payload will be transfer-encoded, if needed, using the specified `Charset`, and a header with the appropriate value will be added. If a `Content-Transfer-Encoding` header already exists, the payload is assumed to already be correctly encoded using that `Content-Transfer-Encoding` and is not modified.

This is a legacy method. On the `EmailMessage` class its functionality is replaced by the `charset` parameter of the `email.emailmessage.EmailMessage.set_content()` method.

```
get_charset()
```

Return the `Charset` instance associated with the message's payload.

This is a legacy method. On the `EmailMessage` class it always returns `None`.

The following methods implement a mapping-like interface for accessing the message's `RFC 2822` headers. Note that there are some semantic differences between these methods and a normal
mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by `keys()`, but in a `Message` object, headers are always returned in the order they appeared in the original message, or were added to the message later. Any header deleted and then re-added are always appended to the end of the header list.

These semantic differences are intentional and are biased toward maximal convenience.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

In a model generated from bytes, any header values that (in contravention of the RFCs) contain non-ASCII bytes will, when retrieved through this interface, be represented as `Header` objects with a charset of `unknown-8bit`.

__len__()            
Return the total number of headers, including duplicates.

__contains__(name)   
Return true if the message object has a field named name. Matching is done case-insensitively and name should not include the trailing colon. Used for the in operator, e.g.:

```python
if 'message-id' in myMessage:
    print('Message-ID:', myMessage['message-id'])
```

__getitem__(name)
Return the value of the named header field. *name* should not include the colon field separator. If the header is missing, `None` is returned; a `KeyError` is never raised.

Note that if the named field appears more than once in the message’s headers, exactly which of those field values will be returned is undefined. Use the `get_all()` method to get the values of all the extant named headers.

```python
__setitem__(name, val)
Add a header to the message with field name *name* and value *val*. The field is appended to the end of the message’s existing fields.

Note that this does *not* overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name *name*, delete the field first, e.g.:

```python
del msg['subject']
msg['subject'] = 'Python rootz!'
```

```python
__delitem__(name)
Delete all occurrences of the field with name *name* from the message’s headers. No exception is raised if the named field isn’t present in the headers.
```

`keys()`
Return a list of all the message’s header field names.

`values()`
Return a list of all the message’s field values.
items()
Return a list of 2-tuples containing all the message’s field headers and values.

get(name, failobj=None)
Return the value of the named header field. This is identical to
__getitem__() except that optional failobj is returned if the
named header is missing (defaults to None).

Here are some additional useful methods:

get_all(name, failobj=None)
Return a list of all the values for the field named name. If there
are no such named headers in the message, failobj is returned
(defaults to None).

add_header(_name, _value, **_params)
Extended header setting. This method is similar to
__setitem__() except that additional header parameters can
be provided as keyword arguments. _name is the header field
to add and _value is the primary value for the header.

For each item in the keyword argument dictionary _params, the
key is taken as the parameter name, with underscores
converted to dashes (since dashes are illegal in Python
identifiers). Normally, the parameter will be added as
key="value" unless the value is None, in which case only
the key will be added. If the value contains non-ASCII
characters, it can be specified as a three tuple in the format
(CHARSET, LANGUAGE, VALUE), where CHARSET is a string
naming the charset to be used to encode the value, LANGUAGE
can usually be set to None or the empty string (see RFC 2231
for other possibilities), and \textit{VALUE} is the string value containing non-ASCII code points. If a three tuple is not passed and the value contains non-ASCII characters, it is automatically encoded in RFC 2231 format using a \texttt{CHARSET} of utf-8 and a \texttt{LANGUAGE} of None.

Here's an example:

```python
msg.add_header('Content-Disposition', 'attachment', filename='bud.gif')
```

This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.gif"
```

An example with non-ASCII characters:

```python
msg.add_header('Content-Disposition', 'attachment', filename=('iso-8859-1', '', 'Fußballer.ppt'))
```

Which produces

```
Content-Disposition: attachment; filename*="iso-8859-1''Fu%DFballer.ppt"
```

\texttt{replace_header()}\_name, \_value\)

Replace a header. Replace the first header found in the message that matches \_name, retaining header order and field name case. If no matching header was found, a \texttt{KeyError} is raised.

\texttt{get_content_type}()

Return the message's content type. The returned string is
coerced to lower case of the form maintype/subtype. If there was no Content-Type header in the message the default type as given by get_default_type() will be returned. Since according to RFC 2045, messages always have a default type, get_content_type() will always return a value.

RFC 2045 defines a message’s default type to be text/plain unless it appears inside a multipart/digest container, in which case it would be message/rfc822. If the Content-Type header has an invalid type specification, RFC 2045 mandates that the default type be text/plain.

get_content_main_type()
Return the message’s main content type. This is the maintype part of the string returned by get_content_type().

get_content_subtype()
Return the message’s sub-content type. This is the subtype part of the string returned by get_content_type().

get_default_type()
Return the default content type. Most messages have a default content type of text/plain, except for messages that are subparts of multipart/digest containers. Such subparts have a default content type of message/rfc822.

set_default_type(ctype)
Set the default content type. ctype should either be text/plain or message/rfc822, although this is not enforced. The default content type is not stored in the Content-Type header.

get_vars(failobj=None, header='content-type', unquote=True)
Return the message’s Content-Type parameters, as a list. The elements of the returned list are 2-tuples of key/value pairs, as split on the '=' sign. The left hand side of the '=' is the key, while the right hand side is the value. If there is no '=' sign in the parameter the value is the empty string, otherwise the value is as described in get_param() and is unquoted if optional unquote is True (the default).

Optional failobj is the object to return if there is no Content-Type header. Optional header is the header to search instead of Content-Type.

This is a legacy method. On the EmailMessage class its functionality is replaced by the params property of the individual header objects returned by the header access methods.

get_param(param, failobj=None, header='content-type', unquote=True)

Return the value of the Content-Type header’s parameter param as a string. If the message has no Content-Type header or if there is no such parameter, then failobj is returned (defaults to None).

Optional header if given, specifies the message header to use instead of Content-Type.

Parameter value keys are always compared case insensitively. The return value can either be a string, or a 3-tuple if the parameter was RFC 2231 encoded. When it’s a 3-tuple, the elements of the value are of the form (CHARSET, LANGUAGE, VALUE). Note that both CHARSET and LANGUAGE can be None, in which case you should consider VALUE to be encoded in the us-
ascii charset. You can usually ignore LANGUAGE.

If your application doesn’t care whether the parameter was encoded as in RFC 2231, you can collapse the parameter value by calling email.utils.collapse_rfc2231_value(), passing in the return value from get_param(). This will return a suitably decoded Unicode string when the value is a tuple, or the original string unquoted if it isn’t. For example:

```python
rawparam = msg.get_param('foo')
param = email.utils.collapse_rfc2231_value(rawparam)
```

In any case, the parameter value (either the returned string, or the VALUE item in the 3-tuple) is always unquoted, unless unquote is set to False.

This is a legacy method. On the EmailMessage class its functionality is replaced by the params property of the individual header objects returned by the header access methods.

```python
set_param(param, value, header='Content-Type', requote=True, charset=None, language='', replace=False)
```

Set a parameter in the Content-Type header. If the parameter already exists in the header, its value will be replaced with value. If the Content-Type header as not yet been defined for this message, it will be set to text/plain and the new parameter value will be appended as per RFC 2045.

Optional header specifies an alternative header to Content-Type, and all parameters will be quoted as necessary unless optional requote is False (the default is True).
If optional `charset` is specified, the parameter will be encoded according to **RFC 2231**. Optional `language` specifies the RFC 2231 language, defaulting to the empty string. Both `charset` and `language` should be strings.

If `replace` is `False` (the default) the header is moved to the end of the list of headers. If `replace` is `True`, the header will be updated in place.

*Changed in version 3.4:* `replace` keyword was added.

### `del_param(param, header='content-type', requote=True)`
Remove the given parameter completely from the `Content-Type` header. The header will be re-written in place without the parameter or its value. All values will be quoted as necessary unless `requote` is `False` (the default is `True`). Optional `header` specifies an alternative to `Content-Type`.

### `set_type(type, header='Content-Type', requote=True)`
Set the main type and subtype for the `Content-Type` header. `type` must be a string in the form `maintype/subtype`, otherwise a `ValueError` is raised.

This method replaces the `Content-Type` header, keeping all the parameters in place. If `requote` is `False`, this leaves the existing header’s quoting as is, otherwise the parameters will be quoted (the default).

An alternative header can be specified in the `header` argument. When the `Content-Type` header is set a `MIME-Version` header is also added.

This is a legacy method. On the `EmailMessage` class its
functionality is replaced by the `make_` and `add_` methods.

**get_filename** *(failobj=None)*
Return the value of the `filename` parameter of the `Content-Disposition` header of the message. If the header does not have a `filename` parameter, this method falls back to looking for the `name` parameter on the `Content-Type` header. If neither is found, or the header is missing, then `failobj` is returned. The returned string will always be unquoted as per `email.utils.unquote()`.

**get_boundary** *(failobj=None)*
Return the value of the `boundary` parameter of the `Content-Type` header of the message, or `failobj` if either the header is missing, or has no `boundary` parameter. The returned string will always be unquoted as per `email.utils.unquote()`.

**set_boundary** *(boundary)*
Set the `boundary` parameter of the `Content-Type` header to `boundary`. `set_boundary()` will always quote `boundary` if necessary. A `HeaderParseError` is raised if the message object has no `Content-Type` header.

Note that using this method is subtly different than deleting the old `Content-Type` header and adding a new one with the new boundary via `add_header()`, because `set_boundary()` preserves the order of the `Content-Type` header in the list of headers. However, it does not preserve any continuation lines which may have been present in the original `Content-Type` header.

**get_content_charset** *(failobj=None)*
Return the `charset` parameter of the `Content-Type` header, coerced to lower case. If there is no `Content-Type` header, or if that header has no `charset` parameter, `failobj` is returned.

Note that this method differs from `get_charset()` which returns the `Charset` instance for the default encoding of the message body.

`get_charsets(failobj=None)`

Return a list containing the character set names in the message. If the message is a `multipart`, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the `charset` parameter in the `Content-Type` header for the represented subpart. However, if the subpart has no `Content-Type` header, no `charset` parameter, or is not of the `text` main MIME type, then that item in the returned list will be `failobj`.

`get_content_disposition()`

Return the lowercased value (without parameters) of the message's `Content-Disposition` header if it has one, or `None`. The possible values for this method are `inline`, `attachment` or `None` if the message follows RFC 2183.

*New in version 3.5.*

`walk()`

The `walk()` method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use
walk() as the iterator in a for loop; each iteration returns the next subpart.

Here's an example that prints the MIME type of every part of a multipart message structure:

```python
>>> for part in msg.walk():
...     print(part.get_content_type())
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
text/plain
walk iterates over the subparts of any part where is_multipart() returns True, even though msg.get_content_maintype() == 'multipart' may return False. We can see this in our example by making use of the _structure debug helper function:

```python
>>> for part in msg.walk():
...     print(part.get_content_maintype() == 'multipart')
...     print(part.is_multipart())
True True
False False
False True
False False
False False
False True
False False
>>> _structure(msg)
multipart/report
text/plain
```
Here the message parts are not multipart, but they do contain subparts. is_multipart() returns True and walk descends into the subparts.

Message objects can also optionally contain two instance attributes, which can be used when generating the plain text of a MIME message.

**preamble**

The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this text can become visible.

The preamble attribute contains this leading extra-armor text for MIME documents. When the Parser discovers some text after the headers but before the first boundary string, it assigns this text to the message's preamble attribute. When the Generator is writing out the plain text representation of a MIME message, and it finds the message has a preamble attribute, it will write this text in the area between the headers and the first boundary. See email.parser and email.generator for details.
Note that if the message object has no preamble, the `preamble` attribute will be `None`.

**epilogue**

The `epilogue` attribute acts the same way as the `preamble` attribute, except that it contains text that appears between the last boundary and the end of the message.

You do not need to set the epilogue to the empty string in order for the `Generator` to print a newline at the end of the file.

**defects**

The `defects` attribute contains a list of all the problems found when parsing this message. See `email.errors` for a detailed description of the possible parsing defects.
19. Internet Data Handling

19.1. email — An email and MIME handling package
19.1.10. `email.mime`: Creating email and MIME objects from scratch

**Source code:** `Lib/email.mime/`

This module is part of the legacy (Compat32) email API. Its functionality is partially replaced by the `contentmanager` in the new API, but in certain applications these classes may still be useful, even in non-legacy code.

Ordinarily, you get a message object structure by passing a file or some text to a parser, which parses the text and returns the root message object. However you can also build a complete message structure from scratch, or even individual `Message` objects by hand. In fact, you can also take an existing structure and add new `Message` objects, move them around, etc. This makes a very convenient interface for slicing-and-dicing MIME messages.

You can create a new object structure by creating `Message` instances, adding attachments and all the appropriate headers manually. For MIME messages though, the `email` package provides some convenient subclasses to make things easier.

Here are the classes:

```python
class email.mime.base.MIMEBase(_maintype, _subtype, *,
policy=compat32, **_params)
    Module: email.mime.base
```
This is the base class for all the MIME-specific subclasses of `Message`. Ordinarily you won’t create instances specifically of `MIMEBase`, although you could. `MIMEBase` is provided primarily as a convenient base class for more specific MIME-aware subclasses.

>_maintype_ is the `Content-Type` major type (e.g. `text` or `image`), and _subtype_ is the `Content-Type` minor type (e.g. `plain` or `gif`). _params_ is a parameter key/value dictionary and is passed directly to `Message.add_header`.

If `policy` is specified, (defaults to the `compat32` policy) it will be passed to `Message`.

The `MIMEBase` class always adds a `Content-Type` header (based on _maintype_, _subtype_, and _params_), and a `MIME-Version` header (always set to 1.0).

**Changed in version 3.6:** Added `policy` keyword-only parameter.

```python
class email.mime.nonmultipart.MIMENonMultipart
    Module: email.mime.nonmultipart
```

A subclass of `MIMEBase`, this is an intermediate base class for MIME messages that are not `multipart`. The primary purpose of this class is to prevent the use of the `attach()` method, which only makes sense for `multipart` messages. If `attach()` is called, a `MultipartConversionError` exception is raised.

```python
class email.mime.multipart.MIMEMultipart(_subtype='mixed', boundary=None, _subparts=None, *, policy=compat32, **_params)
    Module: email.mime.multipart
```
A subclass of `MIMEBase`, this is an intermediate base class for MIME messages that are `multipart`. Optional `_subtype` defaults to `mixed`, but can be used to specify the subtype of the message. A `Content-Type` header of `multipart/_subtype` will be added to the message object. A `MIME-Version` header will also be added.

Optional `boundary` is the multipart boundary string. When `None` (the default), the boundary is calculated when needed (for example, when the message is serialized).

 `_subparts` is a sequence of initial subparts for the payload. It must be possible to convert this sequence to a list. You can always attach new subparts to the message by using the `Message.attach` method.

Optional `policy` argument defaults to `compat32`.

Additional parameters for the `Content-Type` header are taken from the keyword arguments, or passed into the `_params` argument, which is a keyword dictionary.

`Changed in version 3.6`: Added `policy` keyword-only parameter.

class email.mime.application.MIMEApplication(_data, _subtype='octet-stream', _encoder=email.encoders.encode_base64, *, policy=compat32, **_params)
    Module: email.mime.application

A subclass of `MIMENonMultipart`, the `MIMEApplication` class is used to represent MIME message objects of major type `application`. `_data` is a string containing the raw byte data. Optional `_subtype` specifies the MIME subtype and defaults to `octet-stream`.

Optional `_encoder` is a callable (i.e. function) which will perform the
actual encoding of the data for transport. This callable takes one argument, which is the MIMEApplication instance. It should use get_payload() and set_payload() to change the payload to encoded form. It should also add any Content-Transfer-Encoding or other headers to the message object as necessary. The default encoding is base64. See the email.encoders module for a list of the built-in encoders.

Optional policy argument defaults to compat32.

_params are passed straight through to the base class constructor.

Changed in version 3.6: Added policy keyword-only parameter.

class email.mime.audio.MIMEAudio(_audiodata, _subtype=None, _encoder=email.encoders.encode_base64, *, policy=compat32, **_params)

Module: email.mime.audio

A subclass of MIMENonMultipart, the MIMEAudio class is used to create MIME message objects of major type audio. _audiodata is a string containing the raw audio data. If this data can be decoded by the standard Python module sndhdr, then the subtype will be automatically included in the Content-Type header. Otherwise you can explicitly specify the audio subtype via the _subtype argument. If the minor type could not be guessed and _subtype was not given, then TypeError is raised.

Optional _encoder is a callable (i.e. function) which will perform the actual encoding of the audio data for transport. This callable takes one argument, which is the MIMEAudio instance. It should use get_payload() and set_payload() to change the payload to encoded form. It should also add any Content-Transfer-Encoding or
other headers to the message object as necessary. The default encoding is base64. See the `email.encoders` module for a list of the built-in encoders.

Optional `policy` argument defaults to `compat32`.

`*_params` are passed straight through to the base class constructor.

*Changed in version 3.6: Added `policy` keyword-only parameter.*

class `email.mime.image.MIMEImage(_imagedata, _subtype=None, _encoder=email.encoders.encode_base64, *, policy=compat32, ***_params)`

Module: `email.mime.image`

A subclass of `MIMENonMultipart`, the `MIMEImage` class is used to create MIME message objects of major type `image`. `_imagedata` is a string containing the raw image data. If this data can be decoded by the standard Python module `imghdr`, then the subtype will be automatically included in the `Content-Type` header. Otherwise you can explicitly specify the image subtype via the `_subtype` argument. If the minor type could not be guessed and `_subtype` was not given, then `TypeError` is raised.

Optional `_encoder` is a callable (i.e. function) which will perform the actual encoding of the image data for transport. This callable takes one argument, which is the `MIMEImage` instance. It should use `get_payload()` and `set_payload()` to change the payload to encoded form. It should also add any `Content-Transfer-Encoding` or other headers to the message object as necessary. The default encoding is base64. See the `email.encoders` module for a list of the built-in encoders.
Optional *policy* argument defaults to *compat32*.

*_params* are passed straight through to the *MIMEBase* constructor.

*Changed in version 3.6:* Added *policy* keyword-only parameter.

```python
class email.mime.message.MIMEMessage(_msg, _subtype='rfc822', *, policy=compat32)
Module: email.mime.message
```

A subclass of *MIMENonMultipart*, the *MIMEMessage* class is used to create MIME objects of main type *message*. *_msg* is used as the payload, and must be an instance of class *Message* (or a subclass thereof), otherwise a *TypeError* is raised.

Optional *_subtype* sets the subtype of the message; it defaults to *rfc822*.

Optional *policy* argument defaults to *compat32*.

*Changed in version 3.6:* Added *policy* keyword-only parameter.

```python
class email.mime.text.MIMEText(_text, _subtype='plain', _charset=None, *, policy=compat32)
Module: email.mime.text
```

A subclass of *MIMENonMultipart*, the *MIMEText* class is used to create MIME objects of major type *text*. *_text* is the string for the payload. *_subtype* is the minor type and defaults to *plain*. *_charset* is the character set of the text and is passed as an argument to the *MIMENonMultipart* constructor; it defaults to *us-ascii* if the string contains only *ascii* code points, and *utf-8* otherwise. The *_charset* parameter accepts either a string or a *Charset* instance.
Unless the `_charset` argument is explicitly set to `None`, the MIMEText object created will have both a `Content-Type` header with a `charset` parameter, and a `Content-Transfer-Encoding` header. This means that a subsequent `set_payload` call will not result in an encoded payload, even if a charset is passed in the `set_payload` command. You can “reset” this behavior by deleting the `Content-Transfer-Encoding` header, after which a `set_payload` call will automatically encode the new payload (and add a new `Content-Transfer-Encoding` header).

Optional `policy` argument defaults to `compat32`.

*Changed in version 3.5:* `_charset` also accepts `Charset` instances.

*Changed in version 3.6:* Added `policy` keyword-only parameter.
19. Internet Data Handling

19.1. **email** — An email and MIME handling package
19.1.11. **email.header:** Internationalized headers

**Source code:** Lib/email/header.py

This module is part of the legacy (Compat32) email API. In the current API encoding and decoding of headers is handled transparently by the dictionary-like API of the `EmailMessage` class. In addition to uses in legacy code, this module can be useful in applications that need to completely control the character sets used when encoding headers.

The remaining text in this section is the original documentation of the module.

**RFC 2822** is the base standard that describes the format of email messages. It derives from the older **RFC 822** standard which came into widespread use at a time when most email was composed of ASCII characters only. **RFC 2822** is a specification written assuming email contains only 7-bit ASCII characters.

Of course, as email has been deployed worldwide, it has become internationalized, such that language specific character sets can now be used in email messages. The base standard still requires email messages to be transferred using only 7-bit ASCII characters, so a slew of RFCs have been written describing how to encode email containing non-ASCII characters into **RFC 2822**-compliant format. These RFCs include **RFC 2045, RFC 2046, RFC 2047**, and **RFC 2231**. The `email` package supports these standards in its `email.header` and `email.charset` modules.
If you want to include non-ASCII characters in your email headers, say in the Subject or To fields, you should use the Header class and assign the field in the Message object to an instance of Header instead of using a string for the header value. Import the Header class from the email.header module. For example:

```python
>>> from email.message import Message
>>> from email.header import Header
>>> msg = Message()
>>> h = Header('p\xf6stal', 'iso-8859-1')
>>> msg['Subject'] = h
>>> msg.as_string()
'Subject: =?iso-8859-1?q?p=F6stal?=\n\n'
```

Notice here how we wanted the Subject field to contain a non-ASCII character? We did this by creating a Header instance and passing in the character set that the byte string was encoded in. When the subsequent Message instance was flattened, the Subject field was properly RFC 2047 encoded. MIME-aware mail readers would show this header using the embedded ISO-8859-1 character.

Here is the Header class description:

```python
class email.header.Header(s=None, charset=None, maxlinelen=None, header_name=None, continuation_ws=' ', errors='strict')
```

Create a MIME-compliant header that can contain strings in different character sets.

Optional s is the initial header value. If None (the default), the initial header value is not set. You can later append to the header with append() method calls. s may be an instance of bytes or str, but see the append() documentation for semantics.
Optional `charset` serves two purposes: it has the same meaning as the `charset` argument to the `append()` method. It also sets the default character set for all subsequent `append()` calls that omit the `charset` argument. If `charset` is not provided in the constructor (the default), the `us-ascii` character set is used both as s’s initial charset and as the default for subsequent `append()` calls.

The maximum line length can be specified explicitly via `maxlinelen`. For splitting the first line to a shorter value (to account for the field header which isn’t included in s, e.g. `Subject`) pass in the name of the field in `header_name`. The default `maxlinelen` is 76, and the default value for `header_name` is `None`, meaning it is not taken into account for the first line of a long, split header.

Optional `continuation_ws` must be RFC 2822-compliant folding whitespace, and is usually either a space or a hard tab character. This character will be prepended to continuation lines. `continuation_ws` defaults to a single space character.

Optional `errors` is passed straight through to the `append()` method.

```python
append(s, charset=None, errors='strict')
```

Append the string s to the MIME header.

Optional `charset`, if given, should be a `Charset` instance (see `email.charset`) or the name of a character set, which will be converted to a `Charset` instance. A value of `None` (the default) means that the `charset` given in the constructor is used.

`s` may be an instance of `bytes` or `str`. If it is an instance of `bytes`, then `charset` is the encoding of that byte string, and a
UnicodeError will be raised if the string cannot be decoded with that character set.

If `s` is an instance of `str`, then `charset` is a hint specifying the character set of the characters in the string.

In either case, when producing an RFC 2822-compliant header using RFC 2047 rules, the string will be encoded using the output codec of the charset. If the string cannot be encoded using the output codec, a UnicodeError will be raised.

Optional `errors` is passed as the errors argument to the decode call if `s` is a byte string.

```python
encode(splitchars='; \t', maxlinelen=None, linesep='\n')
```

Encode a message header into an RFC-compliant format, possibly wrapping long lines and encapsulating non-ASCII parts in base64 or quoted-printable encodings.

Optional `splitchars` is a string containing characters which should be given extra weight by the splitting algorithm during normal header wrapping. This is in very rough support of RFC 2822's 'higher level syntactic breaks': split points preceded by a splitchar are preferred during line splitting, with the characters preferred in the order in which they appear in the string. Space and tab may be included in the string to indicate whether preference should be given to one over the other as a split point when other split chars do not appear in the line being split. Splitchars does not affect RFC 2047 encoded lines.

`maxlinelen`, if given, overrides the instance's value for the maximum line length.
linesep specifies the characters used to separate the lines of the folded header. It defaults to the most useful value for Python application code (\n), but \r\n can be specified in order to produce headers with RFC-compliant line separators.

*Changed in version 3.2:* Added the linesep argument.

The `Header` class also provides a number of methods to support standard operators and built-in functions.

`__str__()`
- Returns an approximation of the `Header` as a string, using an unlimited line length. All pieces are converted to unicode using the specified encoding and joined together appropriately. Any pieces with a charset of 'unknown-8bit' are decoded as ASCII using the 'replace' error handler.

*Changed in version 3.2:* Added handling for the 'unknown-8bit' charset.

`__eq__`(other)
- This method allows you to compare two `Header` instances for equality.

`__ne__`(other)
- This method allows you to compare two `Header` instances for inequality.

The `email.header` module also provides the following convenient functions.

`email.header.decode_header(header)`
- Decode a message header value without converting the character
set. The header value is in header.
This function returns a list of (decoded_string, charset)
pairs containing each of the decoded parts of the header. charset is
None for non-encoded parts of the header, otherwise a lower case
string containing the name of the character set specified in the
encoded string.
Here’s an example:
>>> from email.header import decode_header
[(b'p\xf6stal', 'iso-8859-1')]
email.header. make_header(decoded_seq, maxlinelen=None,
header_name=None, continuation_ws=' ')
Create a Header instance from a sequence of pairs as returned by
decode_header().
decode_header() takes a header value string and returns a
sequence of pairs of the format (decoded_string, charset)
where charset is the name of the character set.
This function takes one of those sequence of pairs and returns a
Header instance. Optional maxlinelen, header_name, and
continuation_ws are as in the Header constructor.

19.1.12. **email.charset**: Representing character sets

**Source code**: Lib/email/charset.py

This module is part of the legacy (Compat32) email API. In the new API only the aliases table is used.

The remaining text in this section is the original documentation of the module.

This module provides a class `Charset` for representing character sets and character set conversions in email messages, as well as a character set registry and several convenience methods for manipulating this registry. Instances of `Charset` are used in several other modules within the `email` package.

Import this class from the `email.charset` module.

```python
class email.charset.Charset(input_charset=DEFAULT_CHARSET)
    Map character sets to their email properties.

    This class provides information about the requirements imposed on email for a specific character set. It also provides convenience routines for converting between character sets, given the availability of the applicable codecs. Given a character set, it will do its best to provide information on how to use that character set in an email message in an RFC-compliant way.
```
Certain character sets must be encoded with quoted-printable or base64 when used in email headers or bodies. Certain character sets must be converted outright, and are not allowed in email.

Optional input_charset is as described below; it is always coerced to lower case. After being alias normalized it is also used as a lookup into the registry of character sets to find out the header encoding, body encoding, and output conversion codec to be used for the character set. For example, if input_charset is iso-8859-1, then headers and bodies will be encoded using quoted-printable and no output conversion codec is necessary. If input_charset is euc-jp, then headers will be encoded with base64, bodies will not be encoded, but output text will be converted from the euc-jp character set to the iso-2022-jp character set.

Charset instances have the following data attributes:

**input_charset**

The initial character set specified. Common aliases are converted to their official email names (e.g. latin_1 is converted to iso-8859-1). Defaults to 7-bit us-ascii.

**header_encoding**

If the character set must be encoded before it can be used in an email header, this attribute will be set to Charset.QP (for quoted-printable), Charset.BASE64 (for base64 encoding), or Charset.SHORTEST for the shortest of QP or BASE64 encoding. Otherwise, it will be None.

**body_encoding**

Same as header_encoding, but describes the encoding for the mail message's body, which indeed may be different than the
header encoding. `Charset.SHORTEST` is not allowed for `body_encoding`.

**output_charset**
Some character sets must be converted before they can be used in email headers or bodies. If the `input_charset` is one of them, this attribute will contain the name of the character set output will be converted to. Otherwise, it will be `None`.

**input_codec**
The name of the Python codec used to convert the `input_charset` to Unicode. If no conversion codec is necessary, this attribute will be `None`.

**output_codec**
The name of the Python codec used to convert Unicode to the `output_charset`. If no conversion codec is necessary, this attribute will have the same value as the `input_codec`.

`Charset` instances also have the following methods:

**get_body_encoding()**
Return the content transfer encoding used for body encoding.

This is either the string `quoted-printable` or `base64` depending on the encoding used, or it is a function, in which case you should call the function with a single argument, the Message object being encoded. The function should then set the `Content-Transfer-Encoding` header itself to whatever is appropriate.

Returns the string `quoted-printable` if `body_encoding` is QP, returns the string `base64` if `body_encoding` is BASE64,
and returns the string 7bit otherwise.

**get_output_charset()**

Return the output character set.

This is the `output_charset` attribute if that is not `None`, otherwise it is `input_charset`.

**header_encode(string)**

Header-encode the string `string`.

The type of encoding (base64 or quoted-printable) will be based on the `header_encoding` attribute.

**header_encode_lines(string, maxlengths)**

Header-encode a `string` by converting it first to bytes.

This is similar to `header_encode()` except that the string is fit into maximum line lengths as given by the argument `maxlengths`, which must be an iterator: each element returned from this iterator will provide the next maximum line length.

**body_encode(string)**

Body-encode the string `string`.

The type of encoding (base64 or quoted-printable) will be based on the `body_encoding` attribute.

The `Charset` class also provides a number of methods to support standard operations and built-in functions.

**__str__()**

Returns `input_charset` as a string coerced to lower case.
___repr__() is an alias for ___str__().

___eq__(other)
This method allows you to compare two CharSet instances for equality.

___ne__(other)
This method allows you to compare two CharSet instances for inequality.

The email.charset module also provides the following functions for adding new entries to the global character set, alias, and codec registries:

e-mail.charset.add_charset(charset, header_enc=None, body_enc=None, output_charset=None)
Add character properties to the global registry.

charset is the input character set, and must be the canonical name of a character set.

Optional header_enc and body_enc is either CharSet.QP for quoted-printable, CharSet.BASE64 for base64 encoding, CharSet.SHORTEST for the shortest of quoted-printable or base64 encoding, or None for no encoding. SHORTEST is only valid for header_enc. The default is None for no encoding.

Optional output_charset is the character set that the output should be in. Conversions will proceed from input charset, to Unicode, to the output charset when the method CharSet.convert() is called. The default is to output in the same character set as the input.
Both *input_charset* and *output_charset* must have Unicode codec entries in the module's character set-to-codec mapping; use `add_codec()` to add codecs the module does not know about. See the `codecs` module's documentation for more information.

The global character set registry is kept in the module global dictionary `CHARSETS`.

e-mail.charset.*add_alias*(alias, canonical)

Add a character set alias. *alias* is the alias name, e.g. `latin-1`. *canonical* is the character set's canonical name, e.g. `iso-8859-1`.

The global charset alias registry is kept in the module global dictionary `ALIASES`.

e-mail.charset.*add_codec*(charset, codecname)

Add a codec that map characters in the given character set to and from Unicode.

*charset* is the canonical name of a character set. *codecname* is the name of a Python codec, as appropriate for the second argument to the `str`'s `encode()` method.
19.1. **email** — An email and MIME handling package
19.1.13. **email.encoders**: Encoders

**Source code:** Lib/email/encoders.py

This module is part of the legacy (Compat32) email API. In the new API the functionality is provided by the `cte` parameter of the `set_content()` method.

The remaining text in this section is the original documentation of the module.

When creating `Message` objects from scratch, you often need to encode the payloads for transport through compliant mail servers. This is especially true for `image/*` and `text/*` type messages containing binary data.

The `email` package provides some convenient encodings in its `encoders` module. These encoders are actually used by the `MIMEAudio` and `MIMEImage` class constructors to provide default encodings. All encoder functions take exactly one argument, the message object to encode. They usually extract the payload, encode it, and reset the payload to this newly encoded value. They should also set the `Content-Transfer-Encoding` header as appropriate.

Note that these functions are not meaningful for a multipart message. They must be applied to individual subparts instead, and will raise a `TypeError` if passed a message whose type is multipart.

Here are the encoding functions provided:
email.encoders.**encode_quopri**(msg)

Encodes the payload into quoted-printable form and sets the `Content-Transfer-Encoding` header to `quoted-printable` [1]. This is a good encoding to use when most of your payload is normal printable data, but contains a few unprintable characters.

email.encoders.**encode_base64**(msg)

Encodes the payload into base64 form and sets the `Content-Transfer-Encoding` header to `base64`. This is a good encoding to use when most of your payload is unprintable data since it is a more compact form than quoted-printable. The drawback of base64 encoding is that it renders the text non-human readable.

email.encoders.**encode_7or8bit**(msg)

This doesn’t actually modify the message’s payload, but it does set the `Content-Transfer-Encoding` header to either `7bit` or `8bit` as appropriate, based on the payload data.

email.encoders.**encode_noop**(msg)

This does nothing; it doesn’t even set the `Content-Transfer-Encoding` header.

**Footnotes**

[1] Note that encoding with `encode_quopri()` also encodes all tabs and space characters in the data.
19.1.14. **email.utils:**
Miscellaneous utilities

Source code: Lib/email/utils.py

There are a couple of useful utilities provided in the `email.utils` module:

```python
e Email.utils.localtime(dt=None)
```

Return local time as an aware datetime object. If called without arguments, return current time. Otherwise `dt` argument should be a `datetime` instance, and it is converted to the local time zone according to the system time zone database. If `dt` is naive (that is, `dt.tzinfo` is None), it is assumed to be in local time. In this case, a positive or zero value for `isdst` causes `localtime` to presume initially that summer time (for example, Daylight Saving Time) is or is not (respectively) in effect for the specified time. A negative value for `isdst` causes the `localtime` to attempt to divine whether summer time is in effect for the specified time.

*New in version 3.3.*

```python
e Email.utils.make_msgid(idstring=None, domain=None)
```

Returns a string suitable for an RFC 2822-compliant `Message-ID` header. Optional `idstring` if given, is a string used to strengthen the uniqueness of the message id. Optional `domain` if given provides the portion of the msgid after the ‘@’. The default is the local hostname. It is not normally necessary to override this default, but may be useful certain cases, such as a constructing distributed
system that uses a consistent domain name across multiple hosts.

*Changed in version 3.2:* Added the *domain* keyword.

The remaining functions are part of the legacy (`Compat32`) email API. There is no need to directly use these with the new API, since the parsing and formatting they provide is done automatically by the header parsing machinery of the new API.

**email.utils.quote**(str)

Return a new string with backslashes in *str* replaced by two backslashes, and double quotes replaced by backslash-double quote.

**email.utils.unquote**(str)

Return a new string which is an *unquoted* version of *str*. If *str* ends and begins with double quotes, they are stripped off. Likewise if *str* ends and begins with angle brackets, they are stripped off.

**email.utils.parseaddr**(address)

Parse address – which should be the value of some address-containing field such as *To* or *Cc* – into its constituent *realname* and *email address* parts. Returns a tuple of that information, unless the parse fails, in which case a 2-tuple of (`'', '') is returned.

**email.utils.formataddr**(pair, charset='utf-8')

The inverse of `parseaddr()`, this takes a 2-tuple of the form *(realname, email_address)* and returns the string value suitable for a *To* or *Cc* header. If the first element of *pair* is false, then the second element is returned unmodified.

Optional *charset* is the character set that will be used in the RFC 2047 encoding of the *realname* if the *realname* contains non-
ASCII characters. Can be an instance of `str` or a `Charset`. Defaults to `utf-8`.

*Changed in version 3.3:* Added the `charset` option.

e-mail.utils. `getaddresses(fieldvalues)`
This method returns a list of 2-tuples of the form returned by `parseaddr()`. `fieldvalues` is a sequence of header field values as might be returned by `Message.get_all`. Here's a simple example that gets all the recipients of a message:

```python
from email.utils import getaddresses
tos = msg.get_all('to', [])
ccs = msg.get_all('cc', [])
resent_tos = msg.get_all('resent-to', [])
resent_ccs = msg.get_all('resent-cc', [])
all_recipients = getaddresses(tos + ccs + resent_tos + resent_ccs)
```

e-mail.utils. `parsedate(date)`
Attempts to parse a date according to the rules in RFC 2822. However, some mailers don't follow that format as specified, so `parsedate()` tries to guess correctly in such cases. `date` is a string containing an RFC 2822 date, such as "Mon, 20 Nov 1995 19:12:08 -0500". If it succeeds in parsing the date, `parsedate()` returns a 9-tuple that can be passed directly to `time.mktime()`; otherwise `None` will be returned. Note that indexes 6, 7, and 8 of the result tuple are not usable.

e-mail.utils. `parsedate_tz(date)`
Performs the same function as `parsedate()`, but returns either `None` or a 10-tuple; the first 9 elements make up a tuple that can
be passed directly to `time.mktime()`, and the tenth is the offset of the date's timezone from UTC (which is the official term for Greenwich Mean Time) [1]. If the input string has no timezone, the last element of the tuple returned is `None`. Note that indexes 6, 7, and 8 of the result tuple are not usable.

**email.utils.parsedate_to_datetime**(*date*)

The inverse of `format_datetime()`. Performs the same function as `parsedate()`, but on success returns a `datetime`. If the input date has a timezone of `-0000`, the datetime will be a naive datetime, and if the date is conforming to the RFCs it will represent a time in UTC but with no indication of the actual source timezone of the message the date comes from. If the input date has any other valid timezone offset, the datetime will be an aware datetime with the corresponding a timezone `tzinfo`.

*New in version 3.3.*

**email.utils.mktime_tz**(*tuple*)

Turn a 10-tuple as returned by `parsedate_tz()` into a UTC timestamp (seconds since the Epoch). If the timezone item in the tuple is `None`, assume local time.

**email.utils.formatdate**(*timeval=None, localtime=False, usegmt=False*)

Returns a date string as per RFC 2822, e.g.:

```
Fri, 09 Nov 2001 01:08:47 -0000
```

Optional `timeval` if given is a floating point time value as accepted by `time.gmtime()` and `time.localtime()`, otherwise the current time is used.
Optional `localtime` is a flag that when `True`, interprets `timeval`, and returns a date relative to the local timezone instead of UTC, properly taking daylight savings time into account. The default is `False` meaning UTC is used.

Optional `usegmt` is a flag that when `True`, outputs a date string with the timezone as an ascii string `GMT`, rather than a numeric `-0000`. This is needed for some protocols (such as HTTP). This only applies when `localtime` is `False`. The default is `False`.

```
email.utils.format_datetime(dt, usegmt=False)
```

Like `formatdate`, but the input is a `datetime` instance. If it is a naive datetime, it is assumed to be “UTC with no information about the source timezone”, and the conventional `-0000` is used for the timezone. If it is an aware `datetime`, then the numeric timezone offset is used. If it is an aware timezone with offset zero, then `usegmt` may be set to `True`, in which case the string `GMT` is used instead of the numeric timezone offset. This provides a way to generate standards conformant HTTP date headers.

*New in version 3.3.*

```
email.utils.decode_rfc2231(s)
```

Decode the string `s` according to [RFC 2231](https://tools.ietf.org/html/rfc2231).

```
email.utils.encode_rfc2231(s, charset=None, language=None)
```

Encode the string `s` according to [RFC 2231](https://tools.ietf.org/html/rfc2231). Optional `charset` and `language`, if given is the character set name and language name to use. If neither is given, `s` is returned as-is. If `charset` is given but `language` is not, the string is encoded using the empty string for `language`.
email.utils.collapse_rfc2231_value(value, errors='replace', fallback_charset='us-ascii')

When a header parameter is encoded in RFC 2231 format, Message.get_param may return a 3-tuple containing the character set, language, and value. collapse_rfc2231_value() turns this into a unicode string. Optional errors is passed to the errors argument of str's encode() method; it defaults to 'replace'. Optional fallback_charset specifies the character set to use if the one in the RFC 2231 header is not known by Python; it defaults to 'us-ascii'.

For convenience, if the value passed to collapse_rfc2231_value() is not a tuple, it should be a string and it is returned unquoted.

email.utils.decode_params(params)

Decode parameters list according to RFC 2231. params is a sequence of 2-tuples containing elements of the form (content-type, string-value).

Footnotes

[1] Note that the sign of the timezone offset is the opposite of the sign of the \texttt{time.timezone} variable for the same timezone; the latter variable follows the POSIX standard while this module follows RFC 2822.
19. Internet Data Handling

19.1. email — An email and MIME handling package
Iterating over a message object tree is fairly easy with the `Message.walk` method. The `email.iterators` module provides some useful higher level iterations over message object trees.

`email.iterators.body_line_iterator(msg, decode=False)`

This iterates over all the payloads in all the subparts of `msg`, returning the string payloads line-by-line. It skips over all the subpart headers, and it skips over any subpart with a payload that isn’t a Python string. This is somewhat equivalent to reading the flat text representation of the message from a file using `readline()`, skipping over all the intervening headers.

Optional `decode` is passed through to `Message.get_payload`.

`email.iterators.typed_subpart_iterator(msg, maintype='text', subtype=None)`

This iterates over all the subparts of `msg`, returning only those subparts that match the MIME type specified by `maintype` and `subtype`.

Note that `subtype` is optional; if omitted, then subpart MIME type matching is done only with the main type. `maintype` is optional too; it defaults to `text`. 

Thus, by default `typed_subpart_iterator()` returns each subpart that has a MIME type of `text/*`.

The following function has been added as a useful debugging tool. It should not be considered part of the supported public interface for the package.

```
email.iterators._structure(msg, fp=None, level=0, include_default=False)
```

Prints an indented representation of the content types of the message object structure. For example:

```bash
>>> msg = email.message_from_file(somefile)
>>> _structure(msg)
multipart/mixed
   text/plain
   text/plain
   multipart/digest
      message/rfc822
         text/plain
      message/rfc822
         text/plain
      message/rfc822
         text/plain
      message/rfc822
         text/plain
   text/plain
```

Optional `fp` is a file-like object to print the output to. It must be suitable for Python's `print()` function. `level` is used internally. `include_default`, if true, prints the default type as well.
19.2. **json** — JSON encoder and decoder

**Source code:** Lib/json/__init__.py

JSON (JavaScript Object Notation), specified by [RFC 7159](https://tools.ietf.org/html/rfc7159) (which obsoletes [RFC 4627](https://tools.ietf.org/html/rfc4627)) and by [ECMA-404](https://www.ecma-international.org/publications/standards/Ecma-404.htm), is a lightweight data interchange format inspired by JavaScript object literal syntax (although it is not a strict subset of JavaScript [1]).

`json` exposes an API familiar to users of the standard library `marshal` and `pickle` modules.

Encoding basic Python object hierarchies:

```python
>>> import json
>>> json.dumps(['foo', {'bar': ('baz', None, 1.0, 2), 'foo': {'bar': ['baz', None, 1.0, 2]}}, {'c': 0, 'b': 0, 'a': 0}, sort_keys=True], indent=4)
"""foo\
  {'bar':
    'baz': None,
    'foo': ['baz', None, 1.0, 2],
    'c': 0,
    'b': 0,
    'a': 0},

>>> from io import StringIO
>>> io = StringIO()
>>> json.dump(['streaming API'], io)
>>> io.getvalue()
'[
  "streaming API"]'
```
Compact encoding:
>>> import json
>>> json.dumps([1, 2, 3, {'4': 5, '6': 7}], separators
'[1,2,3,{"4":5,"6":7}]'

Pretty printing:
>>> import json
>>> print(json.dumps({'4': 5, '6': 7}, sort_keys=True
{
"4": 5,
"6": 7
}

Decoding JSON:
>>> import json
>>> json.loads('["foo", {"bar":["baz", null, 1.0, 2]}]'
['foo', {'bar': ['baz', None, 1.0, 2]}]
>>> json.loads('"\\"foo\\bar"')
'"foo\x08ar'
>>> from io import StringIO
>>> io = StringIO('["streaming API"]')
>>> json.load(io)
['streaming API']

Specializing JSON object decoding:
>>> import json
>>> def as_complex(dct):
...
if '__complex__' in dct:
...
return complex(dct['real'], dct['imag'])
...
return dct


... json.loads('{"__complex__": true, "real": 1, "imag": 2}')
(1+2j)
>>> import decimal
>>> json.loads('1.1', parse_float=decimal.Decimal)
Decimal('1.1')

Extending JSONEncoder:

>>> import json
>>> class ComplexEncoder(json.JSONEncoder):
...     def default(self, obj):
...         if isinstance(obj, complex):
...             return [obj.real, obj.imag]
...         return json.JSONEncoder.default(self, obj)

>>> json.dumps(2 + 1j, cls=ComplexEncoder)
'[2.0, 1.0]'
>>> ComplexEncoder().encode(2 + 1j)
'[2.0, 1.0]'
>>> list(ComplexEncoder().iterencode(2 + 1j))
['[2.0', ',', '1.0', ',']

Using json.tool from the shell to validate and pretty-print:

$ echo '{"json":"obj"}' | python -m json.tool
{
    "json": "obj"
}
$ echo '{1.2:3.4}' | python -m json.tool
Expecting property name enclosed in double quotes:
See Command Line Interface for detailed documentation.

**Note:** JSON is a subset of YAML 1.2. The JSON produced by this module’s default settings (in particular, the default `separators` value) is also a subset of YAML 1.0 and 1.1. This module can thus also be used as a YAML serializer.
19.2.1. Basic Usage

```python
json.dump(obj, fp, *, skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True, cls=None, indent=None, separators=None, default=None, sort_keys=False, **kw)
```

Serialize `obj` as a JSON formatted stream to `fp` (a supporting file-like object) using this conversion table.

If `skipkeys` is true (default: `False`), then dict keys that are not of a basic type (`str`, `int`, `float`, `bool`, `None`) will be skipped instead of raising a `TypeError`.

The `json` module always produces `str` objects, not `bytes` objects. Therefore, `fp.write()` must support `str` input.

If `ensure_ascii` is true (the default), the output is guaranteed to have all incoming non-ASCII characters escaped. If `ensure_ascii` is false, these characters will be output as-is.

If `check_circular` is false (default: `True`), then the circular reference check for container types will be skipped and a circular reference will result in an `OverflowError` (or worse).

If `allow_nan` is false (default: `True`), then it will be a `ValueError` to serialize out of range `float` values (`nan`, `inf`, `-inf`) in strict compliance of the JSON specification. If `allow_nan` is true, their JavaScript equivalents (`NaN`, `Infinity`, `-Infinity`) will be used.

If `indent` is a non-negative integer or string, then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0, negative, or `""` will only insert newlines.
None (the default) selects the most compact representation. Using a positive integer indent indents that many spaces per level. If indent is a string (such as \t\t\t\t\t), that string is used to indent each level.

*Changed in version 3.2:* Allow strings for indent in addition to integers.

If specified, separators should be an (item_separator, key_separator) tuple. The default is (', ', ': ') if indent is None and (', ', ': ') otherwise. To get the most compact JSON representation, you should specify (', ', ': ') to eliminate whitespace.

*Changed in version 3.4:* Use (', ', ': ') as default if indent is not None.

If specified, default should be a function that gets called for objects that can’t otherwise be serialized. It should return a JSON encodable version of the object or raise a TypeError. If not specified, TypeError is raised.

If sort_keys is true (default: False), then the output of dictionaries will be sorted by key.

To use a custom JSONEncoder subclass (e.g. one that overrides the default() method to serialize additional types), specify it with the cls kwarg; otherwise JSONEncoder is used.

*Changed in version 3.6:* All optional parameters are now keyword-only.

`json.dumps(obj, *, skipkeys=False, ensure_ascii=True, ...`
Serialize `obj` to a JSON formatted `str` using this conversion table. The arguments have the same meaning as in `dump()`.

**Note:** Unlike `pickle` and `marshal`, JSON is not a framed protocol, so trying to serialize multiple objects with repeated calls to `dump()` using the same `fp` will result in an invalid JSON file.

**Note:** Keys in key/value pairs of JSON are always of the type `str`. When a dictionary is converted into JSON, all the keys of the dictionary are coerced to strings. As a result of this, if a dictionary is converted into JSON and then back into a dictionary, the dictionary may not equal the original one. That is, `loads(dumps(x)) != x` if `x` has non-string keys.

## Deserialize

`json.load(fp, *, cls=None, object_hook=None, parse_float=None, parse_int=None, parse_constant=None, object_pairs_hook=None, **kw)`

Deserialaze `fp` (a `.read()`-supporting file-like object containing a JSON document) to a Python object using this conversion table.

`object_hook` is an optional function that will be called with the result of any object literal decoded (a `dict`). The return value of `object_hook` will be used instead of the `dict`. This feature can be used to implement custom decoders (e.g. JSON-RPC class hinting).

`object_pairs_hook` is an optional function that will be called with the result of any object literal decoded with an ordered list of pairs. The return value of `object_pairs_hook` will be used instead of the `dict`. This feature can be used to implement custom decoders that rely
on the order that the key and value pairs are decoded (for example, `collections.OrderedDict()` will remember the order of insertion). If `object_hook` is also defined, the `object_pairs_hook` takes priority.

*Changed in version 3.1:* Added support for `object_pairs_hook`.

`parse_float`, if specified, will be called with the string of every JSON float to be decoded. By default, this is equivalent to `float(num_str)`. This can be used to use another datatype or parser for JSON floats (e.g. `decimal.Decimal`).

`parse_int`, if specified, will be called with the string of every JSON int to be decoded. By default, this is equivalent to `int(num_str)`. This can be used to use another datatype or parser for JSON integers (e.g. `float`).

`parse_constant`, if specified, will be called with one of the following strings: `-Infinity`, `Infinity`, `NaN`. This can be used to raise an exception if invalid JSON numbers are encountered.

*Changed in version 3.1:* `parse_constant` doesn’t get called on ‘null’, ‘true’, ‘false’ anymore.

To use a custom `JSONDecoder` subclass, specify it with the `cls` kwarg; otherwise `JSONDecoder` is used. Additional keyword arguments will be passed to the constructor of the class.

If the data being deserialized is not a valid JSON document, a `JSONDecodeError` will be raised.

*Changed in version 3.6:* All optional parameters are now keyword-only.
json. **loads**(s, *, encoding=None, cls=None, object_hook=None, parse_float=None, parse_int=None, parse_constant=None, object_pairs_hook=None, **kw)

Deserializes s (a str, bytes or bytearray instance containing a JSON document) to a Python object using this conversion table.

The other arguments have the same meaning as in **load()**, except **encoding** which is ignored and deprecated.

If the data being deserialized is not a valid JSON document, a **JSONDecodeError** will be raised.

*Changed in version 3.6:* s can now be of type bytes or bytearray. The input encoding should be UTF-8, UTF-16 or UTF-32.
19.2.2. Encoders and Decoders

class json.**JSONDecoder**(*, *object_hook=None*,
*parse_float=None, parse_int=None, parse_constant=None,*
*strict=True, object_pairs_hook=None*)

Simple JSON decoder.

Performs the following translations in decoding by default:

<table>
<thead>
<tr>
<th>JSON</th>
<th>Python</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>dict</td>
</tr>
<tr>
<td>array</td>
<td>list</td>
</tr>
<tr>
<td>string</td>
<td>str</td>
</tr>
<tr>
<td>number (int)</td>
<td>int</td>
</tr>
<tr>
<td>number (real)</td>
<td>float</td>
</tr>
<tr>
<td>true</td>
<td>True</td>
</tr>
<tr>
<td>false</td>
<td>False</td>
</tr>
<tr>
<td>null</td>
<td>None</td>
</tr>
</tbody>
</table>

It also understands **NaN**, **Infinity**, and **-Infinity** as their corresponding float values, which is outside the JSON spec.

*object_hook*, if specified, will be called with the result of every JSON object decoded and its return value will be used in place of the given dict. This can be used to provide custom deserializations (e.g. to support JSON-RPC class hinting).

*object_pairs_hook*, if specified will be called with the result of every JSON object decoded with an ordered list of pairs. The return value of *object_pairs_hook* will be used instead of the dict. This feature
can be used to implement custom decoders that rely on the order that the key and value pairs are decoded (for example, `collections.OrderedDict()` will remember the order of insertion). If `object_hook` is also defined, the `object_pairs_hook` takes priority.

*Changed in version 3.1:* Added support for `object_pairs_hook`.

`parse_float`, if specified, will be called with the string of every JSON float to be decoded. By default, this is equivalent to `float(num_str)`. This can be used to use another datatype or parser for JSON floats (e.g. `decimal.Decimal`).

`parse_int`, if specified, will be called with the string of every JSON int to be decoded. By default, this is equivalent to `int(num_str)`. This can be used to use another datatype or parser for JSON integers (e.g. `float`).

`parse_constant`, if specified, will be called with one of the following strings: `-Infinity`, `'Infinity'`, `'NaN'`. This can be used to raise an exception if invalid JSON numbers are encountered.

If `strict` is false (`True` is the default), then control characters will be allowed inside strings. Control characters in this context are those with character codes in the 0–31 range, including `\t` (tab), `\n`, `\r` and `\0`.

If the data being deserialized is not a valid JSON document, a `JSONDecodeError` will be raised.

*Changed in version 3.6:* All parameters are now `keyword-only`.

`decode`(*s*)
Return the Python representation of s (a `str` instance containing a JSON document).

`JSONDecodeError` will be raised if the given JSON document is not valid.

**raw_decode(s)**

Decode a JSON document from s (a `str` beginning with a JSON document) and return a 2-tuple of the Python representation and the index in s where the document ended.

This can be used to decode a JSON document from a string that may have extraneous data at the end.

```python
class json.JSONEncoder(*, skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True, sort_keys=False, indent=None, separators=None, default=None)
```
Extensible JSON encoder for Python data structures.

Supports the following objects and types by default:

<table>
<thead>
<tr>
<th>Python</th>
<th>JSON</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dict</code></td>
<td>object</td>
</tr>
<tr>
<td><code>list</code>, <code>tuple</code></td>
<td>array</td>
</tr>
<tr>
<td><code>str</code></td>
<td>string</td>
</tr>
<tr>
<td><code>int</code>, <code>float</code>, <code>int-</code> &amp; <code>float-derived Enums</code></td>
<td>number</td>
</tr>
<tr>
<td><code>True</code></td>
<td><code>true</code></td>
</tr>
<tr>
<td><code>False</code></td>
<td><code>false</code></td>
</tr>
<tr>
<td><code>None</code></td>
<td><code>null</code></td>
</tr>
</tbody>
</table>

*Changed in version 3.4:* Added support for int- and float-derived
Enum classes.

To extend this to recognize other objects, subclass and implement a `default()` method with another method that returns a serializable object for `o` if possible, otherwise it should call the superclass implementation (to raise `TypeError`).

If `skipkeys` is false (the default), then it is a `TypeError` to attempt encoding of keys that are not `str`, `int`, `float` or `None`. If `skipkeys` is true, such items are simply skipped.

If `ensure_ascii` is true (the default), the output is guaranteed to have all incoming non-ASCII characters escaped. If `ensure_ascii` is false, these characters will be output as-is.

If `check_circular` is true (the default), then lists, dicts, and custom encoded objects will be checked for circular references during encoding to prevent an infinite recursion (which would cause an `OverflowError`). Otherwise, no such check takes place.

If `allow_nan` is true (the default), then NaN, Infinity, and -Infinity will be encoded as such. This behavior is not JSON specification compliant, but is consistent with most JavaScript based encoders and decoders. Otherwise, it will be a `ValueError` to encode such floats.

If `sort_keys` is true (default: `False`), then the output of dictionaries will be sorted by key; this is useful for regression tests to ensure that JSON serializations can be compared on a day-to-day basis.

If `indent` is a non-negative integer or string, then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0, negative, or "" will only insert newlines.
None (the default) selects the most compact representation. Using a positive integer indent indents that many spaces per level. If *indent* is a string (such as ".t"), that string is used to indent each level.

*Changed in version 3.2*: Allow strings for *indent* in addition to integers.

If specified, *separators* should be an (*item_separator*, *key_separator*) tuple. The default is (',', ': ') if *indent* is None and (',', ': ') otherwise. To get the most compact JSON representation, you should specify (',', ': ') to eliminate whitespace.

*Changed in version 3.4*: Use (',', ': ') as default if *indent* is not None.

If specified, *default* should be a function that gets called for objects that can’t otherwise be serialized. It should return a JSON encodable version of the object or raise a *TypeError*. If not specified, *TypeError* is raised.

*Changed in version 3.6*: All parameters are now *keyword-only*.

**default(o)**

Implement this method in a subclass such that it returns a serializable object for *o*, or calls the base implementation (to raise a *TypeError*).

For example, to support arbitrary iterators, you could implement *default* like this:

```python
def default(self, o):
```
try:
    iterable = iter(o)
except TypeError:
    pass
else:
    return list(iterable)

# Let the base class default method raise the
return json.JSONEncoder.default(self, o)

code(o)

Return a JSON string representation of a Python data structure, o. For example:

```python
g>> json.JSONEncoder().encode({'foo': ['bar', 'baz']}
```

iterencode(o)

Encode the given object, o, and yield each string representation as available. For example:

```python
gfor chunk in json.JSONEncoder().iterencode(big):
    mysocket.write(chunk)
```
19.2.3. Exceptions

exception json.JSONDecodeError(msg, doc, pos)

Subclass of ValueError with the following additional attributes:

msg
   The unformatted error message.

doc
   The JSON document being parsed.

pos
   The start index of doc where parsing failed.

lineno
   The line corresponding to pos.

colno
   The column corresponding to pos.

New in version 3.5.
19.2.4. Standard Compliance and Interoperability

The JSON format is specified by RFC 7159 and by ECMA-404. This section details this module’s level of compliance with the RFC. For simplicity, JSONEncoder and JSONDecoder subclasses, and parameters other than those explicitly mentioned, are not considered.

This module does not comply with the RFC in a strict fashion, implementing some extensions that are valid JavaScript but not valid JSON. In particular:

- Infinite and NaN number values are accepted and output;
- Repeated names within an object are accepted, and only the value of the last name-value pair is used.

Since the RFC permits RFC-compliant parsers to accept input texts that are not RFC-compliant, this module’s deserializer is technically RFC-compliant under default settings.

19.2.4.1. Character Encodings

The RFC requires that JSON be represented using either UTF-8, UTF-16, or UTF-32, with UTF-8 being the recommended default for maximum interoperability.

As permitted, though not required, by the RFC, this module’s serializer sets ensure_ascii=True by default, thus escaping the output so that the resulting strings only contain ASCII characters.

Other than the ensure_ascii parameter, this module is defined strictly in terms of conversion between Python objects and Unicode.
strings, and thus does not otherwise directly address the issue of character encodings.

The RFC prohibits adding a byte order mark (BOM) to the start of a JSON text, and this module’s serializer does not add a BOM to its output. The RFC permits, but does not require, JSON deserializers to ignore an initial BOM in their input. This module’s deserializer raises a ValueError when an initial BOM is present.

The RFC does not explicitly forbid JSON strings which contain byte sequences that don’t correspond to valid Unicode characters (e.g. unpaired UTF-16 surrogates), but it does note that they may cause interoperability problems. By default, this module accepts and outputs (when present in the original str) code points for such sequences.

19.2.4.2. Infinite and NaN Number Values

The RFC does not permit the representation of infinite or NaN number values. Despite that, by default, this module accepts and outputs Infinity, -Infinity, and NaN as if they were valid JSON number literal values:

```python
>>> # Neither of these calls raises an exception, but
>>> json.dumps(float('-inf'))
'-Infinity'
>>> json.dumps(float('nan'))
'NaN'
>>> # Same when deserializing
>>> json.loads('-Infinity')
-inf
>>> json.loads('NaN')
nan
```
In the serializer, the *allow_nan* parameter can be used to alter this behavior. In the deserializer, the *parse_constant* parameter can be used to alter this behavior.

### 19.2.4.3. Repeated Names Within an Object

The RFC specifies that the names within a JSON object should be unique, but does not mandate how repeated names in JSON objects should be handled. By default, this module does not raise an exception; instead, it ignores all but the last name-value pair for a given name:

```python
>>> weird_json = '{"x": 1, "x": 2, "x": 3}'
>>> json.loads(weird_json)
{'x': 3}
```

The *object_pairs_hook* parameter can be used to alter this behavior.

### 19.2.4.4. Top-level Non-Object, Non-Array Values

The old version of JSON specified by the obsolete [RFC 4627](https://tools.ietf.org/html/rfc4627) required that the top-level value of a JSON text must be either a JSON object or array (Python `dict` or `list`), and could not be a JSON null, boolean, number, or string value. [RFC 7159](https://tools.ietf.org/html/rfc7159) removed that restriction, and this module does not and has never implemented that restriction in either its serializer or its deserializer.

Regardless, for maximum interoperability, you may wish to voluntarily adhere to the restriction yourself.

### 19.2.4.5. Implementation Limitations
Some JSON deserializer implementations may set limits on:

- the size of accepted JSON texts
- the maximum level of nesting of JSON objects and arrays
- the range and precision of JSON numbers
- the content and maximum length of JSON strings

This module does not impose any such limits beyond those of the relevant Python datatypes themselves or the Python interpreter itself.

When serializing to JSON, beware any such limitations in applications that may consume your JSON. In particular, it is common for JSON numbers to be deserialized into IEEE 754 double precision numbers and thus subject to that representation’s range and precision limitations. This is especially relevant when serializing Python int values of extremely large magnitude, or when serializing instances of “exotic” numerical types such as decimal.Decimal.
19.2.5. Command Line Interface

**Source code:** Lib/json/tool.py

The `json.tool` module provides a simple command line interface to validate and pretty-print JSON objects.

If the optional `infile` and `outfile` arguments are not specified, `sys.stdin` and `sys.stdout` will be used respectively:

```bash
$ echo '{"json": "obj"}' | python -m json.tool
{
    "json": "obj"
}
$ echo '{1.2:3.4}' | python -m json.tool
```

Expecting property name enclosed in double quotes: line

*Changed in version 3.5:* The output is now in the same order as the input. Use the `--sort-keys` option to sort the output of dictionaries alphabetically by key.

19.2.5.1. Command line options

**infile**

The JSON file to be validated or pretty-printed:

```bash
$ python -m json.tool mp_films.json
[
    {
        "title": "And Now for Something Completely Different",
        "year": 1971
    }
]`
If `infile` is not specified, read from `sys.stdin`.

**outfile**

Write the output of the `infile` to the given `outfile`. Otherwise, write it to `sys.stdout`.

**--sort-keys**

Sort the output of dictionaries alphabetically by key.

*New in version 3.5.*

**-h, --help**

Show the help message.

**Footnotes**

As noted in the errata for RFC 7159, JSON permits literal U+2028 (LINE SEPARATOR) and U+2029 (PARAGRAPH SEPARATOR) characters in strings, whereas JavaScript (as of ECMAScript Edition 5.1) does not.
Mailcap files are used to configure how MIME-aware applications such as mail readers and Web browsers react to files with different MIME types. (The name “mailcap” is derived from the phrase “mail capability”.) For example, a mailcap file might contain a line like `video/mpeg; xmpeg %s`. Then, if the user encounters an email message or Web document with the MIME type `video/mpeg`, `%s` will be replaced by a filename (usually one belonging to a temporary file) and the `xmpeg` program can be automatically started to view the file.

The mailcap format is documented in RFC 1524, “A User Agent Configuration Mechanism For Multimedia Mail Format Information,” but is not an Internet standard. However, mailcap files are supported on most Unix systems.

```python
mailcap.findmatch(caps, MIMEtype, key='view',
filename='/dev/null', plist=[])
```

Return a 2-tuple; the first element is a string containing the command line to be executed (which can be passed to `os.system()`), and the second element is the mailcap entry for a given MIME type. If no matching MIME type can be found, `(None, None)` is returned.

`key` is the name of the field desired, which represents the type of activity to be performed; the default value is ‘view’, since in the
most common case you simply want to view the body of the MIME-typed data. Other possible values might be 'compose' and 'edit', if you wanted to create a new body of the given MIME type or alter the existing body data. See RFC 1524 for a complete list of these fields.

*filename* is the filename to be substituted for `%s` in the command line; the default value is `/dev/null` which is almost certainly not what you want, so usually you'll override it by specifying a filename.

*plist* can be a list containing named parameters; the default value is simply an empty list. Each entry in the list must be a string containing the parameter name, an equals sign ('='), and the parameter's value. Mailcap entries can contain named parameters like `%{foo}`, which will be replaced by the value of the parameter named ‘foo’. For example, if the command line `showpartial %{id} %{number} %{total}` was in a mailcap file, and *plist* was set to `['id=1', 'number=2', 'total=3']`, the resulting command line would be `showpartial 1 2 3`.

In a mailcap file, the “test” field can optionally be specified to test some external condition (such as the machine architecture, or the window system in use) to determine whether or not the mailcap line applies. `findmatch()` will automatically check such conditions and skip the entry if the check fails.

**mailcap.getcaps()**

Returns a dictionary mapping MIME types to a list of mailcap file entries. This dictionary must be passed to the `findmatch()` function. An entry is stored as a list of dictionaries, but it shouldn't be necessary to know the details of this representation.
The information is derived from all of the mailcap files found on the system. Settings in the user's mailcap file $HOME/.mailcap will override settings in the system mailcap files /etc/mailcap, /usr/etc/mailcap, and /usr/local/etc/mailcap. An example usage:

```python
>>> import mailcap
>>> d = mailcap.getcaps()
>>> mailcap.findmatch(d, 'video/mpeg', filename='tmp1223',
('xmpeg tmp1223', {'view': 'xmpeg %s'}))
```
19.4. **mailbox** — Manipulate mailboxes in various formats

**Source code:** Lib/mailbox.py

This module defines two classes, `Mailbox` and `Message`, for accessing and manipulating on-disk mailboxes and the messages they contain. `Mailbox` offers a dictionary-like mapping from keys to messages. `Message` extends the `email.message` module's `Message` class with format-specific state and behavior. Supported mailbox formats are Maildir, mbox, MH, Babyl, and MMDF.

**See also:**

**Module** [email]

Represent and manipulate messages.
19.4.1. **Mailbox** objects

*class mailbox.Mailbox*

A mailbox, which may be inspected and modified.

The `Mailbox` class defines an interface and is not intended to be instantiated. Instead, format-specific subclasses should inherit from `Mailbox` and your code should instantiate a particular subclass.

The `Mailbox` interface is dictionary-like, with small keys corresponding to messages. Keys are issued by the `Mailbox` instance with which they will be used and are only meaningful to that `Mailbox` instance. A key continues to identify a message even if the corresponding message is modified, such as by replacing it with another message.

Messages may be added to a `Mailbox` instance using the set-like method `add()` and removed using a `del` statement or the set-like methods `remove()` and `discard()`.

`Mailbox` interface semantics differ from dictionary semantics in some noteworthy ways. Each time a message is requested, a new representation (typically a `Message` instance) is generated based upon the current state of the mailbox. Similarly, when a message is added to a `Mailbox` instance, the provided message representation's contents are copied. In neither case is a reference to the message representation kept by the `Mailbox` instance.

The default `Mailbox` iterator iterates over message representations, not keys as the default dictionary iterator does. Moreover, modification of a mailbox during iteration is safe and
well-defined. Messages added to the mailbox after an iterator is created will not be seen by the iterator. Messages removed from the mailbox before the iterator yields them will be silently skipped, though using a key from an iterator may result in a `KeyError` exception if the corresponding message is subsequently removed.

**Warning:** Be very cautious when modifying mailboxes that might be simultaneously changed by some other process. The safest mailbox format to use for such tasks is Maildir; try to avoid using single-file formats such as mbox for concurrent writing. If you’re modifying a mailbox, you **must** lock it by calling the `lock()` and `unlock()` methods **before** reading any messages in the file or making any changes by adding or deleting a message. Failing to lock the mailbox runs the risk of losing messages or corrupting the entire mailbox.

**Mailbox** instances have the following methods:

**add(message)**

Add `message` to the mailbox and return the key that has been assigned to it.

Parameter `message` may be a `Message` instance, an `email.message.Message` instance, a string, a byte string, or a file-like object (which should be open in binary mode). If `message` is an instance of the appropriate format-specific `Message` subclass (e.g., if it’s an `mboxMessage` instance and this is an `mbox` instance), its format-specific information is used. Otherwise, reasonable defaults for format-specific information are used.

*Changed in version 3.2:* Support for binary input was added.
remove(key)
__delitem__(key)
discard(key)

Delete the message corresponding to key from the mailbox.

If no such message exists, a KeyError exception is raised if the method was called as remove() or __delitem__() but no exception is raised if the method was called as discard(). The behavior of discard() may be preferred if the underlying mailbox format supports concurrent modification by other processes.

__setitem__(key, message)

Replace the message corresponding to key with message. Raise a KeyError exception if no message already corresponds to key.

As with add(), parameter message may be a Message instance, an email.message.Message instance, a string, a byte string, or a file-like object (which should be open in binary mode). If message is an instance of the appropriate format-specific Message subclass (e.g., if it’s an mboxMessage instance and this is an mbox instance), its format-specific information is used. Otherwise, the format-specific information of the message that currently corresponds to key is left unchanged.

iterkeys()
keys()

Return an iterator over all keys if called as iterkeys() or return a list of keys if called as keys().
**itervalues()**
**__iter__()**
**values()**

Return an iterator over representations of all messages if called as *itervalues()* or *__iter__()* or return a list of such representations if called as *values()*. The messages are represented as instances of the appropriate format-specific *Message* subclass unless a custom message factory was specified when the *Mailbox* instance was initialized.

**Note:** The behavior of *__iter__()* is unlike that of dictionaries, which iterate over keys.

**iteritems()**
**items()**

Return an iterator over *(key, message)* pairs, where *key* is a key and *message* is a message representation, if called as *iteritems()* or return a list of such pairs if called as *items()*. The messages are represented as instances of the appropriate format-specific *Message* subclass unless a custom message factory was specified when the *Mailbox* instance was initialized.

**get(key, default=None)**
**__getitem__(key)**

Return a representation of the message corresponding to *key*. If no such message exists, *default* is returned if the method was called as *get()* and a *KeyError* exception is raised if the method was called as *__getitem__()*. The message is represented as an instance of the appropriate format-specific *Message* subclass unless a custom message factory was
specified when the Mailbox instance was initialized.

**get_message**(key)
Return a representation of the message corresponding to key as an instance of the appropriate format-specific Message subclass, or raise a KeyError exception if no such message exists.

**get_bytes**(key)
Return a byte representation of the message corresponding to key, or raise a KeyError exception if no such message exists.

*New in version 3.2.*

**get_string**(key)
Return a string representation of the message corresponding to key, or raise a KeyError exception if no such message exists. The message is processed through email.message.Message to convert it to a 7bit clean representation.

**get_file**(key)
Return a file-like representation of the message corresponding to key, or raise a KeyError exception if no such message exists. The file-like object behaves as if open in binary mode. This file should be closed once it is no longer needed.

*Changed in version 3.2:* The file object really is a binary file; previously it was incorrectly returned in text mode. Also, the file-like object now supports the context management protocol: you can use a with statement to automatically close it.
Note: Unlike other representations of messages, file-like representations are not necessarily independent of the Mailbox instance that created them or of the underlying mailbox. More specific documentation is provided by each subclass.

__contains__(key)
Return True if key corresponds to a message, False otherwise.

__len__()
Return a count of messages in the mailbox.

clear()
Delete all messages from the mailbox.

pop(key, default=None)
Return a representation of the message corresponding to key and delete the message. If no such message exists, return default. The message is represented as an instance of the appropriate format-specific Message subclass unless a custom message factory was specified when the Mailbox instance was initialized.

popitem()
Return an arbitrary (key, message) pair, where key is a key and message is a message representation, and delete the corresponding message. If the mailbox is empty, raise a KeyError exception. The message is represented as an instance of the appropriate format-specific Message subclass unless a custom message factory was specified when the
Mailbox instance was initialized.

**update**(arg)
Parameter arg should be a key-to-message mapping or an iterable of (key, message) pairs. Updates the mailbox so that, for each given key and message, the message corresponding to key is set to message as if by using __setitem__() . As with __setitem__(), each key must already correspond to a message in the mailbox or else a KeyError exception will be raised, so in general it is incorrect for arg to be a Mailbox instance.

**Note:** Unlike with dictionaries, keyword arguments are not supported.

**flush()**
Write any pending changes to the filesystem. For some Mailbox subclasses, changes are always written immediately and flush() does nothing, but you should still make a habit of calling this method.

**lock()**
Acquire an exclusive advisory lock on the mailbox so that other processes know not to modify it. An External Clash Error is raised if the lock is not available. The particular locking mechanisms used depend upon the mailbox format. You should always lock the mailbox before making any modifications to its contents.

**unlock()**
Release the lock on the mailbox, if any.
close()
Flush the mailbox, unlock it if necessary, and close any open files. For some Mailbox subclasses, this method does nothing.

19.4.1.1. Maildir

class mailbox.Maildir(dirname, factory=None, create=True)
A subclass of Mailbox for mailboxes in Maildir format. Parameter factory is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If factory is None, MaildirMessage is used as the default message representation. If create is True, the mailbox is created if it does not exist.

It is for historical reasons that dirname is named as such rather than path.

Maildir is a directory-based mailbox format invented for the qmail mail transfer agent and now widely supported by other programs. Messages in a Maildir mailbox are stored in separate files within a common directory structure. This design allows Maildir mailboxes to be accessed and modified by multiple unrelated programs without data corruption, so file locking is unnecessary.

Maildir mailboxes contain three subdirectories, namely: tmp, new, and cur. Messages are created momentarily in the tmp subdirectory and then moved to the new subdirectory to finalize delivery. A mail user agent may subsequently move the message to the cur subdirectory and store information about the state of the message in a special “info” section appended to its file name.
Folders of the style introduced by the Courier mail transfer agent are also supported. Any subdirectory of the main mailbox is considered a folder if ' .' is the first character in its name. Folder names are represented by Maildir without the leading ' .' . Each folder is itself a Maildir mailbox but should not contain other folders. Instead, a logical nesting is indicated using ' .' to delimit levels, e.g., “Archived.2005.07”.

**Note:** The Maildir specification requires the use of a colon (':') in certain message file names. However, some operating systems do not permit this character in file names. If you wish to use a Maildir-like format on such an operating system, you should specify another character to use instead. The exclamation point (' ! ') is a popular choice. For example:

```python
import mailbox
mailbox.Maildir.colon = ' !'
```

The colon attribute may also be set on a per-instance basis.

**Maildir** instances have all of the methods of **Mailbox** in addition to the following:

**list_folders()**

Return a list of the names of all folders.

**get_folder(folder)**

Return a **Maildir** instance representing the folder whose name is *folder*. A **NoSuchMailboxError** exception is raised if the folder does not exist.

**add_folder(folder)**

Create a folder whose name is *folder* and return a **Maildir**
instance representing it.

**remove_folder(folder)**
Delete the folder whose name is *folder*. If the folder contains any messages, a `NotEmptyError` exception will be raised and the folder will not be deleted.

**clean()**
Delete temporary files from the mailbox that have not been accessed in the last 36 hours. The Maildir specification says that mail-reading programs should do this occasionally.

Some **Mailbox** methods implemented by **Maildir** deserve special remarks:

**add(message)**

**__setitem__(key, message)**

**update(arg)**

**Warning:** These methods generate unique file names based upon the current process ID. When using multiple threads, undetected name clashes may occur and cause corruption of the mailbox unless threads are coordinated to avoid using these methods to manipulate the same mailbox simultaneously.

**flush()**
All changes to Maildir mailboxes are immediately applied, so this method does nothing.

**lock()**

**unlock()**
Maildir mailboxes do not support (or require) locking, so these
methods do nothing.

**close()**

Maildir instances do not keep any open files and the underlying mailboxes do not support locking, so this method does nothing.

**get_file(key)**

Depending upon the host platform, it may not be possible to modify or remove the underlying message while the returned file remains open.

Notes on Maildir by its inventor. Includes an updated name-creation scheme and details on “info” semantics.

maildir man page from Courier
Another specification of the format. Describes a common extension for supporting folders.

---

19.4.1.2. **mbox**

class mailbox. **mbox**(path, factory=None, create=True)

A subclass of Mailbox for mailboxes in mbox format. Parameter factory is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If factory is None, mboxMessage is used as the default message representation. If create is True,
the mailbox is created if it does not exist.

The mbox format is the classic format for storing mail on Unix systems. All messages in an mbox mailbox are stored in a single file with the beginning of each message indicated by a line whose first five characters are “From “.

Several variations of the mbox format exist to address perceived shortcomings in the original. In the interest of compatibility, mbox implements the original format, which is sometimes referred to as mboxo. This means that the Content-Length header, if present, is ignored and that any occurrences of “From ” at the beginning of a line in a message body are transformed to “>From ” when storing the message, although occurrences of “>From ” are not transformed to “From ” when reading the message.

Some Mailbox methods implemented by mbox deserve special remarks:

get_file(key)

Using the file after calling flush() or close() on the mbox instance may yield unpredictable results or raise an exception.

lock()
unlock()

Three locking mechanisms are used—dot locking and, if available, the flock() and lockf() system calls.

mbox man page from tin
Another specification of the format, with details on locking.

**Configuring Netscape Mail on Unix: Why The Content-Length Format is Bad**

An argument for using the original mbox format rather than a variation.

**“mbox” is a family of several mutually incompatible mailbox formats**

A history of mbox variations.

19.4.1.3. **MH**

class mailbox.**MH**(path, factory=None, create=True)

A subclass of Mailbox for mailboxes in MH format. Parameter `factory` is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If `factory` is `None`, **MHMessage** is used as the default message representation. If `create` is `True`, the mailbox is created if it does not exist.

MH is a directory-based mailbox format invented for the MH Message Handling System, a mail user agent. Each message in an MH mailbox resides in its own file. An MH mailbox may contain other MH mailboxes (called folders) in addition to messages. Folders may be nested indefinitely. MH mailboxes also support sequences, which are named lists used to logically group messages without moving them to sub-folders. Sequences are defined in a file called `.mh_sequences` in each folder.

The **MH** class manipulates MH mailboxes, but it does not attempt to emulate all of `mh`'s behaviors. In particular, it does not modify and is not affected by the context or `.mh_profile` files that are
used by mh to store its state and configuration.

MH instances have all of the methods of Mailbox in addition to the following:

**list_folders()**

Return a list of the names of all folders.

**get_folder(folder)**

Return an MH instance representing the folder whose name is *folder*. A NoSuchMailboxError exception is raised if the folder does not exist.

**add_folder(folder)**

Create a folder whose name is *folder* and return an MH instance representing it.

**remove_folder(folder)**

Delete the folder whose name is *folder*. If the folder contains any messages, aNotEmptyError exception will be raised and the folder will not be deleted.

**get_sequences()**

Return a dictionary of sequence names mapped to key lists. If there are no sequences, the empty dictionary is returned.

**set_sequences(sequences)**

Re-define the sequences that exist in the mailbox based upon *sequences*, a dictionary of names mapped to key lists, like returned by get_sequences().

**pack()**

Rename messages in the mailbox as necessary to eliminate
gaps in numbering. Entries in the sequences list are updated correspondingly.

**Note:** Already-issued keys are invalidated by this operation and should not be subsequently used.

Some **Mailbox** methods implemented by **MH** deserve special remarks:

```python
remove(key)
__delitem__(key)
discard(key)
```

These methods immediately delete the message. The MH convention of marking a message for deletion by prepending a comma to its name is not used.

```python
lock()
unlock()
```

Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls. For MH mailboxes, locking the mailbox means locking the `.mh_sequences` file and, only for the duration of any operations that affect them, locking individual message files.

```python
get_file(key)
```

Depending upon the host platform, it may not be possible to remove the underlying message while the returned file remains open.

```python
flush()
```

All changes to MH mailboxes are immediately applied, so this method does nothing.
**close()**

MH instances do not keep any open files, so this method is equivalent to `unlock()`.

A GPL-licensed book on **mh** and **nmh**, with some information on the mailbox format.

---

**19.4.1.4. Babyl**

**class** mailbox. **Babyl**(*path*, *factory=None, create=True*)

A subclass of **Mailbox** for mailboxes in Babyl format. Parameter `factory` is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If `factory` is `None`, **BabylMessage** is used as the default message representation. If `create` is `True`, the mailbox is created if it does not exist.

Babyl is a single-file mailbox format used by the Rmail mail user agent included with Emacs. The beginning of a message is indicated by a line containing the two characters Control-Underscore (`\037`) and Control-L (`\014`). The end of a message is indicated by the start of the next message or, in the case of the last message, a line containing a Control-Underscore (`\037`) character.

Messages in a Babyl mailbox have two sets of headers, original
headers and so-called visible headers. Visible headers are typically a subset of the original headers that have been reformatted or abridged to be more attractive. Each message in a Babyl mailbox also has an accompanying list of labels, or short strings that record extra information about the message, and a list of all user-defined labels found in the mailbox is kept in the Babyl options section.

Babyl instances have all of the methods of Mailbox in addition to the following:

**get_labels()**

Return a list of the names of all user-defined labels used in the mailbox.

**Note:** The actual messages are inspected to determine which labels exist in the mailbox rather than consulting the list of labels in the Babyl options section, but the Babyl section is updated whenever the mailbox is modified.

Some Mailbox methods implemented by Babyl deserve special remarks:

**get_file(key)**

In Babyl mailboxes, the headers of a message are not stored contiguously with the body of the message. To generate a file-like representation, the headers and body are copied together into an io.BytesIO instance, which has an API identical to that of a file. As a result, the file-like object is truly independent of the underlying mailbox but does not save memory compared to a string representation.

**lock()**
unlock()

Three locking mechanisms are used—dot locking and, if available, the flock() and lockf() system calls.

Format of Version 5 Babyl Files
A specification of the Babyl format.

Reading Mail with Rmail
The Rmail manual, with some information on Babyl semantics.

19.4.1.5. MMDF

class mailbox. MMDF(path, factory=None, create=True)

A subclass of Mailbox for mailboxes in MMDF format. Parameter factory is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If factory is None, MMDFMessage is used as the default message representation. If create is True, the mailbox is created if it does not exist.

MMDF is a single-file mailbox format invented for the Multichannel Memorandum Distribution Facility, a mail transfer agent. Each message is in the same form as an mbox message but is bracketed before and after by lines containing four Control-A (\001) characters. As with the mbox format, the beginning of each message is indicated by a line whose first five characters are “From “, but additional occurrences of “From ” are not transformed to “>From ” when storing messages because the extra message separator lines prevent mistaking such occurrences for the starts of subsequent messages.
Some Mailbox methods implemented by MMDF deserve special remarks:

**get_file(key)**

Using the file after calling flush() or close() on the MMDF instance may yield unpredictable results or raise an exception.

**lock()**

**unlock()**

Three locking mechanisms are used—dot locking and, if available, the flock() and lockf() system calls.

A specification of MMDF format from the documentation of tin, a newsreader.

**MMDF**

A Wikipedia article describing the Multichannel Memorandum Distribution Facility.
19.4.2. **Message** objects

```python
class mailbox.Message(message=None)
```

If `message` is omitted, the new instance is created in a default, empty state. If `message` is an `email.message.Message` instance, its contents are copied; furthermore, any format-specific information is converted insofar as possible if `message` is a `Message` instance. If `message` is a string, a byte string, or a file, it should contain an **RFC 2822**-compliant message, which is read and parsed. Files should be open in binary mode, but text mode files are accepted for backward compatibility.

The format-specific state and behaviors offered by subclasses vary, but in general it is only the properties that are not specific to a particular mailbox that are supported (although presumably the properties are specific to a particular mailbox format). For example, file offsets for single-file mailbox formats and file names for directory-based mailbox formats are not retained, because they are only applicable to the original mailbox. But state such as whether a message has been read by the user or marked as important is retained, because it applies to the message itself.

There is no requirement that `Message` instances be used to represent messages retrieved using `Mailbox` instances. In some situations, the time and memory required to generate `Message` representations might not be acceptable. For such situations, `Mailbox` instances also offer string and file-like representations,
and a custom message factory may be specified when a Mailbox instance is initialized.

19.4.2.1. MaildirMessage

class mailbox.MaildirMessage(message=None)

A message with Maildir-specific behaviors. Parameter message has the same meaning as with the Message constructor.

Typically, a mail user agent application moves all of the messages in the new subdirectory to the cur subdirectory after the first time the user opens and closes the mailbox, recording that the messages are old whether or not they've actually been read. Each message in cur has an “info” section added to its file name to store information about its state. (Some mail readers may also add an “info” section to messages in new.) The “info” section may take one of two forms: it may contain “2,” followed by a list of standardized flags (e.g., “2,FR”) or it may contain “1,” followed by so-called experimental information. Standard flags for Maildir messages are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Draft</td>
<td>Under composition</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>P</td>
<td>Passed</td>
<td>Forwarded, resent, or bounced</td>
</tr>
<tr>
<td>R</td>
<td>Replied</td>
<td>Replied to</td>
</tr>
<tr>
<td>S</td>
<td>Seen</td>
<td>Read</td>
</tr>
<tr>
<td>T</td>
<td>Trashed</td>
<td>Marked for subsequent deletion</td>
</tr>
</tbody>
</table>

MaildirMessage instances offer the following methods:
get_subdir()
Return either “new” (if the message should be stored in the new subdirectory) or “cur” (if the message should be stored in the cur subdirectory).

Note: A message is typically moved from new to cur after its mailbox has been accessed, whether or not the message is has been read. A message msg has been read if "S" in msg.get_flags() is True.

set_subdir(subdir)
Set the subdirectory the message should be stored in. Parameter subdir must be either “new” or “cur”.

get_flags()
Return a string specifying the flags that are currently set. If the message complies with the standard Maildir format, the result is the concatenation in alphabetical order of zero or one occurrence of each of 'D', 'F', 'P', 'R', 'S', and 'T'. The empty string is returned if no flags are set or if "info" contains experimental semantics.

set_flags(flags)
Set the flags specified by flags and unset all others.

add_flag(flag)
Set the flag(s) specified by flag without changing other flags. To add more than one flag at a time, flag may be a string of more than one character. The current “info” is overwritten whether or not it contains experimental information rather than flags.

remove_flag(flag)
Unset the flag(s) specified by flag without changing other flags. To remove more than one flag at a time, flag maybe a string of more than one character. If “info” contains experimental information rather than flags, the current “info” is not modified.

**get_date()**

Return the delivery date of the message as a floating-point number representing seconds since the epoch.

**set_date(date)**

Set the delivery date of the message to date, a floating-point number representing seconds since the epoch.

**get_info()**

Return a string containing the “info” for a message. This is useful for accessing and modifying “info” that is experimental (i.e., not a list of flags).

**set_info(info)**

Set “info” to info, which should be a string.

When a MaildirMessage instance is created based upon an mboxMessage or MMDFMessage instance, the Status and X-Status headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage or MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>O flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>R flag</td>
<td>A flag</td>
</tr>
<tr>
<td>S flag</td>
<td>R flag</td>
</tr>
<tr>
<td>T flag</td>
<td>D flag</td>
</tr>
</tbody>
</table>
When a `MaildirMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>“cur” subdirectory and S flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>R flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When a `MaildirMessage` instance is created based upon a `BabylMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>“cur” subdirectory and S flag</td>
<td>no “unseen” label</td>
</tr>
<tr>
<td>P flag</td>
<td>“forwarded” or “resent” label</td>
</tr>
<tr>
<td>R flag</td>
<td>“answered” label</td>
</tr>
<tr>
<td>T flag</td>
<td>“deleted” label</td>
</tr>
</tbody>
</table>

19.4.2.2. `mboxMessage`

```python
class mailbox.mboxMessage(message=None)
```

A message with mbox-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

Messages in an mbox mailbox are stored together in a single file. The sender’s envelope address and the time of delivery are typically stored in a line beginning with “From ” that is used to indicate the start of a message, though there is considerable
variation in the exact format of this data among mbox implementations. Flags that indicate the state of the message, such as whether it has been read or marked as important, are typically stored in Status and X-Status headers.

Conventional flags for mbox messages are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Read</td>
<td>Read</td>
</tr>
<tr>
<td>O</td>
<td>Old</td>
<td>Previously detected by MUA</td>
</tr>
<tr>
<td>D</td>
<td>Deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>A</td>
<td>Answered</td>
<td>Replied to</td>
</tr>
</tbody>
</table>

The “R” and “O” flags are stored in the Status header, and the “D”, “F”, and “A” flags are stored in the X-Status header. The flags and headers typically appear in the order mentioned.

mboxMessage instances offer the following methods:

**get_from()**

Return a string representing the “From ” line that marks the start of the message in an mbox mailbox. The leading “From ” and the trailing newline are excluded.

**set_from(from_, time_=None)**

Set the “From ” line to from_, which should be specified without a leading “From ” or trailing newline. For convenience, time_ may be specified and will be formatted appropriately and appended to from_. If time_ is specified, it should be a time.struct_time instance, a tuple suitable for passing to
time.strftime(), or True (to use time.gmtime()).

get_flags()
Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of 'R', 'O', 'D', 'F', and 'A'.

set_flags(flags)
Set the flags specified by flags and unset all others. Parameter flags should be the concatenation in any order of zero or more occurrences of each of 'R', 'O', 'D', 'F', and 'A'.

add_flag(flag)
Set the flag(s) specified by flag without changing other flags. To add more than one flag at a time, flag may be a string of more than one character.

remove_flag(flag)
Unset the flag(s) specified by flag without changing other flags. To remove more than one flag at a time, flag maybe a string of more than one character.

When an mboxMessage instance is created based upon a MaildirMessage instance, a “From ” line is generated based upon the MaildirMessage instance’s delivery date, and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>S flag</td>
</tr>
<tr>
<td>O flag</td>
<td>“cur” subdirectory</td>
</tr>
</tbody>
</table>
When an `mboxMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>A flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When an `mboxMessage` instance is created based upon a `BabylMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” label</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>D flag</td>
<td>“deleted” label</td>
</tr>
<tr>
<td>A flag</td>
<td>“answered” label</td>
</tr>
</tbody>
</table>

When a `Message` instance is created based upon an `MMDFMessage` instance, the “From ” line is copied and all flags directly correspond:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>R flag</td>
</tr>
<tr>
<td>O flag</td>
<td>O flag</td>
</tr>
</tbody>
</table>
19.4.2.3. **MHMessage**

```python
class mailbox.MHMessage(message=None)
```

A message with MH-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

MH messages do not support marks or flags in the traditional sense, but they do support sequences, which are logical groupings of arbitrary messages. Some mail reading programs (although not the standard `mh` and `nmh`) use sequences in much the same way flags are used with other formats, as follows:

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>unseen</td>
<td>Not read, but previously detected by MUA</td>
</tr>
<tr>
<td>replied</td>
<td>Replied to</td>
</tr>
<tr>
<td>flagged</td>
<td>Marked as important</td>
</tr>
</tbody>
</table>

MHMessage instances offer the following methods:

**get_sequences()**

Return a list of the names of sequences that include this message.

**set_sequences(sequences)**

Set the list of sequences that include this message.
Add *sequence* to the list of sequences that include this message.

**remove_sequence**(sequence)

Remove *sequence* from the list of sequences that include this message.

When an `MHMessage` instance is created based upon a `MaildirMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>no S flag</td>
</tr>
<tr>
<td>“replied” sequence</td>
<td>R flag</td>
</tr>
<tr>
<td>“flagged” sequence</td>
<td>F flag</td>
</tr>
</tbody>
</table>

When an `MHMessage` instance is created based upon an `mboxMessage` or `MMDFMessage` instance, the *Status* and *X-Status* headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage or MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>no R flag</td>
</tr>
<tr>
<td>“replied” sequence</td>
<td>A flag</td>
</tr>
<tr>
<td>“flagged” sequence</td>
<td>F flag</td>
</tr>
</tbody>
</table>

When an `MHMessage` instance is created based upon a `BabylMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>“unseen” label</td>
</tr>
</tbody>
</table>
“replied” sequence  “answered” label

19.4.2.4. **BabylMessage**

class mailbox.BabylMessage(*message=None*)

A message with Babyl-specific behaviors. Parameter *message* has the same meaning as with the Message constructor.

Certain message labels, called *attributes*, are defined by convention to have special meanings. The attributes are as follows:

<table>
<thead>
<tr>
<th>Label</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>unseen</td>
<td>Not read, but previously detected by MUA</td>
</tr>
<tr>
<td>deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>filed</td>
<td>Copied to another file or mailbox</td>
</tr>
<tr>
<td>answered</td>
<td>Replied to</td>
</tr>
<tr>
<td>forwarded</td>
<td>Forwarded</td>
</tr>
<tr>
<td>edited</td>
<td>Modified by the user</td>
</tr>
<tr>
<td>resent</td>
<td>Resent</td>
</tr>
</tbody>
</table>

By default, Rmail displays only visible headers. The BabylMessage class, though, uses the original headers because they are more complete. Visible headers may be accessed explicitly if desired.

BabylMessage instances offer the following methods:

**get_labels**()

- Return a list of labels on the message.

**set_labels**(labels)
Set the list of labels on the message to `labels`.

`add_label(label)`
Add `label` to the list of labels on the message.

`remove_label(label)`
Remove `label` from the list of labels on the message.

`get_visible()`
Return an `Message` instance whose headers are the message's visible headers and whose body is empty.

`set_visible(visible)`
Set the message's visible headers to be the same as the headers in `message`. Parameter `visible` should be a `Message` instance, an `email.message.Message` instance, a string, or a file-like object (which should be open in text mode).

`update_visible()`
When a `BabylMessage` instance's original headers are modified, the visible headers are not automatically modified to correspond. This method updates the visible headers as follows: each visible header with a corresponding original header is set to the value of the original header, each visible header without a corresponding original header is removed, and any of `Date`, `From`, `Reply-To`, `To`, `CC`, and `Subject` that are present in the original headers but not the visible headers are added to the visible headers.

When a `BabylMessage` instance is created based upon a `MaildirMessage` instance, the following conversions take place:
<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” label</td>
<td>no S flag</td>
</tr>
<tr>
<td>“deleted” label</td>
<td>T flag</td>
</tr>
<tr>
<td>“answered” label</td>
<td>R flag</td>
</tr>
<tr>
<td>“forwarded” label</td>
<td>P flag</td>
</tr>
</tbody>
</table>

When a `BabylMessage` instance is created based upon an `mboxMessage` or `MMDFMessage` instance, the `Status` and `X-Status` headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th><code>mboxMessage</code> or <code>MMDFMessage</code> state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” label</td>
<td>no R flag</td>
</tr>
<tr>
<td>“deleted” label</td>
<td>D flag</td>
</tr>
<tr>
<td>“answered” label</td>
<td>A flag</td>
</tr>
</tbody>
</table>

When a `BabylMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th><code>MHMessage</code> state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” label</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>“answered” label</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

19.4.2.5. **MMDFMessage**

```python
class mailbox.MMDFMessage(message=None)
```

A message with MMDF-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

As with message in an mbox mailbox, MMDF messages are stored
with the sender’s address and the delivery date in an initial line beginning with “From “. Likewise, flags that indicate the state of the message are typically stored in Status and X-Status headers.

Conventional flags for MMDF messages are identical to those of mbox message and are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Read</td>
<td>Read</td>
</tr>
<tr>
<td>O</td>
<td>Old</td>
<td>Previously detected by MUA</td>
</tr>
<tr>
<td>D</td>
<td>Deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>A</td>
<td>Answered</td>
<td>Replied to</td>
</tr>
</tbody>
</table>

The “R” and “O” flags are stored in the Status header, and the “D”, “F”, and “A” flags are stored in the X-Status header. The flags and headers typically appear in the order mentioned.

MMDFMessage instances offer the following methods, which are identical to those offered by mboxMessage:

get_from()

Return a string representing the “From ” line that marks the start of the message in an mbox mailbox. The leading “From ” and the trailing newline are excluded.

set_from(from_, time_=None)

Set the “From ” line to from_, which should be specified without a leading “From ” or trailing newline. For convenience, time_ may be specified and will be formatted appropriately and appended to from_. If time_ is specified, it should be a
time.struct_time instance, a tuple suitable for passing to time.strftime(), or True (to use time.gmtime()).

**get_flags()**

Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of 'R', 'O', 'D', 'F', and 'A'.

**set_flags(flags)**

Set the flags specified by flags and unset all others. Parameter flags should be the concatenation in any order of zero or more occurrences of each of 'R', 'O', 'D', 'F', and 'A'.

**add_flag(flag)**

Set the flag(s) specified by flag without changing other flags. To add more than one flag at a time, flag may be a string of more than one character.

**remove_flag(flag)**

Unset the flag(s) specified by flag without changing other flags. To remove more than one flag at a time, flag may be a string of more than one character.

When an MMDFMessage instance is created based upon a MaildirMessage instance, a “From ” line is generated based upon the MaildirMessage instance’s delivery date, and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>S flag</td>
</tr>
<tr>
<td>O flag</td>
<td>“cur” subdirectory</td>
</tr>
</tbody>
</table>
When an `MMDFMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>A flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When an `MMDFMessage` instance is created based upon a `BabylMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” label</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>D flag</td>
<td>“deleted” label</td>
</tr>
<tr>
<td>A flag</td>
<td>“answered” label</td>
</tr>
</tbody>
</table>

When an `MMDFMessage` instance is created based upon an `mboxMessage` instance, the “From ” line is copied and all flags directly correspond:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>R flag</td>
</tr>
<tr>
<td>O flag</td>
<td>O flag</td>
</tr>
<tr>
<td>-------</td>
<td>-------</td>
</tr>
<tr>
<td>D flag</td>
<td>D flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>A flag</td>
<td>A flag</td>
</tr>
</tbody>
</table>
19.4.3. Exceptions

The following exception classes are defined in the mailbox module:

`exception mailbox.Error`

The based class for all other module-specific exceptions.

`exception mailbox.NoSuchMailboxError`

Raised when a mailbox is expected but is not found, such as when instantiating a Mailbox subclass with a path that does not exist (and with the create parameter set to False), or when opening a folder that does not exist.

`exception mailbox.NotEmptyError`

Raised when a mailbox is not empty but is expected to be, such as when deleting a folder that contains messages.

`exception mailbox.ExternalClashError`

Raised when some mailbox-related condition beyond the control of the program causes it to be unable to proceed, such as when failing to acquire a lock that another program already holds a lock, or when a uniquely-generated file name already exists.

`exception mailbox.FormatError`

Raised when the data in a file cannot be parsed, such as when an MH instance attempts to read a corrupted .mh_sequences file.
19.4.4. Examples

A simple example of printing the subjects of all messages in a mailbox that seem interesting:

```python
import mailbox
for message in mailbox.mbox('~/mbox'):
    subject = message['subject']  # Could possibly be None.
    if subject and 'python' in subject.lower():
        print(subject)
```

To copy all mail from a Babyl mailbox to an MH mailbox, converting all of the format-specific information that can be converted:

```python
import mailbox
import email.errors
list_names = ('python-list', 'python-dev', 'python-bugs')
```
```python
boxes = {name: mailbox.mbox('~/email/%s' % name) for name in list_names}

inbox = mailbox.Maildir('~/Maildir', factory=None)

for key in inbox.iterkeys():
    try:
        message = inbox[key]
    except email.errors.MessageParseError:
        continue  # The message is malformed.

for name in list_names:
    list_id = message['list-id']
    if list_id and name in list_id:
        # Get mailbox to use
        box = boxes[name]

        # Write copy to disk before removing original.
        # That's better than losing a message copied to disk.
        box.lock()
        box.add(message)
        box.flush()
        box.unlock()

        # Remove original message
        inbox.lock()
        inbox.discard(key)
        inbox.flush()
        inbox.unlock()
        break  # Found destination, stop looking.

for box in boxes.itervalues():
    box.close()
```

19.5. `mimetypes` — Map filenames to MIME types

Source code: `Lib/mimetypes.py`

The `mimetypes` module converts between a filename or URL and the MIME type associated with the filename extension. Conversions are provided from filename to MIME type and from MIME type to filename extension; encodings are not supported for the latter conversion.

The module provides one class and a number of convenience functions. The functions are the normal interface to this module, but some applications may be interested in the class as well.

The functions described below provide the primary interface for this module. If the module has not been initialized, they will call `init()` if they rely on the information `init()` sets up.

`mimetypes.guess_type(url, strict=True)`

Guess the type of a file based on its filename or URL, given by `url`. The return value is a tuple `(type, encoding)` where `type` is `None` if the type can’t be guessed (missing or unknown suffix) or a string of the form `'type/subtype'`, usable for a MIME `content-type` header.

`encoding` is `None` for no encoding or the name of the program used to encode (e.g. `compress` or `gzip`). The encoding is suitable for use as a `Content-Encoding` header, **not** as a `Content-Transfer-Encoding` header. The mappings are table driven. Encoding suffixes are case sensitive; type suffixes are first tried case
sensitively, then case insensitivity.

The optional `strict` argument is a flag specifying whether the list of
known MIME types is limited to only the official types registered
with IANA. When `strict` is `True` (the default), only the IANA types
are supported; when `strict` is `False`, some additional non-standard
but commonly used MIME types are also recognized.

**mimetypes.guess_all_extensions(type, strict=True)**

Guess the extensions for a file based on its MIME type, given by
`type`. The return value is a list of strings giving all possible filename
extensions, including the leading dot (`'.'`). The extensions are not
guaranteed to have been associated with any particular data
stream, but would be mapped to the MIME type `type` by
`guess_type()`.

The optional `strict` argument has the same meaning as with the
`guess_type()` function.

**mimetypes.guess_extension(type, strict=True)**

Guess the extension for a file based on its MIME type, given by
`type`. The return value is a string giving a filename extension,
including the leading dot (`'.'`). The extension is not guaranteed
to have been associated with any particular data stream, but would
be mapped to the MIME type `type` by `guess_type()` If no
extension can be guessed for `type`, None is returned.

The optional `strict` argument has the same meaning as with the
`guess_type()` function.

Some additional functions and data items are available for controlling
the behavior of the module.
mimetypes. **init**(*files=None*)

Initialize the internal data structures. If given, *files* must be a sequence of file names which should be used to augment the default type map. If omitted, the file names to use are taken from `knownfiles`; on Windows, the current registry settings are loaded. Each file named in *files* or `knownfiles` takes precedence over those named before it. Calling `init()` repeatedly is allowed.

Specifying an empty list for *files* will prevent the system defaults from being applied: only the well-known values will be present from a built-in list.

*Changed in version 3.2:* Previously, Windows registry settings were ignored.

mimetypes. **read_mime_types**(*filename*)

Load the type map given in the file *filename*, if it exists. The type map is returned as a dictionary mapping filename extensions, including the leading dot (`.'), to strings of the form `'type/subtype'`. If the file *filename* does not exist or cannot be read, None is returned.

mimetypes. **add_type**(*type, ext, strict=True*)

Add a mapping from the MIME type *type* to the extension *ext*. When the extension is already known, the new type will replace the old one. When the type is already known the extension will be added to the list of known extensions.

When *strict* is `True` (the default), the mapping will be added to the official MIME types, otherwise to the non-standard ones.

mimetypes. **inited**
Flag indicating whether or not the global data structures have been initialized. This is set to `True` by `init()`.

**mimetypes.** knownfiles

List of type map file names commonly installed. These files are typically named `mime.types` and are installed in different locations by different packages.

**mimetypes.** suffix_map

Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately.

**mimetypes.** encodings_map

Dictionary mapping filename extensions to encoding types.

**mimetypes.** types_map

Dictionary mapping filename extensions to MIME types.

**mimetypes.** common_types

Dictionary mapping filename extensions to non-standard, but commonly found MIME types.

An example usage of the module:

```python
>>> import mimetypes
>>> mimetypes.init()
>>> mimetypes.knownfiles
['/etc/mime.types', '/etc/httpd/mime.types', ... ]
>>> mimetypes.suffix_map['.tgz']
'.tar.gz'
>>> mimetypes.encodings_map['.gz']
```
'gzip'

>>> mimetypes.types_map['.tgz']
'application/x-tar-gz'
19.5.1. MimeTypes Objects

The `MimeTypes` class may be useful for applications which may want more than one MIME-type database; it provides an interface similar to the one of the `mimetypes` module.

```python
class mimetypes.MimeTypes(filenames=(), strict=True)
```

This class represents a MIME-types database. By default, it provides access to the same database as the rest of this module. The initial database is a copy of that provided by the module, and may be extended by loading additional `mime.types`-style files into the database using the `read()` or `readfp()` methods. The mapping dictionaries may also be cleared before loading additional data if the default data is not desired.

The optional `filenames` parameter can be used to cause additional files to be loaded “on top” of the default database.

**suffix_map**

Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately. This is initially a copy of the global `suffix_map` defined in the module.

**encodings_map**

Dictionary mapping filename extensions to encoding types. This is initially a copy of the global `encodings_map` defined in the module.
**types_map**

Tuple containing two dictionaries, mapping filename extensions to MIME types: the first dictionary is for the non-standards types and the second one is for the standard types. They are initialized by `common_types` and `types_map`.

**types_map_inv**

Tuple containing two dictionaries, mapping MIME types to a list of filename extensions: the first dictionary is for the non-standards types and the second one is for the standard types. They are initialized by `common_types` and `types_map`.

**guess_extension**(type, strict=True)

Similar to the `guess_extension()` function, using the tables stored as part of the object.

**guess_type**(url, strict=True)

Similar to the `guess_type()` function, using the tables stored as part of the object.

**guess_all_extensions**(type, strict=True)

Similar to the `guess_all_extensions()` function, using the tables stored as part of the object.

**read**(filename, strict=True)

Load MIME information from a file named `filename`. This uses `readfp()` to parse the file.

If `strict` is `True`, information will be added to list of standard types, else to the list of non-standard types.

**readfp**(fp, strict=True)
Load MIME type information from an open file `fp`. The file must have the format of the standard `mime.types` files.

If `strict` is `True`, information will be added to the list of standard types, else to the list of non-standard types.

**read_windows_registry**(*strict=True*)

Load MIME type information from the Windows registry. Availability: Windows.

If `strict` is `True`, information will be added to the list of standard types, else to the list of non-standard types.

*New in version 3.2.*
This module provides functions for encoding binary data to printable ASCII characters and decoding such encodings back to binary data. It provides encoding and decoding functions for the encodings specified in RFC 3548, which defines the Base16, Base32, and Base64 algorithms, and for the de-facto standard Ascii85 and Base85 encodings.

The RFC 3548 encodings are suitable for encoding binary data so that it can safely sent by email, used as parts of URLs, or included as part of an HTTP POST request. The encoding algorithm is not the same as the uuencode program.

There are two interfaces provided by this module. The modern interface supports encoding bytes-like objects to ASCII bytes, and decoding bytes-like objects or strings containing ASCII to bytes. Both base-64 alphabets defined in RFC 3548 (normal, and URL- and filesystem-safe) are supported.

The legacy interface does not support decoding from strings, but it does provide functions for encoding and decoding to and from file objects. It only supports the Base64 standard alphabet, and it adds newlines every 76 characters as per RFC 2045. Note that if you are looking for RFC 2045 support you probably want to be looking at the email package instead.
*Changed in version 3.3:* ASCII-only Unicode strings are now accepted by the decoding functions of the modern interface.

*Changed in version 3.4:* Any *bytes-like objects* are now accepted by all encoding and decoding functions in this module. Ascii85/Base85 support added.

The modern interface provides:

```python
base64.b64encode(s, altchars=None)
```

Encode the *bytes-like object* `s` using Base64 and return the encoded *bytes*.

Optional `altchars` must be a *bytes-like object* of at least length 2 (additional characters are ignored) which specifies an alternative alphabet for the `+` and `/` characters. This allows an application to e.g. generate URL or filesystem safe Base64 strings. The default is `None`, for which the standard Base64 alphabet is used.

```python
base64.b64decode(s, altchars=None, validate=False)
```

Decode the Base64 encoded *bytes-like object* or ASCII string `s` and return the decoded *bytes*.

Optional `altchars` must be a *bytes-like object* or ASCII string of at least length 2 (additional characters are ignored) which specifies the alternative alphabet used instead of the `+` and `/` characters.

A `binascii.Error` exception is raised if `s` is incorrectly padded.

If `validate` is `False` (the default), characters that are neither in the normal base-64 alphabet nor the alternative alphabet are discarded prior to the padding check. If `validate` is `True`, these non-alphabet characters in the input result in a `binascii.Error`. 
base64. **standard_b64encode(s)**

Encode **bytes-like object** s using the standard Base64 alphabet and return the encoded **bytes**.

base64. **standard_b64decode(s)**

Decode **bytes-like object** or ASCII string s using the standard Base64 alphabet and return the decoded **bytes**.

base64. **urlsafe_b64encode(s)**

Encode **bytes-like object** s using the URL- and filesystem-safe alphabet, which substitutes - instead of + and _ instead of / in the standard Base64 alphabet, and return the encoded **bytes**. The result can still contain =.

base64. **urlsafe_b64decode(s)**

Decode **bytes-like object** or ASCII string s using the URL- and filesystem-safe alphabet, which substitutes - instead of + and _ instead of / in the standard Base64 alphabet, and return the decoded **bytes**.

base64. **b32encode(s)**

Encode the **bytes-like object** s using Base32 and return the encoded **bytes**.

base64. **b32decode(s, casefold=False, map01=None)**

Decode the Base32 encoded **bytes-like object** or ASCII string s and return the decoded **bytes**.

Optional **casefold** is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is False.

**RFC 3548** allows for optional mapping of the digit 0 (zero) to the
letter O (oh), and for optional mapping of the digit 1 (one) to either the letter I (eye) or letter L (el). The optional argument \texttt{map01} when not \texttt{None}, specifies which letter the digit 1 should be mapped to (when \texttt{map01} is not \texttt{None}, the digit 0 is always mapped to the letter O). For security purposes the default is \texttt{None}, so that 0 and 1 are not allowed in the input.

A \texttt{binascii.Error} is raised if \texttt{s} is incorrectly padded or if there are non-alphabet characters present in the input.

\texttt{base64.b16encode(s)}

Encode the \texttt{bytes-like object} \texttt{s} using Base16 and return the encoded \texttt{bytes}.

\texttt{base64.b16decode(s, casefold=False)}

Decode the Base16 encoded \texttt{bytes-like object} or ASCII string \texttt{s} and return the decoded \texttt{bytes}.

Optional \texttt{casefold} is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is \texttt{False}.

A \texttt{binascii.Error} is raised if \texttt{s} is incorrectly padded or if there are non-alphabet characters present in the input.

\texttt{base64.a85encode(b, *, foldspaces=False, wrapcol=0, pad=False, adobe=False)}

Encode the \texttt{bytes-like object} \texttt{b} using Ascii85 and return the encoded \texttt{bytes}.

\texttt{foldspaces} is an optional flag that uses the special short sequence ‘y’ instead of 4 consecutive spaces (ASCII 0x20) as supported by ‘btoa’. This feature is not supported by the “standard” Ascii85 encoding.
wrapcol controls whether the output should have newline (b'\n') characters added to it. If this is non-zero, each output line will be at most this many characters long.

pad controls whether the input is padded to a multiple of 4 before encoding. Note that the btoa implementation always pads.

adobe controls whether the encoded byte sequence is framed with <~ and ~> , which is used by the Adobe implementation.

New in version 3.4.

base64. a85decode(b, *, foldspaces=False, adobe=False, ignorechars=b' \t\n\r\v')

Decode the Ascii85 encoded bytes-like object or ASCII string b and return the decoded bytes.

foldspaces is a flag that specifies whether the 'y' short sequence should be accepted as shorthand for 4 consecutive spaces (ASCII 0x20). This feature is not supported by the "standard" Ascii85 encoding.

adobe controls whether the input sequence is in Adobe Ascii85 format (i.e. is framed with <~ and ~>).

ignorechars should be a bytes-like object or ASCII string containing characters to ignore from the input. This should only contain whitespace characters, and by default contains all whitespace characters in ASCII.

New in version 3.4.

base64. b85encode(b, pad=False)

Encode the bytes-like object b using base85 (as used in e.g. git-
style binary diffs) and return the encoded bytes.

If pad is true, the input is padded with b'\0' so its length is a multiple of 4 bytes before encoding.

*New in version 3.4.*

**base64. b85decode**(b)

Decode the base85-encoded bytes-like object or ASCII string b and return the decoded bytes. Padding is implicitly removed, if necessary.

*New in version 3.4.*

**Note:** Both Base85 and Ascii85 have an expansion factor of 5 to 4 (5 Base85 or Ascii85 characters can encode 4 binary bytes), while the better-known Base64 has an expansion factor of 6 to 4. They are therefore more efficient when space expensive. They differ by details such as the character map used for encoding.

The legacy interface:

**base64. decode**(input, output)

Decode the contents of the binary input file and write the resulting binary data to the output file. input and output must be file objects. input will be read until input.readline() returns an empty bytes object.

**base64. decodebytes**(s)

Decode the bytes-like object s, which must contain one or more lines of base64 encoded data, and return the decoded bytes.

*New in version 3.1.*
base64. **decodestring**(s)

Deprecated alias of **decodebytes()**.

*Deprecated since version 3.1.*

base64. **encode**(input, output)

Encode the contents of the binary input file and write the resulting base64 encoded data to the output file. input and output must be **file objects**. input will be read until **input.read()** returns an empty bytes object. **encode()** inserts a newline character (b'\n') after every 76 bytes of the output, as well as ensuring that the output always ends with a newline, as per **RFC 2045** (MIME).

base64. **encodebytes**(s)

Encode the bytes-like object s, which can contain arbitrary binary data, and return **bytes** containing the base64-encoded data, with newlines (b'\n') inserted after every 76 bytes of output, and ensuring that there is a trailing newline, as per **RFC 2045** (MIME).

*New in version 3.1.*

base64. **encodestring**(s)

Deprecated alias of **encodebytes()**.

*Deprecated since version 3.1.*

An example usage of the module:

```python
>>> import base64
>>> encoded = base64.b64encode(b'data to be encoded'
>>> encoded
b'ZGF0YSB0byBiZSBlbmNvZGVk'
>>> data = base64.b64decode(encoded)
>>> data
```

Module **binascii**

Support module containing ASCII-to-binary and binary-to-ASCII conversions.

**RFC 1521** - MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies

Section 5.2, “Base64 Content-Transfer-Encoding,” provides the definition of the base64 encoding.
19.7. `binhex` — Encode and decode binhex4 files

**Source code:** Lib/binhex.py

This module encodes and decodes files in binhex4 format, a format allowing representation of Macintosh files in ASCII. Only the data fork is handled.

The `binhex` module defines the following functions:

`binhex.binhex(input, output)`

Convert a binary file with filename `input` to binhex file `output`. The `output` parameter can either be a filename or a file-like object (any object supporting a `write()` and `close()` method).

`binhex.hexbin(input, output)`

Decode a binhex file `input`. `input` may be a filename or a file-like object supporting `read()` and `close()` methods. The resulting file is written to a file named `output`, unless the argument is `None` in which case the output filename is read from the binhex file.

The following exception is also defined:

`exception binhex.Error`

Exception raised when something can’t be encoded using the binhex format (for example, a filename is too long to fit in the filename field), or when input is not properly encoded binhex data.

See also:
Module `binascii`

Support module containing ASCII-to-binary and binary-to-ASCII conversions.
19.7.1. Notes

There is an alternative, more powerful interface to the coder and decoder, see the source for details.

If you code or decode textfiles on non-Macintosh platforms they will still use the old Macintosh newline convention (carriage-return as end of line).
19.8. `binascii` — Convert between binary and ASCII

The `binascii` module contains a number of methods to convert between binary and various ASCII-encoded binary representations. Normally, you will not use these functions directly but use wrapper modules like `uu`, `base64`, or `binhex` instead. The `binascii` module contains low-level functions written in C for greater speed that are used by the higher-level modules.

**Note:** `a2b_*` functions accept Unicode strings containing only ASCII characters. Other functions only accept bytes-like objects (such as `bytes`, `bytearray` and other objects that support the buffer protocol).

*Changed in version 3.3:* ASCII-only unicode strings are now accepted by the `a2b_*` functions.

The `binascii` module defines the following functions:

`binascii.a2b_uu(string)`

Convert a single line of uuencoded data back to binary and return the binary data. Lines normally contain 45 (binary) bytes, except for the last line. Line data may be followed by whitespace.

`binascii.b2a_uu(data)`

Convert binary data to a line of ASCII characters, the return value is the converted line, including a newline char. The length of `data` should be at most 45.
binascii.**a2b_base64**(string)
Convert a block of base64 data back to binary and return the
binary data. More than one line may be passed at a time.

binascii.**b2a_base64**(data, *, newline=True)
Convert binary data to a line of ASCII characters in base64 coding.
The return value is the converted line, including a newline char if
newline is true. The output of this function conforms to **RFC 3548**.

*Changed in version 3.6:* Added the newline parameter.

binascii.**a2b_qp**(data, header=False)
Convert a block of quoted-printable data back to binary and return
the binary data. More than one line may be passed at a time. If the
optional argument header is present and true, underscores will be
decoded as spaces.

binascii.**b2a_qp**(data, quotetabs=False, istext=True,
header=False)
Convert binary data to a line(s) of ASCII characters in quoted-
printable encoding. The return value is the converted line(s). If the
optional argument quotetabs is present and true, all tabs and
spaces will be encoded. If the optional argument istext is present
and true, newlines are not encoded but trailing whitespace will be
encoded. If the optional argument header is present and true,
spaces will be encoded as underscores per RFC1522. If the
optional argument header is present and false, newline characters
will be encoded as well; otherwise linefeed conversion might
corr upt the binary data stream.

binascii.**a2b_hqx**(string)
Convert binhex4 formatted ASCII data to binary, without doing
RLE-decompression. The string should contain a complete number of binary bytes, or (in case of the last portion of the binhex4 data) have the remaining bits zero.

**binascii.**`rledecode_hqx(data)`
Perform RLE-decompression on the data, as per the binhex4 standard. The algorithm uses `0x90` after a byte as a repeat indicator, followed by a count. A count of 0 specifies a byte value of `0x90`. The routine returns the decompressed data, unless data input data ends in an orphaned repeat indicator, in which case the *Incomplete* exception is raised.

*Changed in version 3.2*: Accept only bytestring or bytearray objects as input.

**binascii.**`rlecode_hqx(data)`
Perform binhex4 style RLE-compression on `data` and return the result.

**binascii.**`b2a_hqx(data)`
Perform hexbin4 binary-to-ASCII translation and return the resulting string. The argument should already be RLE-coded, and have a length divisible by 3 (except possibly the last fragment).

**binascii.**`crc_hqx(data, value)`
Compute a 16-bit CRC value of `data`, starting with `value` as the initial CRC, and return the result. This uses the CRC-CCITT polynomial \(x^{16} + x^{12} + x^{5} + 1\), often represented as `0x1021`. This CRC is used in the binhex4 format.

**binascii.**`crc32(data[, value])`
Compute CRC-32, the 32-bit checksum of `data`, starting with an
initial CRC of value. The default initial CRC is zero. The algorithm is consistent with the ZIP file checksum. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm. Use as follows:

```python
print(binascii.crc32(b"hello world"))
# Or, in two pieces:
crc = binascii.crc32(b"hello")
crc = binascii.crc32(b" world", crc)
print('crc32 = {:#010x}'.format(crc))
```

*Changed in version 3.0:* The result is always unsigned. To generate the same numeric value across all Python versions and platforms, use `crc32(data) & 0xffffffff`.

- `binascii.b2a_hex(data)`
- `binascii.hexlify(data)`

Return the hexadecimal representation of the binary `data`. Every byte of `data` is converted into the corresponding 2-digit hex representation. The returned bytes object is therefore twice as long as the length of `data`.

- `binascii.a2b_hex(hexstr)`
- `binascii.unhexlify(hexstr)`

Return the binary data represented by the hexadecimal string `hexstr`. This function is the inverse of `b2a_hex()`. `hexstr` must contain an even number of hexadecimal digits (which can be upper or lower case), otherwise an `Error` exception is raised.

- `exception binascii.Error` Exception raised on errors. These are usually programming errors.

- `exception binascii.Incomplete`
Exception raised on incomplete data. These are usually not programming errors, but may be handled by reading a little more data and trying again.

See also:

**Module** base64  
Support for RFC compliant base64-style encoding in base 16, 32, 64, and 85.

**Module** binhex  
Support for the binhex format used on the Macintosh.

**Module** uu  
Support for UU encoding used on Unix.

**Module** quopri  
Support for quoted-printable encoding used in MIME email messages.
19.9. `quopri` — Encode and decode MIME quoted-printable data

**Source code:** Lib/quopri.py

This module performs quoted-printable transport encoding and decoding, as defined in **RFC 1521**: “MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies”. The quoted-printable encoding is designed for data where there are relatively few nonprintable characters; the base64 encoding scheme available via the `base64` module is more compact if there are many such characters, as when sending a graphics file.

`quopri.decode(input, output, header=False)`

Decode the contents of the `input` file and write the resulting decoded binary data to the `output` file. `input` and `output` must be binary file objects. If the optional argument `header` is present and true, underscore will be decoded as space. This is used to decode “Q”-encoded headers as described in **RFC 1522**: “MIME (Multipurpose Internet Mail Extensions) Part Two: Message Header Extensions for Non-ASCII Text”.

`quopri.encode(input, output, quotetabs, header=False)`

Encode the contents of the `input` file and write the resulting quoted-printable data to the `output` file. `input` and `output` must be binary file objects. `quotetabs`, a flag which controls whether to encode embedded spaces and tabs must be provided and when true it
encodes such embedded whitespace, and when false it leaves them unencoded. Note that spaces and tabs appearing at the end of lines are always encoded, as per RFC 1521. header is a flag which controls if spaces are encoded as underscores as per RFC 1522.

quopri.\texttt{decodestring}(s, header=False)

Like \texttt{decode()}, except that it accepts a source \texttt{bytes} and returns the corresponding decoded \texttt{bytes}.

quopri.\texttt{encodestring}(s, quotetabs=False, header=False)

Like \texttt{encode()}, except that it accepts a source \texttt{bytes} and returns the corresponding encoded \texttt{bytes}. By default, it sends a \texttt{False} value to \texttt{quotetabs} parameter of the \texttt{encode()} function.

See also:

\textbf{Module base64}

Encode and decode MIME base64 data
19.10. **uu** — Encode and decode uuencode files

**Source code:** Lib/uu.py

This module encodes and decodes files in uuencode format, allowing arbitrary binary data to be transferred over ASCII-only connections. Wherever a file argument is expected, the methods accept a file-like object. For backwards compatibility, a string containing a pathname is also accepted, and the corresponding file will be opened for reading and writing; the pathname `'-.'` is understood to mean the standard input or output. However, this interface is deprecated; it's better for the caller to open the file itself, and be sure that, when required, the mode is `'rb'` or `'wb'` on Windows.

This code was contributed by Lance Ellinghouse, and modified by Jack Jansen.

The **uu** module defines the following functions:

**uu.** `encode(in_file, out_file, name=None, mode=None)`

Uuencode file `in_file` into file `out_file`. The uuencoded file will have the header specifying `name` and `mode` as the defaults for the results of decoding the file. The default defaults are taken from `in_file`, or `'-.'` and `0o666` respectively.

**uu.** `decode(in_file, out_file=None, mode=None, quiet=False)`

This call decodes uuencoded file `in_file` placing the result on file `out_file`. If `out_file` is a pathname, `mode` is used to set the permission bits if the file must be created. Defaults for `out_file` and
mode are taken from the uuencode header. However, if the file specified in the header already exists, a uu.Error is raised.

decode() may print a warning to standard error if the input was produced by an incorrect uuencoder and Python could recover from that error. Setting quiet to a true value silences this warning.

exception uu.Error
Subclass of Exception, this can be raised by uu.decode() under various situations, such as described above, but also including a badly formatted header, or truncated input file.

20.1. **html** — HyperText Markup Language support

**Source code:** `Lib/html/__init__.py`

This module defines utilities to manipulate HTML.

```python
html.escape(s, quote=True)
```

Convert the characters & , < and > in string `s` to HTML-safe sequences. Use this if you need to display text that might contain such characters in HTML. If the optional flag `quote` is true, the characters (') and (') are also translated; this helps for inclusion in an HTML attribute value delimited by quotes, as in `<a href="...">`.

*New in version 3.2.*

```python
html.unescape(s)
```

Convert all named and numeric character references (e.g. &gt;, &lt;62; , &x3e;) in the string `s` to the corresponding unicode characters. This function uses the rules defined by the HTML 5 standard for both valid and invalid character references, and the list of HTML 5 named character references.

*New in version 3.4.*

Submodules in the `html` package are:

- `html.parser` – HTML/XHTML parser with lenient parsing mode
html.entities – HTML entity definitions
This module defines a class `HTMLParser` which serves as the basis for parsing text files formatted in HTML (HyperText Mark-up Language) and XHTML.

```python
class html.parser.HTMLParser(*, convert_charrefs=True)
```

Create a parser instance able to parse invalid markup.

If `convert_charrefs` is `True` (the default), all character references (except the ones in `script/style` elements) are automatically converted to the corresponding Unicode characters.

An `HTMLParser` instance is fed HTML data and calls handler methods when start tags, end tags, text, comments, and other markup elements are encountered. The user should subclass `HTMLParser` and override its methods to implement the desired behavior.

This parser does not check that end tags match start tags or call the end-tag handler for elements which are closed implicitly by closing an outer element.

*Changed in version 3.4*: `convert_charrefs` keyword argument added.

*Changed in version 3.5*: The default value for argument
convert_charrefs is now True.
20.2.1. Example HTML Parser Application

As a basic example, below is a simple HTML parser that uses the HTMLParser class to print out start tags, end tags, and data as they are encountered:

```python
from html.parser import HTMLParser

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print("Encountered a start tag:", tag)

    def handle_endtag(self, tag):
        print("Encountered an end tag:", tag)

    def handle_data(self, data):
        print("Encountered some data:", data)

parser = MyHTMLParser()
parser.feed('<html><head><title>Test</title></head>']
    '<body><h1>Parse me!</h1></body></html>
```

The output will then be:

```
Encountered a start tag: html
Encountered a start tag: head
Encountered a start tag: title
Encountered some data: Test
Encountered an end tag: title
Encountered an end tag: head
Encountered a start tag: body
Encountered a start tag: h1
Encountered some data: Parse me!
Encountered an end tag: h1
```
Encountered an end tag: body
Encountered an end tag: html
20.2.2. **HTMLParser** Methods

**HTMLParser** instances have the following methods:

**HTMLParser.**`feed(data)`

Feed some text to the parser. It is processed insofar as it consists of complete elements; incomplete data is buffered until more data is fed or **close()** is called. `data` must be `str`.

**HTMLParser.**`close()`

Force processing of all buffered data as if it were followed by an end-of-file mark. This method may be redefined by a derived class to define additional processing at the end of the input, but the redefined version should always call the **HTMLParser** base class method **close()**.

**HTMLParser.**`reset()`

Reset the instance. Loses all unprocessed data. This is called implicitly at instantiation time.

**HTMLParser.**`getpos()`

Return current line number and offset.

**HTMLParser.**`get_starttag_text()`

Return the text of the most recently opened start tag. This should not normally be needed for structured processing, but may be useful in dealing with HTML “as deployed” or for re-generating input with minimal changes (whitespace between attributes can be preserved, etc.).

The following methods are called when data or markup elements are
encountered and they are meant to be overridden in a subclass. The base class implementations do nothing (except for 

**HTMLParser**. **handle_starttag**(tag, attrs)

This method is called to handle the start of a tag (e.g. `<div id="main">`).

The tag argument is the name of the tag converted to lower case. The attrs argument is a list of (name, value) pairs containing the attributes found inside the tag’s <> brackets. The name will be translated to lower case, and quotes in the value have been removed, and character and entity references have been replaced.

For instance, for the tag `<A HREF="https://www.cwi.nl/">`, this method would be called as `handle_starttag('a', [('href', 'https://www.cwi.nl/')])`.

All entity references from `html.entities` are replaced in the attribute values.

**HTMLParser**. **handle_endtag**(tag)

This method is called to handle the end tag of an element (e.g. `</div>`).

The tag argument is the name of the tag converted to lower case.

**HTMLParser**. **handle_startendtag**(tag, attrs)

Similar to `handle_starttag()`, but called when the parser encounters an XHTML-style empty tag (`<img ... />`). This method may be overridden by subclasses which require this particular lexical information; the default implementation simply
calls handle_starttag() and handle_endtag().

**HTMLParser. handle_data(data)**

This method is called to process arbitrary data (e.g. text nodes and the content of `<script>...</script>` and `<style>...</style>`).

**HTMLParser. handle_entityref(name)**

This method is called to process a named character reference of the form `&name;` (e.g. `&gt;`), where name is a general entity reference (e.g. `'gt'`). This method is never called if `convert_charrefs` is True.

**HTMLParser. handle_charref(name)**

This method is called to process decimal and hexadecimal numeric character references of the form `&#NNN;` and `&#xNNN;`. For example, the decimal equivalent for `&gt;` is `&#62;`, whereas the hexadecimal is `&#x3E;`; in this case the method will receive '62' or 'x3E'. This method is never called if `convert_charrefs` is True.

**HTMLParser. handle_comment(data)**

This method is called when a comment is encountered (e.g. `<!-- comment-->`).

For example, the comment `<!-- comment -->` will cause this method to be called with the argument ' comment '.

The content of Internet Explorer conditional comments (condcoms) will also be sent to this method, so, for `<![if IE 9]>IE9-specific content<![endif]-->`, this method will receive '[if IE 9]>IE9-specific content<![endif]'.
**HTMLParser.** `handle_decl(decl)`

This method is called to handle an HTML doctype declaration (e.g. `<!DOCTYPE html>`).

The `decl` parameter will be the entire contents of the declaration inside the `<!...>` markup (e.g. `'DOCTYPE html'`).

**HTMLParser.** `handle_pi(data)`

Method called when a processing instruction is encountered. The `data` parameter will contain the entire processing instruction. For example, for the processing instruction `<?proc color='red'>`, this method would be called as `handle_pi("proc color='red'")`. It is intended to be overridden by a derived class; the base class implementation does nothing.

**Note:** The `HTMLParser` class uses the SGML syntactic rules for processing instructions. An XHTML processing instruction using the trailing '?' will cause the '?' to be included in `data`.

**HTMLParser.** `unknown_decl(data)`

This method is called when an unrecognized declaration is read by the parser.

The `data` parameter will be the entire contents of the declaration inside the `<![...]>` markup. It is sometimes useful to be overridden by a derived class. The base class implementation does nothing.
20.2.3. Examples

The following class implements a parser that will be used to illustrate more examples:

```python
from html.parser import HTMLParser
from html.entities import name2codepoint

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print("Start tag:", tag)
        for attr in attrs:
            print("attr:", attr)

    def handle_endtag(self, tag):
        print("End tag:", tag)

    def handle_data(self, data):
        print("Data:", data)

    def handle_comment(self, data):
        print("Comment:", data)

    def handle_entityref(self, name):
        c = chr(name2codepoint[name])
        print("Named ent:", c)

    def handle_charref(self, name):
        if name.startswith('x'):
            c = chr(int(name[1:], 16))
        else:
            c = chr(int(name))
        print("Num ent:", c)

    def handle_decl(self, data):
```
```python
def print("Decl :", data)
parser = MyHTMLParser()

Parsing a doctype:

```
attr: ('type', 'text/javascript')
Data      : alert("<strong>hello!</strong>");
End tag   : script

Parsing comments:

>>> parser.feed('<!-- a comment -->'
...         '<!--[if IE 9]>IE-specific content<![endif]-->
Comment : a comment
Comment : [if IE 9]>IE-specific content<![endif]

Parsing named and numeric character references and converting them to the correct char (note: these 3 references are all equivalent to '<'>):

>>> parser.feed('&gt;&amp;#62;&amp;#x3E;')
Named ent: >
Num ent  : >
Num ent  : >

Feeding incomplete chunks to feed() works, but handle_data() might be called more than once (unless convert_charrefs is set to True):

>>> for chunk in ['<sp', 'an>buff', 'ered ', 'text</sp']
...     parser.feed(chunk)
... Start tag: span
Data      : buff
Data      : ered
Data      : text
End tag   : span

Parsing invalid HTML (e.g. unquoted attributes) also works:
>>> parser.feed('<p><a class=link href=#main>tag soup</a>')
Start tag: p
Start tag: a
  attr: ('class', 'link')
  attr: ('href', '#main')
Data   : tag soup
End tag : p
End tag : a
20.3. html.entities — Definitions of HTML general entities

Source code: Lib/html/entities.py

This module defines four dictionaries, html5, name2codepoint, codepoint2name, and entitydefs.

html.entities.html5
   A dictionary that maps HTML5 named character references [1] to the equivalent Unicode character(s), e.g. html5['gt;'] == '>'. Note that the trailing semicolon is included in the name (e.g. 'gt;'), however some of the names are accepted by the standard even without the semicolon: in this case the name is present with and without the ';'. See also html.unescape().

   New in version 3.3.

html.entities.entitydefs
   A dictionary mapping XHTML 1.0 entity definitions to their replacement text in ISO Latin-1.

html.entities.name2codepoint
   A dictionary that maps HTML entity names to the Unicode code points.

html.entities.codepoint2name
   A dictionary that maps Unicode code points to HTML entity names.
Footnotes

[1] See https://www.w3.org/TR/html5/syntax.html#named-character-references
20.4. XML Processing Modules

Source code: Lib/xml/

Python's interfaces for processing XML are grouped in the `xml` package.

**Warning:** The XML modules are not secure against erroneous or maliciously constructed data. If you need to parse untrusted or unauthenticated data see the XML vulnerabilities and The defusedxml and defusedexpat Packages sections.

It is important to note that modules in the `xml` package require that there be at least one SAX-compliant XML parser available. The Expat parser is included with Python, so the `xml.parsers.expat` module will always be available.

The documentation for the `xml.dom` and `xml.sax` packages are the definition of the Python bindings for the DOM and SAX interfaces.

The XML handling submodules are:

- `xml.etree.ElementTree`: the ElementTree API, a simple and lightweight XML processor
- `xml.dom`: the DOM API definition
- `xml.dom.minidom`: a minimal DOM implementation
- `xml.dom.pulldom`: support for building partial DOM trees
- `xml.sax`: SAX2 base classes and convenience functions
- `xml.parsers.expat`: the Expat parser binding
20.4.1. XML vulnerabilities

The XML processing modules are not secure against maliciously constructed data. An attacker can abuse XML features to carry out denial of service attacks, access local files, generate network connections to other machines, or circumvent firewalls.

The following table gives an overview of the known attacks and whether the various modules are vulnerable to them.

<table>
<thead>
<tr>
<th>kind</th>
<th>sax</th>
<th>etree</th>
<th>minidom</th>
<th>pulldom</th>
</tr>
</thead>
<tbody>
<tr>
<td>billion laughs</td>
<td>Vulnerable</td>
<td>Vulnerable</td>
<td>Vulnerable</td>
<td>Vulnerable</td>
</tr>
<tr>
<td>quadratic blowup</td>
<td>Vulnerable</td>
<td>Vulnerable</td>
<td>Vulnerable</td>
<td>Vulnerable</td>
</tr>
<tr>
<td>external entity expansion</td>
<td>Vulnerable</td>
<td>Safe (1)</td>
<td>Safe (2)</td>
<td>Vulnerable</td>
</tr>
<tr>
<td>DTD retrieval</td>
<td>Vulnerable</td>
<td>Safe</td>
<td>Safe</td>
<td>Vulnerable</td>
</tr>
<tr>
<td>decompression bomb</td>
<td>Safe</td>
<td>Safe</td>
<td>Safe</td>
<td>Safe</td>
</tr>
</tbody>
</table>

1. `xml.etree.ElementTree` doesn’t expand external entities and raises a `ParserError` when an entity occurs.
2. `xml.dom.minidom` doesn’t expand external entities and simply returns the unexpanded entity verbatim.
3. `xmlrpclib` doesn’t expand external entities and omits them.

billion laughs / exponential entity expansion

The Billion Laughs attack – also known as exponential entity expansion – uses multiple levels of nested entities. Each entity refers to another entity several times, and the final entity definition contains a small string. The exponential expansion results in
several gigabytes of text and consumes lots of memory and CPU
time.

quadratic blowup entity expansion
A quadratic blowup attack is similar to a Billion Laughs attack; it
abuses entity expansion, too. Instead of nested entities it repeats
one large entity with a couple of thousand chars over and over
again. The attack isn't as efficient as the exponential case but it
avoids triggering parser countermeasures that forbid deeply-nested
entities.

external entity expansion
Entity declarations can contain more than just text for replacement.
They can also point to external resources or local files. The XML
parser accesses the resource and embeds the content into the
XML document.

DTD retrieval
Some XML libraries like Python’s xml.dom.pulldom retrieve
document type definitions from remote or local locations. The feature
has similar implications as the external entity expansion issue.

decompression bomb
Decompression bombs (aka ZIP bomb) apply to all XML libraries
that can parse compressed XML streams such as gzipped HTTP
streams or LZMA-compressed files. For an attacker it can reduce
the amount of transmitted data by three magnitudes or more.

The documentation for defusedxml on PyPI has further information
about all known attack vectors with examples and references.
20.4.2. The defusedxml and defusedexpat Packages

defusedxml is a pure Python package with modified subclasses of all stdlib XML parsers that prevent any potentially malicious operation. Use of this package is recommended for any server code that parses untrusted XML data. The package also ships with example exploits and extended documentation on more XML exploits such as XPath injection.

defusedexpat provides a modified libexpat and a patched pyexpat module that have countermeasures against entity expansion DoS attacks. The defusedexpat module still allows a sane and configurable amount of entity expansions. The modifications may be included in some future release of Python, but will not be included in any bugfix releases of Python because they break backward compatibility.
20.5. `xml.etree.ElementTree` — The ElementTree XML API

**Source code:** [Lib/xml/etree/ElementTree.py](https://www.python.org/library/xml.etree.elementtree.html)

The `xml.etree.ElementTree` module implements a simple and efficient API for parsing and creating XML data.

*Changed in version 3.3:* This module will use a fast implementation whenever available. The `xml.etree.cElementTree` module is deprecated.

**Warning:** The `xml.etree.ElementTree` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see [XML vulnerabilities](https://www.python.org/).
20.5.1. Tutorial

This is a short tutorial for using xml.etree.ElementTree (ET in short). The goal is to demonstrate some of the building blocks and basic concepts of the module.

20.5.1.1. XML tree and elements

XML is an inherently hierarchical data format, and the most natural way to represent it is with a tree. ET has two classes for this purpose - ElementTree represents the whole XML document as a tree, and Element represents a single node in this tree. Interactions with the whole document (reading and writing to/from files) are usually done on the ElementTree level. Interactions with a single XML element and its sub-elements are done on the Element level.

20.5.1.2. Parsing XML

We'll be using the following XML document as the sample data for this section:

```xml
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank>1</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank>4</rank>
    </country>
</data>
```
<year>2011</year>
<gdppc>59900</gdppc>
<neighbor name="Malaysia" direction="N"/>
</country>

<country name="Panama">
  <rank>68</rank>
  <year>2011</year>
  <gdppc>13600</gdppc>
  <neighbor name="Costa Rica" direction="W"/>
  <neighbor name="Colombia" direction="E"/>
</country>
</data>

We can import this data by reading from a file:

```python
import xml.etree.ElementTree as ET
tree = ET.parse('country_data.xml')
root = tree.getroot()
```

Or directly from a string:

```python
root = ET.fromstring(country_data_as_string)
```

`fromstring()` parses XML from a string directly into an `Element`, which is the root element of the parsed tree. Other parsing functions may create an `ElementTree`. Check the documentation to be sure.

As an `Element`, `root` has a tag and a dictionary of attributes:

```python
>>> root.tag
'data'
>>> root.attrib
{}
```

It also has children nodes over which we can iterate:
>>> for child in root:
...    print(child.tag, child.attrib)
...

country {'name': 'Liechtenstein'}
country {'name': 'Singapore'}
country {'name': 'Panama'}

Children are nested, and we can access specific child nodes by index:

>>> root[0][1].text
'2008'

**Note:** Not all elements of the XML input will end up as elements of the parsed tree. Currently, this module skips over any XML comments, processing instructions, and document type declarations in the input. Nevertheless, trees built using this module's API rather than parsing from XML text can have comments and processing instructions in them; they will be included when generating XML output. A document type declaration may be accessed by passing a custom `TreeBuilder` instance to the `XMLParser` constructor.

### 20.5.1.3. Pull API for non-blocking parsing

Most parsing functions provided by this module require the whole document to be read at once before returning any result. It is possible to use an `XMLParser` and feed data into it incrementally, but it is a push API that calls methods on a callback target, which is too low-level and inconvenient for most needs. Sometimes what the user really wants is to be able to parse XML incrementally, without blocking operations, while enjoying the convenience of fully constructed `Element` objects.
The most powerful tool for doing this is `XMLPullParser`. It does not require a blocking read to obtain the XML data, and is instead fed with data incrementally with `XMLPullParser.feed()` calls. To get the parsed XML elements, call `XMLPullParser.read_events()`. Here is an example:

```python
>>> parser = ET.XMLPullParser([('start', 'end')]
>>> parser.feed('<mytag>sometext')
>>> list(parser.read_events())
[(('start', <Element 'mytag' at 0x7fa66db2be58>)]
>>> parser.feed(' more text</mytag>')
>>> for event, elem in parser.read_events():
...    print(event)
...    print(elem.tag, 'text=', elem.text)
end```

The obvious use case is applications that operate in a non-blocking fashion where the XML data is being received from a socket or read incrementally from some storage device. In such cases, blocking reads are unacceptable.

Because it's so flexible, `XMLPullParser` can be inconvenient to use for simpler use-cases. If you don't mind your application blocking on reading XML data but would still like to have incremental parsing capabilities, take a look at `iterparse()`. It can be useful when you're reading a large XML document and don't want to hold it wholly in memory.

### 20.5.1.4. Finding interesting elements

`Element` has some useful methods that help iterate recursively over all the sub-tree below it (its children, their children, and so on). For
example, `Element.iter()`:

```python
>>> for neighbor in root.iter('neighbor'):
...     print(neighbor.attrib)
...
{'name': 'Austria', 'direction': 'E'}
{'name': 'Switzerland', 'direction': 'W'}
{'name': 'Malaysia', 'direction': 'N'}
{'name': 'Costa Rica', 'direction': 'W'}
{'name': 'Colombia', 'direction': 'E'}
```

`Element.findall()` finds only elements with a tag which are direct children of the current element. `Element.find()` finds the first child with a particular tag, and `Element.text` accesses the element’s text content. `Element.get()` accesses the element’s attributes:

```python
>>> for country in root.findall('country'):
...     rank = country.find('rank').text
...     name = country.get('name')
...     print(name, rank)
...
Liechtenstein 1
Singapore 4
Panama 68
```

More sophisticated specification of which elements to look for is possible by using XPath.

### 20.5.1.5. Modifying an XML File

`ElementTree` provides a simple way to build XML documents and write them to files. The `ElementTree.write()` method serves this purpose.
Once created, an `Element` object may be manipulated by directly changing its fields (such as `Element.text`), adding and modifying attributes (`Element.set()`) method), as well as adding new children (for example with `Element.append()`).

Let's say we want to add one to each country's rank, and add an updated attribute to the rank element:

```python
>>> for rank in root.iter('rank'):
...    new_rank = int(rank.text) + 1
...    rank.text = str(new_rank)
...    rank.set('updated', 'yes')

>>> tree.write('output.xml')
```

Our XML now looks like this:

```xml
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank updated="yes">2</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank updated="yes">5</rank>
        <year>2011</year>
        <gdppc>59900</gdppc>
        <neighbor name="Malaysia" direction="N"/>
    </country>
    <country name="Panama">
        <rank updated="yes">69</rank>
        <year>2011</year>
```
We can remove elements using `Element.remove()`. Let's say we want to remove all countries with a rank higher than 50:

```python
>>> for country in root.findall('country'):
...    rank = int(country.find('rank').text)
...    if rank > 50:
...        root.remove(country)
...>>> tree.write('output.xml')
```

Our XML now looks like this:

```xml
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank updated="yes">2</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank updated="yes">5</rank>
        <year>2011</year>
        <gdppc>59900</gdppc>
        <neighbor name="Malaysia" direction="N"/>
    </country>
</data>
```
20.5.1.6. Building XML documents

The SubElement() function also provides a convenient way to create new sub-elements for a given element:

```python
>>> a = ET.Element('a')
>>> b = ET.SubElement(a, 'b')
>>> c = ET.SubElement(a, 'c')
>>> d = ET.SubElement(c, 'd')
>>> ET.dump(a)
<a><b /></c><d /></a>
```

20.5.1.7. Parsing XML with Namespaces

If the XML input has namespaces, tags and attributes with prefixes in the form prefix:sometag get expanded to {uri}sometag where the prefix is replaced by the full URI. Also, if there is a default namespace, that full URI gets prepended to all of the non-prefixed tags.

Here is an XML example that incorporates two namespaces, one with the prefix “fictional” and the other serving as the default namespace:

```xml
<?xml version="1.0"?>
<actors xmlns:fictional="http://characters.example.com"
       xmlns="http://people.example.com">
  <actor>
    <name>John Cleese</name>
    <fictional:character>Lancelot</fictional:character>
    <fictional:character>Archie Leach</fictional:character>
  </actor>
  <actor>
    <name>Eric Idle</name>
    <fictional:character>Sir Robin</fictional:character>
  </actor>
</actors>
```
One way to search and explore this XML example is to manually add the URI to every tag or attribute in the xpath of a `find()` or `findall()`:

```python
class root = fromstring(xml_text)
for actor in root.findall('{http://people.example.com}actor'):
    name = actor.find('{http://people.example.com}name').text
    print(name.text)
    for char in actor.findall('{http://characters.example.com}character'):
        print('    |-->', char.text)
```

A better way to search the namespaced XML example is to create a dictionary with your own prefixes and use those in the search functions:

```python
ns = {'real_person': 'http://people.example.com',
      'role': 'http://characters.example.com'}

for actor in root.findall('real_person:actor', ns):
    name = actor.find('real_person:name', ns).text
    print(name.text)
    for char in actor.findall('role:character', ns):
        print('    |-->', char.text)
```

These two approaches both output:

```
John Cleese
    |--> Lancelot
```
20.5.1.8. Additional resources

See [http://effbot.org/zone/element-index.htm](http://effbot.org/zone/element-index.htm) for tutorials and links to other docs.
20.5.2. XPath support

This module provides limited support for XPath expressions for locating elements in a tree. The goal is to support a small subset of the abbreviated syntax; a full XPath engine is outside the scope of the module.

20.5.2.1. Example

Here’s an example that demonstrates some of the XPath capabilities of the module. We’ll be using the countrydata XML document from the Parsing XML section:

```python
import xml.etree.ElementTree as ET

root = ET.fromstring(countrydata)

# Top-level elements
root.findall(".")

# All 'neighbor' grand-children of 'country' children
# elements
root.findall("./country/neighbor")

# Nodes with name='Singapore' that have a 'year' child
root.findall("./year/..[@name='Singapore']")

# 'year' nodes that are children of nodes with name='Singapore'
root.findall("./*[@name='Singapore']/year")

# All 'neighbor' nodes that are the second child of
root.findall("./neighbor[2]")
```
### 20.5.2.2. Supported XPath syntax

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>tag</code></td>
<td>Selects all child elements with the given tag. For example, <code>spam</code> selects all child elements named <code>spam</code>, and <code>spam/egg</code> selects all grandchildren named <code>egg</code> in all children named <code>spam</code>.</td>
</tr>
<tr>
<td><code>*</code></td>
<td>Selects all child elements. For example, <code>*/egg</code> selects all grandchildren named <code>egg</code>.</td>
</tr>
<tr>
<td>`.</td>
<td>Selects the current node. This is mostly useful at the beginning of the path, to indicate that it's a relative path.</td>
</tr>
<tr>
<td><code>//</code></td>
<td>Selects all subelements, on all levels beneath the current element. For example, <code>./egg</code> selects all <code>egg</code> elements in the entire tree.</td>
</tr>
<tr>
<td><code>..</code></td>
<td>Selects the parent element. Returns <code>None</code> if the path attempts to reach the ancestors of the start element (the element <code>find</code> was called on).</td>
</tr>
<tr>
<td><code>[@attrib]</code></td>
<td>Selects all elements that have the given attribute.</td>
</tr>
<tr>
<td><code>[@attrib='value']</code></td>
<td>Selects all elements for which the given attribute has the given value. The value cannot contain quotes.</td>
</tr>
<tr>
<td><code>[tag]</code></td>
<td>Selects all elements that have a child named <code>tag</code>. Only immediate children are supported.</td>
</tr>
<tr>
<td><code>[tag='text']</code></td>
<td>Selects all elements that have a child named <code>tag</code> whose complete text content,</td>
</tr>
</tbody>
</table>
including descendants, equals the given text.

| **[position]** | Selects all elements that are located at the given position. The position can be either an integer (1 is the first position), the expression `last()` (for the last position), or a position relative to the last position (e.g. `last()-1`). |

Predicates (expressions within square brackets) must be preceded by a tag name, an asterisk, or another predicate. `position` predicates must be preceded by a tag name.
20.5.3. Reference

20.5.3.1. Functions

```python
xml.etree.ElementTree.Comment(text=None)
```

Comment element factory. This factory function creates a special element that will be serialized as an XML comment by the standard serializer. The comment string can be either a bytestring or a Unicode string. `text` is a string containing the comment string. Returns an element instance representing a comment.

Note that `XMLParser` skips over comments in the input instead of creating comment objects for them. An `ElementTree` will only contain comment nodes if they have been inserted into the tree using one of the `Element` methods.

```python
xml.etree.ElementTree.dump(elem)
```

Writes an element tree or element structure to `sys.stdout`. This function should be used for debugging only.

The exact output format is implementation dependent. In this version, it's written as an ordinary XML file.

`elem` is an element tree or an individual element.

```python
xml.etree.ElementTree.fromstring(text)
```

Parses an XML section from a string constant. Same as `XML()`. `text` is a string containing XML data. Returns an `Element` instance.

```python
xml.etree.ElementTree.fromstringlist(sequence, parser=None)
```

Parses an XML document from a sequence of string fragments. *sequence* is a list or other sequence containing XML data fragments. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns an *Element* instance.

*New in version 3.2.*

```python
xml.etree.ElementTree.iselement(element)
```

Checks if an object appears to be a valid element object. *element* is an element instance. Returns a true value if this is an element object.

```python
xml.etree.ElementTree.iterparse(source, events=None, parser=None)
```

Parses an XML section into an element tree incrementally, and reports what’s going on to the user. *source* is a filename or file object containing XML data. *events* is a sequence of events to report back. The supported events are the strings "start", "end", "start-ns" and "end-ns" (the “ns” events are used to get detailed namespace information). If *events* is omitted, only "end" events are reported. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. *parser* must be a subclass of *XMLParser* and can only use the default *TreeBuilder* as a target. Returns an iterator providing *(event, elem)* pairs.

Note that while *iterparse()* builds the tree incrementally, it issues blocking reads on *source* (or the file it names). As such, it’s unsuitable for applications where blocking reads can’t be made. For fully non-blocking parsing, see *XMLPullParser*. 

Note: **iterparse()** only guarantees that it has seen the “>” character of a starting tag when it emits a “start” event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present. If you need a fully populated element, look for “end” events instead.

*Deprecated since version 3.4:* The **parser** argument.

```python
deprecated
xml.etree.ElementTree.parse(source, parser=None)
```

Parses an XML section into an element tree. *source* is a filename or file object containing XML data. *parser* is an optional parser instance. If not given, the standard **XMLParser** parser is used. Returns an **ElementTree** instance.

```python
deprecated
xml.etree.ElementTree.ProcessingInstruction(target, text=None)
```

PI element factory. This factory function creates a special element that will be serialized as an XML processing instruction. *target* is a string containing the PI target. *text* is a string containing the PI contents, if given. Returns an element instance, representing a processing instruction.

Note that **XMLParser** skips over processing instructions in the input instead of creating comment objects for them. An **ElementTree** will only contain processing instruction nodes if they have been inserted into to the tree using one of the **Element** methods.

```python
xml.etree.ElementTree.register_namespace(prefix, uri)
```

Registers a namespace prefix. The registry is global, and any
existing mapping for either the given prefix or the namespace URI will be removed. *prefix* is a namespace prefix. *uri* is a namespace uri. Tags and attributes in this namespace will be serialized with the given prefix, if at all possible.

*New in version 3.2.*

```python
xml.etree.ElementTree.SubElement(parent, tag, attrib={}, **extra)
```

Subelement factory. This function creates an element instance, and appends it to an existing element.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. *parent* is the parent element. *tag* is the subelement name. *attrib* is an optional dictionary, containing element attributes. *extra* contains additional attributes, given as keyword arguments. Returns an element instance.

```python
xml.etree.ElementTree.tostring(element, encoding="us-ascii", method="xml", *, short_empty_elements=True)
```

Generates a string representation of an XML element, including all subelements. *element* is an `Element` instance. *encoding* [1] is the output encoding (default is US-ASCII). Use `encoding="unicode"` to generate a Unicode string (otherwise, a bytestring is generated). *method* is either "xml", "html" or "text" (default is "xml"). *short_empty_elements* has the same meaning as in `ElementTree.write()`. Returns an (optionally) encoded string containing the XML data.

*New in version 3.4: The short_empty_elements parameter.*

```python
xml.etree.ElementTree.tostringlist(element, encoding="us-ascii", method="xml", *, short_empty_elements=True)
```
Generates a string representation of an XML element, including all subelements. `element` is an `Element` instance. `encoding` [1] is the output encoding (default is US-ASCII). Use `encoding="unicode"` to generate a Unicode string (otherwise, a bytestring is generated). `method` is either "xml", "html" or "text" (default is "xml"). `short_empty_elements` has the same meaning as in `ElementTree.write()`. Returns a list of (optionally) encoded strings containing the XML data. It does not guarantee any specific sequence, except that `b"".join(tostringlist(element)) == tostring(element).

New in version 3.2.

New in version 3.4: The `short_empty_elements` parameter.

`xml.etree.ElementTree.XML(text, parser=None)`  
Parses an XML section from a string constant. This function can be used to embed “XML literals” in Python code. `text` is a string containing XML data. `parser` is an optional parser instance. If not given, the standard `XMLParser` parser is used. Returns an `Element` instance.

`xml.etree.ElementTree.XMLID(text, parser=None)`  
Parses an XML section from a string constant, and also returns a dictionary which maps from element id:s to elements. `text` is a string containing XML data. `parser` is an optional parser instance. If not given, the standard `XMLParser` parser is used. Returns a tuple containing an `Element` instance and a dictionary.

20.5.3.2. Element Objects
class xml.etree.ElementTree.Element(tag, attrib={}, **extra)

Element class. This class defines the Element interface, and provides a reference implementation of this interface.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. tag is the element name. attrib is an optional dictionary, containing element attributes. extra contains additional attributes, given as keyword arguments.

tag
A string identifying what kind of data this element represents (the element type, in other words).

text
tail
These attributes can be used to hold additional data associated with the element. Their values are usually strings but may be any application-specific object. If the element is created from an XML file, the text attribute holds either the text between the element’s start tag and its first child or end tag, or None, and the tail attribute holds either the text between the element’s end tag and the next tag, or None. For the XML data

```xml
<a><b>1</c><d/></c></b>3</a>4</b></a>
```

the a element has None for both text and tail attributes, the b element has text "1" and tail "4", the c element has text "2" and tail None, and the d element has text None and tail "3".

To collect the inner text of an element, see itertext(), for example "".join(element.itertext()).

Applications may store arbitrary objects in these attributes.
attrib
A dictionary containing the element’s attributes. Note that while the `attrib` value is always a real mutable Python dictionary, an ElementTree implementation may choose to use another internal representation, and create the dictionary only if someone asks for it. To take advantage of such implementations, use the dictionary methods below whenever possible.

The following dictionary-like methods work on the element attributes.

clear()
Resets an element. This function removes all subelements, clears all attributes, and sets the text and tail attributes to `None`.

get(key, default=None)
Gets the element attribute named `key`.

Returns the attribute value, or `default` if the attribute was not found.

items()
Returns the element attributes as a sequence of (name, value) pairs. The attributes are returned in an arbitrary order.

keys()
Returns the elements attribute names as a list. The names are returned in an arbitrary order.

set(key, value)
Set the attribute `key` on the element to `value`. 
The following methods work on the element’s children (subelements).

**append(subelement)**

Adds the element `subelement` to the end of this element's internal list of subelements. Raises `TypeError` if `subelement` is not an `Element`.

**extend(subelements)**

Appends `subelements` from a sequence object with zero or more elements. Raises `TypeError` if a subelement is not an `Element`.

*New in version 3.2.*

**find(match, namespaces=None)**

Finds the first subelement matching `match`. `match` may be a tag name or a path. Returns an element instance or `None`. `namespaces` is an optional mapping from namespace prefix to full name.

**findall(match, namespaces=None)**

Finds all matching subelements, by tag name or path. Returns a list containing all matching elements in document order. `namespaces` is an optional mapping from namespace prefix to full name.

**findtext(match, default=None, namespaces=None)**

Finds text for the first subelement matching `match`. `match` may be a tag name or a path. Returns the text content of the first matching element, or `default` if no element was found. Note that if the matching element has no text content an empty string is
returned. *namespaces* is an optional mapping from namespace prefix to full name.

**getchildren()**

*Deprecated since version 3.2:* Use `list(elem)` or iteration.

**getiterator**(tag=None)

*Deprecated since version 3.2:* Use method `Element.iter()` instead.

**insert**(index, subelement)

Inserts `subelement` at the given position in this element. Raises `TypeError` if `subelement` is not an `Element`.

**iter**(tag=None)

Creates a tree iterator with the current element as the root. The iterator iterates over this element and all elements below it, in document (depth first) order. If `tag` is not `None` or `'*'`, only elements whose tag equals `tag` are returned from the iterator. If the tree structure is modified during iteration, the result is undefined.

*New in version 3.2.*

**iterfind**(match, namespaces=None)

Finds all matching subelements, by tag name or `path`. Returns an iterable yielding all matching elements in document order. `namespaces` is an optional mapping from namespace prefix to full name.

*New in version 3.2.*

**itertext()**
Creates a text iterator. The iterator loops over this element and all subelements, in document order, and returns all inner text.

*New in version 3.2.*

**makeelement**(tag, attrib)

Creates a new element object of the same type as this element. Do not call this method, use the `SubElement()` factory function instead.

**remove**(subelement)

Removes `subelement` from the element. Unlike the find* methods this method compares elements based on the instance identity, not on tag value or contents.

*Element* objects also support the following sequence type methods for working with subelements: `__delitem__()`, `__getitem__()`, `__setitem__()`, `__len__()`. 

Caution: Elements with no subelements will test as `False`. This behavior will change in future versions. Use specific `len(elem)` or `elem is None` test instead.

```python
element = root.find('foo')

if not element:  # careful!
    print("element not found, or element has no s"

if element is None:
    print("element not found")
```

20.5.3.3. ElementTree Objects
class xml.etree.ElementTree.ElementTree

ElementTree wrapper class. This class represents an entire element hierarchy, and adds some extra support for serialization to and from standard XML.

`element` is the root element. The tree is initialized with the contents of the XML `file` if given.

_setroot(element)

Replaces the root element for this tree. This discards the current contents of the tree, and replaces it with the given element. Use with care. `element` is an element instance.

find(match, namespaces=None)

Same as `Element.find()`, starting at the root of the tree.

findall(match, namespaces=None)

Same as `Element.findall()`, starting at the root of the tree.

findtext(match, default=None, namespaces=None)

Same as `Element.findtext()`, starting at the root of the tree.

getiterator(tag=None)

_Deprecated since version 3.2:_ Use method `ElementTree.iter()` instead.

getroot()

Returns the root element for this tree.

iter(tag=None)

Creates and returns a tree iterator for the root element. The
iterator loops over all elements in this tree, in section order. tag is the tag to look for (default is to return all elements).

**iterfind**(match, namespaces=None)

Same as **Element.iterfind()**, starting at the root of the tree.

*New in version 3.2.*

**parse**(source, parser=None)

Loads an external XML section into this element tree. source is a file name or file object. parser is an optional parser instance. If not given, the standard XMLParser parser is used. Returns the section root element.

**write**(file, encoding="us-ascii", xml_declaration=None, default_namespace=None, method="xml", *, short_empty_elements=True)

Writes the element tree to a file, as XML. file is a file name, or a file object opened for writing. encoding [1] is the output encoding (default is US-ASCII). xml_declaration controls if an XML declaration should be added to the file. Use False for never, True for always, None for only if not US-ASCII or UTF-8 or Unicode (default is None). default_namespace sets the default XML namespace (for “xmlns”). method is either "xml", "html" or "text" (default is "xml"). The keyword-only short_empty_elements parameter controls the formatting of elements that contain no content. If True (the default), they are emitted as a single self-closed tag, otherwise they are emitted as a pair of start/end tags.

The output is either a string (**str**) or binary (**bytes**). This is
controlled by the `encoding` argument. If `encoding` is "unicode", the output is a string; otherwise, it's binary. Note that this may conflict with the type of file if it's an open file object; make sure you do not try to write a string to a binary stream and vice versa.

*New in version 3.4:* The `short_empty_elements` parameter.

This is the XML file that is going to be manipulated:

```xml
<html>
  <head>
    <title>Example page</title>
  </head>
  <body>
    <p>Moved to <a href="http://example.org/">example</a> or <a href="http://example.com/">example.com</a></p>
  </body>
</html>
```

Example of changing the attribute “target” of every link in first paragraph:

```python
>>> from xml.etree.ElementTree import ElementTree
>>> tree = ElementTree()
>>> tree.parse("index.xhtml")
<Element 'html' at 0xb77e6fac>
>>> p = tree.find("body/p")    # Finds first occurrence
>>> p
<Element 'p' at 0xb77ec26c>
>>> links = list(p.iter("a"))   # Returns list of all
>>> links
[<Element 'a' at 0xb77ec2ac>, <Element 'a' at 0xb77e6ff>]
>>> for i in links:    # Iterates through all
...    i.attrib["target"] = "blank"
```
20.5.3.4. QName Objects

class xml.etree.ElementTree.QName(text_or_uri, tag=\None)

QName wrapper. This can be used to wrap a QName attribute value, in order to get proper namespace handling on output. 
text_or_uri is a string containing the QName value, in the form 
\{uri\}local, or, if the tag argument is given, the URI part of a QName. 
If tag is given, the first argument is interpreted as a URI, and this 
argument is interpreted as a local name. QName instances are 
opaque.

20.5.3.5. TreeBuilder Objects

class
xml.etree.ElementTree.TreeBuilder(element_factory=\None)

Generic element structure builder. This builder converts a 
sequence of start, data, and end method calls to a well-formed 
element structure. You can use this class to build an element 
structure using a custom XML parser, or a parser for some other 
XML-like format. element_factory, when given, must be a callable 
accepting two positional arguments: a tag and a dict of attributes. It 
is expected to return a new element instance.

close()

Flushes the builder buffers, and returns the toplevel document 
element. Returns an Element instance.

data(data)

Adds text to the current element. data is a string. This should be
either a bytestring, or a Unicode string.

**end**(tag)
Closes the current element. *tag* is the element name. Returns the closed element.

**start**(tag, attrs)
Opens a new element. *tag* is the element name. *attrs* is a dictionary containing element attributes. Returns the opened element.

In addition, a custom *TreeBuilder* object can provide the following method:

**doctype**(name, pubid, system)
Handles a doctype declaration. *name* is the doctype name. *pubid* is the public identifier. *system* is the system identifier. This method does not exist on the default *TreeBuilder* class.

*New in version 3.2.*

**20.5.3.6. XMLParser Objects**

```python
class xml.etree.ElementTree.XMPParser(html=0,
    target=None, encoding=None)
```
This class is the low-level building block of the module. It uses xml.parsers.expat for efficient, event-based parsing of XML. It can be fed XML data incrementally with the `feed()` method, and parsing events are translated to a push API - by invoking callbacks on the *target* object. If *target* is omitted, the standard *TreeBuilder* is used. The *html* argument was historically used for backwards compatibility and is now deprecated. If *encoding* [1]
is given, the value overrides the encoding specified in the XML file.

*Deprecated since version 3.4:* The `html` argument. The remaining arguments should be passed via keyword to prepare for the removal of the `html` argument.

**close()**

Finishes feeding data to the parser. Returns the result of calling the close() method of the `target` passed during construction; by default, this is the toplevel document element.

**doctype**(name, `pubid`, `system`)

*Deprecated since version 3.2:* Define the `TreeBuilder.doctype()` method on a custom `TreeBuilder` target.

**feed**(data)

Feeds data to the parser. `data` is encoded data.

`XMLParser.feed()` calls `target's start(tag, attrs_dict)` method for each opening tag, its `end(tag)` method for each closing tag, and data is processed by method `data(data)`. `XMLParser.close()` calls `target's method close()`. `XMLParser` can be used not only for building a tree structure. This is an example of counting the maximum depth of an XML file:

```python
>>> from xml.etree.ElementTree import XMLParser
>>> class MaxDepth: # The target
...     maxDepth = 0
...     depth = 0
...     def start(self, tag, attrib): # Called
...         self.depth += 1
...         if self.depth > self.maxDepth:
```
20.5.3.7. XMLPullParser Objects

class xml.etree.ElementTree.XMLPullParser(events=None)

A pull parser suitable for non-blocking applications. Its input-side API is similar to that of XMLParser, but instead of pushing calls to a callback target, XMLPullParser collects an internal list of parsing events and lets the user read from it. events is a sequence of events to report back. The supported events are the strings
"start", "end", "start-ns" and "end-ns" (the “ns” events are used to get detailed namespace information). If events is omitted, only "end" events are reported.

**feed**(data)
Feed the given bytes data to the parser.

**close()**
Signal the parser that the data stream is terminated. Unlike `XMLParser.close()`, this method always returns `None`. Any events not yet retrieved when the parser is closed can still be read with `read_events()`.

**read_events()**
Return an iterator over the events which have been encountered in the data fed to the parser. The iterator yields (event, elem) pairs, where event is a string representing the type of event (e.g. "end") and elem is the encountered `Element` object.

Events provided in a previous call to `read_events()` will not be yielded again. Events are consumed from the internal queue only when they are retrieved from the iterator, so multiple readers iterating in parallel over iterators obtained from `read_events()` will have unpredictable results.

**Note:** `XMLPullParser` only guarantees that it has seen the “>” character of a starting tag when it emits a “start” event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present. If you need a fully populated element, look for “end” events
instead.

New in version 3.4.

20.5.3.8. Exceptions

class xml.etree.ElementTree.ParseError
   XML parse error, raised by the various parsing methods in this module when parsing fails. The string representation of an instance of this exception will contain a user-friendly error message. In addition, it will have the following attributes available:

   code
      A numeric error code from the expat parser. See the documentation of xml.parsers.expats for the list of error codes and their meanings.

   position
      A tuple of line, column numbers, specifying where the error occurred.

Footnotes

(1, 2, 3, 4) The encoding string included in XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not. See https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and https://www.iana.org/assignments/character-sets/character-sets.xhtml.

Created using Sphinx 1.6.3.
20.6. `xml.dom` — The Document Object Model API

**Source code:** `Lib/xml/dom/__init__.py`

The Document Object Model, or “DOM,” is a cross-language API from the World Wide Web Consortium (W3C) for accessing and modifying XML documents. A DOM implementation presents an XML document as a tree structure, or allows client code to build such a structure from scratch. It then gives access to the structure through a set of objects which provided well-known interfaces.

The DOM is extremely useful for random-access applications. SAX only allows you a view of one bit of the document at a time. If you are looking at one SAX element, you have no access to another. If you are looking at a text node, you have no access to a containing element. When you write a SAX application, you need to keep track of your program’s position in the document somewhere in your own code. SAX does not do it for you. Also, if you need to look ahead in the XML document, you are just out of luck.

Some applications are simply impossible in an event driven model with no access to a tree. Of course you could build some sort of tree yourself in SAX events, but the DOM allows you to avoid writing that code. The DOM is a standard tree representation for XML data.

The Document Object Model is being defined by the W3C in stages, or “levels” in their terminology. The Python mapping of the API is substantially based on the DOM Level 2 recommendation.
DOM applications typically start by parsing some XML into a DOM. How this is accomplished is not covered at all by DOM Level 1, and Level 2 provides only limited improvements: There is a DOMImplementation object class which provides access to Document creation methods, but no way to access an XML reader/parser/Document builder in an implementation-independent way. There is also no well-defined way to access these methods without an existing Document object. In Python, each DOM implementation will provide a function getDOMImplementation(). DOM Level 3 adds a Load/Store specification, which defines an interface to the reader, but this is not yet available in the Python standard library.

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification; this portion of the reference manual describes the interpretation of the specification in Python.

The specification provided by the W3C defines the DOM API for Java, ECMAScript, and OMG IDL. The Python mapping defined here is based in large part on the IDL version of the specification, but strict compliance is not required (though implementations are free to support the strict mapping from IDL). See section Conformance for a detailed discussion of mapping requirements.

See also:

**Document Object Model (DOM) Level 2 Specification**

The W3C recommendation upon which the Python DOM API is based.

**Document Object Model (DOM) Level 1 Specification**
The W3C recommendation for the DOM supported by `xml.dom.minidom`.

**Python Language Mapping Specification**
This specifies the mapping from OMG IDL to Python.
20.6.1. Module Contents

The `xml.dom` contains the following functions:

```python
xml.dom.registerDOMImplementation(name, factory)
```

Register the `factory` function with the name `name`. The factory function should return an object which implements the DOMImplementation interface. The factory function can return the same object every time, or a new one for each call, as appropriate for the specific implementation (e.g. if that implementation supports some customization).

```python
xml.dom.getDOMImplementation(name=None, features=())
```

Return a suitable DOM implementation. The `name` is either well-known, the module name of a DOM implementation, or `None`. If it is not `None`, imports the corresponding module and returns a DOMImplementation object if the import succeeds. If no name is given, and if the environment variable PYTHON_DOM is set, this variable is used to find the implementation.

If `name` is not given, this examines the available implementations to find one with the required feature set. If no implementation can be found, raise an `ImportError`. The features list must be a sequence of `(feature, version)` pairs which are passed to the `hasFeature()` method on available DOMImplementation objects.

Some convenience constants are also provided:

```python
xml.dom.EMPTY_NAMESPACE
```

The value used to indicate that no namespace is associated with a
node in the DOM. This is typically found as the namespaceURI of a node, or used as the namespaceURI parameter to a namespaces-specific method.

`xml.dom.XML_NAMESPACE`

The namespace URI associated with the reserved prefix `xml`, as defined by *Namespaces in XML* (section 4).

`xml.dom.XMLNS_NAMESPACE`

The namespace URI for namespace declarations, as defined by *Document Object Model (DOM) Level 2 Core Specification* (section 1.1.8).

`xml.dom.XHTML_NAMESPACE`

The URI of the XHTML namespace as defined by *XHTML 1.0: The Extensible HyperText Markup Language* (section 3.1.1).

In addition, `xml.dom` contains a base Node class and the DOM exception classes. The Node class provided by this module does not implement any of the methods or attributes defined by the DOM specification; concrete DOM implementations must provide those. The Node class provided as part of this module does provide the constants used for the `nodeType` attribute on concrete Node objects; they are located within the class rather than at the module level to conform with the DOM specifications.
20.6.2. Objects in the DOM

The definitive documentation for the DOM is the DOM specification from the W3C.

Note that DOM attributes may also be manipulated as nodes instead of as simple strings. It is fairly rare that you must do this, however, so this usage is not yet documented.

<table>
<thead>
<tr>
<th>Interface</th>
<th>Section</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>

<td>Element Objects</td>
<td>Element nodes in the document hierarchy.</td>
</tr>
</tbody>
</table>
An additional section describes the exceptions defined for working with the DOM in Python.

20.6.2.1. DOMImplementation Objects

The DOMImplementation interface provides a way for applications to determine the availability of particular features in the DOM they are using. DOM Level 2 added the ability to create new Document and DocumentType objects using the DOMImplementation as well.

DOMImplementation. hasFeature(feature, version)

Return true if the feature identified by the pair of strings feature and version is implemented.

DOMImplementation. createDocument(namespaceUri, qualifiedName, doctype)
Return a new Document object (the root of the DOM), with a child Element object having the given namespaceUri and qualifiedName. The doctype must be a DocumentType object created by createDocumentType(), or None. In the Python DOM API, the first two arguments can also be None in order to indicate that no Element child is to be created.

```python
DOMImplementation.createDocumentType(qualifiedName, publicId, systemId)
```

Return a new DocumentType object that encapsulates the given qualifiedName, publicId, and systemId strings, representing the information contained in an XML document type declaration.

### 20.6.2.2. Node Objects

All of the components of an XML document are subclasses of Node.

**Node.nodeType**

An integer representing the node type. Symbolic constants for the types are on the Node object: ELEMENT_NODE, ATTRIBUTE_NODE, TEXT_NODE, CDATA_SECTION_NODE, ENTITY_NODE, PROCESSING_INSTRUCTION_NODE, COMMENT_NODE, DOCUMENT_NODE, DOCUMENT_TYPE_NODE, NOTATION_NODE. This is a read-only attribute.

**Node.parentNode**

The parent of the current node, or None for the document node. The value is always a Node object or None. For Element nodes, this will be the parent element, except for the root element, in which case it will be the Document object. For Attr nodes, this is always None. This is a read-only attribute.
Node. **attributes**
A NamedNodeMap of attribute objects. Only elements have actual values for this; others provide `None` for this attribute. This is a read-only attribute.

Node. **previousSibling**
The node that immediately precedes this one with the same parent. For instance the element with an end-tag that comes just before the `self` element's start-tag. Of course, XML documents are made up of more than just elements so the previous sibling could be text, a comment, or something else. If this node is the first child of the parent, this attribute will be `None`. This is a read-only attribute.

Node. **nextSibling**
The node that immediately follows this one with the same parent. See also `previousSibling`. If this is the last child of the parent, this attribute will be `None`. This is a read-only attribute.

Node. **childNodes**
A list of nodes contained within this node. This is a read-only attribute.

Node. **firstChild**
The first child of the node, if there are any, or `None`. This is a read-only attribute.

Node. **lastChild**
The last child of the node, if there are any, or `None`. This is a read-only attribute.

Node. **localName**
The part of the `tagName` following the colon if there is one, else
the entire `tagName`. The value is a string.

**Node. prefix**

The part of the `tagName` preceding the colon if there is one, else the empty string. The value is a string, or `None`.

**Node. namespaceURI**

The namespace associated with the element name. This will be a string or `None`. This is a read-only attribute.

**Node. nodeName**

This has a different meaning for each node type; see the DOM specification for details. You can always get the information you would get here from another property such as the `tagName` property for elements or the `name` property for attributes. For all node types, the value of this attribute will be either a string or `None`. This is a read-only attribute.

**Node. nodeValue**

This has a different meaning for each node type; see the DOM specification for details. The situation is similar to that with `nodeName`. The value is a string or `None`.

**Node. hasAttributes()**

Returns true if the node has any attributes.

**Node. hasChildNodes()**

Returns true if the node has any child nodes.

**Node. isSameNode(other)**

Returns true if `other` refers to the same node as this node. This is especially useful for DOM implementations which use any sort of
proxy architecture (because more than one object can refer to the same node).

**Note:** This is based on a proposed DOM Level 3 API which is still in the “working draft” stage, but this particular interface appears uncontroversial. Changes from the W3C will not necessarily affect this method in the Python DOM interface (though any new W3C API for this would also be supported).

Node. **appendChild**(newChild)

Add a new child node to this node at the end of the list of children, returning *newChild*. If the node was already in the tree, it is removed first.

Node. **insertBefore**(newChild, refChild)

Insert a new child node before an existing child. It must be the case that *refChild* is a child of this node; if not, **ValueError** is raised. *newChild* is returned. If *refChild* is **None**, it inserts *newChild* at the end of the children’s list.

Node. **removeChild**(oldChild)

Remove a child node. *oldChild* must be a child of this node; if not, **ValueError** is raised. *oldChild* is returned on success. If *oldChild* will not be used further, its **unlink()** method should be called.

Node. **replaceChild**(newChild, oldChild)

Replace an existing node with a new node. It must be the case that *oldChild* is a child of this node; if not, **ValueError** is raised.

Node. **normalize**( )

Join adjacent text nodes so that all stretches of text are stored as single **Text** instances. This simplifies processing text from a DOM
tree for many applications.

Node.

Node.cloneNode(deep)

Clone this node. Setting deep means to clone all child nodes as well. This returns the clone.

20.6.2.3. NodeList Objects

A NodeList represents a sequence of nodes. These objects are used in two ways in the DOM Core recommendation: an Element object provides one as its list of child nodes, and the getElementsByTagName() and getElementsByTagNameNS() methods of Node return objects with this interface to represent query results.

The DOM Level 2 recommendation defines one method and one attribute for these objects:

NodeList.item(i)

Return the i'th item from the sequence, if there is one, or None. The index i is not allowed to be less than zero or greater than or equal to the length of the sequence.

NodeList.length

The number of nodes in the sequence.

In addition, the Python DOM interface requires that some additional support is provided to allow NodeList objects to be used as Python sequences. All NodeList implementations must include support for __len__() and __getitem__(); this allows iteration over the NodeList in for statements and proper support for the len() built-in function.
If a DOM implementation supports modification of the document, the NodeList implementation must also support the __setitem__() and __delitem__() methods.

20.6.2.4. DocumentType Objects

Information about the notations and entities declared by a document (including the external subset if the parser uses it and can provide the information) is available from a DocumentType object. The DocumentType for a document is available from the Document object's doctype attribute; if there is no DOCTYPE declaration for the document, the document's doctype attribute will be set to None instead of an instance of this interface.

DocumentType is a specialization of Node, and adds the following attributes:

**DocumentType.publicId**

The public identifier for the external subset of the document type definition. This will be a string or None.

**DocumentType.systemId**

The system identifier for the external subset of the document type definition. This will be a URI as a string, or None.

**DocumentType.internalSubset**

A string giving the complete internal subset from the document. This does not include the brackets which enclose the subset. If the document has no internal subset, this should be None.

**DocumentType.name**

The name of the root element as given in the DOCTYPE
declaration, if present.

**DocumentType**. **entities**

This is a NamedNodeMap giving the definitions of external entities. For entity names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be `None` if the information is not provided by the parser, or if no entities are defined.

**DocumentType**. **notations**

This is a NamedNodeMap giving the definitions of notations. For notation names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be `None` if the information is not provided by the parser, or if no notations are defined.

### 20.6.2.5. Document Objects

A Document represents an entire XML document, including its constituent elements, attributes, processing instructions, comments etc. Remember that it inherits properties from Node.

**Document**. **documentElement**

The one and only root element of the document.

**Document**. **createElement**(tagName)

Create and return a new element node. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as `insertBefore()` or `appendChild()`.

**Document**. **createElementNS**(namespaceURI, tagName)
Create and return a new element with a namespace. The `tagName` may have a prefix. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as `insertBefore()` or `appendChild()`.

**Document.** `createTextNode(data)`

Create and return a text node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

**Document.** `createComment(data)`

Create and return a comment node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

**Document.** `createProcessingInstruction(target, data)`

Create and return a processing instruction node containing the `target` and `data` passed as parameters. As with the other creation methods, this one does not insert the node into the tree.

**Document.** `createAttribute(name)`

Create and return an attribute node. This method does not associate the attribute node with any particular element. You must use `setAttributeNode()` on the appropriate Element object to use the newly created attribute instance.

**Document.** `createAttributeNS(namespaceURI, qualifiedName)`

Create and return an attribute node with a namespace. The `tagName` may have a prefix. This method does not associate the attribute node with any particular element. You must use `setAttributeNode()` on the appropriate Element object to
use the newly created attribute instance.

**Document**. `getElementsByTagName(tagName)`

Search for all descendants (direct children, children’s children, etc.) with a particular element type name.

**Document**. `getElementsByTagNameNS(namespaceURI, localName)`

Search for all descendants (direct children, children’s children, etc.) with a particular namespace URI and localname. The localname is the part of the namespace after the prefix.

### 20.6.2.6. Element Objects

Element is a subclass of Node, so inherits all the attributes of that class.

**Element**. `tagName`

The element type name. In a namespace-using document it may have colons in it. The value is a string.

**Element**. `getElementsByTagName(tagName)`

Same as equivalent method in the Document class.

**Element**. `getElementsByTagNameNS(namespaceURI, localName)`

Same as equivalent method in the Document class.

**Element**. `hasAttribute(name)`

Returns true if the element has an attribute named by `name`.

**Element**. `hasAttributeNS(namespaceURI, localName)`
Returns true if the element has an attribute named by namespaceURI and localName.

Element .getAttribute(name)
Return the value of the attribute named by name as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

Element .getAttributeNode(attrname)
Return the Attr node for the attribute named by attrname.

Element .getAttributeNS(namespaceURI, localName)
Return the value of the attribute named by namespaceURI and localName as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

Element .getAttributeNodeNS(namespaceURI, localName)
Return an attribute value as a node, given a namespaceURI and localName.

Element .removeAttribute(name)
Remove an attribute by name. If there is no matching attribute, a NotFoundErr is raised.

Element .removeAttributeNode(oldAttr)
Remove and return oldAttr from the attribute list, if present. If oldAttr is not present, NotFoundErr is raised.

Element .removeAttributeNS(namespaceURI, localName)
Remove an attribute by name. Note that it uses a localName, not a qname. No exception is raised if there is no matching attribute.

Element .setAttribute(name, value)
Set an attribute value from a string.

**Element**. `setAttributeNode(newAttr)`

Add a new attribute node to the element, replacing an existing attribute if necessary if the name attribute matches. If a replacement occurs, the old attribute node will be returned. If `newAttr` is already in use, `InuseAttributeErr` will be raised.

**Element**. `setAttributeNodeNS(newAttr)`

Add a new attribute node to the element, replacing an existing attribute if necessary if the namespaceURI and localName attributes match. If a replacement occurs, the old attribute node will be returned. If `newAttr` is already in use, `InuseAttributeErr` will be raised.

**Element**. `setAttributeNS(namespaceURI, qname, value)`

Set an attribute value from a string, given a `namespaceURI` and a `qname`. Note that a qname is the whole attribute name. This is different than above.

### 20.6.2.7. Attr Objects

`Attr` inherits from `Node`, so inherits all its attributes.

**Attr**. `name`

The attribute name. In a namespace-using document it may include a colon.

**Attr**. `localName`

The part of the name following the colon if there is one, else the entire name. This is a read-only attribute.
Attr. **prefix**

The part of the name preceding the colon if there is one, else the empty string.

Attr. **value**

The text value of the attribute. This is a synonym for the `nodeValue` attribute.

---

### 20.6.2.8. NamedNodeMap Objects

NamedNodeMap does *not* inherit from Node.

**NamedNodeMap. `length`**

The length of the attribute list.

**NamedNodeMap. `item(index)`**

Return an attribute with a particular index. The order you get the attributes in is arbitrary but will be consistent for the life of a DOM. Each item is an attribute node. Get its value with the `value` attribute.

There are also experimental methods that give this class more mapping behavior. You can use them or you can use the standardized `getAttribute*()` family of methods on the Element objects.

---

### 20.6.2.9. Comment Objects

Comment represents a comment in the XML document. It is a subclass of Node, but cannot have child nodes.

**Comment. `data`**

The content of the comment as a string. The attribute contains all
characters between the leading <!-- and trailing -->, but does not include them.

20.6.2.10. Text and CDATASection Objects

The Text interface represents text in the XML document. If the parser and DOM implementation support the DOM's XML extension, portions of the text enclosed in CDATA marked sections are stored in CDATASection objects. These two interfaces are identical, but provide different values for the nodeType attribute.

These interfaces extend the Node interface. They cannot have child nodes.

Text.data

The content of the text node as a string.

Note: The use of a CDATASection node does not indicate that the node represents a complete CDATA marked section, only that the content of the node was part of a CDATA section. A single CDATA section may be represented by more than one node in the document tree. There is no way to determine whether two adjacent CDATASection nodes represent different CDATA marked sections.

20.6.2.11. ProcessingInstruction Objects

Represents a processing instruction in the XML document; this inherits from the Node interface and cannot have child nodes.

ProcessingInstruction.target

The content of the processing instruction up to the first whitespace
character. This is a read-only attribute.

ProcessingInstruction.data

The content of the processing instruction following the first whitespace character.

20.6.2.12. Exceptions

The DOM Level 2 recommendation defines a single exception, DOMException, and a number of constants that allow applications to determine what sort of error occurred. DOMException instances carry a code attribute that provides the appropriate value for the specific exception.

The Python DOM interface provides the constants, but also expands the set of exceptions so that a specific exception exists for each of the exception codes defined by the DOM. The implementations must raise the appropriate specific exception, each of which carries the appropriate value for the code attribute.

exception xml.dom.DOMException

Base exception class used for all specific DOM exceptions. This exception class cannot be directly instantiated.

exception xml.dom DomstringSizeErr

Raised when a specified range of text does not fit into a string. This is not known to be used in the Python DOM implementations, but may be received from DOM implementations not written in Python.

exception xml.dom HierarchyRequestErr

Raised when an attempt is made to insert a node where the node type is not allowed.
exception xml.dom.**IndexSizeErr**
Raised when an index or size parameter to a method is negative or exceeds the allowed values.

exception xml.dom.**InuseAttributeErr**
Raised when an attempt is made to insert an Attr node that is already present elsewhere in the document.

exception xml.dom.**InvalidAccessErr**
Raised if a parameter or an operation is not supported on the underlying object.

exception xml.dom.**InvalidCharacterErr**
This exception is raised when a string parameter contains a character that is not permitted in the context it’s being used in by the XML 1.0 recommendation. For example, attempting to create an Element node with a space in the element type name will cause this error to be raised.

exception xml.dom.**InvalidModificationErr**
Raised when an attempt is made to modify the type of a node.

exception xml.dom.**InvalidStateErr**
Raised when an attempt is made to use an object that is not defined or is no longer usable.

exception xml.dom.**NamespaceErr**
If an attempt is made to change any object in a way that is not permitted with regard to the Namespaces in XML recommendation, this exception is raised.

exception xml.dom.**NotFoundError**
Exception when a node does not exist in the referenced context.
For example, `NamedNodeMap.removeNamedItem()` will raise this if the node passed in does not exist in the map.

`exception xml.dom.NotSupportedErr`  
Raised when the implementation does not support the requested type of object or operation.

`exception xml.dom.NoDataAllowedErr`  
This is raised if data is specified for a node which does not support data.

`exception xml.dom.NoModificationAllowedErr`  
Raised on attempts to modify an object where modifications are not allowed (such as for read-only nodes).

`exception xml.dom.SyntaxErr`  
Raised when an invalid or illegal string is specified.

`exception xml.dom.WrongDocumentErr`  
Raised when a node is inserted in a different document than it currently belongs to, and the implementation does not support migrating the node from one document to the other.

The exception codes defined in the DOM recommendation map to the exceptions described above according to this table:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOMSTRING_SIZE_ERR</td>
<td>DomstringSizeErr</td>
</tr>
<tr>
<td>HIERARCHY_REQUEST_ERR</td>
<td>HierarchyRequestErr</td>
</tr>
<tr>

</tbody>
</table>
20.6.3. Conformance

This section describes the conformance requirements and relationships between the Python DOM API, the W3C DOM recommendations, and the OMG IDL mapping for Python.

20.6.3.1. Type Mapping

The IDL types used in the DOM specification are mapped to Python types according to the following table.

<table>
<thead>
<tr>
<th>IDL Type</th>
<th>Python Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>bool or int</td>
</tr>
<tr>
<td>int</td>
<td>int</td>
</tr>
<tr>
<td>long int</td>
<td>int</td>
</tr>
<tr>
<td>unsigned int</td>
<td>int</td>
</tr>
<tr>
<td>DOMString</td>
<td>str or bytes</td>
</tr>
<tr>
<td>null</td>
<td>None</td>
</tr>
</tbody>
</table>

20.6.3.2. Accessor Methods

The mapping from OMG IDL to Python defines accessor functions for IDL attribute declarations in much the way the Java mapping does. Mapping the IDL declarations

```java
readonly attribute string someValue;
attribute string anotherValue;
```

yields three accessor functions: a “get” method for someValue
(_get_someValue()), and “get” and “set” methods for anotherValue  (_get_anotherValue()  and _set_anotherValue()). The mapping, in particular, does not require that the IDL attributes are accessible as normal Python attributes: object.someValue is not required to work, and may raise an AttributeError.

The Python DOM API, however, does require that normal attribute access work. This means that the typical surrogates generated by Python IDL compilers are not likely to work, and wrapper objects may be needed on the client if the DOM objects are accessed via CORBA. While this does require some additional consideration for CORBA DOM clients, the implementers with experience using DOM over CORBA from Python do not consider this a problem. Attributes that are declared readonly may not restrict write access in all DOM implementations.

In the Python DOM API, accessor functions are not required. If provided, they should take the form defined by the Python IDL mapping, but these methods are considered unnecessary since the attributes are accessible directly from Python. “Set” accessors should never be provided for readonly attributes.

The IDL definitions do not fully embody the requirements of the W3C DOM API, such as the notion of certain objects, such as the return value of getElementsByTagName(), being “live”. The Python DOM API does not require implementations to enforce such requirements.
20.7. `xml.dom.minidom` — Minimal DOM implementation

**Source code:** `Lib/xml/dom/minidom.py`

`xml.dom.minidom` is a minimal implementation of the Document Object Model interface, with an API similar to that in other languages. It is intended to be simpler than the full DOM and also significantly smaller. Users who are not already proficient with the DOM should consider using the `xml.etree.ElementTree` module for their XML processing instead.

**Warning:** The `xml.dom.minidom` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

DOM applications typically start by parsing some XML into a DOM. With `xml.dom.minidom`, this is done through the parse functions:

```python
from xml.dom.minidom import parse, parseString

dom1 = parse('c:\temp\mydata.xml')  # parse an XML file

datasource = open('c:\temp\mydata.xml')
dom2 = parse(datasource)  # parse an open file

dom3 = parseString('<myxml>Some data<empty/> some more data</myxml>')
```

The `parse()` function can take either a filename or an open file.
xml.dom.minidom.parse(filename_or_file, parser=None, bufsize=None)

Return a Document from the given input. filename_or_file may be either a file name, or a file-like object. parser, if given, must be a SAX2 parser object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the parseString() function instead:

xml.dom.minidom.parseString(string, parser=None)

Return a Document that represents the string. This method creates an io.StringIO object for the string and passes that on to parse().

Both functions return a Document object representing the content of the document.

What the parse() and parseString() functions do is connect an XML parser with a “DOM builder” that can accept parse events from any SAX parser and convert them into a DOM tree. The name of the functions are perhaps misleading, but are easy to grasp when learning the interfaces. The parsing of the document will be completed before these functions return; it’s simply that these functions do not provide a parser implementation themselves.

You can also create a Document by calling a method on a “DOM Implementation” object. You can get this object either by calling the
getDOMImplementation() function in the xml.dom package or the xml.dom.minidom module. Once you have a Document, you can add child nodes to it to populate the DOM:

```python
from xml.dom.minidom import getDOMImplementation
impl = getDOMImplementation()
newdoc = impl.createDocument(None, "some_tag", None)
top_element = newdoc.documentElement
text = newdoc.createElementText('Some textual content.')
top_element.appendChild(text)
```

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification. The main property of the document object is the documentElement property. It gives you the main element in the XML document: the one that holds all others. Here is an example program:

```python
dom3 = parseString("<myxml>Some data</myxml>")
assert dom3.documentElement.tagName == "myxml"
```

When you are finished with a DOM tree, you may optionally call the unlink() method to encourage early cleanup of the now-unneeded objects. unlink() is an xml.dom.minidom-specific extension to the DOM API that renders the node and its descendants are essentially useless. Otherwise, Python's garbage collector will eventually take care of the objects in the tree.

See also:

Document Object Model (DOM) Level 1 Specification
The W3C recommendation for the DOM supported by xml.dom.minidom.
20.7.1. DOM Objects

The definition of the DOM API for Python is given as part of the xml.dom module documentation. This section lists the differences between the API and xml.dom.minidom.

Node. **unlink()**

Break internal references within the DOM so that it will be garbage collected on versions of Python without cyclic GC. Even when cyclic GC is available, using this can make large amounts of memory available sooner, so calling this on DOM objects as soon as they are no longer needed is good practice. This only needs to be called on the Document object, but may be called on child nodes to discard children of that node.

You can avoid calling this method explicitly by using the **with** statement. The following code will automatically unlink *dom* when the **with** block is exited:

```python
with xml.dom.minidom.parse(datasource) as dom:
  ...
  # Work with dom.
```

Node. **writexml(writer, indent='', addindent='', newl='')**

Write XML to the writer object. The writer should have a write() method which matches that of the file object interface. The **indent** parameter is the indentation of the current node. The **addindent** parameter is the incremental indentation to use for subnodes of the current one. The **newl** parameter specifies the string to use to terminate newlines.

For the Document node, an additional keyword argument
"encoding" can be used to specify the encoding field of the XML header.

Node. `toxml(encoding=None)`

Return a string or byte string containing the XML represented by the DOM node.

With an explicit `encoding` [1] argument, the result is a byte string in the specified encoding. With no `encoding` argument, the result is a Unicode string, and the XML declaration in the resulting string does not specify an encoding. Encoding this string in an encoding other than UTF-8 is likely incorrect, since UTF-8 is the default encoding of XML.

Node. `toprettyxml(indent="", newl="", encoding="")`

Return a pretty-printed version of the document. `indent` specifies the indentation string and defaults to a tabulator; `newl` specifies the string emitted at the end of each line and defaults to `\n`.

The `encoding` argument behaves like the corresponding argument of `toxml()`.
20.7.2. DOM Example

This example program is a fairly realistic example of a simple program. In this particular case, we do not take much advantage of the flexibility of the DOM.

```python
import xml.dom.minidom

document = """"
<slideshow>
<title>Demo slideshow</title>
<slide><title>Slide title</title>
<point>This is a demo</point>
<point>Of a program for processing slides</point>
</slide>

<slide><title>Another demo slide</title>
<point>It is important</point>
<point>To have more than</point>
<point>one slide</point>
</slide>
"""

dom = xml.dom.minidom.parseString(document)

def getText(nodelist):
    rc = []
    for node in nodelist:
        if node.nodeType == node.TEXT_NODE:
            rc.append(node.data)
    return "".join(rc)

def handleSlideshow(slideshow):
    print("<html>")
```
handleSlideshowTitle(slideshow.getElementsByTagName("slide"))
slides = slideshow.getElementsByTagName("slide")
handleToc(slides)
handleSlides(slides)
print("</html>")

def handleSlides(slides):
    for slide in slides:
        handleSlide(slide)

def handleSlide(slide):
    handleSlideTitle(slide.getElementsByTagName("title"))
    handlePoints(slide.getElementsByTagName("point"))

def handleSlideshowTitle(title):
    print("<title>%s</title>" % getText(title.childNodes))

def handleSlideTitle(title):
    print("<h2>%s</h2>" % getText(title.childNodes))

def handlePoints(points):
    print("<ul>")
    for point in points:
        handlePoint(point)
    print("</ul>")

def handlePoint(point):
    print("<li>%s</li>" % getText(point.childNodes))

def handleToc(slides):
    for slide in slides:
        title = slide.getElementsByTagName("title")
        print("<p>%s</p>" % getText(title.childNodes))

handleSlideshow(dom)
20.7.3. minidom and the DOM standard

The `xml.dom.minidom` module is essentially a DOM 1.0-compatible DOM with some DOM 2 features (primarily namespace features).

Usage of the DOM interface in Python is straight-forward. The following mapping rules apply:

- Interfaces are accessed through instance objects. Applications should not instantiate the classes themselves; they should use the creator functions available on the Document object. Derived interfaces support all operations (and attributes) from the base interfaces, plus any new operations.
- Operations are used as methods. Since the DOM uses only `in` parameters, the arguments are passed in normal order (from left to right). There are no optional arguments. `void` operations return `None`.
- IDL attributes map to instance attributes. For compatibility with the OMG IDL language mapping for Python, an attribute `foo` can also be accessed through accessor methods `_get_foo()` and `_set_foo()`. `readonly` attributes must not be changed; this is not enforced at runtime.
- The types `short int`, `unsigned int`, `unsigned long long`, and `boolean` all map to Python integer objects.
- The type `DOMString` maps to Python strings. `xml.dom.minidom` supports either bytes or strings, but will normally produce strings. Values of type `DOMString` may also be `None` where allowed to have the IDL `null` value by the DOM specification from the W3C.
- `const` declarations map to variables in their respective scope (e.g. `xml.dom.minidom.Node.PROCESSING_INSTRUCTION_NODE`).
they must not be changed.

- **DOMException** is currently not supported in `xml.dom.minidom`. Instead, `xml.dom.minidom` uses standard Python exceptions such as `TypeError` and `AttributeError`.
- NodeList objects are implemented using Python's built-in list type. These objects provide the interface defined in the DOM specification, but with earlier versions of Python they do not support the official API. They are, however, much more “Pythonic” than the interface defined in the W3C recommendations.

The following interfaces have no implementation in `xml.dom.minidom`:

- DOMTimeStamp
- DocumentType
- DOMImplementation
- CharacterData
- CDATASection
- Notation
- Entity
- EntityReference
- DocumentFragment

Most of these reflect information in the XML document that is not of general utility to most DOM users.

**Footnotes**

The encoding name included in the XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not valid in an XML document’s declaration, even though Python accepts it as an encoding name. See [https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl](https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl) and [https://www.iana.org/assignments/character-](https://www.iana.org/assignments/character-)
20.8. `xml.dom.pulldom` — Support for building partial DOM trees

Source code: `Lib/xml/dom/pulldom.py`

The `xml.dom.pulldom` module provides a “pull parser” which can also be asked to produce DOM-accessible fragments of the document where necessary. The basic concept involves pulling “events” from a stream of incoming XML and processing them. In contrast to SAX which also employs an event-driven processing model together with callbacks, the user of a pull parser is responsible for explicitly pulling events from the stream, looping over those events until either processing is finished or an error condition occurs.

**Warning:** The `xml.dom.pulldom` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see [XML vulnerabilities](#).

Example:

```python
from xml.dom import pulldom

doc = pulldom.parse('sales_items.xml')
for event, node in doc:
    if event == pulldom.START_ELEMENT and node.tagName:
        if int(node.getAttribute('price')) > 50:
            doc.expandNode(node)
            print(node.toxml())
```
event is a constant and can be one of:

- START_ELEMENT
- END_ELEMENT
- COMMENT
- START_DOCUMENT
- END_DOCUMENT
- CHARACTERS
- PROCESSING_INSTRUCTION
- IGNORABLE_WHITESPACE

node is an object of type xml.dom.minidom.Document, xml.dom.minidom.Element or xml.dom.minidom.Text.

Since the document is treated as a “flat” stream of events, the document “tree” is implicitly traversed and the desired elements are found regardless of their depth in the tree. In other words, one does not need to consider hierarchical issues such as recursive searching of the document nodes, although if the context of elements were important, one would either need to maintain some context-related state (i.e. remembering where one is in the document at any given point) or to make use of the DOMEventStream.expandNode() method and switch to DOM-related processing.

class xml.dom.pulldom.PullDom(documentFactory=None)
    Subclass of xml.sax.handler.ContentHandler.

class xml.dom.pulldom.SAX2DOM(documentFactory=None)
    Subclass of xml.sax.handler.ContentHandler.

xmldom.pulldom.parse(stream_or_string, parser=None, bufsize=None)
Return a `DOMEventStream` from the given input. `stream_or_string` may be either a file name, or a file-like object. `parser`, if given, must be an `XMLReader` object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the `parseString()` function instead:

```python
xml.dom.pulldom.parseString(string, parser=None)
```

Return a `DOMEventStream` that represents the (Unicode) `string`.

```python
xml.dom.pulldom.default_bufsize
```

Default value for the `bufsize` parameter to `parse()`.

The value of this variable can be changed before calling `parse()` and the new value will take effect.
20.8.1. DOMEventStream Objects

class xml.dom.pulldom.DOMEventStream(stream, parser, bufsize)

getEvent()

Return a tuple containing event and the current node as
xml.dom.minidom.Document if event equals
START_DOCUMENT, xml.dom.minidom.Element if event
equals START_ELEMENT or END_ELEMENT or
xml.dom.minidom.Text if event equals CHARACTERS. The
current node does not contain information about its children,
unless expandNode() is called.

expandNode(node)

Expands all children of node into node. Example:

```python
from xml.dom import pulldom

xml = '<html><title>Foo</title><p>Some text <div>and more</div></p>

doc = pulldom.parseString(xml)

for event, node in doc:
    if event == pulldom.START_ELEMENT and node:
        # Following statement only prints '<p/>
        print(node lxml())
        doc.expandNode(node)
        # Following statement prints node with
        print(node lxml())
```

reset()
20.9. **xml.sax** — Support for SAX2 parsers

**Source code:** Lib/xml/sax/__init__.py

The **xml.sax** package provides a number of modules which implement the Simple API for XML (SAX) interface for Python. The package itself provides the SAX exceptions and the convenience functions which will be most used by users of the SAX API.

**Warning:** The **xml.sax** module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see [XML vulnerabilities](#).

The convenience functions are:

**xml.sax.**`make_parser(parser_list=[])`  
Create and return a SAX **XMLReader** object. The first parser found will be used. If `parser_list` is provided, it must be a sequence of strings which name modules that have a function named `create_parser()`. Modules listed in `parser_list` will be used before modules in the default list of parsers.

**xml.sax.**`parse(filename_or_stream, handler, error_handler=handler.ErrorHandler())`  
Create a SAX parser and use it to parse a document. The document, passed in as `filename_or_stream`, can be a filename or a file object. The `handler` parameter needs to be a SAX **ContentHandler** instance. If `error_handler` is given, it must be a
SAX `ErrorHandler` instance; if omitted, `SAXParseException` will be raised on all errors. There is no return value; all work must be done by the `handler` passed in.

```python
xml.sax.parseString(string, handler, error_handler=handler.ErrorHandler())
```

Similar to `parse()`, but parses from a buffer `string` received as a parameter. `string` must be a `str` instance or a `bytes-like object`.

*Changed in version 3.5:* Added support of `str` instances.

A typical SAX application uses three kinds of objects: readers, handlers and input sources. “Reader” in this context is another term for parser, i.e. some piece of code that reads the bytes or characters from the input source, and produces a sequence of events. The events then get distributed to the handler objects, i.e. the reader invokes a method on the handler. A SAX application must therefore obtain a reader object, create or open the input sources, create the handlers, and connect these objects all together. As the final step of preparation, the reader is called to parse the input. During parsing, methods on the handler objects are called based on structural and syntactic events from the input data.

For these objects, only the interfaces are relevant; they are normally not instantiated by the application itself. Since Python does not have an explicit notion of interface, they are formally introduced as classes, but applications may use implementations which do not inherit from the provided classes. The `InputSource`, `Locator`, `Attributes`, `AttributesNS`, and `XMLReader` interfaces are defined in the module `xml.sax.xmlreader`. The handler interfaces are defined in `xml.sax.handler`. For convenience, `InputSource` (which is often instantiated directly) and the handler classes are also available from
XML. These interfaces are described below.

In addition to these classes, XML provides the following exception classes.

```python
exception xml.sax.SAXException(msg, exception=None)
```
Encapsulate an XML error or warning. This class can contain basic error or warning information from either the XML parser or the application: it can be subclassed to provide additional functionality or to add localization. Note that although the handlers defined in the ErrorHandler interface receive instances of this exception, it is not required to actually raise the exception — it is also useful as a container for information.

When instantiated, `msg` should be a human-readable description of the error. The optional `exception` parameter, if given, should be None or an exception that was caught by the parsing code and is being passed along as information.

This is the base class for the other SAX exception classes.

```python
exception xml.sax.SAXParseException(msg, exception, locator)
```
Subclass of SAXException raised on parse errors. Instances of this class are passed to the methods of the SAX ErrorHandler interface to provide information about the parse error. This class supports the SAX Locator interface as well as the SAXException interface.

```python
exception xml.sax.SAXNotRecognizedException(msg, exception=None)
```
Subclass of SAXException raised when a SAX XMLReader is
confronted with an unrecognized feature or property. SAX applications and extensions may use this class for similar purposes.

```python
exception xml.sax.SAXNotSupportedException(msg, exception=None)
```

Subclass of `SAXException` raised when a SAX `XMLReader` is asked to enable a feature that is not supported, or to set a property to a value that the implementation does not support. SAX applications and extensions may use this class for similar purposes.

See also:

**SAX: The Simple API for XML**

This site is the focal point for the definition of the SAX API. It provides a Java implementation and online documentation. Links to implementations and historical information are also available.

**Module** `xml.sax.handler`

Definitions of the interfaces for application-provided objects.

**Module** `xml.sax.saxutils`

Convenience functions for use in SAX applications.

**Module** `xml.sax.xmlreader`

Definitions of the interfaces for parser-provided objects.
20.9.1. SAXException Objects

The `SAXException` exception class supports the following methods:

- **SAXException. `getMessage()`**
  
  Return a human-readable message describing the error condition.

- **SAXException. `getException()`**
  
  Return an encapsulated exception object, or `None`. 
20.10. xml.sax.handler — Base classes for SAX handlers

**Source code:** Lib/xml/sax/handler.py

The SAX API defines four kinds of handlers: content handlers, DTD handlers, error handlers, and entity resolvers. Applications normally only need to implement those interfaces whose events they are interested in; they can implement the interfaces in a single object or in multiple objects. Handler implementations should inherit from the base classes provided in the module `xml.sax.handler`, so that all methods get default implementations.

*class xml.sax.handler.ContentHandler*

This is the main callback interface in SAX, and the one most important to applications. The order of events in this interface mirrors the order of the information in the document.

*class xml.sax.handler.DTDHandler*

Handle DTD events.

This interface specifies only those DTD events required for basic parsing (unparsed entities and attributes).

*class xml.sax.handler.EntityResolver*

Basic interface for resolving entities. If you create an object implementing this interface, then register the object with your Parser, the parser will call the method in your object to resolve all external entities.
class xml.sax.handler.ErrorHandler

Interface used by the parser to present error and warning messages to the application. The methods of this object control whether errors are immediately converted to exceptions or are handled in some other way.

In addition to these classes, xml.sax.handler provides symbolic constants for the feature and property names.

xml.sax.handler.feature_namespaces

value: "http://xml.org/sax/features/namespaces"
true: Perform Namespace processing.
false: Optionally do not perform Namespace processing (implies namespace-prefixes; default).
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_namespace_prefixes

value: "http://xml.org/sax/features/namespace-prefixes"
true: Report the original prefixed names and attributes used for Namespace declarations.
false: Do not report attributes used for Namespace declarations, and optionally do not report original prefixed names (default).
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_string_interning

value: "http://xml.org/sax/features/string-interning"
true: All element names, prefixes, attribute names, Namespace URIs, and local names are interned using the built-in intern function.
false: Names are not necessarily interned, although they may be
xml.sax.handler.feature_validation

value: "http://xml.org/sax/features/validation"
true: Report all validation errors (implies external-general-entities and external-parameter-entities).
false: Do not report validation errors.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_external_ges

value: "http://xml.org/sax/features/external-general-entities"
true: Include all external general (text) entities.
false: Do not include external general entities.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_external_pes

value: "http://xml.org/sax/features/external-parameter-entities"
true: Include all external parameter entities, including the external DTD subset.
false: Do not include any external parameter entities, even the external DTD subset.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.all_features

List of all features.

xml.sax.handler.property_lexical_handler

value: "http://xml.org/sax/properties/lexical-handler"
data type: xml.sax.sax2lib.LexicalHandler (not supported in Python 2)
description: An optional extension handler for lexical events like comments.
access: read/write

xml.sax.handler.**property_declaration_handler**

value: "http://xml.org/sax/properties/declaration-handler"
data type: xml.sax.sax2lib.DeclHandler (not supported in Python 2)
description: An optional extension handler for DTD-related events other than notations and unparsed entities.
access: read/write

xml.sax.handler.**property_dom_node**

value: "http://xml.org/sax/properties/dom-node"
data type: org.w3c.dom.Node (not supported in Python 2)
description: When parsing, the current DOM node being visited if this is a DOM iterator; when not parsing, the root DOM node for iteration.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.**property_xml_string**

value: "http://xml.org/sax/properties/xml-string"
data type: String
description: The literal string of characters that was the source for the current event.
access: read-only

xml.sax.handler.**all_properties**

List of all known property names.
20.10.1. ContentHandler Objects

Users are expected to subclass `ContentHandler` to support their application. The following methods are called by the parser on the appropriate events in the input document:

**ContentHandler.** `setDocumentLocator(locator)`

Called by the parser to give the application a locator for locating the origin of document events.

SAX parsers are strongly encouraged (though not absolutely required) to supply a locator: if it does so, it must supply the locator to the application by invoking this method before invoking any of the other methods in the DocumentHandler interface.

The locator allows the application to determine the end position of any document-related event, even if the parser is not reporting an error. Typically, the application will use this information for reporting its own errors (such as character content that does not match an application’s business rules). The information returned by the locator is probably not sufficient for use with a search engine.

Note that the locator will return correct information only during the invocation of the events in this interface. The application should not attempt to use it at any other time.

**ContentHandler.** `startDocument()`

Receive notification of the beginning of a document.

The SAX parser will invoke this method only once, before any other methods in this interface or in DTDHandler (except for `setDocumentLocator()`).
ContentHandler. **endDocument()**

Receive notification of the end of a document.

The SAX parser will invoke this method only once, and it will be the last method invoked during the parse. The parser shall not invoke this method until it has either abandoned parsing (because of an unrecoverable error) or reached the end of input.

ContentHandler. **startPrefixMapping**(prefix, uri)

Begin the scope of a prefix-URI Namespace mapping.

The information from this event is not necessary for normal Namespace processing: the SAX XML reader will automatically replace prefixes for element and attribute names when the **feature_namespaces** feature is enabled (the default).

There are cases, however, when applications need to use prefixes in character data or in attribute values, where they cannot safely be expanded automatically; the **startPrefixMapping()** and **endPrefixMapping()** events supply the information to the application to expand prefixes in those contexts itself, if necessary.

Note that **startPrefixMapping()** and **endPrefixMapping()** events are not guaranteed to be properly nested relative to each-other: all **startPrefixMapping()** events will occur before the corresponding **startElement()** event, and all **endPrefixMapping()** events will occur after the corresponding **endElement()** event, but their order is not guaranteed.

ContentHandler. **endPrefixMapping**(prefix)

End the scope of a prefix-URI mapping.

See **startPrefixMapping()** for details. This event will always
occur after the corresponding `endElement()` event, but the order of `endPrefixMapping()` events is not otherwise guaranteed.

`ContentHandler.startElement(name, attrs)`
Signals the start of an element in non-namespaces mode.

The `name` parameter contains the raw XML 1.0 name of the element type as a string and the `attrs` parameter holds an object of the `Attributes` interface (see *The Attributes Interface*) containing the attributes of the element. The object passed as `attrs` may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the `copy()` method of the `attrs` object.

`ContentHandler.endElement(name)`
Signals the end of an element in non-namespaces mode.

The `name` parameter contains the name of the element type, just as with the `startElement()` event.

`ContentHandler.startElementNS(name, qname, attrs)`
Signals the start of an element in namespace mode.

The `name` parameter contains the name of the element type as a `(uri, localname)` tuple, the `qname` parameter contains the raw XML 1.0 name used in the source document, and the `attrs` parameter holds an instance of the `AttributesNS` interface (see *The AttributesNS Interface*) containing the attributes of the element. If no namespace is associated with the element, the `uri` component of `name` will be `None`. The object passed as `attrs` may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the
attributes, use the `copy()` method of the `attrs` object.

Parsers may set the `qname` parameter to `None`, unless the `feature_namespace_prefixes` feature is activated.

`ContentHandler.endElementNS(name, qname)`
Signals the end of an element in namespace mode.

The `name` parameter contains the name of the element type, just as with the `startElementNS()` method, likewise the `qname` parameter.

`ContentHandler.characters(content)`
Receive notification of character data.

The Parser will call this method to report each chunk of character data. SAX parsers may return all contiguous character data in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity so that the Locator provides useful information.

`content` may be a string or bytes instance; the `expat` reader module always produces strings.

**Note:** The earlier SAX 1 interface provided by the Python XML Special Interest Group used a more Java-like interface for this method. Since most parsers used from Python did not take advantage of the older interface, the simpler signature was chosen to replace it. To convert old code to the new interface, use `content` instead of slicing content with the old `offset` and `length` parameters.

`ContentHandler.ignorableWhitespace(whitespace)`
Receive notification of ignorable whitespace in element content.

Validating Parsers must use this method to report each chunk of ignorable whitespace (see the W3C XML 1.0 recommendation, section 2.10): non-validating parsers may also use this method if they are capable of parsing and using content models.

SAX parsers may return all contiguous whitespace in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity, so that the Locator provides useful information.

ContentHandler.\texttt{processingInstruction}(\texttt{target, data})

Receive notification of a processing instruction.

The Parser will invoke this method once for each processing instruction found: note that processing instructions may occur before or after the main document element.

A SAX parser should never report an XML declaration (XML 1.0, section 2.8) or a text declaration (XML 1.0, section 4.3.1) using this method.

ContentHandler.\texttt{skippedEntity}(\texttt{name})

Receive notification of a skipped entity.

The Parser will invoke this method once for each entity skipped. Non-validating processors may skip entities if they have not seen the declarations (because, for example, the entity was declared in an external DTD subset). All processors may skip external entities, depending on the values of the \texttt{feature_external_ges} and the \texttt{feature_external_pes} properties.
20.10.2. DTDHandler Objects

`DTDHandler` instances provide the following methods:

`DTDHandler.notationDecl(name, publicId, systemId)`
Handle a notation declaration event.

`DTDHandler.unparsedEntityDecl(name, publicId, systemId, ndata)`
Handle an unparsed entity declaration event.
20.10.3. EntityResolver Objects

EntityResolver. **resolveEntity**(publicId, systemId)

Resolve the system identifier of an entity and return either the system identifier to read from as a string, or an InputSource to read from. The default implementation returns systemId.
20.10.4. ErrorHandler Objects

Objects with this interface are used to receive error and warning information from the XMLReader. If you create an object that implements this interface, then register the object with your XMLReader, the parser will call the methods in your object to report all warnings and errors. There are three levels of errors available: warnings, (possibly) recoverable errors, and unrecoverable errors. All methods take a SAXParseException as the only parameter. Errors and warnings may be converted to an exception by raising the passed-in exception object.

ErrorHandler.error(exception)

Called when the parser encounters a recoverable error. If this method does not raise an exception, parsing may continue, but further document information should not be expected by the application. Allowing the parser to continue may allow additional errors to be discovered in the input document.

ErrorHandler.fatalError(exception)

Called when the parser encounters an error it cannot recover from; parsing is expected to terminate when this method returns.

ErrorHandler.warning(exception)

Called when the parser presents minor warning information to the application. Parsing is expected to continue when this method returns, and document information will continue to be passed to the application. Raising an exception in this method will cause parsing to end.
20.11. **xml.sax.saxutils** —
SAX Utilities

**Source code:** Lib/xml/sax/saxutils.py

The module *xml.sax.saxutils* contains a number of classes and functions that are commonly useful when creating SAX applications, either in direct use, or as base classes.

```python
xml.sax.saxutils.escape(data, entities={})
```

Escape `&`, `<`, and `>` in a string of data.

You can escape other strings of data by passing a dictionary as the optional `entities` parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. The characters `&`, `<` and `>` are always escaped, even if `entities` is provided.

```python
xml.sax.saxutils.unescape(data, entities={})
```

Unescape `&amp;`, `&lt;`, and `&gt;` in a string of data.

You can unescape other strings of data by passing a dictionary as the optional `entities` parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. `&amp;`, `&lt;`, and `&gt;` are always unescaped, even if `entities` is provided.

```python
xml.sax.saxutils.quoteattr(data, entities={})
```

Similar to `escape()`, but also prepares `data` to be used as an attribute value. The return value is a quoted version of `data` with

```python
xml.sax.saxutils.unquoteattr(data, entities={})
```

Unquote `&amp;`, `&lt;`, and `&gt;` in a string of data.

You can unquote other strings of data by passing a dictionary as the optional `entities` parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. `&amp;`, `&lt;`, and `&gt;` are always unquoted, even if `entities` is provided.
any additional required replacements. `quoteattr()` will select a quote character based on the content of `data`, attempting to avoid encoding any quote characters in the string. If both single- and double-quote characters are already in `data`, the double-quote characters will be encoded and `data` will be wrapped in double-quotes. The resulting string can be used directly as an attribute value:

```python
>>> print("<element attr=%s>" % quoteattr("ab ' cd &quot; ef")
<element attr="ab ' cd &quot; ef")
```

This function is useful when generating attribute values for HTML or any SGML using the reference concrete syntax.

```python
class xml.sax.saxutils.XMLGenerator(out=None, encoding='iso-8859-1', short_empty_elements=False)
```

This class implements the `ContentHandler` interface by writing SAX events back into an XML document. In other words, using an `XMLGenerator` as the content handler will reproduce the original document being parsed. `out` should be a file-like object which will default to `sys.stdout`. `encoding` is the encoding of the output stream which defaults to `iso-8859-1`. `short_empty_elements` controls the formatting of elements that contain no content: if `False` (the default) they are emitted as a pair of start/end tags, if set to `True` they are emitted as a single self-closed tag.

*New in version 3.2:* The `short_empty_elements` parameter.

```python
class xml.sax.saxutils.XMLFilterBase(base)
```

This class is designed to sit between an `XMLReader` and the client application’s event handlers. By default, it does nothing but pass requests up to the reader and events on to the handlers
unmodified, but subclasses can override specific methods to modify the event stream or the configuration requests as they pass through.

```python
xml.sax.saxutils.prepare_input_source(source, base='')
```

This function takes an input source and an optional base URL and returns a fully resolved `InputSource` object ready for reading. The input source can be given as a string, a file-like object, or an `InputSource` object; parsers will use this function to implement the polymorphic `source` argument to their `parse()` method.
20.12. `xml.sax.xmlreader` — Interface for XML parsers

**Source code:** Lib/xml/sax/xmlreader.py

SAX parsers implement the `XMLReader` interface. They are implemented in a Python module, which must provide a function `create_parser()`. This function is invoked by `xml.sax.make_parser()` with no arguments to create a new parser object.

```python
class xml.sax.xmlreader.XMLReader
    Base class which can be inherited by SAX parsers.

class xml.sax.xmlreader.IncrementalParser
    In some cases, it is desirable not to parse an input source at once, but to feed chunks of the document as they get available. Note that the reader will normally not read the entire file, but read it in chunks as well; still `parse()` won’t return until the entire document is processed. So these interfaces should be used if the blocking behaviour of `parse()` is not desirable.
```

When the parser is instantiated it is ready to begin accepting data from the feed method immediately. After parsing has been finished with a call to close the reset method must be called to make the parser ready to accept new data, either from feed or using the parse method.

Note that these methods must *not* be called during parsing, that is, after `parse` has been called and before it returns.
By default, the class also implements the parse method of the XMLReader interface using the feed, close and reset methods of the IncrementalParser interface as a convenience to SAX 2.0 driver writers.

```python
class xml.sax.xmlreader.Locator
    Interface for associating a SAX event with a document location. A locator object will return valid results only during calls to DocumentHandler methods; at any other time, the results are unpredictable. If information is not available, methods may return None.
```

```python
class xml.sax.xmlreader.InputSource(system_id=None)
    Encapsulation of the information needed by the XMLReader to read entities.

    This class may include information about the public identifier, system identifier, byte stream (possibly with character encoding information) and/or the character stream of an entity.

    Applications will create objects of this class for use in the XMLReader.parse() method and for returning from EntityResolver.resolveEntity.

    An InputSource belongs to the application, the XMLReader is not allowed to modify InputSource objects passed to it from the application, although it may make copies and modify those.
```

```python
class xml.sax.xmlreader.AttributesImpl(attrs)
    This is an implementation of the Attributes interface (see section The Attributes Interface). This is a dictionary-like object which represents the element attributes in a startElement() call. In addition to the most useful dictionary operations, it supports
a number of other methods as described by the interface. Objects of this class should be instantiated by readers; `attrs` must be a dictionary-like object containing a mapping from attribute names to attribute values.

```python
class xml.sax.xmlreader.AttributesNSImpl(attrs, qnames)
```
Namespace-aware variant of `AttributesImpl`, which will be passed to `startElementNS()`. It is derived from `AttributesImpl`, but understands attribute names as two-tuples of `namespaceURI` and `localname`. In addition, it provides a number of methods expecting qualified names as they appear in the original document. This class implements the `AttributesNS` interface (see section The AttributesNS Interface).
20.12.1. XMLReader Objects

The XMLReader interface supports the following methods:

**XMLReader.** `parse(source)`

Process an input source, producing SAX events. The `source` object can be a system identifier (a string identifying the input source — typically a file name or a URL), a file-like object, or an InputSource object. When `parse()` returns, the input is completely processed, and the parser object can be discarded or reset.

*Changed in version 3.5: Added support of character streams.*

**XMLReader.** `getContentHandler()`

Return the current `ContentHandler`.

**XMLReader.** `setContentHandler(handler)`

Set the current `ContentHandler`. If no `ContentHandler` is set, content events will be discarded.

**XMLReader.** `getDTDHandler()`

Return the current `DTDHandler`.

**XMLReader.** `setDTDHandler(handler)`

Set the current `DTDHandler`. If no `DTDHandler` is set, DTD events will be discarded.

**XMLReader.** `getEntityResolver()`

Return the current `EntityResolver`.

**XMLReader.** `setEntityResolver(handler)`
Set the current `EntityResolver`. If no `EntityResolver` is set, attempts to resolve an external entity will result in opening the system identifier for the entity, and fail if it is not available.

`XMLReader.getErrorHandler()`

Return the current `ErrorHandler`.

`XMLReader.setErrorHandler(handler)`

Set the current error handler. If no `ErrorHandler` is set, errors will be raised as exceptions, and warnings will be printed.

`XMLReader.setLocale(locale)`

Allow an application to set the locale for errors and warnings.

SAX parsers are not required to provide localization for errors and warnings; if they cannot support the requested locale, however, they must raise a SAX exception. Applications may request a locale change in the middle of a parse.

`XMLReader.getFeature(featurename)`

Return the current setting for feature `featurename`. If the feature is not recognized, `SAXNotRecognizedException` is raised. The well-known featurenames are listed in the module `xml.sax.handler`.

`XMLReader.setFeature(featurename, value)`

Set the `featurename` to `value`. If the feature is not recognized, `SAXNotRecognizedException` is raised. If the feature or its setting is not supported by the parser, `SAXNotSupportedException` is raised.

`XMLReader.getProperty(propertyname)`
Return the current setting for property `propertyname`. If the property is not recognized, a SAXNotRecognizedException is raised. The well-known propertynames are listed in the module `xml.sax.handler`.

**XMLReader. `setProperty(propertyname, value)`**

Set the `propertyname` to `value`. If the property is not recognized, SAXNotRecognizedException is raised. If the property or its setting is not supported by the parser, SAXNotSupportedException is raised.
20.12.2. IncrementalParser Objects

Instances of `IncrementalParser` offer the following additional methods:

**IncrementalParser.**`feed(data)`

Process a chunk of `data`.

**IncrementalParser.**`close()`

Assume the end of the document. That will check well-formedness conditions that can be checked only at the end, invoke handlers, and may clean up resources allocated during parsing.

**IncrementalParser.**`reset()`

This method is called after `close` has been called to reset the parser so that it is ready to parse new documents. The results of calling `parse` or `feed` after `close` without calling `reset` are undefined.
20.12.3. Locator Objects

Instances of Locator provide these methods:

**Locator.
getColumnNumber()**

Return the column number where the current event begins.

**Locator.
getLineNumber()**

Return the line number where the current event begins.

**Locator.
getPublicId()**

Return the public identifier for the current event.

**Locator.
getSystemId()**

Return the system identifier for the current event.
20.12.4. InputSource Objects

InputSource. **setPublicId**(id)
Sets the public identifier of this *InputSource*.

InputSource. **getPublicId**()
Returns the public identifier of this *InputSource*.

InputSource. **setSystemId**(id)
Sets the system identifier of this *InputSource*.

InputSource. **getSystemId**()
Returns the system identifier of this *InputSource*.

InputSource. **setEncoding**(encoding)
Sets the character encoding of this *InputSource*.

The encoding must be a string acceptable for an XML encoding declaration (see section 4.3.3 of the XML recommendation).

The encoding attribute of the *InputSource* is ignored if the *InputSource* also contains a character stream.

InputSource. **getEncoding**()
Get the character encoding of this InputSource.

InputSource. **setByteStream**(bytefile)
Set the byte stream (a *binary file*) for this input source.

The SAX parser will ignore this if there is also a character stream specified, but it will use a byte stream in preference to opening a URI connection itself.
If the application knows the character encoding of the byte stream, it should set it with the `setEncoding` method.

**`InputSource.getByteStream()`**

Get the byte stream for this input source.

The `getEncoding` method will return the character encoding for this byte stream, or None if unknown.

**`InputSource.setCharacterStream(charfile)`**

Set the character stream (a text file) for this input source.

If there is a character stream specified, the SAX parser will ignore any byte stream and will not attempt to open a URI connection to the system identifier.

**`InputSource.getCharacterStream()`**

Get the character stream for this input source.
20.12.5. The Attributes Interface

Attributes objects implement a portion of the mapping protocol, including the methods copy(), get(), __contains__(), items(), keys(), and values(). The following methods are also provided:

Attributes.getLength()
Return the number of attributes.

Attributes.getNames()
Return the names of the attributes.

Attributes.getType(name)
Returns the type of the attribute name, which is normally 'CDATA'.

Attributes.getValue(name)
Return the value of attribute name.
20.12.6. The AttributesNS Interface

This interface is a subtype of the Attributes interface (see section The Attributes Interface). All methods supported by that interface are also available on AttributesNS objects.

The following methods are also available:

AttributesNS. `getValueByQName(name)`
    Return the value for a qualified name.

AttributesNS. `getNameByQName(name)`
    Return the (namespace, localname) pair for a qualified name.

AttributesNS. `getQNameByName(name)`
    Return the qualified name for a (namespace, localname) pair.

AttributesNS. `getQNames()`
    Return the qualified names of all attributes.
20.13. `xml.parsers.expat` — Fast XML parsing using Expat

**Warning:** The pyexpat module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see [XML vulnerabilities](#).

The `xml.parsers.expat` module is a Python interface to the Expat non-validating XML parser. The module provides a single extension type, `xmlparser`, that represents the current state of an XML parser. After an `xmlparser` object has been created, various attributes of the object can be set to handler functions. When an XML document is then fed to the parser, the handler functions are called for the character data and markup in the XML document.

This module uses the pyexpat module to provide access to the Expat parser. Direct use of the pyexpat module is deprecated.

This module provides one exception and one type object:

```python
definition

**exception** `xml.parsers.expat.ExpatError`

The exception raised when Expat reports an error. See section [ExpatError Exceptions](#) for more information on interpreting Expat errors.

**exception** `xml.parsers.expat.error`

Alias for `ExpatError`.

`xml.parsers.expat.XMLParserType`

The type of the return values from the `ParserCreate()` function.
The `xml.parsers.expat` module contains two functions:

`xml.parsers.expat.ErrorString(erno)`

Returns an explanatory string for a given error number `errno`.

`xml.parsers.expat.ParserCreate(encoding=None, namespace_separator=None)`

Creates and returns a new `xmlparser` object. `encoding`, if specified, must be a string naming the encoding used by the XML data. Expat doesn’t support as many encodings as Python does, and its repertoire of encodings can’t be extended; it supports UTF-8, UTF-16, ISO-8859-1 (Latin1), and ASCII. If `encoding` [1] is given it will override the implicit or explicit encoding of the document.

Expat can optionally do XML namespace processing for you, enabled by providing a value for `namespace_separator`. The value must be a one-character string; a `ValueError` will be raised if the string has an illegal length (`None` is considered the same as omission). When namespace processing is enabled, element type names and attribute names that belong to a namespace will be expanded. The element name passed to the element handlers `StartElementHandler` and `EndElementHandler` will be the concatenation of the namespace URI, the namespace separator character, and the local part of the name. If the namespace separator is a zero byte (`chr(0)`) then the namespace URI and the local part will be concatenated without any separator.

For example, if `namespace_separator` is set to a space character (`' '`) and the following document is parsed:

```xml
<?xml version="1.0"?>
<root xmlns="http://default-namespace.org/"
     xmlns:py = "http://www.python.org/ns/">
StartElementHandler will receive the following strings for each element:

http://default-namespace.org/root
http://www.python.org/ns/ elem1
elem2

Due to limitations in the Expat library used by pyexpat, the xmlparser instance returned can only be used to parse a single XML document. Call ParserCreate for each document to provide unique parser instances.

See also:

The Expat XML Parser
Home page of the Expat project.
20.13.1. XMLParser Objects

xmlparser objects have the following methods:

xmlparser.**Parse**(data[, isfinal])

Parses the contents of the string `data`, calling the appropriate handler functions to process the parsed data. `isfinal` must be true on the final call to this method; it allows the parsing of a single file in fragments, not the submission of multiple files. `data` can be the empty string at any time.

xmlparser.**ParseFile**(file)

Parse XML data reading from the object `file`. `file` only needs to provide the `read(nbytes)` method, returning the empty string when there’s no more data.

xmlparser.**SetBase**(base)

Sets the base to be used for resolving relative URIs in system identifiers in declarations. Resolving relative identifiers is left to the application: this value will be passed through as the `base` argument to the `ExternalEntityRefHandler()`, `NotationDeclHandler()`, and `UnparsedEntityDeclHandler()` functions.

xmlparser.**GetBase**()

Returns a string containing the base set by a previous call to `SetBase()`, or `None` if `SetBase()` hasn’t been called.

xmlparser.**GetInputContext**()

Returns the input data that generated the current event as a string. The data is in the encoding of the entity which contains the text.
When called while an event handler is not active, the return value is None.

`xmlparser.ExternalEntityParserCreate(context[, encoding])`
Create a “child” parser which can be used to parse an external parsed entity referred to by content parsed by the parent parser. The `context` parameter should be the string passed to the `ExternalEntityRefHandler()` handler function, described below. The child parser is created with the `ordered_attributes` and `specified_attributes` set to the values of this parser.

`xmlparser.SetParamEntityParsing(flag)`  
Control parsing of parameter entities (including the external DTD subset). Possible `flag` values are `XML_PARAM_ENTITY_PARSING_NEVER`, `XML_PARAM_ENTITY_PARSING_UNLESS_STANDALONE` and `XML_PARAM_ENTITY_PARSING_ALWAYS`. Return true if setting the flag was successful.

`xmlparser.UseForeignDTD([flag])`
Calling this with a true value for `flag` (the default) will cause Expat to call the `ExternalEntityRefHandler` with `None` for all arguments to allow an alternate DTD to be loaded. If the document does not contain a document type declaration, the `ExternalEntityRefHandler` will still be called, but the `StartDoctypeDeclHandler` and `EndDoctypeDeclHandler` will not be called.

Passing a false value for `flag` will cancel a previous call that passed a true value, but otherwise has no effect.
This method can only be called before the `Parse()` or `ParseFile()` methods are called; calling it after either of those have been called causes `ExpatError` to be raised with the `code` attribute set to `errors.codes[errors.XML_ERROR_CANT_CHANGE_FEATURE_`

`xmlparser` objects have the following attributes:

`xmlparser.buffer_size`

The size of the buffer used when `buffer_text` is true. A new buffer size can be set by assigning a new integer value to this attribute. When the size is changed, the buffer will be flushed.

`xmlparser.buffer_text`

Setting this to true causes the `xmlparser` object to buffer textual content returned by Expat to avoid multiple calls to the `CharacterDataHandler()` callback whenever possible. This can improve performance substantially since Expat normally breaks character data into chunks at every line ending. This attribute is false by default, and may be changed at any time.

`xmlparser.buffer_used`

If `buffer_text` is enabled, the number of bytes stored in the buffer. These bytes represent UTF-8 encoded text. This attribute has no meaningful interpretation when `buffer_text` is false.

`xmlparser.ordered_attributes`

Setting this attribute to a non-zero integer causes the attributes to be reported as a list rather than a dictionary. The attributes are presented in the order found in the document text. For each attribute, two list entries are presented: the attribute name and the attribute value. (Older versions of this module also used this
format.) By default, this attribute is false; it may be changed at any time.

**xmlparser.specified_attributes**

If set to a non-zero integer, the parser will report only those attributes which were specified in the document instance and not those which were derived from attribute declarations. Applications which set this need to be especially careful to use what additional information is available from the declarations as needed to comply with the standards for the behavior of XML processors. By default, this attribute is false; it may be changed at any time.

The following attributes contain values relating to the most recent error encountered by an xmlparser object, and will only have correct values once a call to Parse() or ParseFile() has raised an `xml.parsers.expat.ExpatError` exception.

**xmlparser.ErrorByteIndex**

Byte index at which an error occurred.

**xmlparser.ErrorCode**

Numeric code specifying the problem. This value can be passed to the `ErrorString()` function, or compared to one of the constants defined in the `errors` object.

**xmlparser.ErrorColumnNumber**

Column number at which an error occurred.

**xmlparser>ErrorLineNumber**

Line number at which an error occurred.

The following attributes contain values relating to the current parse location in an xmlparser object. During a callback reporting a parse
event they indicate the location of the first of the sequence of characters that generated the event. When called outside of a callback, the position indicated will be just past the last parse event (regardless of whether there was an associated callback).

**xmlparser.**CurrentByteIndex

Current byte index in the parser input.

**xmlparser.**CurrentColumnNumber

Current column number in the parser input.

**xmlparser.**CurrentLineNumber

Current line number in the parser input.

Here is the list of handlers that can be set. To set a handler on an xmlparser object o, use o.handlername = func. handlername must be taken from the following list, and func must be a callable object accepting the correct number of arguments. The arguments are all strings, unless otherwise stated.

**xmlparser.**XmlDeclHandler(version, encoding, standalone)

Called when the XML declaration is parsed. The XML declaration is the (optional) declaration of the applicable version of the XML recommendation, the encoding of the document text, and an optional “standalone” declaration. version and encoding will be strings, and standalone will be 1 if the document is declared standalone, 0 if it is declared not to be standalone, or -1 if the standalone clause was omitted. This is only available with Expat version 1.95.0 or newer.

**xmlparser.**StartDoctypeDeclHandler(doctypeName, systemId, publicId, has_internal_subset)

Called when Expat begins parsing the document type declaration
(<!DOCTYPE ...). The `doctypeName` is provided exactly as presented. The `systemId` and `publicId` parameters give the system and public identifiers if specified, or `None` if omitted. `has_internal_subset` will be true if the document contains and internal document declaration subset. This requires Expat version 1.2 or newer.

`xmlparser.EndDoctypeDeclHandler()`
Called when Expat is done parsing the document type declaration. This requires Expat version 1.2 or newer.

`xmlparser.ElementDeclHandler(name, model)`
Called once for each element type declaration. `name` is the name of the element type, and `model` is a representation of the content model.

`xmlparser.AttlistDeclHandler(elname, attname, type, default, required)`
Called for each declared attribute for an element type. If an attribute list declaration declares three attributes, this handler is called three times, once for each attribute. `elname` is the name of the element to which the declaration applies and `attname` is the name of the attribute declared. The attribute type is a string passed as `type`; the possible values are `'CDATA'`, `'ID'`, `'IDREF'`, ... `default` gives the default value for the attribute used when the attribute is not specified by the document instance, or `None` if there is no default value (`#IMPLIED` values). If the attribute is required to be given in the document instance, `required` will be true. This requires Expat version 1.95.0 or newer.

`xmlparser.StartElementHandler(name, attributes)`
Called for the start of every element. `name` is a string containing
the element name, and attributes is the element attributes. If ordered_attributes is true, this is a list (see ordered_attributes for a full description). Otherwise it's a dictionary mapping names to values.

xmlparser. EndElementHandler(name)
   Called for the end of every element.

xmlparser. ProcessingInstructionHandler(target, data)
   Called for every processing instruction.

xmlparser. CharacterDataHandler(data)
   Called for character data. This will be called for normal character data, CDATA marked content, and ignorable whitespace. Applications which must distinguish these cases can use the StartCdataSectionHandler, EndCdataSectionHandler, and ElementDeclHandler callbacks to collect the required information.

xmlparser. UnparsedEntityDeclHandler(entityName, base, systemId, publicId, notationName)
   Called for unparsed (NDATA) entity declarations. This is only present for version 1.2 of the Expat library; for more recent versions, use EntityDeclHandler instead. (The underlying function in the Expat library has been declared obsolete.)

xmlparser. EntityDeclHandler(entityName, is_parameter_entity, value, base, systemId, publicId, notationName)
   Called for all entity declarations. For parameter and internal entities, value will be a string giving the declared contents of the entity; this will be None for external entities. The notationName
parameter will be `None` for parsed entities, and the name of the notation for unparsed entities. `is_parameter_entity` will be true if the entity is a parameter entity or false for general entities (most applications only need to be concerned with general entities). This is only available starting with version 1.95.0 of the Expat library.

```python
def NotationDeclHandler(notationName, base, systemId, publicId):
    Called for notation declarations. `notationName`, `base`, and `systemId`, and `publicId` are strings if given. If the public identifier is omitted, `publicId` will be `None`.
```

```python
def StartNamespaceDeclHandler(prefix, uri):
    Called when an element contains a namespace declaration. Namespace declarations are processed before the `StartElementHandler` is called for the element on which declarations are placed.
```

```python
def EndNamespaceDeclHandler(prefix):
    Called when the closing tag is reached for an element that contained a namespace declaration. This is called once for each namespace declaration on the element in the reverse of the order for which the `StartNamespaceDeclHandler` was called to indicate the start of each namespace declaration’s scope. Calls to this handler are made after the corresponding `EndElementHandler` for the end of the element.
```

```python
def CommentHandler(data):
    Called for comments. `data` is the text of the comment, excluding the leading `<!--` and trailing `-->`.
```

```python
def StartCdataSectionHandler():
    Called for comments. `data` is the text of the comment, excluding the leading `<!--` and trailing `-->`.
```
Called at the start of a CDATA section. This and `EndCdataSectionHandler` are needed to be able to identify the syntactical start and end for CDATA sections.

```java
xmlparser.EndCdataSectionHandler()
```
Called at the end of a CDATA section.

```java
xmlparser.DefaultHandler(data)
```
Called for any characters in the XML document for which no applicable handler has been specified. This means characters that are part of a construct which could be reported, but for which no handler has been supplied.

```java
xmlparser.DefaultHandlerExpand(data)
```
This is the same as the `DefaultHandler()`, but doesn't inhibit expansion of internal entities. The entity reference will not be passed to the default handler.

```java
xmlparser.NotStandaloneHandler()
```
Called if the XML document hasn't been declared as being a standalone document. This happens when there is an external subset or a reference to a parameter entity, but the XML declaration does not set standalone to `yes` in an XML declaration. If this handler returns 0, then the parser will raise an `XML_ERROR_NOT_STANDALONE` error. If this handler is not set, no exception is raised by the parser for this condition.

```java
xmlparser.ExternalEntityRefHandler(context, base, systemId, publicId)
```
Called for references to external entities. `base` is the current base, as set by a previous call to `SetBase()`. The public and system identifiers, `systemId` and `publicId`, are strings if given; if the public
identifier is not given, *publicId* will be *None*. The *context* value is opaque and should only be used as described below.

For external entities to be parsed, this handler must be implemented. It is responsible for creating the sub-parser using `ExternalEntityParserCreate(context)`, initializing it with the appropriate callbacks, and parsing the entity. This handler should return an integer; if it returns 0, the parser will raise an `XML_ERROR_EXTERNAL_ENTITY_HANDLING` error, otherwise parsing will continue.

If this handler is not provided, external entities are reported by the `DefaultHandler` callback, if provided.
20.13.2. ExpatError Exceptions

**ExpatError** exceptions have a number of interesting attributes:

**ExpatError**.code

Expat's internal error number for the specific error. The **errors.messages** dictionary maps these error numbers to Expat's error messages. For example:

```python
from xml.parsers.expat import ParserCreate, ExpatError
p = ParserCreate()
try:
    p.Parse(some_xml_document)
except ExpatError as err:
    print("Error:", errors.messages[err.code])
```

The **errors** module also provides error message constants and a dictionary **codes** mapping these messages back to the error codes, see below.

**ExpatError**.lineno

Line number on which the error was detected. The first line is numbered 1.

**ExpatError**.offset

Character offset into the line where the error occurred. The first column is numbered 0.
20.13.3. Example

The following program defines three handlers that just print out their arguments.

```python
import xml.parsers.expat

# 3 handler functions
def start_element(name, attrs):
    print('Start element:', name, attrs)
def end_element(name):
    print('End element:', name)
def char_data(data):
    print('Character data:', repr(data))

p = xml.parsers.expat.ParserCreate()
p.StartElementHandler = start_element
p.EndElementHandler = end_element
p.CharacterDataHandler = char_data

p.Parse("""<?xml version="1.0"?>
<parent id="top"><child1 name="paul">Text goes here</child1>
<child2 name="fred">More text</child2>
</parent>""", 1)
```

The output from this program is:

```
Start element: parent {'id': 'top'}
Start element: child1 {'name': 'paul'}
Character data: 'Text goes here'
End element: child1
Character data: '\n'
Start element: child2 {'name': 'fred'}
```
Character data: 'More text'
End element: child2
Character data: '\n'
End element: parent
20.13.4. Content Model Descriptions

Content models are described using nested tuples. Each tuple contains four values: the type, the quantifier, the name, and a tuple of children. Children are simply additional content model descriptions.

The values of the first two fields are constants defined in the `xml.parsers.expat.model` module. These constants can be collected in two groups: the model type group and the quantifier group.

The constants in the model type group are:

- `xml.parsers.expat.model.XML_CTYPE_ANY`
  
  The element named by the model name was declared to have a content model of ANY.

- `xml.parsers.expat.model.XML_CTYPE_CHOICE`
  
  The named element allows a choice from a number of options; this is used for content models such as (A | B | C).

- `xml.parsers.expat.model.XML_CTYPE_EMPTY`
  
  Elements which are declared to be EMPTY have this model type.

- `xml.parsers.expat.model.XML_CTYPE_MIXED`

- `xml.parsers.expat.model.XML_CTYPE_NAME`

- `xml.parsers.expat.model.XML_CTYPE_SEQ`
  
  Models which represent a series of models which follow one after the other are indicated with this model type. This is used for models such as (A, B, C).

The constants in the quantifier group are:
xml.parsers.expat.model.XML_CQUANT_NONE
No modifier is given, so it can appear exactly once, as for A.

xml.parsers.expat.model.XML_CQUANT_OPT
The model is optional: it can appear once or not at all, as for A?.

xml.parsers.expat.model.XML_CQUANT_PLUS
The model must occur one or more times (like A+).

xml.parsers.expat.model.XML_CQUANT_REP
The model must occur zero or more times, as for A*.
20.13.5. Expat error constants

The following constants are provided in the `xml.parsers.expat.errors` module. These constants are useful in interpreting some of the attributes of the ExpatError exception objects raised when an error has occurred. Since for backwards compatibility reasons, the constants' value is the error message and not the numeric error code, you do this by comparing its `code` attribute with `errors.codes[errors.XML_ERROR_CONSTANT_NAME]`.

The `errors` module has the following attributes:

- `xml.parsers.expat.errors.codes`: A dictionary mapping numeric error codes to their string descriptions.
  
  *New in version 3.2.*

- `xml.parsers.expat.errors.messages`: A dictionary mapping string descriptions to their error codes.
  
  *New in version 3.2.*

- `xml.parsers.expat.errors.XML_ERROR_ASYNC_ENTITY`: An entity reference in an attribute value referred to an external entity instead of an internal entity.

- `xml.parsers.expat.errors.XML_ERROR_ATTRIBUTE_EXTERNAL_ENTITY_REF`: An entity reference in an attribute value referred to an external entity instead of an internal entity.

- `xml.parsers.expat.errors.XML_ERROR_BAD_CHAR_REF`: A character reference referred to a character which is illegal in XML
An entity reference referred to an entity which was declared with a notation, so cannot be parsed.

An attribute was used more than once in a start tag.

An XML declaration was found somewhere other than the start of the input data.

The document contains no elements (XML requires all documents to contain exactly one top-level element).

Expat was not able to allocate memory internally.

A parameter entity reference was found where it was not allowed.
xml.parsers.expat.errors.XML_ERROR_PARTIAL_CHAR
An incomplete character was found in the input.

xmiparsers.expat.errors.XML_ERROR_RECURSIVE_ENT]
An entity reference contained another reference to the same entity; possibly via a different name, and possibly indirectly.

xml.parsers.expat.errors.XML_ERROR_SYNTAX
Some unspecified syntax error was encountered.

xml.parsers.expat.errors.XML_ERROR_TAG_MISMATCH
An end tag did not match the innermost open start tag.

xml.parsers.expat.errors.XML_ERROR_UNCLOSED_TOKEN
Some token (such as a start tag) was not closed before the end of the stream or the next token was encountered.

xml.parsers.expat.errors.XML_ERROR_UNDEFINDED_ENT]
A reference was made to an entity which was not defined.

xml.parsers.expat.errors.XML_ERROR_UNKNOWNENCOD]
The document encoding is not supported by Expat.

xml.parsers.expat.errors.XML_ERROR_UNCLOSEDCDATA
A CDATA marked section was not closed.

xml.parsers.expat.errors.XML_ERROR_EXTERNAL_ENTI]
xml.parsers.expat.errors.XML_ERROR_NOT_STANDALONE
The parser determined that the document was not “standalone” though it declared itself to be in the XML declaration, and the NotStandaloneHandler was set and returned 0.

xml.parsers.expat.errors.XML_ERROR_UNEXPECTED_STA
An operation was requested that requires DTD support to be compiled in, but Expat was configured without DTD support. This should never be reported by a standard build of the xml.parsers.expat module.

A behavioral change was requested after parsing started that can only be changed before parsing has started. This is (currently) only raised by UseForeignDTD().

An undeclared prefix was found when namespace processing was enabled.

The document attempted to remove the namespace declaration associated with a prefix.

A parameter entity contained incomplete markup.

The document contained no document element at all.

There was an error parsing a text declaration in an external entity.

Characters were found in the public id that are not allowed.
The requested operation was made on a suspended parser, but isn’t allowed. This includes attempts to provide additional input or to stop the parser.

\texttt{xml.parsers.expat.errors.XML\_ERROR\_NOT\_SUSPENDED}

An attempt to resume the parser was made when the parser had not been suspended.

\texttt{xml.parsers.expat.errors.XML\_ERROR\_ABORTED}

This should not be reported to Python applications.

\texttt{xml.parsers.expat.errors.XML\_ERROR\_FINISHED}

The requested operation was made on a parser which was finished parsing input, but isn’t allowed. This includes attempts to provide additional input or to stop the parser.

\texttt{xml.parsers.expat.errors.XML\_ERROR\_SUSPEND\_PE}

Footnotes

The encoding string included in XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not. See https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and https://www.iana.org/assignments/character-sets/character-sets.xhtml.

21. Internet Protocols and Support

The modules described in this chapter implement Internet protocols and support for related technology. They are all implemented in Python. Most of these modules require the presence of the system-dependent module `socket`, which is currently supported on most popular platforms. Here is an overview:

- **21.1. webbrowser — Convenient Web-browser controller**
  - 21.1.1. Browser Controller Objects

- **21.2. cgi — Common Gateway Interface support**
  - 21.2.1. Introduction
  - 21.2.2. Using the cgi module
  - 21.2.3. Higher Level Interface
  - 21.2.4. Functions
  - 21.2.5. Caring about security
  - 21.2.6. Installing your CGI script on a Unix system
  - 21.2.7. Testing your CGI script
  - 21.2.8. Debugging CGI scripts
  - 21.2.9. Common problems and solutions

- **21.3. cgitb — Traceback manager for CGI scripts**

- **21.4. wsgiref — WSGI Utilities and Reference Implementation**
  - 21.4.1. wsgiref.util — WSGI environment utilities
  - 21.4.2. wsgiref.headers — WSGI response header tools
  - 21.4.3. wsgiref.simple_server — a simple WSGI HTTP server
  - 21.4.4. wsgiref.validate — WSGI conformance checker
  - 21.4.5. wsgiref.handlers — server/gateway base classes
  - 21.4.6. Examples

- **21.5. urllib — URL handling modules**

- **21.6. urllib.request — Extensible library for opening URLs**
  - 21.6.1. Request Objects
- 21.6.2. OpenerDirector Objects
- 21.6.3. BaseHandler Objects
- 21.6.4. HTTPRedirectHandler Objects
- 21.6.5. HTTPCookieProcessor Objects
- 21.6.6. ProxyHandler Objects
- 21.6.7. HTTPPasswordMgr Objects
- 21.6.8. HTTPPasswordMgrWithPriorAuth Objects
- 21.6.9. AbstractBasicAuthHandler Objects
- 21.6.10. HTTPBasicAuthHandler Objects
- 21.6.11. ProxyBasicAuthHandler Objects
- 21.6.13. HTTPDigestAuthHandler Objects
- 21.6.15. HTTPHandler Objects
- 21.6.16. HTTPSHandler Objects
- 21.6.17. FileHandler Objects
- 21.6.18. DataHandler Objects
- 21.6.19. FTPHandler Objects
- 21.6.20. CacheFTPHandler Objects
- 21.6.21. UnknownHandler Objects
- 21.6.22. HTTPErrorProcessor Objects
- 21.6.23. Examples
- 21.6.24. Legacy interface
- 21.6.25. urllib.request Restrictions

- 21.7. urllib.response — Response classes used by urllib
- 21.8. urllib.parse — Parse URLs into components
  - 21.8.1. URL Parsing
  - 21.8.2. Parsing ASCII Encoded Bytes
  - 21.8.3. Structured Parse Results
  - 21.8.4. URL Quoting
- 21.9. urllib.error — Exception classes raised by urllib.request
- 21.10. urllib.robotparser — Parser for robots.txt
- 21.11. http — HTTP modules
21.11.1. HTTP status codes

- 21.12.1. HTTPConnection Objects
- 21.12.2. HTTPResponse Objects
- 21.12.3. Examples
- 21.12.4. HTTPMessage Objects

21.13. ftplib — FTP protocol client
- 21.13.1. FTP Objects
- 21.13.2. FTP_TLS Objects

21.14. poplib — POP3 protocol client
- 21.14.1. POP3 Objects
- 21.14.2. POP3 Example

21.15. imaplib — IMAP4 protocol client
- 21.15.1. IMAP4 Objects
- 21.15.2. IMAP4 Example

21.16. nntplib — NNTP protocol client
- 21.16.1. NNTP Objects
  - 21.16.1.1. Attributes
  - 21.16.1.2. Methods
- 21.16.2. Utility functions

21.17. smtplib — SMTP protocol client
- 21.17.1. SMTP Objects
- 21.17.2. SMTP Example

21.18. smtpd — SMTP Server
- 21.18.1. SMTPServer Objects
- 21.18.2. DebuggingServer Objects
- 21.18.3. PureProxy Objects
- 21.18.4. MailmanProxy Objects
- 21.18.5. SMTPChannel Objects

21.19. telnetlib — Telnet client
- 21.19.1. Telnet Objects
- 21.19.2. Telnet Example

21.20. uuid — UUID objects according to RFC 4122
21.20.1. Example

21.21. socketserver — A framework for network servers
   21.21.1. Server Creation Notes
   21.21.2. Server Objects
   21.21.3. Request Handler Objects
   21.21.4. Examples
     - 21.21.4.1. socketserver.TCPServer Example
     - 21.21.4.2. socketserver.UDPServer Example
     - 21.21.4.3. Asynchronous Mixins

21.22. http.server — HTTP servers

21.23. http.cookies — HTTP state management
   21.23.1. Cookie Objects
   21.23.2. Morsel Objects
   21.23.3. Example

21.24. http.cookiejar — Cookie handling for HTTP clients
   21.24.2. FileCookieJar subclasses and co-operation with web browsers
   21.24.3. CookiePolicy Objects
   21.24.4. DefaultCookiePolicy Objects
   21.24.5. Cookie Objects
   21.24.6. Examples

21.25. xmlrpc — XMLRPC server and client modules

21.26. xmlrpc.client — XML-RPC client access
   21.26.2. DateTime Objects
   21.26.3. Binary Objects
   21.26.4. Fault Objects
   21.26.5. ProtocolError Objects
   21.26.6. MultiCall Objects
   21.26.7. Convenience Functions
   21.26.9. Example of Client and Server Usage
21.27. xmlrpc.server — Basic XML-RPC servers
   
   21.27.1. SimpleXMLRPCServer Objects
      
      21.27.1.1. SimpleXMLRPCServer Example
   
   21.27.2. CGIXMLRPCRequestHandler
   
   21.27.3. Documenting XMLRPC server
   
   21.27.4. DocXMLRPCServer Objects
   
   21.27.5. DocCGIXMLRPCRequestHandler

21.28. ipaddress — IPv4/IPv6 manipulation library

   21.28.1. Convenience factory functions
   
   21.28.2. IP Addresses
      
      21.28.2.1. Address objects
      
      21.28.2.2. Conversion to Strings and Integers
      
      21.28.2.3. Operators
         
         21.28.2.3.1. Comparison operators
         
         21.28.2.3.2. Arithmetic operators
      
   21.28.3. IP Network definitions
      
      21.28.3.1. Prefix, net mask and host mask
      
      21.28.3.2. Network objects
      
      21.28.3.3. Operators
         
         21.28.3.3.1. Logical operators
         
         21.28.3.3.2. Iteration
         
         21.28.3.3.3. Networks as containers of addresses
      
   21.28.4. Interface objects
   
   21.28.5. Other Module Level Functions
   
   21.28.6. Custom Exceptions
21.1. **webbrowser** — Convenient Web-browser controller

**Source code: Lib/webbrowser.py**

The *webbrowser* module provides a high-level interface to allow displaying Web-based documents to users. Under most circumstances, simply calling the *open()* function from this module will do the right thing.

Under Unix, graphical browsers are preferred under X11, but text-mode browsers will be used if graphical browsers are not available or an X11 display isn’t available. If text-mode browsers are used, the calling process will block until the user exits the browser.

If the environment variable BROWSER exists, it is interpreted as the *os.pathsep*-separated list of browsers to try ahead of the platform defaults. When the value of a list part contains the string %%s, then it is interpreted as a literal browser command line to be used with the argument URL substituted for %%s; if the part does not contain %%s, it is simply interpreted as the name of the browser to launch. [1]

For non-Unix platforms, or when a remote browser is available on Unix, the controlling process will not wait for the user to finish with the browser, but allow the remote browser to maintain its own windows on the display. If remote browsers are not available on Unix, the controlling process will launch a new browser and wait.

The script *webbrowser* can be used as a command-line interface for the module. It accepts a URL as the argument. It accepts the following
optional parameters: -n opens the URL in a new browser window, if possible; -t opens the URL in a new browser page (“tab”). The options are, naturally, mutually exclusive. Usage example:

```python
python -m webbrowser -t "http://www.python.org"
```

The following exception is defined:

```python
exception webbrowser.Error

Exception raised when a browser control error occurs.
```

The following functions are defined:

```python
webbrowser.open(url, new=0, autoraise=True)

Display url using the default browser. If new is 0, the url is opened in the same browser window if possible. If new is 1, a new browser window is opened if possible. If new is 2, a new browser page (“tab”) is opened if possible. If autoraise is True, the window is raised if possible (note that under many window managers this will occur regardless of the setting of this variable).

Note that on some platforms, trying to open a filename using this function, may work and start the operating system's associated program. However, this is neither supported nor portable.

```python
webbrowser.open_new(url)

Open url in a new window of the default browser, if possible, otherwise, open url in the only browser window.

```python
webbrowser.open_new_tab(url)

Open url in a new page (“tab”) of the default browser, if possible, otherwise equivalent to open_new().```
webbrowser.get(using=None)

Return a controller object for the browser type using. If using is None, return a controller for a default browser appropriate to the caller’s environment.

webbrowser.register(name, constructor, instance=None)

Register the browser type name. Once a browser type is registered, the get() function can return a controller for that browser type. If instance is not provided, or is None, constructor will be called without parameters to create an instance when needed. If instance is provided, constructor will never be called, and may be None.

This entry point is only useful if you plan to either set the BROWSER variable or call get() with a nonempty argument matching the name of a handler you declare.

A number of browser types are predefined. This table gives the type names that may be passed to the get() function and the corresponding instantiations for the controller classes, all defined in this module.

<table>

</tr>
<tr>
<td>'chromium-browser'</td>
<td>Chromium('chromium-browser')</td>
<td></td>
</tr>
</tbody>
</table>

**Notes:**

1. “Konqueror” is the file manager for the KDE desktop environment for Unix, and only makes sense to use if KDE is running. Some way of reliably detecting KDE would be nice; the KDEDIR variable is not sufficient. Note also that the name “kfm” is used even when using the konqueror command with KDE 2 — the implementation selects the best strategy for running Konqueror.

2. Only on Windows platforms.
3. Only on Mac OS X platform.

*New in version 3.3:* Support for Chrome/Chromium has been added.

Here are some simple examples:

```python
url = 'http://docs.python.org/

# Open URL in a new tab, if a browser window is already open.
webbrowser.open_new_tab(url)

# Open URL in new window, raising the window if possible.
webbrowser.open_new(url)
```
21.1.1. Browser Controller Objects

Browser controllers provide these methods which parallel three of the module-level convenience functions:

controller. **open**(url, new=0, autoraise=True)

Display *url* using the browser handled by this controller. If *new* is 1, a new browser window is opened if possible. If *new* is 2, a new browser page (“tab”) is opened if possible.

controller. **open_new**(url)

Open *url* in a new window of the browser handled by this controller, if possible, otherwise, open *url* in the only browser window. Alias **open_new()**.

controller. **open_new_tab**(url)

Open *url* in a new page (“tab”) of the browser handled by this controller, if possible, otherwise equivalent to **open_new()**.

Footnotes

[1] Executables named here without a full path will be searched in the directories given in the PATH environment variable.
21.2. **cgi** — Common Gateway Interface support

**Source code:** [Lib/cgi.py](Lib/cgi.py)

Support module for Common Gateway Interface (CGI) scripts.

This module defines a number of utilities for use by CGI scripts written in Python.
21.2.1. Introduction

A CGI script is invoked by an HTTP server, usually to process user input submitted through an HTML `<FORM>` or `<ISINDEX>` element.

Most often, CGI scripts live in the server's special `cgi-bin` directory. The HTTP server places all sorts of information about the request (such as the client's hostname, the requested URL, the query string, and lots of other goodies) in the script's shell environment, executes the script, and sends the script's output back to the client.

The script's input is connected to the client too, and sometimes the form data is read this way; at other times the form data is passed via the "query string" part of the URL. This module is intended to take care of the different cases and provide a simpler interface to the Python script. It also provides a number of utilities that help in debugging scripts, and the latest addition is support for file uploads from a form (if your browser supports it).

The output of a CGI script should consist of two sections, separated by a blank line. The first section contains a number of headers, telling the client what kind of data is following. Python code to generate a minimal header section looks like this:

```python
print("Content-Type: text/html") # HTML is followed
print() # blank line, end of headers
```

The second section is usually HTML, which allows the client software to display nicely formatted text with header, in-line images, etc. Here's Python code that prints a simple piece of HTML:

```python
print("<TITLE>CGI script output</TITLE>")
```
print("<H1>This is my first CGI script</H1>")
print("Hello, world!")
21.2.2. Using the cgi module

Begin by writing `import cgi`.

When you write a new script, consider adding these lines:

```python
import cgitb
cgitb.enable()
```

This activates a special exception handler that will display detailed reports in the Web browser if any errors occur. If you’d rather not show the guts of your program to users of your script, you can have the reports saved to files instead, with code like this:

```python
import cgitb
cgitb.enable(display=0, logdir="/path/to/logdir")
```

It’s very helpful to use this feature during script development. The reports produced by `cgitb` provide information that can save you a lot of time in tracking down bugs. You can always remove the `cgitb` line later when you have tested your script and are confident that it works correctly.

To get at submitted form data, use the `FieldStorage` class. If the form contains non-ASCII characters, use the `encoding` keyword parameter set to the value of the encoding defined for the document. It is usually contained in the META tag in the HEAD section of the HTML document or by the `Content-Type` header). This reads the form contents from the standard input or the environment (depending on the value of various environment variables set according to the CGI standard). Since it may consume standard input, it should be instantiated only once.
The `FieldStorage` instance can be indexed like a Python dictionary. It allows membership testing with the `in` operator, and also supports the standard dictionary method `keys()` and the built-in function `len()`. Form fields containing empty strings are ignored and do not appear in the dictionary; to keep such values, provide a true value for the optional `keep_blank_values` keyword parameter when creating the `FieldStorage` instance.

For instance, the following code (which assumes that the `Content-Type` header and blank line have already been printed) checks that the fields `name` and `addr` are both set to a non-empty string:

```python
form = cgi.FieldStorage()
if "name" not in form or "addr" not in form:
    print("<H1>Error</H1>")
    print("Please fill in the name and addr fields.
return
print("<p>name:", form["name"].value)
print("<p>addr:", form["addr"].value)
...further form processing here...
```

Here the fields, accessed through `form[key]`, are themselves instances of `FieldStorage` (or `MiniFieldStorage`, depending on the form encoding). The value attribute of the instance yields the string value of the field. The `getvalue()` method returns this string value directly; it also accepts an optional second argument as a default to return if the requested key is not present.

If the submitted form data contains more than one field with the same name, the object retrieved by `form[key]` is not a `FieldStorage` or `MiniFieldStorage` instance but a list of such instances. Similarly, in this situation, `form.getvalue(key)` would return a list of strings. If
you expect this possibility (when your HTML form contains multiple fields with the same name), use the `getlist()` method, which always returns a list of values (so that you do not need to special-case the single item case). For example, this code concatenates any number of username fields, separated by commas:

```python
value = form.getlist("username")
usernames = ",".join(value)
```

If a field represents an uploaded file, accessing the value via the value attribute or the `getvalue()` method reads the entire file in memory as bytes. This may not be what you want. You can test for an uploaded file by testing either the filename attribute or the `file` attribute. You can then read the data from the `file` attribute before it is automatically closed as part of the garbage collection of the `FieldStorage` instance (the `read()` and `readline()` methods will return bytes):

```python
fileitem = form["userfile"]
if fileitem.file:
    # It's an uploaded file; count lines
    linecount = 0
    while True:
        line = fileitem.file.readline()
        if not line: break
        linecount = linecount + 1
```

FieldStorage objects also support being used in a `with` statement, which will automatically close them when done.

If an error is encountered when obtaining the contents of an uploaded file (for example, when the user interrupts the form submission by clicking on a Back or Cancel button) the `done` attribute of the object
for the field will be set to the value -1.

The file upload draft standard entertains the possibility of uploading multiple files from one field (using a recursive multipart/* encoding). When this occurs, the item will be a dictionary-like FieldStorage item. This can be determined by testing its type attribute, which should be multipart/form-data (or perhaps another MIME type matching multipart/*). In this case, it can be iterated over recursively just like the top-level form object.

When a form is submitted in the “old” format (as the query string or as a single data part of type application/x-www-form-urlencoded), the items will actually be instances of the class MiniFieldStorage. In this case, the list, file, and filename attributes are always None.

A form submitted via POST that also has a query string will contain both FieldStorage and MiniFieldStorage items.

*Changed in version 3.4:* The file attribute is automatically closed upon the garbage collection of the creating FieldStorage instance.

*Changed in version 3.5:* Added support for the context management protocol to the FieldStorage class.
21.2.3. Higher Level Interface

The previous section explains how to read CGI form data using the FieldStorage class. This section describes a higher level interface which was added to this class to allow one to do it in a more readable and intuitive way. The interface doesn’t make the techniques described in previous sections obsolete — they are still useful to process file uploads efficiently, for example.

The interface consists of two simple methods. Using the methods you can process form data in a generic way, without the need to worry whether only one or more values were posted under one name.

In the previous section, you learned to write following code anytime you expected a user to post more than one value under one name:

```python
item = form.getvalue("item")
if isinstance(item, list):
    # The user is requesting more than one item.
else:
    # The user is requesting only one item.
```

This situation is common for example when a form contains a group of multiple checkboxes with the same name:

```html
<input type="checkbox" name="item" value="1" />
<input type="checkbox" name="item" value="2" />
```

In most situations, however, there’s only one form control with a particular name in a form and then you expect and need only one value associated with this name. So you write a script containing for example this code:
The problem with the code is that you should never expect that a client will provide valid input to your scripts. For example, if a curious user appends another \texttt{user=foo} pair to the query string, then the script would crash, because in this situation the \texttt{form.getvalue("user")} method call returns a list instead of a string. Calling the \texttt{upper()} method on a list is not valid (since lists do not have a method of this name) and results in an \texttt{AttributeError} exception.

Therefore, the appropriate way to read form data values was to always use the code which checks whether the obtained value is a single value or a list of values. That’s annoying and leads to less readable scripts.

A more convenient approach is to use the methods \texttt{getfirst()} and \texttt{getlist()} provided by this higher level interface.

\textbf{FieldStorage.\texttt{getfirst}(name, default=None)}

This method always returns only one value associated with form field \textit{name}. The method returns only the first value in case that more values were posted under such name. Please note that the order in which the values are received may vary from browser to browser and should not be counted on. [1] If no such form field or value exists then the method returns the value specified by the optional parameter \textit{default}. This parameter defaults to \texttt{None} if not specified.

\textbf{FieldStorage.\texttt{getlist}(name)}

This method always returns a list of values associated with form field \textit{name}. The method returns an empty list if no such form field or value exists for \textit{name}. It returns a list consisting of one item if
only one such value exists.

Using these methods you can write nice compact code:

```python
import cgi
form = cgi.FieldStorage()
user = form.getfirst("user", "").upper()  # This way it's safe.
for item in form.getlist("item"):
    do_something(item)
```
21.2.4. Functions

These are useful if you want more control, or if you want to employ some of the algorithms implemented in this module in other circumstances.

cgi.\texttt{parse}(fp=None, \texttt{environ}=os.environ, keep\_blank\_values=False, strict\_parsing=False)
Parse a query in the environment or from a file (the file defaults to \texttt{sys.stdin}). The \texttt{keep\_blank\_values} and \texttt{strict\_parsing} parameters are passed to \texttt{urllib.parse.parse\_qs()} unchanged.

cgi.\texttt{parse\_qs}(qs, keep\_blank\_values=False, strict\_parsing=False)
This function is deprecated in this module. Use \texttt{urllib.parse.parse\_qs()} instead. It is maintained here only for backward compatibility.

cgi.\texttt{parse\_qsl}(qs, keep\_blank\_values=False, strict\_parsing=False)
This function is deprecated in this module. Use \texttt{urllib.parse.parse\_qsl()} instead. It is maintained here only for backward compatibility.

cgi.\texttt{parse\_multipart}(fp, pdict)
Parse input of type \texttt{multipart/form-data} (for file uploads). Arguments are \texttt{fp} for the input file and \texttt{pdict} for a dictionary containing other parameters in the \texttt{Content-Type} header.

Returns a dictionary just like \texttt{urllib.parse.parse\_qs()} keys
are the field names, each value is a list of values for that field. This is easy to use but not much good if you are expecting megabytes to be uploaded — in that case, use the FieldStorage class instead which is much more flexible.

Note that this does not parse nested multipart parts — use FieldStorage for that.

cgi.parse_header(string)
Parse a MIME header (such as Content-Type) into a main value and a dictionary of parameters.

cgi.test()
Robust test CGI script, usable as main program. Writes minimal HTTP headers and formats all information provided to the script in HTML form.

cgi.print_environ()
Format the shell environment in HTML.

cgi.print_form(form)
Format a form in HTML.

cgi.print_directory()
Format the current directory in HTML.

cgi.print_environ_usage()
Print a list of useful (used by CGI) environment variables in HTML.

cgi.escape(s, quote=False)
Convert the characters ' & ', '<' and '>' in string s to HTML-safe sequences. Use this if you need to display text that might contain such characters in HTML. If the optional flag quote is true, the
quotation mark character (""") is also translated; this helps for inclusion in an HTML attribute value delimited by double quotes, as in `<a href="...">`. Note that single quotes are never translated.

*Deprecated since version 3.2:* This function is unsafe because `quote` is false by default, and therefore deprecated. Use `html.escape()` instead.
21.2.5. Caring about security

There’s one important rule: if you invoke an external program (via the `os.system()` or `os.popen()` functions, or others with similar functionality), make very sure you don’t pass arbitrary strings received from the client to the shell. This is a well-known security hole whereby clever hackers anywhere on the Web can exploit a gullible CGI script to invoke arbitrary shell commands. Even parts of the URL or field names cannot be trusted, since the request doesn’t have to come from your form!

To be on the safe side, if you must pass a string gotten from a form to a shell command, you should make sure the string contains only alphanumeric characters, dashes, underscores, and periods.
21.2.6. Installing your CGI script on a Unix system

Read the documentation for your HTTP server and check with your local system administrator to find the directory where CGI scripts should be installed; usually this is in a directory `cgi-bin` in the server tree.

Make sure that your script is readable and executable by “others”; the Unix file mode should be `0o755` octal (use `chmod 0755 filename`). Make sure that the first line of the script contains `#!` starting in column 1 followed by the pathname of the Python interpreter, for instance:

```
#!/usr/local/bin/python
```

Make sure the Python interpreter exists and is executable by “others”.

Make sure that any files your script needs to read or write are readable or writable, respectively, by “others” — their mode should be `0o644` for readable and `0o666` for writable. This is because, for security reasons, the HTTP server executes your script as user “nobody”, without any special privileges. It can only read (write, execute) files that everybody can read (write, execute). The current directory at execution time is also different (it is usually the server’s cgi-bin directory) and the set of environment variables is also different from what you get when you log in. In particular, don’t count on the shell’s search path for executables (PATH) or the Python module search path (`PYTHONPATH`) to be set to anything interesting.

If you need to load modules from a directory which is not on Python's
default module search path, you can change the path in your script, before importing other modules. For example:

```python
import sys
sys.path.insert(0, "/usr/home/joe/lib/python")
sys.path.insert(0, "/usr/local/lib/python")
```

(This way, the directory inserted last will be searched first!)

Instructions for non-Unix systems will vary; check your HTTP server’s documentation (it will usually have a section on CGI scripts).
21.2.7. Testing your CGI script

Unfortunately, a CGI script will generally not run when you try it from the command line, and a script that works perfectly from the command line may fail mysteriously when run from the server. There’s one reason why you should still test your script from the command line: if it contains a syntax error, the Python interpreter won’t execute it at all, and the HTTP server will most likely send a cryptic error to the client.

Assuming your script has no syntax errors, yet it does not work, you have no choice but to read the next section.
21.2.8. Debugging CGI scripts

First of all, check for trivial installation errors — reading the section above on installing your CGI script carefully can save you a lot of time. If you wonder whether you have understood the installation procedure correctly, try installing a copy of this module file (cgi.py) as a CGI script. When invoked as a script, the file will dump its environment and the contents of the form in HTML form. Give it the right mode etc, and send it a request. If it’s installed in the standard cgi-bin directory, it should be possible to send it a request by entering a URL into your browser of the form:

```
http://yourhostname/cgi-bin/cgi.py?name=Joe+Blow&addr=At+Home
```

If this gives an error of type 404, the server cannot find the script – perhaps you need to install it in a different directory. If it gives another error, there’s an installation problem that you should fix before trying to go any further. If you get a nicely formatted listing of the environment and form content (in this example, the fields should be listed as “addr” with value “At Home” and “name” with value “Joe Blow”), the cgi.py script has been installed correctly. If you follow the same procedure for your own script, you should now be able to debug it.

The next step could be to call thecgi module’s test() function from your script: replace its main code with the single statement

```
cgi.test()
```

This should produce the same results as those gotten from installing the cgi.py file itself.
When an ordinary Python script raises an unhandled exception (for whatever reason: of a typo in a module name, a file that can’t be opened, etc.), the Python interpreter prints a nice traceback and exits. While the Python interpreter will still do this when your CGI script raises an exception, most likely the traceback will end up in one of the HTTP server’s log files, or be discarded altogether.

Fortunately, once you have managed to get your script to execute some code, you can easily send tracebacks to the Web browser using the `cgitb` module. If you haven’t done so already, just add the lines:

```python
import cgitb
cgitb.enable()
```

to the top of your script. Then try running it again; when a problem occurs, you should see a detailed report that will likely make apparent the cause of the crash.

If you suspect that there may be a problem in importing the `cgitb` module, you can use an even more robust approach (which only uses built-in modules):

```python
import sys
sys.stderr = sys.stdout
print("Content-Type: text/plain")
print()
...your code here...
```

This relies on the Python interpreter to print the traceback. The content type of the output is set to plain text, which disables all HTML processing. If your script works, the raw HTML will be displayed by your client. If it raises an exception, most likely after the first two lines have been printed, a traceback will be displayed. Because no HTML
interpretation is going on, the traceback will be readable.
21.2.9. Common problems and solutions

- Most HTTP servers buffer the output from CGI scripts until the script is completed. This means that it is not possible to display a progress report on the client’s display while the script is running.
- Check the installation instructions above.
- Check the HTTP server’s log files. (\texttt{tail -f logfile} in a separate window may be useful!)
- Always check a script for syntax errors first, by doing something like \texttt{python script.py}.
- If your script does not have any syntax errors, try adding \texttt{import cgitb; cgitb.enable()} to the top of the script.
- When invoking external programs, make sure they can be found. Usually, this means using absolute path names — \texttt{PATH} is usually not set to a very useful value in a CGI script.
- When reading or writing external files, make sure they can be read or written by the userid under which your CGI script will be running: this is typically the userid under which the web server is running, or some explicitly specified userid for a web server’s \texttt{suexec} feature.
- Don’t try to give a CGI script a set-uid mode. This doesn’t work on most systems, and is a security liability as well.

Footnotes

Note that some recent versions of the HTML specification do state what order the field values should be supplied in, but knowing whether a request was received from a conforming browser, or even from a browser at all, is tedious and error-prone.

\footnote{Note that some recent versions of the HTML specification do state what order the field values should be supplied in, but knowing whether a request was received from a conforming browser, or even from a browser at all, is tedious and error-prone.}
21.3. **cgitb** — Traceback manager for CGI scripts

**Source code:** Lib/cgitb.py

The `cgitb` module provides a special exception handler for Python scripts. (Its name is a bit misleading. It was originally designed to display extensive traceback information in HTML for CGI scripts. It was later generalized to also display this information in plain text.) After this module is activated, if an uncaught exception occurs, a detailed, formatted report will be displayed. The report includes a traceback showing excerpts of the source code for each level, as well as the values of the arguments and local variables to currently running functions, to help you debug the problem. Optionally, you can save this information to a file instead of sending it to the browser.

To enable this feature, simply add this to the top of your CGI script:

```python
import cgitb
cgitb.enable()
```

The options to the `enable()` function control whether the report is displayed in the browser and whether the report is logged to a file for later analysis.

```
cgitb.enable(display=1, logdir=None, context=5, format="html")
```

This function causes the `cgitb` module to take over the interpreter’s default handling for exceptions by setting the value of `sys.excepthook`. 
The optional argument *display* defaults to 1 and can be set to 0 to suppress sending the traceback to the browser. If the argument *logdir* is present, the traceback reports are written to files. The value of *logdir* should be a directory where these files will be placed. The optional argument *context* is the number of lines of context to display around the current line of source code in the traceback; this defaults to 5. If the optional argument *format* is "html", the output is formatted as HTML. Any other value forces plain text output. The default value is "html".

```python
cgitb.handler(info=None)
```
This function handles an exception using the default settings (that is, show a report in the browser, but don’t log to a file). This can be used when you’ve caught an exception and want to report it using `cgitb`. The optional *info* argument should be a 3-tuple containing an exception type, exception value, and traceback object, exactly like the tuple returned by `sys.exc_info()`. If the *info* argument is not supplied, the current exception is obtained from `sys.exc_info()`.
21.4. `wsgiref` — WSGI Utilities and Reference Implementation

The Web Server Gateway Interface (WSGI) is a standard interface between web server software and web applications written in Python. Having a standard interface makes it easy to use an application that supports WSGI with a number of different web servers.

Only authors of web servers and programming frameworks need to know every detail and corner case of the WSGI design. You don’t need to understand every detail of WSGI just to install a WSGI application or to write a web application using an existing framework.

`wsgiref` is a reference implementation of the WSGI specification that can be used to add WSGI support to a web server or framework. It provides utilities for manipulating WSGI environment variables and response headers, base classes for implementing WSGI servers, a demo HTTP server that serves WSGI applications, and a validation tool that checks WSGI servers and applications for conformance to the WSGI specification (PEP 3333).

See https://wsgi.readthedocs.org/ for more information about WSGI, and links to tutorials and other resources.
21.4.1. `wsgiref.util` – WSGI environment utilities

This module provides a variety of utility functions for working with WSGI environments. A WSGI environment is a dictionary containing HTTP request variables as described in PEP 3333. All of the functions taking an `environ` parameter expect a WSGI-compliant dictionary to be supplied; please see PEP 3333 for a detailed specification.

`wsgiref.util.guess_scheme(environ)`

Return a guess for whether `wsgi.url_scheme` should be “http” or “https”, by checking for a HTTPS environment variable in the `environ` dictionary. The return value is a string.

This function is useful when creating a gateway that wraps CGI or a CGI-like protocol such as FastCGI. Typically, servers providing such protocols will include a HTTPS variable with a value of “1” “yes”, or “on” when a request is received via SSL. So, this function returns “https” if such a value is found, and “http” otherwise.

`wsgiref.util.request_uri(environ, include_query=True)`

Return the full request URI, optionally including the query string, using the algorithm found in the “URL Reconstruction” section of PEP 3333. If `include_query` is false, the query string is not included in the resulting URI.

`wsgiref.util.application_uri(environ)`

Similar to `request_uri()`, except that the PATH_INFO and QUERY_STRING variables are ignored. The result is the base URI of the application object addressed by the request.
wsgiref.util.shift_path_info(environ)

Shift a single name from PATH_INFO to SCRIPT_NAME and return the name. The environ dictionary is modified in-place; use a copy if you need to keep the original PATH_INFO or SCRIPT_NAME intact.

If there are no remaining path segments in PATH_INFO, None is returned.

Typically, this routine is used to process each portion of a request URI path, for example to treat the path as a series of dictionary keys. This routine modifies the passed-in environment to make it suitable for invoking another WSGI application that is located at the target URI. For example, if there is a WSGI application at /foo, and the request URI path is /foo/bar/baz, and the WSGI application at /foo calls shift_path_info(), it will receive the string “bar”, and the environment will be updated to be suitable for passing to a WSGI application at /foo/bar. That is, SCRIPT_NAME will change from /foo to /foo/bar, and PATH_INFO will change from /bar/baz to /baz.

When PATH_INFO is just a “/”, this routine returns an empty string and appends a trailing slash to SCRIPT_NAME, even though empty path segments are normally ignored, and SCRIPT_NAME doesn’t normally end in a slash. This is intentional behavior, to ensure that an application can tell the difference between URIs ending in /x from ones ending in /x/ when using this routine to do object traversal.

wsgiref.util.setup_testing_defaults(environ)

Update environ with trivial defaults for testing purposes.

This routine adds various parameters required for WSGI, including
HTTP_HOST, SERVER_NAME, SERVER_PORT, REQUEST_METHOD, SCRIPT_NAME, PATH_INFO, and all of the `PEP 3333`-defined `wsgi.*` variables. It only supplies default values, and does not replace any existing settings for these variables.

This routine is intended to make it easier for unit tests of WSGI servers and applications to set up dummy environments. It should NOT be used by actual WSGI servers or applications, since the data is fake!

Example usage:

```python
from wsgiref.util import setup_testing_defaults
from wsgiref.simple_server import make_server

# A relatively simple WSGI application. It's going to print out the environment dictionary after being updated by setup_testing_defaults.
def simple_app(environ, start_response):
    setup_testing_defaults(environ)

    status = '200 OK'
    headers = [('Content-type', 'text/plain; charset=utf-8')]

    start_response(status, headers)

    ret = [("%s: %s\n" % (key, value)).encode("utf-8") for key, value in environ.items()]
    return ret

with make_server('', 8000, simple_app) as httpd:
    print("Serving on port 8000...")
    httpd.serve_forever()
```

In addition to the environment functions above, the `wsgiref.util`
module also provides these miscellaneous utilities:

wsgiref.util.is_hop_by_hop(header_name)

Return true if 'header_name' is an HTTP/1.1 “Hop-by-Hop” header, as defined by RFC 2616.

class wsgiref.util.FileWrapper(filelike, blksize=8192)

A wrapper to convert a file-like object to an iterator. The resulting objects support both __getitem__() and __iter__() iteration styles, for compatibility with Python 2.1 and Jython. As the object is iterated over, the optional blksize parameter will be repeatedly passed to the filelike object’s read() method to obtain bytestrings to yield. When read() returns an empty bytestring, iteration is ended and is not resumable.

If filelike has a close() method, the returned object will also have a close() method, and it will invoke the filelike object’s close() method when called.

Example usage:

```python
from io import StringIO
from wsgiref.util import FileWrapper

# We're using a StringIO-buffer for as the file-like
filelike = StringIO("This is an example file-like
wrapper = FileWrapper(filelike, blksize=5)

for chunk in wrapper:
    print(chunk)
```
21.4.2. `wsgiref.headers` – WSGI response header tools

This module provides a single class, `Headers`, for convenient manipulation of WSGI response headers using a mapping-like interface.

```python
class wsgiref.headers.Headers([headers])
```

Create a mapping-like object wrapping `headers`, which must be a list of header name/value tuples as described in PEP 3333. The default value of `headers` is an empty list.

`Headers` objects support typical mapping operations including `__getitem__()`, `get()`, `__setitem__()`, `setdefault()`, `__delitem__()`, and `__contains__()`. For each of these methods, the key is the header name (treated case-insensitively), and the value is the first value associated with that header name. Setting a header deletes any existing values for that header, then adds a new value at the end of the wrapped header list. Headers’ existing order is generally maintained, with new headers added to the end of the wrapped list.

Unlike a dictionary, `Headers` objects do not raise an error when you try to get or delete a key that isn’t in the wrapped header list. Getting a nonexistent header just returns `None`, and deleting a nonexistent header does nothing.

`Headers` objects also support `keys()`, `values()`, and `items()` methods. The lists returned by `keys()` and `items()` can include the same key more than once if there is a multi-valued header. The `len()` of a `Headers` object is the same as the length of its
items(), which is the same as the length of the wrapped header list. In fact, the items() method just returns a copy of the wrapped header list.

Calling bytes() on a Headers object returns a formatted bytestring suitable for transmission as HTTP response headers. Each header is placed on a line with its value, separated by a colon and a space. Each line is terminated by a carriage return and line feed, and the bytestring is terminated with a blank line.

In addition to their mapping interface and formatting features, Headers objects also have the following methods for querying and adding multi-valued headers, and for adding headers with MIME parameters:

**get_all(name)**

Return a list of all the values for the named header.

The returned list will be sorted in the order they appeared in the original header list or were added to this instance, and may contain duplicates. Any fields deleted and re-inserted are always appended to the header list. If no fields exist with the given name, returns an empty list.

**add_header(name, value, **_params)**

Add a (possibly multi-valued) header, with optional MIME parameters specified via keyword arguments.

name is the header field to add. Keyword arguments can be used to set MIME parameters for the header field. Each parameter must be a string or None. Underscores in parameter names are converted to dashes, since dashes are illegal in Python identifiers, but many MIME parameter names include
dashes. If the parameter value is a string, it is added to the header value parameters in the form `name="value"`. If it is `None`, only the parameter name is added. (This is used for MIME parameters without a value.) Example usage:

```python
h.add_header('content-disposition', 'attachment')
```

The above will add a header that looks like this:

```
Content-Disposition: attachment; filename="bud.gif"
```

*Changed in version 3.5: headers parameter is optional.*
21.4.3. `wsgiref.simple_server` – a simple WSGI HTTP server

This module implements a simple HTTP server (based on `http.server`) that serves WSGI applications. Each server instance serves a single WSGI application on a given host and port. If you want to serve multiple applications on a single host and port, you should create a WSGI application that parses `PATH_INFO` to select which application to invoke for each request. (E.g., using the `shift_path_info()` function from `wsgiref.util`.)

`wsgiref.simple_server.make_server(host, port, app, server_class=WSGIServer, handler_class=WSGIServerRequestHandler)`

Create a new WSGI server listening on `host` and `port`, accepting connections for `app`. The return value is an instance of the supplied `server_class`, and will process requests using the specified `handler_class`. `app` must be a WSGI application object, as defined by PEP 3333.

Example usage:

```python
from wsgiref.simple_server import make_server, demo_app

with make_server('', 8000, demo_app) as httpd:
    print("Serving HTTP on port 8000...")

    # Respond to requests until process is killed
    httpd.serve_forever()

    # Alternative: serve one request, then exit
    httpd.handle_request()
```
wsgiref.simple_server.demo_app(environ, start_response)

This function is a small but complete WSGI application that returns a text page containing the message “Hello world!” and a list of the key/value pairs provided in the `environ` parameter. It’s useful for verifying that a WSGI server (such as `wsgiref.simple_server`) is able to run a simple WSGI application correctly.

class wsgiref.simple_server.WSGIServer(server_address, RequestHandlerClass)

Create a `WSGIServer` instance. `server_address` should be a `(host, port)` tuple, and `RequestHandlerClass` should be the subclass of `http.server.BaseHTTPRequestHandler` that will be used to process requests.

You do not normally need to call this constructor, as the `make_server()` function can handle all the details for you.

`WSGIServer` is a subclass of `http.server.HTTPServer`, so all of its methods (such as `serve_forever()` and `handle_request()`) are available. `WSGIServer` also provides these WSGI-specific methods:

**set_app(application)**

Sets the callable `application` as the WSGI application that will receive requests.

**get_app()**

Returns the currently-set application callable.

Normally, however, you do not need to use these additional methods, as `set_app()` is normally called by `make_server()`,
and the `get_app()` exists mainly for the benefit of request handler instances.

```python
class wsgiref.simple_server.WSGIRequestHandler(request, client_address, server)
```

Create an HTTP handler for the given `request` (i.e. a socket), `client_address` (a `(host, port)` tuple), and `server` (`WSGIServer` instance).

You do not need to create instances of this class directly; they are automatically created as needed by `WSGIServer` objects. You can, however, subclass this class and supply it as a `handler_class` to the `make_server()` function. Some possibly relevant methods for overriding in subclasses:

**get_environ()**

Returns a dictionary containing the WSGI environment for a request. The default implementation copies the contents of the `WSGIServer` object's `base_environ` dictionary attribute and then adds various headers derived from the HTTP request. Each call to this method should return a new dictionary containing all of the relevant CGI environment variables as specified in PEP 3333.

**get_stderr()**

Return the object that should be used as the `wsgi.errors` stream. The default implementation just returns `sys.stderr`.

**handle()**

Process the HTTP request. The default implementation creates a handler instance using a `wsgiref.handlers` class to
implement the actual WSGI application interface.
21.4.4. **wsgiref.validate** — WSGI conformance checker

When creating new WSGI application objects, frameworks, servers, or middleware, it can be useful to validate the new code's conformance using `wsgiref.validate`. This module provides a function that creates WSGI application objects that validate communications between a WSGI server or gateway and a WSGI application object, to check both sides for protocol conformance.

Note that this utility does not guarantee complete **PEP 3333** compliance; an absence of errors from this module does not necessarily mean that errors do not exist. However, if this module does produce an error, then it is virtually certain that either the server or application is not 100% compliant.

This module is based on the `paste.lint` module from Ian Bicking's “Python Paste” library.

**wsgiref.validate.validator**(application)

Wrap `application` and return a new WSGI application object. The returned application will forward all requests to the original `application`, and will check that both the `application` and the server invoking it are conforming to the WSGI specification and to RFC 2616.

Any detected nonconformance results in an `AssertionError` being raised; note, however, that how these errors are handled is server-dependent. For example, `wsgiref.simple_server` and other servers based on `wsgiref.handlers` (that don't override the error handling methods to do something else) will simply output
a message that an error has occurred, and dump the traceback to `sys.stderr` or some other error stream.

This wrapper may also generate output using the `warnings` module to indicate behaviors that are questionable but which may not actually be prohibited by PEP 3333. Unless they are suppressed using Python command-line options or the `warnings` API, any such warnings will be written to `sys.stderr` (not `wsgi.errors`, unless they happen to be the same object).

Example usage:

```python
from wsgiref.validate import validator
from wsgiref.simple_server import make_server

def simple_app(environ, start_response):
    status = '200 OK'  # HTTP Status
    headers = [('Content-type', 'text/plain')]  # HTTP Headers
    start_response(status, headers)

    # This is going to break because we need to return a list, and the validator is going to inform us
    return b"Hello World"

# This is the application wrapped in a validator
validator_app = validator(simple_app)

with make_server('', 8000, validator_app) as httpd:
    print("Listening on port 8000....")
    httpd.serve_forever()
```
21.4.5. **wsgiref.handlers** – server/gateway base classes

This module provides base handler classes for implementing WSGI servers and gateways. These base classes handle most of the work of communicating with a WSGI application, as long as they are given a CGI-like environment, along with input, output, and error streams.

### class wsgiref.handlers.CGIHandler

CGI-based invocation via `sys.stdin`, `sys.stdout`, `sys.stderr` and `os.environ`. This is useful when you have a WSGI application and want to run it as a CGI script. Simply invoke `CGIHandler().run(app)`, where `app` is the WSGI application object you wish to invoke.

This class is a subclass of `BaseCGIHandler` that sets `wsgi.run_once` to true, `wsgi.multithread` to false, and `wsgi.multiprocess` to true, and always uses `sys` and `os` to obtain the necessary CGI streams and environment.

### class wsgiref.handlers.IISCGIHandler

A specialized alternative to `CGIHandler`, for use when deploying on Microsoft's IIS web server, without having set the config `allowPathInfo` option (IIS>=7) or metabase `allowPathInfoForScriptMappings` (IIS<7).

By default, IIS gives a `PATH_INFO` that duplicates the `SCRIPT_NAME` at the front, causing problems for WSGI applications that wish to implement routing. This handler strips any such duplicated path.
IIS can be configured to pass the correct PATH_INFO, but this causes another bug where PATH_TRANSLATED is wrong. Luckily this variable is rarely used and is not guaranteed by WSGI. On IIS<7, though, the setting can only be made on a vhost level, affecting all other script mappings, many of which break when exposed to the PATH_TRANSLATED bug. For this reason IIS<7 is almost never deployed with the fix. (Even IIS7 rarely uses it because there is still no UI for it.)

There is no way for CGI code to tell whether the option was set, so a separate handler class is provided. It is used in the same way as CGIHandler, i.e., by calling IISCGIHandler().run(app), where app is the WSGI application object you wish to invoke.

*New in version 3.2.*

class wsgiref.handlers.BaseCGIHandler(stdin, stdout, stderr, environ, multithread=True, multiprocessing=False)

Similar to CGIHandler, but instead of using the sys and os modules, the CGI environment and I/O streams are specified explicitly. The multithread and multiprocessing values are used to set the wsgi.multithread and wsgi.multiprocess flags for any applications run by the handler instance.

This class is a subclass of SimpleHandler intended for use with software other than HTTP "origin servers". If you are writing a gateway protocol implementation (such as CGI, FastCGI, SCGI, etc.) that uses a Status: header to send an HTTP status, you probably want to subclass this instead of SimpleHandler.

class wsgiref.handlers.SimpleHandler(stdin, stdout, stderr, environ, multithread=True, multiprocessing=False)
Similar to `BaseCGIHandler`, but designed for use with HTTP origin servers. If you are writing an HTTP server implementation, you will probably want to subclass this instead of `BaseCGIHandler`.

This class is a subclass of `BaseHandler`. It overrides the `__init__`, `get_stdin()`, `get_stderr()`, `add_cgi_vars()`, `_write()`, and `_flush()` methods to support explicitly setting the environment and streams via the constructor. The supplied environment and streams are stored in the `stdin`, `stdout`, `stderr`, and `environ` attributes.

The `write()` method of `stdout` should write each chunk in full, like `io.BufferedIOBase`.

```python
class wsgiref.handlers.BaseHandler
    This is an abstract base class for running WSGI applications. Each instance will handle a single HTTP request, although in principle you could create a subclass that was reusable for multiple requests.

    `BaseHandler` instances have only one method intended for external use:

    `run(app)`
    Run the specified WSGI application, `app`.

    All of the other `BaseHandler` methods are invoked by this method in the process of running the application, and thus exist primarily to allow customizing the process.

    The following methods MUST be overridden in a subclass:
```
_write(data)
Buffer the bytes data for transmission to the client. It’s okay if
this method actually transmits the data; BaseHandler just
separates write and flush operations for greater efficiency when
the underlying system actually has such a distinction.

_flush()
Force buffered data to be transmitted to the client. It’s okay if
this method is a no-op (i.e., if _write() actually sends the
data).

get_stdin()
Return an input stream object suitable for use as the
wsgi.input of the request currently being processed.

get_stderr()
Return an output stream object suitable for use as the
wsgi.errors of the request currently being processed.

add_cgi_vars()
Insert CGI variables for the current request into the environ
attribute.

Here are some other methods and attributes you may wish to
override. This list is only a summary, however, and does not
include every method that can be overridden. You should consult
the docstrings and source code for additional information before
attempting to create a customized BaseHandler subclass.

Attributes and methods for customizing the WSGI environment:

wsgi_multithread
The value to be used for the `wsgi.multithread` environment variable. It defaults to true in `BaseHandler`, but may have a different default (or be set by the constructor) in the other subclasses.

**wsgi_multiprocess**

The value to be used for the `wsgi.multiprocess` environment variable. It defaults to true in `BaseHandler`, but may have a different default (or be set by the constructor) in the other subclasses.

**wsgi_run_once**

The value to be used for the `wsgi.run_once` environment variable. It defaults to false in `BaseHandler`, but `CGIHandler` sets it to true by default.

**os_environ**

The default environment variables to be included in every request's WSGI environment. By default, this is a copy of `os.environ` at the time that `wsgiref.handlers` was imported, but subclasses can either create their own at the class or instance level. Note that the dictionary should be considered read-only, since the default value is shared between multiple classes and instances.

**server_software**

If the `origin_server` attribute is set, this attribute's value is used to set the default `SERVER_SOFTWARE` WSGI environment variable, and also to set a default `Server:` header in HTTP responses. It is ignored for handlers (such as `BaseCGIHandler` and `CGIHandler`) that are not HTTP origin servers.
*Changed in version 3.3:* The term “Python” is replaced with implementation specific term like “CPython”, “Jython” etc.

**get_scheme()**
Return the URL scheme being used for the current request. The default implementation uses the guess_scheme() function from *wsgiref.util* to guess whether the scheme should be “http” or “https”, based on the current request’s environ variables.

**setup_environ()**
Set the environ attribute to a fully-populated WSGI environment. The default implementation uses all of the above methods and attributes, plus the get_stdin(), get_stderr(), and add_cgi_vars() methods and the wsgi_file_wrapper attribute. It also inserts a SERVER_SOFTWARE key if not present, as long as the origin_server attribute is a true value and the server_software attribute is set.

Methods and attributes for customizing exception handling:

**log_exception(exc_info)**
Log the exc_info tuple in the server log. exc_info is a (type, value, traceback) tuple. The default implementation simply writes the traceback to the request’s wsgi.errors stream and flushes it. Subclasses can override this method to change the format or retarget the output, mail the traceback to an administrator, or whatever other action may be deemed suitable.

**traceback_limit**
The maximum number of frames to include in tracebacks output by the default `log_exception()` method. If None, all frames are included.

**error_output** *(environ, start_response)*

This method is a WSGI application to generate an error page for the user. It is only invoked if an error occurs before headers are sent to the client.

This method can access the current error information using `sys.exc_info()`, and should pass that information to `start_response` when calling it (as described in the “Error Handling” section of PEP 3333).

The default implementation just uses the `error_status`, `error_headers`, and `error_body` attributes to generate an output page. Subclasses can override this to produce more dynamic error output.

Note, however, that it's not recommended from a security perspective to spit out diagnostics to any old user; ideally, you should have to do something special to enable diagnostic output, which is why the default implementation doesn’t include any.

**error_status**

The HTTP status used for error responses. This should be a status string as defined in PEP 3333; it defaults to a 500 code and message.

**error_headers**

The HTTP headers used for error responses. This should be a list of WSGI response headers `((name, value)` tuples), as
described in PEP 3333. The default list just sets the content type to text/plain.

**error_body**
The error response body. This should be an HTTP response body bytestring. It defaults to the plain text, “A server error occurred. Please contact the administrator.”

Methods and attributes for PEP 3333’s “Optional Platform-Specific File Handling” feature:

**wsgi_file_wrapper**
A wsgi.file_wrapper factory, or None. The default value of this attribute is the wsgiref.util.FileWrapper class.

**sendfile()**
Override to implement platform-specific file transmission. This method is called only if the application’s return value is an instance of the class specified by the wsgi_file_wrapper attribute. It should return a true value if it was able to successfully transmit the file, so that the default transmission code will not be executed. The default implementation of this method just returns a false value.

Miscellaneous methods and attributes:

**origin_server**
This attribute should be set to a true value if the handler's _write() and _flush() are being used to communicate directly to the client, rather than via a CGI-like gateway protocol that wants the HTTP status in a special Status: header.

This attribute’s default value is true in BaseHandler, but false
in `BaseCGIHandler` and `CGIHandler`.

**http_version**

If `origin_server` is true, this string attribute is used to set the HTTP version of the response set to the client. It defaults to "1.0".

**wsgiref.handlers.read_environ()**

Transcode CGI variables from `os.environ` to PEP 3333 “bytes in unicode” strings, returning a new dictionary. This function is used by `CGIHandler` and `IISCGIHandler` in place of directly using `os.environ`, which is not necessarily WSGI-compliant on all platforms and web servers using Python 3 – specifically, ones where the OS's actual environment is Unicode (i.e. Windows), or ones where the environment is bytes, but the system encoding used by Python to decode it is anything other than ISO-8859-1 (e.g. Unix systems using UTF-8).

If you are implementing a CGI-based handler of your own, you probably want to use this routine instead of just copying values out of `os.environ` directly.

*New in version 3.2.*
21.4.6. Examples

This is a working “Hello World” WSGI application:

```python
from wsgiref.simple_server import make_server

def hello_world_app(environ, start_response):
    status = '200 OK'  # HTTP Status
    headers = [('Content-type', 'text/plain; charset=utf-8')]
    start_response(status, headers)

    return [b"Hello World"]

with make_server('', 8000, hello_world_app) as httpd:
    print("Serving on port 8000...")

    httpd.serve_forever()
```

Last updated on Oct 03, 2017. Found a bug?

Created using Sphinx 1.6.3.
21.5. **urllib** — URL handling modules

Source code: Lib/urllib/

`urllib` is a package that collects several modules for working with URLs:

- `urllib.request` for opening and reading URLs
- `urllib.error` containing the exceptions raised by `urllib.request`
- `urllib.parse` for parsing URLs
- `urllib.robotparser` for parsing `robots.txt` files
21.6. `urllib.request` — Extensible library for opening URLs

Source code: `Lib/urllib/request.py`

The `urllib.request` module defines functions and classes which help in opening URLs (mostly HTTP) in a complex world — basic and digest authentication, redirections, cookies and more.

See also: The Requests package is recommended for a higher-level HTTP client interface.

The `urllib.request` module defines the following functions:

```python
urllib.request.urlopen(url, data=None, [timeout,]*, cafile=None, capath=None, cadefault=False, context=None)
```

Open the URL `url`, which can be either a string or a `Request` object.

`data` must be an object specifying additional data to be sent to the server, or `None` if no such data is needed. See `Request` for details.

`urllib.request` module uses HTTP/1.1 and includes `Connection:close` header in its HTTP requests.

The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the
global default timeout setting will be used). This actually only works for HTTP, HTTPS and FTP connections.

If *context* is specified, it must be a `ssl.SSLContext` instance describing the various SSL options. See `HTTPSConnection` for more details.

The optional *cafile* and *capath* parameters specify a set of trusted CA certificates for HTTPS requests. *cafile* should point to a single file containing a bundle of CA certificates, whereas *capath* should point to a directory of hashed certificate files. More information can be found in `ssl.SSLContext.load_verify_locations()`.

The *cadefault* parameter is ignored.

This function always returns an object which can work as a context manager and has methods such as

- `geturl()` — return the URL of the resource retrieved, commonly used to determine if a redirect was followed
- `info()` — return the meta-information of the page, such as headers, in the form of an `email.message_from_string()` instance (see Quick Reference to HTTP Headers)
- `getcode()` — return the HTTP status code of the response.

For HTTP and HTTPS URLs, this function returns a `http.client.HTTPResponse` object slightly modified. In addition to the three new methods above, the *msg* attribute contains the same information as the *reason* attribute — the reason phrase returned by server — instead of the response headers as it is specified in the documentation for `HTTPResponse`.

For FTP, file, and data URLs and requests explicitly handled by
legacy URLopener and FancyURLopener classes, this function returns a urllib.response.addinfourl object.

Raises URLError on protocol errors.

Note that None may be returned if no handler handles the request (though the default installed global OpenerDirector uses UnknownHandler to ensure this never happens).

In addition, if proxy settings are detected (for example, when a *_proxy environment variable like http_proxy is set), ProxyHandler is default installed and makes sure the requests are handled through the proxy.

The legacy urllib.urlopen function from Python 2.6 and earlier has been discontinued; urllib.request.urlopen() corresponds to the old urllib2.urlopen. Proxy handling, which was done by passing a dictionary parameter to urllib.urlopen, can be obtained by using ProxyHandler objects.

*Changed in version 3.2:* cafie and capath were added.

*Changed in version 3.2:* HTTPS virtual hosts are now supported if possible (that is, if ssl.HAS_SNI is true).

*New in version 3.2:* data can be an iterable object.

*Changed in version 3.3:* cadefault was added.

*Changed in version 3.4.3:* context was added.

*Deprecated since version 3.6:* cafie, capath and cadefault are deprecated in favor of context. Please use
ssl.SSLContext.load_cert_chain() instead, or let
ssl.create_default_context() select the system’s trusted
CA certificates for you.

urllib.request.install_opener(opener)
Install an OpenerDirector instance as the default global opener.
Installing an opener is only necessary if you want urlopen to use
that opener; otherwise, simply call OpenerDirector.open()
instead of urlopen(). The code does not check for a real
OpenerDirector, and any class with the appropriate interface
will work.

urllib.request.build_opener([handler, ...])
Return an OpenerDirector instance, which chains the handlers
in the order given. handlers can be either instances of
BaseHandler, or subclasses of BaseHandler (in which case it
must be possible to call the constructor without any parameters).
Instances of the following classes will be in front of the handlers,
unless the handlers contain them, instances of them or subclasses
of them: ProxyHandler (if proxy settings are detected),
UnknownHandler, HTTPHandler, HTTPDefaultErrorHandler,
HTTPRedirectHandler, FTPHandler, FileHandler, HTTPErrorProcessor.

If the Python installation has SSL support (i.e., if the ssl module
can be imported), HTTPSHandler will also be added.

A BaseHandler subclass may also change its handler_order
attribute to modify its position in the handlers list.

urllib.request.pathname2url(path)
Convert the pathname path from the local syntax for a path to the form used in the path component of a URL. This does not produce a complete URL. The return value will already be quoted using the quote() function.

\texttt{urllib.request.url2pathname(path)}

Convert the path component path from a percent-encoded URL to the local syntax for a path. This does not accept a complete URL. This function uses \texttt{unquote()} to decode path.

\texttt{urllib.request.getproxies()}

This helper function returns a dictionary of scheme to proxy server URL mappings. It scans the environment for variables named \texttt{<scheme>_proxy}, in a case insensitive approach, for all operating systems first, and when it cannot find it, looks for proxy information from Mac OS X System Configuration for Mac OS X and Windows Systems Registry for Windows. If both lowercase and uppercase environment variables exist (and disagree), lowercase is preferred.

\textbf{Note:} If the environment variable REQUEST\_METHOD is set, which usually indicates your script is running in a CGI environment, the environment variable HTTP\_PROXY (uppercase _PROXY) will be ignored. This is because that variable can be injected by a client using the “Proxy:” HTTP header. If you need to use an HTTP proxy in a CGI environment, either use ProxyHandler explicitly, or make sure the variable name is in lowercase (or at least the _proxy suffix).

The following classes are provided:

\texttt{class urllib.request.Request(url, data=None, headers={},}
This class is an abstraction of a URL request.

$url$ should be a string containing a valid URL.

data must be an object specifying additional data to send to the server, or None if no such data is needed. Currently HTTP requests are the only ones that use data. The supported object types include bytes, file-like objects, and iterables. If no Content-Length nor Transfer-Encoding header field has been provided, HTTPHandler will set these headers according to the type of data. Content-Length will be used to send bytes objects, while Transfer-Encoding: chunked as specified in RFC 7230, Section 3.3.1 will be used to send files and other iterables.

For an HTTP POST request method, data should be a buffer in the standard application/x-www-form-urlencoded format. The urllib.parse.urlencode() function takes a mapping or sequence of 2-tuples and returns an ASCII string in this format. It should be encoded to bytes before being used as the data parameter.

headers should be a dictionary, and will be treated as if add_header() was called with each key and value as arguments. This is often used to “spooft” the User-Agent header value, which is used by a browser to identify itself – some HTTP servers only allow requests coming from common browsers as opposed to scripts. For example, Mozilla Firefox may identify itself as "Mozilla/5.0 (X11; U; Linux i686) Gecko/20071127 Firefox/2.0.0.11", while urllib’s default user agent string is "Python-urllib/2.6" (on Python 2.6).
An appropriate `Content-Type` header should be included if the `data` argument is present. If this header has not been provided and `data` is not `None`, `Content-Type: application/x-www-form-urlencoded` will be added as a default.

The final two arguments are only of interest for correct handling of third-party HTTP cookies:

- `origin_req_host` should be the request-host of the origin transaction, as defined by [RFC 2965](https://tools.ietf.org/html/rfc2965). It defaults to `http.cookiejar.request_host(self)`. This is the host name or IP address of the original request that was initiated by the user. For example, if the request is for an image in an HTML document, this should be the request-host of the request for the page containing the image.

- `unverifiable` should indicate whether the request is unverifiable, as defined by RFC 2965. It defaults to `False`. An unverifiable request is one whose URL the user did not have the option to approve. For example, if the request is for an image in an HTML document, and the user had no option to approve the automatic fetching of the image, this should be true.

- `method` should be a string that indicates the HTTP request method that will be used (e.g. `'HEAD'`). If provided, its value is stored in the `method` attribute and is used by `get_method()`. The default is `'GET'` if `data` is `None` or `'POST'` otherwise. Subclasses may indicate a different default method by setting the `method` attribute in the class itself.

Note: The request will not work as expected if the data object is unable to deliver its content more than once (e.g. a file or an...
iterable that can produce the content only once) and the request is retried for HTTP redirects or authentication. The data is sent to the HTTP server right away after the headers. There is no support for a 100-continue expectation in the library.

Changed in version 3.3: Request.method argument is added to the Request class.

Changed in version 3.4: Default Request.method may be indicated at the class level.

Changed in version 3.6: Do not raise an error if the Content-Length has not been provided and data is neither None nor a bytes object. Fall back to use chunked transfer encoding instead.

class urllib.request.OpenerDirector
    The OpenerDirector class opens URLs via BaseHandlers chained together. It manages the chaining of handlers, and recovery from errors.

class urllib.request.BaseHandler
    This is the base class for all registered handlers — and handles only the simple mechanics of registration.

class urllib.request.HTTPDefaultErrorHandler
    A class which defines a default handler for HTTP error responses; all responses are turned into HTTPError exceptions.

class urllib.request.HTTPRedirectHandler
    A class to handle redirections.

class
urllib.request.HTTPCookieProcessor(cookiejar=None)
A class to handle HTTP Cookies.

```python
class urllib.request.ProxyHandler(proxies=None)
```

Cause requests to go through a proxy. If `proxies` is given, it must be a dictionary mapping protocol names to URLs of proxies. The default is to read the list of proxies from the environment variables `<protocol>_proxy`. If no proxy environment variables are set, then in a Windows environment proxy settings are obtained from the registry's Internet Settings section, and in a Mac OS X environment proxy information is retrieved from the OS X System Configuration Framework.

To disable autodetected proxy pass an empty dictionary.

The `no_proxy` environment variable can be used to specify hosts which shouldn't be reached via proxy; if set, it should be a comma-separated list of hostname suffixes, optionally with `:port` appended, for example `cern.ch,ncsa.uiuc.edu,some.host:8080`.

**Note:** `HTTP_PROXY` will be ignored if a variable `REQUEST_METHOD` is set; see the documentation on `getproxies()`.

```python
class urllib.request.HTTPPasswordMgr
```

Keep a database of `(realm, uri) -> (user, password)` mappings.

```python
class urllib.request.HTTPPasswordMgrWithDefaultRealm
```

Keep a database of `(realm, uri) -> (user, password)` mappings. A realm of `None` is considered a catch-all realm, which
is searched if no other realm fits.

```python
class urllib.request.HTTPPasswordMgrWithPriorAuth
```

A variant of `HTTPPasswordMgrWithDefaultRealm` that also has a database of `uri -> is_authenticated` mappings. Can be used by a BasicAuth handler to determine when to send authentication credentials immediately instead of waiting for a 401 response first.

*New in version 3.5.*

```python
class urllib.request.AbstractBasicAuthHandler(password_mgr=None)
```

This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. `password_mgr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported. If `passwd_mgr` also provides `is_authenticated` and `update_authenticated` methods (see `HTTPPasswordMgrWithPriorAuth Objects`), then the handler will use the `is_authenticated` result for a given URI to determine whether or not to send authentication credentials with the request. If `is_authenticated` returns `True` for the URI, credentials are sent. If `is_authenticated` is `False`, credentials are not sent, and then if a 401 response is received the request is re-sent with the authentication credentials. If authentication succeeds, `update_authenticated` is called to set `is_authenticated True` for the URI, so that subsequent requests to the URI or any of its super-URIs will automatically include the authentication credentials.

*New in version 3.5: Added `is_authenticated` support.*
class urllib.request.HTTPBasicAuthHandler(password_mgr=None):
    Handle authentication with the remote host. *password_mgr*, if given, should be something that is compatible with HTTPPasswordMgr; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported. HTTPBasicAuthHandler will raise a ValueError when presented with a wrong Authentication scheme.

class urllib.request.ProxyBasicAuthHandler(password_mgr=None):
    Handle authentication with the proxy. *password_mgr*, if given, should be something that is compatible with HTTPPasswordMgr; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported.

class urllib.request.AbstractDigestAuthHandler(password_mgr=None):
    This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. *password_mgr*, if given, should be something that is compatible with HTTPPasswordMgr; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported.

class urllib.request.HTTPDigestAuthHandler(password_mgr=None):
    Handle authentication with the remote host. *password_mgr*, if given, should be something that is compatible with HTTPPasswordMgr; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported. When both Digest Authentication Handler and Basic Authentication Handler are both added, Digest Authentication is always tried first. If the
Digest Authentication returns a 40x response again, it is sent to Basic Authentication handler to Handle. This Handler method will raise a `ValueError` when presented with an authentication scheme other than Digest or Basic.

*Changed in version 3.3:* Raise `ValueError` on unsupported Authentication Scheme.

```python
class urllib.request.ProxyDigestAuthHandler(password_mgr)
    Handle authentication with the proxy. `password_mgr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported.

class urllib.request.HTTPHandler
    A class to handle opening of HTTP URLs.

class urllib.request.HTTPSHandler(debuglevel=0, context=None, check_hostname=None)
    A class to handle opening of HTTPS URLs. `context` and `check_hostname` have the same meaning as in `http.client.HTTPSConnection`.

    *Changed in version 3.2:* `context` and `check_hostname` were added.

class urllib.request.FileHandler
    Open local files.

class urllib.request.DataHandler
    Open data URLs.

    *New in version 3.4.*
class urllib.request.FTPHandler
  Open FTP URLs.

class urllib.request.CacheFTPHandler
  Open FTP URLs, keeping a cache of open FTP connections to minimize delays.

class urllib.request.UnknownHandler
  A catch-all class to handle unknown URLs.

class urllib.request.HTTPErrorProcessor
  Process HTTP error responses.
21.6.1. Request Objects

The following methods describe `Request`’s public interface, and so all may be overridden in subclasses. It also defines several public attributes that can be used by clients to inspect the parsed request.

Request. **full_url**

The original URL passed to the constructor.

*Changed in version 3.4.*

Request.full_url is a property with setter, getter and a deleter. Getting `full_url` returns the original request URL with the fragment, if it was present.

Request. **type**

The URI scheme.

Request. **host**

The URI authority, typically a host, but may also contain a port separated by a colon.

Request. **origin_req_host**

The original host for the request, without port.

Request. **selector**

The URI path. If the `Request` uses a proxy, then selector will be the full URL that is passed to the proxy.

Request. **data**

The entity body for the request, or `None` if not specified.

*Changed in version 3.4:* Changing value of `Request.data` now
deletes “Content-Length” header if it was previously set or calculated.

**Request.unverifiable**

boolean, indicates whether the request is unverifiable as defined by RFC 2965.

**Request.method**

The HTTP request method to use. By default its value is None, which means that `get_method()` will do its normal computation of the method to be used. Its value can be set (thus overriding the default computation in `get_method()`) either by providing a default value by setting it at the class level in a Request subclass, or by passing a value in to the Request constructor via the method argument.

*New in version 3.3.*

*Changed in version 3.4:* A default value can now be set in subclasses; previously it could only be set via the constructor argument.

**Request.get_method()**

Return a string indicating the HTTP request method. If `Request.method` is not None, return its value, otherwise return 'GET' if `Request.data` is None, or 'POST' if it’s not. This is only meaningful for HTTP requests.

*Changed in version 3.3:* `get_method` now looks at the value of `Request.method`.

**Request.add_header(key, val)**

Add another header to the request. Headers are currently ignored
by all handlers except HTTP handlers, where they are added to the list of headers sent to the server. Note that there cannot be more than one header with the same name, and later calls will overwrite previous calls in case the key collides. Currently, this is no loss of HTTP functionality, since all headers which have meaning when used more than once have a (header-specific) way of gaining the same functionality using only one header.

Request.\texttt{add\_unredirected\_header}(key, header)

Add a header that will not be added to a redirected request.

Request.\texttt{has\_header}(header)

Return whether the instance has the named header (checks both regular and unredirected).

Request.\texttt{remove\_header}(header)

Remove named header from the request instance (both from regular and unredirected headers).

\textit{New in version 3.4.}

Request.\texttt{get\_full\_url}()

Return the URL given in the constructor.

\textit{Changed in version 3.4.}

Returns Request.\texttt{full\_url}

Request.\texttt{set\_proxy}(host, type)

Prepare the request by connecting to a proxy server. The host and type will replace those of the instance, and the instance's selector will be the original URL given in the constructor.
Request. **get_header**(header_name, default=None)

Return the value of the given header. If the header is not present, return the default value.

Request. **header_items()**

Return a list of tuples (header_name, header_value) of the Request headers.

*Changed in version 3.4*: The request methods add_data, has_data, get_data, get_type, get_host, get_selector, get_origin_req_host and is_unverifiable that were deprecated since 3.3 have been removed.
21.6.2. OpenerDirector Objects

OpenerDirector instances have the following methods:

OpenerDirector.\texttt{add\_handler}(\texttt{handler})

\texttt{handler} should be an instance of \texttt{BaseHandler}. The following methods are searched, and added to the possible chains (note that HTTP errors are a special case).

- \texttt{protocol\_open()} — signal that the handler knows how to open protocol URLs.
- \texttt{http\_error\_type()} — signal that the handler knows how to handle HTTP errors with HTTP error code \texttt{type}.
- \texttt{protocol\_error()} — signal that the handler knows how to handle errors from (non-http) protocol.
- \texttt{protocol\_request()} — signal that the handler knows how to pre-process protocol requests.
- \texttt{protocol\_response()} — signal that the handler knows how to post-process protocol responses.

OpenerDirector.\texttt{open}(\texttt{url}, \texttt{data=None}, \texttt{timeout})

Open the given \texttt{url} (which can be a request object or a string), optionally passing the given \texttt{data}. Arguments, return values and exceptions raised are the same as those of \texttt{urlopen()} (which simply calls the \texttt{open()} method on the currently installed global OpenerDirector). The optional \texttt{timeout} parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). The timeout feature actually works only for HTTP, HTTPS and FTP connections).
OpenerDirector.$error(proto, *args)

Handle an error of the given protocol. This will call the registered error handlers for the given protocol with the given arguments (which are protocol specific). The HTTP protocol is a special case which uses the HTTP response code to determine the specific error handler; refer to the http_error_*() methods of the handler classes.

Return values and exceptions raised are the same as those of urlopen().

OpenerDirector objects open URLs in three stages:

The order in which these methods are called within each stage is determined by sorting the handler instances.

1. Every handler with a method named like protocol_request() has that method called to pre-process the request.

2. Handlers with a method named like protocol_open() are called to handle the request. This stage ends when a handler either returns a non-None value (ie. a response), or raises an exception (usually URLError). Exceptions are allowed to propagate.

In fact, the above algorithm is first tried for methods named default_open(). If all such methods return None, the algorithm is repeated for methods named like protocol_open(). If all such methods return None, the algorithm is repeated for methods named unknown_open().

Note that the implementation of these methods may involve calls of the parent OpenerDirector instance’s open() and
error() methods.

3. Every handler with a method named like `protocol_response()` has that method called to post-process the response.
21.6.3. BaseHandler Objects

BaseHandler objects provide a couple of methods that are directly useful, and others that are meant to be used by derived classes. These are intended for direct use:

BaseHandler.add_parent(director)
    Add a director as parent.

BaseHandler.close()
    Remove any parents.

The following attribute and methods should only be used by classes derived from BaseHandler.

Note: The convention has been adopted that subclasses defining protocol_request() or protocol_response() methods are named *Processor; all others are named *Handler.

BaseHandler.parent
    A valid OpenerDirector, which can be used to open using a different protocol, or handle errors.

BaseHandler.default_open(req)
    This method is not defined in BaseHandler, but subclasses should define it if they want to catch all URLs.

    This method, if implemented, will be called by the parent OpenerDirector. It should return a file-like object as described in the return value of the open() of OpenerDirector, or None. It should raise URLError, unless a truly exceptional thing happens
(for example, `MemoryError` should not be mapped to `URLError`).

This method will be called before any protocol-specific open method.

**BaseHandler. `protocol_open`**

This method is *not* defined in `BaseHandler`, but subclasses should define it if they want to handle URLs with the given protocol.

This method, if defined, will be called by the parent `OpenerDirector`. Return values should be the same as for `default_open()`.

**BaseHandler. `unknown_open`**

This method is *not* defined in `BaseHandler`, but subclasses should define it if they want to catch all URLs with no specific registered handler to open it.

This method, if implemented, will be called by the parent `OpenerDirector`. Return values should be the same as for `default_open()`.

**BaseHandler. `http_error_default`**

This method is *not* defined in `BaseHandler`, but subclasses should override it if they intend to provide a catch-all for otherwise unhandled HTTP errors. It will be called automatically by the `OpenerDirector` getting the error, and should not normally be called in other circumstances.

`req` will be a `Request` object, `fp` will be a file-like object with the HTTP error body, `code` will be the three-digit code of the error, `msg`
will be the user-visible explanation of the code and \textit{hdrs} will be a mapping object with the headers of the error.

Return values and exceptions raised should be the same as those of \texttt{urlopen()}.

\texttt{BaseHandler.http\_error\_nnn}(\textit{req}, \textit{fp}, \textit{code}, \textit{msg}, \textit{hdrs})

\textit{nnn} should be a three-digit HTTP error code. This method is also not defined in \texttt{BaseHandler}, but will be called, if it exists, on an instance of a subclass, when an HTTP error with code \textit{nnn} occurs.

Subclasses should override this method to handle specific HTTP errors.

Arguments, return values and exceptions raised should be the same as for \texttt{http\_error\_default()}.

\texttt{BaseHandler.protocol\_request}(\textit{req})

This method is \textit{not} defined in \texttt{BaseHandler}, but subclasses should define it if they want to pre-process requests of the given protocol.

This method, if defined, will be called by the parent \texttt{OpenerDirector}. \textit{req} will be a \texttt{Request} object. The return value should be a \texttt{Request} object.

\texttt{BaseHandler.protocol\_response}(\textit{req}, \textit{response})

This method is \textit{not} defined in \texttt{BaseHandler}, but subclasses should define it if they want to post-process responses of the given protocol.

This method, if defined, will be called by the parent \texttt{OpenerDirector}. \textit{req} will be a \texttt{Request} object. \textit{response} will be
an object implementing the same interface as the return value of `urlopen()`. The return value should implement the same interface as the return value of `urlopen()`.
21.6.4. HTTPRedirectHandler Objects

**Note:** Some HTTP redirections require action from this module's client code. If this is the case, `HTTPError` is raised. See RFC 2616 for details of the precise meanings of the various redirection codes.

An `HTTPError` exception raised as a security consideration if the HTTPRedirectHandler is presented with a redirected URL which is not an HTTP, HTTPS or FTP URL.

HTTPRedirectHandler. `redirect_request(req, fp, code, msg, hdrs, newurl)`

Return a `Request` or `None` in response to a redirect. This is called by the default implementations of the `http_error_30*()` methods when a redirection is received from the server. If a redirection should take place, return a new `Request` to allow `http_error_30*()` to perform the redirect to `newurl`. Otherwise, raise `HTTPError` if no other handler should try to handle this URL, or return `None` if you can’t but another handler might.

**Note:** The default implementation of this method does not strictly follow RFC 2616, which says that 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and the default implementation reproduces this behavior.

HTTPRedirectHandler. `http_error_301(req, fp, code, msg, hdrs)`

Redirect to the `Location:` or `URI:` URL. This method is called by
the parent `OpenerDirector` when getting an HTTP ‘moved permanently’ response.

`HTTPRequestHandler.http_error_302(req, fp, code, msg, hdrs)`
The same as `http_error_301()`, but called for the ‘found’ response.

`HTTPRequestHandler.http_error_303(req, fp, code, msg, hdrs)`
The same as `http_error_301()`, but called for the ‘see other’ response.

`HTTPRequestHandler.http_error_307(req, fp, code, msg, hdrs)`
The same as `http_error_301()`, but called for the ‘temporary redirect’ response.
21.6.5. HTTPCookieProcessor Objects

HTTPCookieProcessor instances have one attribute:

HTTPCookieProcessor. **cookiejar**

The `http.cookiejar.CookieJar` in which cookies are stored.
21.6.6. ProxyHandler Objects

ProxyHandler. **protocol_open**(request)

The ProxyHandler will have a method protocol_open() for every protocol which has a proxy in the proxies dictionary given in the constructor. The method will modify requests to go through the proxy, by calling request.set_proxy(), and call the next handler in the chain to actually execute the protocol.
21.6.7. HTTPPasswordMgr Objects

These methods are available on HTTPPasswordMgr and HTTPPasswordMgrWithDefaultRealm objects.

HTTPPasswordMgr. `add_password(realm, uri, user, passwd)`

`uri` can be either a single URI, or a sequence of URIs. `realm`, `user` and `passwd` must be strings. This causes `(user, passwd)` to be used as authentication tokens when authentication for `realm` and a super-URI of any of the given URIs is given.

HTTPPasswordMgr. `find_user_password(realm, authuri)`

Get user/password for given realm and URI, if any. This method will return `(None, None)` if there is no matching user/password.

For HTTPPasswordMgrWithDefaultRealm objects, the realm `None` will be searched if the given `realm` has no matching user/password.
21.6.8. HTTPPasswordMgrWithPriorAuth Objects

This password manager extends HTTPPasswordMgrWithDefaultRealm to support tracking URIs for which authentication credentials should always be sent.

HTTPPasswordMgrWithPriorAuth.add_password(realm, uri, user, passwd, is_authenticated=False)

realm, uri, user, passwd are as for HTTPPasswordMgr.add_password(). is_authenticated sets the initial value of the is_authenticated flag for the given URI or list of URIs. If is_authenticated is specified as True, realm is ignored.

HTTPPasswordMgr.find_user_password(realm, authuri)

Same as for HTTPPasswordMgrWithDefaultRealm objects

HTTPPasswordMgrWithPriorAuth.update_authenticated(uri, isAuthenticated=False)

Update the is_authenticated flag for the given uri or list of URIs.

HTTPPasswordMgrWithPriorAuth.is_authenticated(self, authuri)

Returns the current state of the is_authenticated flag for the given URI.
21.6.9. AbstractBasicAuthHandler Objects

AbstractBasicAuthHandler. **http_error_auth_requed**(authreq, host, req, headers)

Handle an authentication request by getting a user/password pair, and re-trying the request. authreq should be the name of the header where the information about the realm is included in the request, host specifies the URL and path to authenticate for, req should be the (failed) Request object, and headers should be the error headers.

*host* is either an authority (e.g. "python.org") or a URL containing an authority component (e.g. "http://python.org/"). In either case, the authority must not contain a userinfo component (so, "python.org" and "python.org:80" are fine, "joe:password@python.org" is not).
21.6.10. HTTPBasicAuthHandler Objects

HTTPBasicAuthHandler. **http_error_401**(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.
21.6.11. ProxyBasicAuthHandler Objects

ProxyBasicAuthHandler. **http_error_407**(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.
21.6.12. AbstractDigestAuthHandler
Objects

AbstractDigestAuthHandler.\texttt{http\_error\_auth\_reqed}\(\texttt{(authreq, host, req, headers)}\)

\texttt{authreq} should be the name of the header where the information about the realm is included in the request, \texttt{host} should be the host to authenticate to, \texttt{req} should be the (failed) \texttt{Request} object, and \texttt{headers} should be the error headers.
21.6.13. HTTPDigestAuthHandler Objects

HTTPDigestAuthHandler.\texttt{http\_error\_401}(\textit{req, fp, code, msg, hdrs})

Retry the request with authentication information, if available.

ProxyDigestAuthHandler.\texttt{http\_error\_407}(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.
21.6.15. HTTPHandler Objects

HTTPHandler. **http_open**(req)

Send an HTTP request, which can be either GET or POST, depending on `req.has_data()`.
21.6.16. HTTPSHandler Objects

HTTPSHandler.\texttt{https\_open}(\textit{req})

Send an HTTPS request, which can be either GET or POST, depending on \textit{req}.\texttt{has\_data}().
21.6.17. FileHandler Objects

FileHandler. **file_open**(req)

Open the file locally, if there is no host name, or the host name is 'localhost'.

*Changed in version 3.2:* This method is applicable only for local hostnames. When a remote hostname is given, an **URLError** is raised.
21.6.18. DataHandler Objects

`DataHandler.data_open(req)`

Read a data URL. This kind of URL contains the content encoded in the URL itself. The data URL syntax is specified in RFC 2397. This implementation ignores white spaces in base64 encoded data URLs so the URL may be wrapped in whatever source file it comes from. But even though some browsers don’t mind about a missing padding at the end of a base64 encoded data URL, this implementation will raise an `ValueError` in that case.
21.6.19. FTPHandler Objects

FTPHandler. **ftp_open**(req)

Open the FTP file indicated by *req*. The login is always done with empty username and password.
21.6.20. CacheFTPHandler Objects

CacheFTPHandler objects are FTPHandler objects with the following additional methods:

CacheFTPHandler. `setTimeout(t)`
  Set timeout of connections to \( t \) seconds.

CacheFTPHandler. `setMaxConns(m)`
  Set maximum number of cached connections to \( m \).
21.6.21. UnknownHandler Objects

UnknownHandler. **unknown_open()**

Raise a **URLError** exception.
HTTPErrorProcessor.Objects

HTTPErrorProcessor.http_response()
Process HTTP error responses.

For 200 error codes, the response object is returned immediately.

For non-200 error codes, this simply passes the job on to the
protocol_error_code() handler methods, via
OpenerDirector.error(). Eventually,
HTTPDefaultErrorHandler will raise an HTTPError if no
other handler handles the error.

HTTPErrorProcessor.https_response()
Process HTTPS error responses.

The behavior is same as http_response().
21.6.23. Examples

In addition to the examples below, more examples are given in HOWTO Fetch Internet Resources Using The urllib Package.

This example gets the python.org main page and displays the first 300 bytes of it.

```
>>> import urllib.request
>>> with urllib.request.urlopen('http://www.python.org/... print(f.read(300))
...
b'<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
<head>
<meta http-equiv="content-type" content="text/html;
<title>Python Programming '</title>
```

Note that urlopen returns a bytes object. This is because there is no way for urlopen to automatically determine the encoding of the byte stream it receives from the HTTP server. In general, a program will decode the returned bytes object to string once it determines or guesses the appropriate encoding.

The following W3C document, https://www.w3.org/International/Oncharset, lists the various ways in which an (X)HTML or an XML document could have specified its encoding information.

As the python.org website uses utf-8 encoding as specified in its meta tag, we will use the same for decoding the bytes object.

```
>>> with urllib.request.urlopen('http://www.python.org/... print(f.read(100).decode('utf-8'))
```
It is also possible to achieve the same result without using the context manager approach.

In the following example, we are sending a data-stream to the stdin of a CGI and reading the data it returns to us. Note that this example will only work when the Python installation supports SSL.

The code for the sample CGI used in the above example is:

```bash
#!/usr/bin/env python
import sys
data = sys.stdin.read()
print('Content-type: text/plain

Got Data: "%s"' % data)
```

Here is an example of doing a PUT request using Request:
import urllib.request
DATA = b'some data'
req = urllib.request.Request(url='http://localhost:8080')
with urllib.request.urlopen(req) as f:
    pass
print(f.status)
print(f.reason)

Use of Basic HTTP Authentication:

import urllib.request
# Create an OpenerDirector with support for Basic HTTP Authentication...
auth_handler = urllib.request.HTTPBasicAuthHandler()
auth_handler.add_password(realm='PDQ Application',
                           uri='https://mahler:8092/site-updates.py',
                           user='klem',
                           passwd='kadidd!ehopper')
opener = urllib.request.build_opener(auth_handler)
# ...and install it globally so it can be used with urllib.request.urlopen(opener)
urllib.request.urlopen('http://www.example.com/login.html')

build_opener() provides many handlers by default, including a ProxyHandler. By default, ProxyHandler uses the environment variables named `<scheme>_proxy`, where `<scheme>` is the URL scheme involved. For example, the http_proxy environment variable is read to obtain the HTTP proxy's URL.

This example replaces the default ProxyHandler with one that uses programmatically-supplied proxy URLs, and adds proxy authorization support with ProxyBasicAuthHandler.
proxy_handler = urllib.request.ProxyHandler({'http':
proxy_auth_handler = urllib.request.ProxyBasicAuthHandler()
proxy_auth_handler.add_password('realm', 'host', 'user',
opener = urllib.request.build_opener(proxy_handler,
# This time, rather than install the OpenerDirector,
opener.open('http://www.example.com/login.html')

Adding HTTP headers:

Use the headers argument to the Request constructor, or:

import urllib.request
req = urllib.request.Request('http://www.example.com/
req.add_header('Referer', 'http://www.python.org/')
# Customize the default User-Agent header value:
req.add_header('User-Agent', 'urllib-example/0.1 (Contact:	.	.	.)'
r = urllib.request.urlopen(req)

OpenerDirector automatically adds a User-Agent header to every
Request. To change this:

import urllib.request
opener = urllib.request.build_opener()
opener.addheaders = [('User-agent', 'Mozilla/5.0')]
opener.open('http://www.example.com/

Also, remember that a few standard headers (Content-Length, Content-Type and Host) are added when the Request is passed to
urlopen() (or OpenerDirector.open()).

Here is an example session that uses the GET method to retrieve a
URL containing parameters:
The following example uses the **POST** method instead. Note that params output from urlencode is encoded to bytes before it is sent to urlopen as data:

```python
>>> import urllib.request
>>> import urllib.parse
>>> params = urllib.parse.urlencode({'spam': 1, 'eggs': 2})
>>> url = "http://www.musical.com/cgi-bin/query?%s"
>>> with urllib.request.urlopen(url % params) as f:
...   print(f.read().decode('utf-8'))
...
```

The following example uses an explicitly specified HTTP proxy, overriding environment settings:

```python
>>> import urllib.request
>>> proxies = {'http': 'http://proxy.example.com:8080/'}
>>> opener = urllib.request.FancyURLopener(proxies)
>>> with opener.open("http://www.python.org") as f:
...   f.read().decode('utf-8')
...
```

The following example uses no proxies at all, overriding environment settings:
>>> import urllib.request
>>> opener = urllib.request.FancyURLopener({})
>>> with opener.open("http://www.python.org/") as f:
...     f.read().decode('utf-8')
...
21.6.24. Legacy interface

The following functions and classes are ported from the Python 2 module `urllib` (as opposed to `urllib2`). They might become deprecated at some point in the future.

`urllib.request.urlretrieve(url, filename=None, reporthook=None, data=None)`

Copy a network object denoted by a URL to a local file. If the URL points to a local file, the object will not be copied unless filename is supplied. Return a tuple (`filename, headers`) where `filename` is the local file name under which the object can be found, and `headers` is whatever the `info()` method of the object returned by `urlopen()` returned (for a remote object). Exceptions are the same as for `urlopen()`.

The second argument, if present, specifies the file location to copy to (if absent, the location will be a tempfile with a generated name). The third argument, if present, is a hook function that will be called once on establishment of the network connection and once after each block read thereafter. The hook will be passed three arguments; a count of blocks transferred so far, a block size in bytes, and the total size of the file. The third argument may be `-1` on older FTP servers which do not return a file size in response to a retrieval request.

The following example illustrates the most common usage scenario:

```python
>>> import urllib.request
>>> local_filename, headers = urllib.request.urlretrieve...
>>> html = open(local_filename)
```
If the `url` uses the `http:` scheme identifier, the optional `data` argument may be given to specify a POST request (normally the request type is GET). The `data` argument must be a bytes object in standard `application/x-www-form-urlencoded` format; see the `urllib.parse.urlencode()` function.

`urlretrieve()` will raise `ContentTooShortError` when it detects that the amount of data available was less than the expected amount (which is the size reported by a `Content-Length` header). This can occur, for example, when the download is interrupted.

The `Content-Length` is treated as a lower bound: if there’s more data to read, `urlretrieve` reads more data, but if less data is available, it raises the exception.

You can still retrieve the downloaded data in this case, it is stored in the `content` attribute of the exception instance.

If no `Content-Length` header was supplied, `urlretrieve` can not check the size of the data it has downloaded, and just returns it. In this case you just have to assume that the download was successful.

`urllib.request.urlopen()`

Cleans up temporary files that may have been left behind by previous calls to `urlretrieve()`.

`class urllib.request.URLopener(proxies=None, **x509)`

*Deprecated since version 3.3.*
Base class for opening and reading URLs. Unless you need to support opening objects using schemes other than http:, ftp:, or file:, you probably want to use FancyURLopener.

By default, the URLopener class sends a User-Agent header of urllib/VVV, where VVV is the urllib version number. Applications can define their own User-Agent header by subclassing URLopener or FancyURLopener and setting the class attribute version to an appropriate string value in the subclass definition.

The optional proxies parameter should be a dictionary mapping scheme names to proxy URLs, where an empty dictionary turns proxies off completely. Its default value is None, in which case environmental proxy settings will be used if present, as discussed in the definition of urlopen(), above.

Additional keyword parameters, collected in x509, may be used for authentication of the client when using the https: scheme. The keywords key_file and cert_file are supported to provide an SSL key and certificate; both are needed to support client authentication.

URLopener objects will raise an OSError exception if the server returns an error code.

open(fullurl, data=None)

Open fullurl using the appropriate protocol. This method sets up cache and proxy information, then calls the appropriate open method with its input arguments. If the scheme is not recognized, open_unknown() is called. The data argument has the same meaning as the data argument of urlopen().
open_unknown(fullurl, data=None)

Overridable interface to open unknown URL types.

retrieve(url, filename=None, reporthook=None, data=None)

Retrieves the contents of url and places it in filename. The return value is a tuple consisting of a local filename and either an email.message.Message object containing the response headers (for remote URLs) or None (for local URLs). The caller must then open and read the contents of filename. If filename is not given and the URL refers to a local file, the input filename is returned. If the URL is non-local and filename is not given, the filename is the output of tempfile.mktemp() with a suffix that matches the suffix of the last path component of the input URL. If reporthook is given, it must be a function accepting three numeric parameters: A chunk number, the maximum size chunks are read in and the total size of the download (-1 if unknown). It will be called once at the start and after each chunk of data is read from the network. reporthook is ignored for local URLs.

If the url uses the http: scheme identifier, the optional data argument may be given to specify a POST request (normally the request type is GET). The data argument must in standard application/x-www-form-urlencoded format; see the urllib.parse.urlencode() function.

version

Variable that specifies the user agent of the opener object. To get urllib to tell servers that it is a particular user agent, set this in a subclass as a class variable or in the constructor before calling the base constructor.
class urllib.request.FancyURLopener(...)

*Deprecated since version 3.3.*

FancyURLopener subclasses URLopener providing default handling for the following HTTP response codes: 301, 302, 303, 307 and 401. For the 30x response codes listed above, the Location header is used to fetch the actual URL. For 401 response codes (authentication required), basic HTTP authentication is performed. For the 30x response codes, recursion is bounded by the value of the maxtries attribute, which defaults to 10.

For all other response codes, the method http_error_default() is called which you can override in subclasses to handle the error appropriately.

**Note:** According to the letter of RFC 2616, 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and urllib reproduces this behaviour.

The parameters to the constructor are the same as those for URLopener.

**Note:** When performing basic authentication, a FancyURLopener instance calls its prompt_user_passwd() method. The default implementation asks the users for the required information on the controlling terminal. A subclass may override this method to support more appropriate behavior if needed.

The FancyURLopener class offers one additional method that
should be overloaded to provide the appropriate behavior:

**prompt_user_passwd**(*host, realm*)

Return information needed to authenticate the user at the given host in the specified security realm. The return value should be a tuple, *(user, password)*, which can be used for basic authentication.

The implementation prompts for this information on the terminal; an application should override this method to use an appropriate interaction model in the local environment.
21.6.25. **urllib.request** Restrictions

- Currently, only the following protocols are supported: HTTP (versions 0.9 and 1.0), FTP, local files, and data URLs.

  *Changed in version 3.4:* Added support for data URLs.

- The caching feature of `urllibretrieve()` has been disabled until someone finds the time to hack proper processing of Expiration time headers.

- There should be a function to query whether a particular URL is in the cache.

- For backward compatibility, if a URL appears to point to a local file but the file can't be opened, the URL is re-interpreted using the FTP protocol. This can sometimes cause confusing error messages.

- The `urlopen()` and `urllibretrieve()` functions can cause arbitrarily long delays while waiting for a network connection to be set up. This means that it is difficult to build an interactive Web client using these functions without using threads.

- The data returned by `urlopen()` or `urllibretrieve()` is the raw data returned by the server. This may be binary data (such as an image), plain text or (for example) HTML. The HTTP protocol provides type information in the reply header, which can be inspected by looking at the `Content-Type` header. If the returned data is HTML, you can use the module `html.parser` to parse it.

- The code handling the FTP protocol cannot differentiate between
a file and a directory. This can lead to unexpected behavior when attempting to read a URL that points to a file that is not accessible. If the URL ends in a /, it is assumed to refer to a directory and will be handled accordingly. But if an attempt to read a file leads to a 550 error (meaning the URL cannot be found or is not accessible, often for permission reasons), then the path is treated as a directory in order to handle the case when a directory is specified by a URL but the trailing / has been left off. This can cause misleading results when you try to fetch a file whose read permissions make it inaccessible; the FTP code will try to read it, fail with a 550 error, and then perform a directory listing for the unreadable file. If fine-grained control is needed, consider using the ftplib module, subclassing FancyURLopener, or changing _urloper to meet your needs.
21.7. **urllib.response** —
Response classes used by urllib

The `urllib.response` module defines functions and classes which define a minimal file-like interface, including `read()` and `readline()`. The typical response object is an `addinfo` instance, which defines an `info()` method and that returns headers and a `geturl()` method that returns the url. Functions defined by this module are used internally by the `urllib.request` module.
21. Internet Protocols and Support
21.8. `urllib.parse` — Parse URLs into components

**Source code:** Lib/urllib/parse.py

This module defines a standard interface to break Uniform Resource Locator (URL) strings up in components (addressing scheme, network location, path etc.), to combine the components back into a URL string, and to convert a “relative URL” to an absolute URL given a “base URL.”

The module has been designed to match the Internet RFC on Relative Uniform Resource Locators. It supports the following URL schemes: `file`, `ftp`, `gopher`, `hdl`, `http`, `https`, `imap`, `mailto`, `mms`, `news`, `nntp`, `prospero`, `rsync`, `rtsp`, `rtspu`, `sftp`, `shttp`, `sip`, `sips`, `snews`, `svn`, `svn+ssh`, `telnet`, `wais`, `ws`, `wss`.

The `urllib.parse` module defines functions that fall into two broad categories: URL parsing and URL quoting. These are covered in detail in the following sections.
21.8.1. URL Parsing

The URL parsing functions focus on splitting a URL string into its components, or on combining URL components into a URL string.

urllib.parse.\texttt{urlparse}(urlstring, scheme='', allow_fragments=True)

Parse a URL into six components, returning a 6-tuple. This corresponds to the general structure of a URL: 
\texttt{scheme://netloc/path;parameters?query#fragment}.
Each tuple item is a string, possibly empty. The components are not broken up in smaller parts (for example, the network location is a single string), and \% escapes are not expanded. The delimiters as shown above are not part of the result, except for a leading slash in the \textit{path} component, which is retained if present. For example:

```python
>>> from urllib.parse import urlparse
>>> o = urlparse('http://www.cwi.nl:80/%7Eguido/Python.html')
>>> o
ParseResult(scheme='http', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html', params='', query='', fragment='')
>>> o.scheme
'http'
>>> o.port
80
>>> o.geturl()
'http://www.cwi.nl:80/%7Eguido/Python.html'
```

Following the syntax specifications in RFC 1808, urlparse recognizes a netloc only if it is properly introduced by ‘//’. Otherwise the input is presumed to be a relative URL and thus to start with a
The `scheme` argument gives the default addressing scheme, to be used only if the URL does not specify one. It should be the same type (text or bytes) as `urlstring`, except that the default value `' '` is always allowed, and is automatically converted to `b' '` if appropriate.

If the `allow_fragments` argument is false, fragment identifiers are not recognized. Instead, they are parsed as part of the path, parameters or query component, and fragment is set to the empty string in the return value.

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheme</td>
<td>0</td>
<td>URL scheme specifier</td>
<td><code>scheme</code> parameter</td>
</tr>
<tr>

<td></td>
<td>Host name (lower case)</td>
<td>None</td>
</tr>
<tr>
<td>port</td>
<td></td>
<td>Port number as integer, if present</td>
<td>None</td>
</tr>
</tbody>
</table>

Reading the port attribute will raise a `ValueError` if an invalid port is specified in the URL. See section Structured Parse Results for more information on the result object.

Unmatched square brackets in the netloc attribute will raise a `ValueError`.

**Changed in version 3.2:** Added IPv6 URL parsing capabilities.

**Changed in version 3.3:** The fragment is now parsed for all URL schemes (unless `allow_fragment` is false), in accordance with RFC 3986. Previously, a whitelist of schemes that support fragments existed.

**Changed in version 3.6:** Out-of-range port numbers now raise `ValueError`, instead of returning `None`.

`urllib.parse.parse_qs(qs, keep_blank_values=False)`
Parse a query string given as a string argument (data of type \texttt{application/x-www-form-urlencoded}). Data are returned as a dictionary. The dictionary keys are the unique query variable names and the values are lists of values for each name.

The optional argument \texttt{keep\_blank\_values} is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument \texttt{strict\_parsing} is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a \texttt{ValueError} exception.

The optional \texttt{encoding} and \texttt{errors} parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the \texttt{bytes.decode()} method.

Use the \texttt{urllib.parse.urlencode()} function (with the \texttt{doseq} parameter set to \texttt{True}) to convert such dictionaries into query strings.

\textit{Changed in version 3.2:} Add \texttt{encoding} and \texttt{errors} parameters.

\texttt{urllib.parse.parse\_qsl(qs, keep\_blank\_values=False, strict\_parsing=False, encoding='utf-8', errors='replace')}

Parse a query string given as a string argument (data of type \texttt{application/x-www-form-urlencoded}). Data are returned as a list of name, value pairs.
The optional argument `keep_blank_values` is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument `strict_parsing` is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a `ValueError` exception.

The optional `encoding` and `errors` parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the `bytes.decode()` method.

Use the `urllib.parse.urlencode()` function to convert such lists of pairs into query strings.

*Changed in version 3.2*: Add `encoding` and `errors` parameters.

`urllib.parse.urlunparse(parts)`

Construct a URL from a tuple as returned by `urlparse()`. The `parts` argument can be any six-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a `?` with an empty query; the RFC states that these are equivalent).

`urllib.parse.urlsplit(urlstring, scheme='', allow_fragments=True)`

This is similar to `urlparse()`, but does not split the params from the URL. This should generally be used instead of `urlparse()` if the more recent URL syntax allowing parameters to be applied to each segment of the `path` portion of the URL (see RFC 2396) is
wanted. A separate function is needed to separate the path segments and parameters. This function returns a 5-tuple: (addressing scheme, network location, path, query, fragment identifier).

The return value is actually an instance of a subclass of tuple. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheme</td>
<td>0</td>
<td>URL scheme specifier</td>
<td>scheme parameter</td>
</tr>
<tr>
<td>netloc</td>
<td>1</td>
<td>Network location part</td>
<td>empty string</td>
</tr>
<tr>
<td>path</td>
<td>2</td>
<td>Hierarchical path</td>
<td>empty string</td>
</tr>
<tr>
<td>query</td>
<td>3</td>
<td>Query component</td>
<td>empty string</td>
</tr>
<tr>
<td>fragment</td>
<td>4</td>
<td>Fragment identifier</td>
<td>empty string</td>
</tr>
<tr>
<td>username</td>
<td></td>
<td>User name</td>
<td>None</td>
</tr>
<tr>
<td>password</td>
<td></td>
<td>Password</td>
<td>None</td>
</tr>
<tr>
<td>hostname</td>
<td></td>
<td>Host name (lower case)</td>
<td>None</td>
</tr>
<tr>
<td>port</td>
<td></td>
<td>Port number as integer, if present</td>
<td>None</td>
</tr>
</tbody>
</table>

Reading the port attribute will raise a ValueError if an invalid port is specified in the URL. See section Structured Parse Results for more information on the result object.

Unmatched square brackets in the netloc attribute will raise a ValueError.
Changed in version 3.6: Out-of-range port numbers now raise `ValueError`, instead of returning `None`.

`urllib.parse.urlunsplit(parts)`

Combine the elements of a tuple as returned by `urlsplit()` into a complete URL as a string. The `parts` argument can be any five-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a ? with an empty query; the RFC states that these are equivalent).

`urllib.parse.urljoin(base, url, allow_fragments=True)`

Construct a full (“absolute”) URL by combining a “base URL” (`base`) with another URL (`url`). Informally, this uses components of the base URL, in particular the addressing scheme, the network location and (part of) the path, to provide missing components in the relative URL. For example:

```python
>>> from urllib.parse import urljoin
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html', 'http://www.cwi.nl/%7Eguido/FAQ.html')
'http://www.cwi.nl/%7Eguido/FAQ.html'
```

The `allow_fragments` argument has the same meaning and default as for `urlparse()`.

**Note:** If `url` is an absolute URL (that is, starting with // or scheme://), the `url`’s host name and/or scheme will be present in the result. For example:

```python
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html', '//www.python.org/%7Eguido')
'http://www.python.org/%7Eguido'
```
If you do not want that behavior, preprocess the `url` with `urlsplit()` and `urlunsplit()`, removing possible `scheme` and `netloc` parts.

*Changed in version 3.5:* Behaviour updated to match the semantics defined in [RFC 3986](https://tools.ietf.org/html/rfc3986).

`urllib.parse.urldefrag(url)`

If `url` contains a fragment identifier, return a modified version of `url` with no fragment identifier, and the fragment identifier as a separate string. If there is no fragment identifier in `url`, return `url` unmodified and an empty string.

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>url</code></td>
<td>0</td>
<td>URL with no fragment</td>
<td>empty string</td>
</tr>
<tr>
<td><code>fragment</code></td>
<td>1</td>
<td>Fragment identifier</td>
<td>empty string</td>
</tr>
</tbody>
</table>

See section [Structured Parse Results](https://docs.python.org/3/library/urllib.parse.html#structured-parse-results) for more information on the result object.

*Changed in version 3.2:* Result is a structured object rather than a simple 2-tuple.
21.8.2. Parsing ASCII Encoded Bytes

The URL parsing functions were originally designed to operate on character strings only. In practice, it is useful to be able to manipulate properly quoted and encoded URLs as sequences of ASCII bytes. Accordingly, the URL parsing functions in this module all operate on bytes and bytearray objects in addition to str objects.

If str data is passed in, the result will also contain only str data. If bytes or bytearray data is passed in, the result will contain only bytes data.

Attempting to mix str data with bytes or bytearray in a single function call will result in a TypeError being raised, while attempting to pass in non-ASCII byte values will trigger UnicodeDecodeError.

To support easier conversion of result objects between str and bytes, all return values from URL parsing functions provide either an encode() method (when the result contains str data) or a decode() method (when the result contains bytes data). The signatures of these methods match those of the corresponding str and bytes methods (except that the default encoding is 'ascii' rather than 'utf-8'). Each produces a value of a corresponding type that contains either bytes data (for encode() methods) or str data (for decode() methods).

Applications that need to operate on potentially improperly quoted URLs that may contain non-ASCII data will need to do their own decoding from bytes to characters before invoking the URL parsing methods.
The behaviour described in this section applies only to the URL parsing functions. The URL quoting functions use their own rules when producing or consuming byte sequences as detailed in the documentation of the individual URL quoting functions.

*Changed in version 3.2:* URL parsing functions now accept ASCII encoded byte sequences
21.8.3. Structured Parse Results

The result objects from the `urlparse()`, `urlsplit()` and `urldefrag()` functions are subclasses of the `tuple` type. These subclasses add the attributes listed in the documentation for those functions, the encoding and decoding support described in the previous section, as well as an additional method:

`urllib.parse.SplitResult.geturl()`

Return the re-combined version of the original URL as a string. This may differ from the original URL in that the scheme may be normalized to lower case and empty components may be dropped. Specifically, empty parameters, queries, and fragment identifiers will be removed.

For `urldefrag()` results, only empty fragment identifiers will be removed. For `urlsplit()` and `urlparse()` results, all noted changes will be made to the URL returned by this method.

The result of this method remains unchanged if passed back through the original parsing function:

```python
>>> from urllib.parse import urlsplit
>>> url = 'HTTP://www.Python.org/doc/#'
>>> r1 = urlsplit(url)
>>> r1.geturl()
'http://www.Python.org/doc/'
>>> r2 = urlsplit(r1.geturl())
>>> r2.geturl()
'http://www.Python.org/doc/'
```

The following classes provide the implementations of the structured
parse results when operating on `str` objects:

```
class urllib.parse.**DefragResult**(url, fragment)
```
Concrete class for `urldefrag()` results containing `str` data. The `encode()` method returns a `DefragResultBytes` instance.

*New in version 3.2.*

```
class urllib.parse.**ParseResult**(scheme, netloc, path, params, query, fragment)
```
Concrete class for `urlparse()` results containing `str` data. The `encode()` method returns a `ParseResultBytes` instance.

```
class urllib.parse.**SplitResult**(scheme, netloc, path, query, fragment)
```
Concrete class for `urlsplit()` results containing `str` data. The `encode()` method returns a `SplitResultBytes` instance.

The following classes provide the implementations of the parse results when operating on `bytes` or `bytearray` objects:

```
class urllib.parse.**DefragResultBytes**(url, fragment)
```
Concrete class for `urldefrag()` results containing `bytes` data. The `decode()` method returns a `DefragResult` instance.

*New in version 3.2.*

```
class urllib.parse.**ParseResultBytes**(scheme, netloc, path, params, query, fragment)
```
Concrete class for `urlparse()` results containing `bytes` data. The `decode()` method returns a `ParseResult` instance.

*New in version 3.2.*
class urllib.parse.SplitResultBytes(scheme, netloc, path, query, fragment)

Concrete class for urlsplit() results containing bytes data. The decode() method returns a SplitResult instance.

New in version 3.2.
21.8.4. URL Quoting

The URL quoting functions focus on taking program data and making it safe for use as URL components by quoting special characters and appropriately encoding non-ASCII text. They also support reversing these operations to recreate the original data from the contents of a URL component if that task isn't already covered by the URL parsing functions above.

urllib.parse.quote(string, safe='/', encoding=None, errors=None)

Replace special characters in string using the %xx escape. Letters, digits, and the characters '_.-' are never quoted. By default, this function is intended for quoting the path section of URL. The optional safe parameter specifies additional ASCII characters that should not be quoted — its default value is '/'.

string may be either a str or a bytes.

The optional encoding and errors parameters specify how to deal with non-ASCII characters, as accepted by the str.encode() method. encoding defaults to 'utf-8'. errors defaults to 'strict', meaning unsupported characters raise a UnicodeEncodeError. encoding and errors must not be supplied if string is a bytes, or a TypeError is raised.

Note that quote(string, safe, encoding, errors) is equivalent to quote_from_bytes(string.encode(encoding, errors), safe).
Example: `quote('/El Niño/')` yields `/El%20Ni%23B1o/`.

`urllib.parse.quote_plus(string, safe='', encoding=None, errors=None)`

Like `quote()`, but also replace spaces by plus signs, as required for quoting HTML form values when building up a query string to go into a URL. Plus signs in the original string are escaped unless they are included in `safe`. It also does not have `safe` default to `/`.

Example: `quote_plus('/El Niño/')` yields `%2FEl+Ni%C3%B1o%2F`.

`urllib.parse.quote_from_bytes(bytes, safe=')`

Like `quote()`, but accepts a `bytes` object rather than a `str`, and does not perform string-to-bytes encoding.

Example: `quote_from_bytes(b'a&\xef')` yields `a%26%EF`.

`urllib.parse.unquote(string, encoding='utf-8', errors='replace')`

Replace `%xx` escapes by their single-character equivalent. The optional `encoding` and `errors` parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the `bytes.decode()` method.

`string` must be a `str`.

`encoding` defaults to 'utf-8'. `errors` defaults to 'replace', meaning invalid sequences are replaced by a placeholder character.

Example: `unquote('/El%20Ni%C3%B1o/')` yields `/El Niño/`.
urllib.parse.unquote_plus(string, encoding='utf-8', errors='replace')

Like unquote(), but also replace plus signs by spaces, as required for unquoting HTML form values.

string must be a str.

Example: unquote_plus('/El+Ni%C3%B1o/') yields '/El Niño/'.

urllib.parse.unquote_to_bytes(string)

Replace %xx escapes by their single-octet equivalent, and return a bytes object.

string may be either a str or a bytes.

If it is a str, unescaped non-ASCII characters in string are encoded into UTF-8 bytes.

Example: unquote_to_bytes('a%26%EF') yields b'a&\xEF'.

urllib.parse.urlencoded(query, doseq=False, safe='', encoding=None, errors=None, quote_via=quote_plus)

Convert a mapping object or a sequence of two-element tuples, which may contain str or bytes objects, to a percent-encoded ASCII text string. If the resultant string is to be used as a data for POST operation with the urlopen() function, then it should be encoded to bytes, otherwise it would result in a TypeError.

The resulting string is a series of key=value pairs separated by '& ' characters, where both key and value are quoted using the quote_via function. By default, quote_plus() is used to quote
the values, which means spaces are quoted as a ' +' character and ' / ' characters are encoded as %2F, which follows the standard for GET requests (application/x-www-form-urlencoded). An alternate function that can be passed as quote_via is quote(), which will encode spaces as %20 and not encode ' / ' characters. For maximum control of what is quoted, use quote and specify a value for safe.

When a sequence of two-element tuples is used as the query argument, the first element of each tuple is a key and the second is a value. The value element in itself can be a sequence and in that case, if the optional parameter doseq is evaluates to True, individual key=value pairs separated by ' & ' are generated for each element of the value sequence for the key. The order of parameters in the encoded string will match the order of parameter tuples in the sequence.

The safe, encoding, and errors parameters are passed down to quote_via (the encoding and errors parameters are only passed when a query element is a str).

To reverse this encoding process, parse_qs() and parse_qsl() are provided in this module to parse query strings into Python data structures.

Refer to urllib examples to find out how urlencode method can be used for generating query string for a URL or data for POST.

Changed in version 3.2: Query parameter supports bytes and string objects.

New in version 3.5: quote_via parameter.
See also:

**RFC 3986** - **Uniform Resource Identifiers**
This is the current standard (STD66). Any changes to urllib.parse module should conform to this. Certain deviations could be observed, which are mostly for backward compatibility purposes and for certain de-facto parsing requirements as commonly observed in major browsers.

**RFC 2732** - **Format for Literal IPv6 Addresses in URL's.**
This specifies the parsing requirements of IPv6 URLs.

**RFC 2396** - **Uniform Resource Identifiers (URI): Generic Syntax**
Document describing the generic syntactic requirements for both Uniform Resource Names (URNs) and Uniform Resource Locators (URLs).

**RFC 2368** - **The mailto URL scheme.**
Parsing requirements for mailto URL schemes.

**RFC 1808** - **Relative Uniform Resource Locators**
This Request For Comments includes the rules for joining an absolute and a relative URL, including a fair number of “Abnormal Examples” which govern the treatment of border cases.

**RFC 1738** - **Uniform Resource Locators (URL)**
This specifies the formal syntax and semantics of absolute URLs.
21.9. **urllib.error** — Exception classes raised by **urllib.request**

Source code: Lib/urllib/error.py

The **urllib.error** module defines the exception classes for exceptions raised by **urllib.request**. The base exception class is **URLError**.

The following exceptions are raised by **urllib.error** as appropriate:

- **exception urllib.error.URLError**
  The handlers raise this exception (or derived exceptions) when they run into a problem. It is a subclass of **OSError**.

  - **reason**
    The reason for this error. It can be a message string or another exception instance.

  *Changed in version 3.3:* **URLError** has been made a subclass of **OSError** instead of **IOError**.

- **exception urllib.error.HTTPError**
  Though being an exception (a subclass of **URLError**), an **HTTPError** can also function as a non-exceptional file-like return value (the same thing that **urlopen()** returns). This is useful when handling exotic HTTP errors, such as requests for
authentication.

**code**

An HTTP status code as defined in RFC 2616. This numeric value corresponds to a value found in the dictionary of codes as found in http.server.BaseHTTPRequestHandler.responses.

**reason**

This is usually a string explaining the reason for this error.

**headers**

The HTTP response headers for the HTTP request that caused the HTTPError.

*New in version 3.4.*

**exception** urllib.error.ContentTooShortError *(msg, content)*

This exception is raised when the urlretrieve() function detects that the amount of the downloaded data is less than the expected amount (given by the Content-Length header). The content attribute stores the downloaded (and supposedly truncated) data.
21.10. **urllib.robotparser** — Parser for robots.txt

**Source code:** Lib/urllib/robotparser.py

This module provides a single class, `RobotFileParser`, which answers questions about whether or not a particular user agent can fetch a URL on the Web site that published the `robots.txt` file. For more details on the structure of `robots.txt` files, see http://www.robotstxt.org/orig.html.

```python
class urllib.robotparser.RobotFileParser(url='')
```

This class provides methods to read, parse and answer questions about the `robots.txt` file at `url`.

```python
set_url(url)
```

Sets the URL referring to a `robots.txt` file.

```python
read()
```

Reads the `robots.txt` URL and feeds it to the parser.

```python
parse(lines)
```

Parses the lines argument.

```python
can_fetch(useragent, url)
```

Returns `True` if the `useragent` is allowed to fetch the `url` according to the rules contained in the parsed `robots.txt` file.
mtime()
Returns the time the robots.txt file was last fetched. This is useful for long-running web spiders that need to check for new robots.txt files periodically.

modified()
Sets the time the robots.txt file was last fetched to the current time.

crawl_delay(useragent)
Returns the value of the Crawl-delay parameter from robots.txt for the useragent in question. If there is no such parameter or it doesn't apply to the useragent specified or the robots.txt entry for this parameter has invalid syntax, return None.

New in version 3.6.

request_rate(useragent)
Returns the contents of the Request-rate parameter from robots.txt in the form of a namedtuple() (requests, seconds). If there is no such parameter or it doesn't apply to the useragent specified or the robots.txt entry for this parameter has invalid syntax, return None.

New in version 3.6.

The following example demonstrates basic use of the RobotFileParser class:

```python
>>> import urllib.robotparser
>>> rp = urllib.robotparser.RobotFileParser()
```
>>> rp.set_url("http://www.musi-cal.com/robots.txt")
>>> rp.read()
>>> rrate = rp.request_rate("*")
>>> rrate.requests
3
>>> rrate.seconds
20
>>> rp.crawl_delay("*")
6
>>> rp.can_fetch("*", "http://www.musi-cal.com/cgi-bin/search?city=San+Francisco")
False
>>> rp.can_fetch("*", "http://www.musi-cal.com/"")
True
21.11. **http** — HTTP modules

**Source code:** Lib/http/__init__.py

`http` is a package that collects several modules for working with the HyperText Transfer Protocol:

- **http.client** is a low-level HTTP protocol client; for high-level URL opening use `urllib.request`
- **http.server** contains basic HTTP server classes based on `socketserver`
- **http.cookies** has utilities for implementing state management with cookies
- **http.cookiejar** provides persistence of cookies

`http` is also a module that defines a number of HTTP status codes and associated messages through the `http.HTTPStatus` enum:

```python
class http.HTTPStatus
    New in version 3.5.

    A subclass of `enum.IntEnum` that defines a set of HTTP status codes, reason phrases and long descriptions written in English.

Usage:

```python
>>> from http import HTTPStatus
>>> HTTPStatus.OK
<HTTPStatus.OK: 200>
>>> HTTPStatus.OK == 200
True
>>> http.HTTPStatus.OK.value
```
200
>>> HTTPStatus.OK.phrase
'OK'
>>> HTTPStatus.OK.description
'Request fulfilled, document follows'
>>> list(HTTPStatus)
[<HTTPStatus.CONTINUE: 100>, <HTTPStatus.SWITCHING_PROTOCOLS: 101>, ...]
## 21.11.1. HTTP status codes

Supported, IANA-registered status codes available in http.HTTPStatus are:

<table>
<thead>
<tr>

</table>
In order to preserve backwards compatibility, enum values are also present in the `http.client` module in the form of constants. The enum name is equal to the constant name (i.e. `http.HTTPStatus.OK` is also available as `http.client.OK`).

**Source code:** Lib/http/client.py

This module defines classes which implement the client side of the HTTP and HTTPS protocols. It is normally not used directly — the module `urllib.request` uses it to handle URLs that use HTTP and HTTPS.

**See also:** The Requests package is recommended for a higher-level HTTP client interface.

**Note:** HTTPS support is only available if Python was compiled with SSL support (through the ssl module).

The module provides the following classes:

```python
class http.client.HTTPConnection(host, port=None, [timeout, ]source_address=None)
```

An `HTTPConnection` instance represents one transaction with an HTTP server. It should be instantiated passing it a host and optional port number. If no port number is passed, the port is extracted from the host string if it has the form `host:port`, else the default HTTP port (80) is used. If the optional `timeout` parameter is given, blocking operations (like connection attempts) will timeout after that many seconds (if it is not given, the global default timeout setting is used). The optional `source_address` parameter may be a tuple of a (host, port) to use as the source
address the HTTP connection is made from.

For example, the following calls all create instances that connect to the server at the same host and port:

```python
>>> h1 = http.client.HTTPConnection('www.python.org')
>>> h2 = http.client.HTTPConnection('www.python.org:80')
>>> h3 = http.client.HTTPConnection('www.python.org')
>>> h4 = http.client.HTTPConnection('www.python.org')
```

*Changed in version 3.2:* `source_address` was added.

*Changed in version 3.4:* The `strict` parameter was removed. HTTP 0.9-style “Simple Responses” are not longer supported.

```python
class http.client.HTTPSConnection(host, port=None, key_file=None, cert_file=None, [timeout, ]source_address=None, *, context=None, check_hostname=None)
```

A subclass of `HTTPConnection` that uses SSL for communication with secure servers. Default port is `443`. If `context` is specified, it must be a `ssl.SSLContext` instance describing the various SSL options.

Please read Security considerations for more information on best practices.

*Changed in version 3.2:* `source_address`, `context` and `check_hostname` were added.

*Changed in version 3.2:* This class now supports HTTPS virtual hosts if possible (that is, if `ssl.HAS_SNI` is true).

*Changed in version 3.4:* The `strict` parameter was removed. HTTP
0.9-style “Simple Responses” are no longer supported.

*Changed in version 3.4.3:* This class now performs all the necessary certificate and hostname checks by default. To revert to the previous, unverified, behavior `ssl._create_unverified_context()` can be passed to the `context` parameter.

*Deprecated since version 3.6:* `key_file` and `cert_file` are deprecated in favor of `context`. Please use `ssl.SSLContext.load_cert_chain()` instead, or let `ssl.create_default_context()` select the system’s trusted CA certificates for you.

The `check_hostname` parameter is also deprecated; the `ssl.SSLContext.check_hostname` attribute of `context` should be used instead.

```python
class http.client.HTTPResponse(sock, debuglevel=0, method=None, url=None)
```

Class whose instances are returned upon successful connection. Not instantiated directly by user.

*Changed in version 3.4:* The `strict` parameter was removed. HTTP 0.9 style “Simple Responses” are no longer supported.

The following exceptions are raised as appropriate:

```python
exception http.client.HTTPException
```

The base class of the other exceptions in this module. It is a subclass of `Exception`.

```python
exception http.client.NotConnected
```
A subclass of `HTTPException`.

**exception** `http.client.InvalidURL`

A subclass of `HTTPException`, raised if a port is given and is either non-numeric or empty.

**exception** `http.client.UnknownProtocol`

A subclass of `HTTPException`.

**exception** `http.client.UnknownTransferEncoding`

A subclass of `HTTPException`.

**exception** `http.client.UnimplementedFileMode`

A subclass of `HTTPException`.

**exception** `http.clientIncompleteRead`

A subclass of `HTTPException`.

**exception** `http.client.ImproperConnectionState`

A subclass of `HTTPException`.

**exception** `http.client.CannotSendRequest`

A subclass of `ImproperConnectionState`.

**exception** `http.client.CannotSendHeader`

A subclass of `ImproperConnectionState`.

**exception** `http.client.ResponseNotReady`

A subclass of `ImproperConnectionState`.

**exception** `http.client.BadStatusLine`

A subclass of `HTTPException`. Raised if a server responds with a HTTP status code that we don't understand.
exception http.client.LineTooLong

A subclass of HTTPException. Raised if an excessively long line is received in the HTTP protocol from the server.

exception http.client.RemoteDisconnected

A subclass of ConnectionResetError and BadStatusLine. Raised by HTTPConnection.getresponse() when the attempt to read the response results in no data read from the connection, indicating that the remote end has closed the connection.

New in version 3.5: Previously, BadStatusLine('') was raised.

The constants defined in this module are:

http.client.HTTP_PORT

The default port for the HTTP protocol (always 80).

http.client.HTTPS_PORT

The default port for the HTTPS protocol (always 443).

http.client.responses

This dictionary maps the HTTP 1.1 status codes to the W3C names.

Example:

http.client.responses[http.client.NOT_FOUND] is 'Not Found'.

See HTTP status codes for a list of HTTP status codes that are available in this module as constants.
21.12.1. HTTPConnection Objects

HTTPConnection instances have the following methods:

```
HTTPConnection.request(method, url, body=None, headers={}, *, encode_chunked=False)
```

This will send a request to the server using the HTTP request method `method` and the selector `url`.

If `body` is specified, the specified data is sent after the headers are finished. It may be a `str`, a bytes-like object, an open file object, or an iterable of bytes. If `body` is a string, it is encoded as ISO-8859-1, the default for HTTP. If it is a bytes-like object, the bytes are sent as is. If it is a file object, the contents of the file is sent; this file object should support at least the `read()` method. If the file object is an instance of `io.TextIOBase`, the data returned by the `read()` method will be encoded as ISO-8859-1, otherwise the data returned by `read()` is sent as is. If `body` is an iterable, the elements of the iterable are sent as is until the iterable is exhausted.

The `headers` argument should be a mapping of extra HTTP headers to send with the request.

If `headers` contains neither Content-Length nor Transfer-Encoding, but there is a request body, one of those header fields will be added automatically. If `body` is `None`, the Content-Length header is set to 0 for methods that expect a body (PUT, POST, and PATCH). If `body` is a string or a bytes-like object that is not also a file, the Content-Length header is set to its length. Any other type of `body` (files and iterables in general) will be chunk-encoded, and the
Transfer-Encoding header will automatically be set instead of Content-Length.

The `encode_chunked` argument is only relevant if Transfer-Encoding is specified in `headers`. If `encode_chunked` is `False`, the HTTPConnection object assumes that all encoding is handled by the calling code. If it is `True`, the body will be chunk-encoded.

**Note:** Chunked transfer encoding has been added to the HTTP protocol version 1.1. Unless the HTTP server is known to handle HTTP 1.1, the caller must either specify the Content-Length, or must pass a `str` or bytes-like object that is not also a file as the body representation.

*New in version 3.2:* `body` can now be an iterable.

*Changed in version 3.6:* If neither Content-Length nor Transfer-Encoding are set in `headers`, file and iterable `body` objects are now chunk-encoded. The `encode_chunked` argument was added. No attempt is made to determine the Content-Length for file objects.

**HTTPConnection.** `getresponse()`

Should be called after a request is sent to get the response from the server. Returns an `HTTPResponse` instance.

**Note:** Note that you must have read the whole response before you can send a new request to the server.

*Changed in version 3.5:* If a `ConnectionError` or subclass is raised, the `HTTPConnection` object will be ready to reconnect when a new request is sent.

**HTTPConnection.** `set_debuglevel(level)`
Set the debugging level. The default debug level is 0, meaning no debugging output is printed. Any value greater than 0 will cause all currently defined debug output to be printed to stdout. The debuglevel is passed to any new HTTPResponse objects that are created.

New in version 3.1.

HTTPConnection.set_tunnel(host, port=None, headers=None)
Set the host and the port for HTTP Connect Tunnelling. This allows running the connection through a proxy server.

The host and port arguments specify the endpoint of the tunneled connection (i.e. the address included in the CONNECT request, not the address of the proxy server).

The headers argument should be a mapping of extra HTTP headers to send with the CONNECT request.

For example, to tunnel through a HTTPS proxy server running locally on port 8080, we would pass the address of the proxy to the HTTPSConnection constructor, and the address of the host that we eventually want to reach to the set_tunnel() method:

```python
>>> import http.client
>>> conn = http.client.HTTPSConnection("localhost
>>> conn.set_tunnel("www.python.org")
>>> conn.request("HEAD","/index.html")
```

New in version 3.2.

HTTPConnection.connect()
Connect to the server specified when the object was created. By
default, this is called automatically when making a request if the client does not already have a connection.

HTTPConnection.close()
Close the connection to the server.

As an alternative to using the request() method described above, you can also send your request step by step, by using the four functions below.

HTTPConnection.putrequest(method, url, skip_host=False, skip_accept_encoding=False)
This should be the first call after the connection to the server has been made. It sends a line to the server consisting of the method string, the url string, and the HTTP version (HTTP/1.1). To disable automatic sending of Host: or Accept-Encoding: headers (for example to accept additional content encodings), specify skip_host or skip_accept_encoding with non-False values.

HTTPConnection.putheader(header, argument[, ...])
Send an RFC 822-style header to the server. It sends a line to the server consisting of the header, a colon and a space, and the first argument. If more arguments are given, continuation lines are sent, each consisting of a tab and an argument.

HTTPConnection.endheaders(message_body=None, *, encode_chunked=False)
Send a blank line to the server, signalling the end of the headers. The optional message_body argument can be used to pass a message body associated with the request.

If encode_chunked is True, the result of each iteration of
message_body will be chunk-encoded as specified in RFC 7230, Section 3.3.1. How the data is encoded is dependent on the type of message_body. If message_body implements the buffer interface the encoding will result in a single chunk. If message_body is a collections.Iterable, each iteration of message_body will result in a chunk. If message_body is a file object, each call to .read() will result in a chunk. The method automatically signals the end of the chunk-encoded data immediately after message_body.

**Note:** Due to the chunked encoding specification, empty chunks yielded by an iterator body will be ignored by the chunk-encoder. This is to avoid premature termination of the read of the request by the target server due to malformed encoding.

*New in version 3.6:* Chunked encoding support. The encode_chunked parameter was added.

HTTPConnection.**send**(data)

Send data to the server. This should be used directly only after the endheaders() method has been called and before getresponse() is called.
21.12.2. HTTPResponse Objects

An HTTPResponse instance wraps the HTTP response from the server. It provides access to the request headers and the entity body. The response is an iterable object and can be used in a with statement.

*Changed in version 3.5:* The io.BufferedIOBase interface is now implemented and all of its reader operations are supported.

HTTPResponse.read([amt])

Reads and returns the response body, or up to the next amt bytes.

HTTPResponse.readinto(b)

Reads up to the next len(b) bytes of the response body into the buffer b. Returns the number of bytes read.

*New in version 3.3.*

HTTPResponse.getheader(name, default=None)

Return the value of the header name, or default if there is no header matching name. If there is more than one header with the name name, return all of the values joined by ‘,’. If ‘default’ is any iterable other than a single string, its elements are similarly returned joined by commas.

HTTPResponse.getheaders()

Return a list of (header, value) tuples.

HTTPResponse.fileno()

Return the fileno of the underlying socket.
**HTTPResponse**. `msg`

**HTTPResponse**. `version`
HTTP protocol version used by server. 10 for HTTP/1.0, 11 for HTTP/1.1.

**HTTPResponse**. `status`
Status code returned by server.

**HTTPResponse**. `reason`
Reason phrase returned by server.

**HTTPResponse**. `debuglevel`
A debugging hook. If `debuglevel` is greater than zero, messages will be printed to stdout as the response is read and parsed.

**HTTPResponse**. `closed`
Is `True` if the stream is closed.
21.12.3. Examples

Here is an example session that uses the GET method:

```python
>>> import http.client
>>> conn = http.client.HTTPSConnection("www.python.org")
>>> conn.request("GET", "/")
>>> r1 = conn.getresponse()
>>> print(r1.status, r1.reason)
200 OK
>>> data1 = r1.read()  # This will return entire content.
>>> # The following example demonstrates reading data in chunks.
>>> conn.request("GET", "/")
>>> r1 = conn.getresponse()
>>> while not r1.closed:
...     print(r1.read(200))  # 200 bytes
b'<!doctype html>\n<![
...     ...
>>> # Example of an invalid request
>>> conn.request("GET", "/parrot.spam")
>>> r2 = conn.getresponse()
>>> print(r2.status, r2.reason)
404 Not Found
>>> data2 = r2.read()
>>> conn.close()
```

Here is an example session that uses the HEAD method. Note that the HEAD method never returns any data.

```python
>>> import http.client
>>> conn = http.client.HTTPSConnection("www.python.org")
>>> conn.request("HEAD", "/")
>>> res = conn.getresponse()
>>> print(res.status, res.reason)
```
Here is an example session that shows how to POST requests:

```python
>>> import http.client, urllib.parse
>>> params = urllib.parseurlencode({ '@number': 12524 })
>>> headers = {'Content-type': 'application/x-www-form-urlencoded',
...    'Accept': 'text/plain'}
>>> conn = http.client.HTTPConnection("bugs.python.org")
>>> conn.request("POST", ", params, headers)
>>> response = conn.getresponse()
>>> print(response.status, response.reason)
302 Found
>>> data = response.read()
>>> data
b'Redirecting to <a href="http://bugs.python.org/issue12524">http://bugs.python.org/issue12524</a>
>>> conn.close()
```

Client side HTTP PUT requests are very similar to POST requests. The difference lies only the server side where HTTP server will allow resources to be created via PUT request. It should be noted that custom HTTP methods are also handled in `urllib.request.Request` by sending the appropriate `method` attribute. Here is an example session that shows how to do PUT request using http.client:

```python
>>> # This creates an HTTP message
>>> # with the content of BODY as the enclosed representation
>>> # for the resource http://localhost:8080/file
```
... >>> import http.client
>>> BODY = "***filecontents***"
>>> conn = http.client.HTTPConnection("localhost", 8080)
>>> conn.request("PUT", "/file", BODY)
>>> response = conn.getresponse()
>>> print(response.status, response.reason)
200, OK
21.12.4. HTTPMessage Objects

An http.client.HTTPMessage instance holds the headers from an HTTP response. It is implemented using the email.message.Message class.
This module defines the class FTP and a few related items. The FTP class implements the client side of the FTP protocol. You can use this to write Python programs that perform a variety of automated FTP jobs, such as mirroring other FTP servers. It is also used by the module urllib.request to handle URLs that use FTP. For more information on FTP (File Transfer Protocol), see Internet RFC 959.

Here's a sample session using the ftplib module:

```python
>>> from ftplib import FTP
>>> ftp = FTP('ftp.debian.org')  # connect to host
>>> ftp.login()                 # user anonymous
'230 Login successful.'
>>> ftp.cwd('debian')          # change into "debian" directory
>>> ftp.retrlines('LIST')      # list directory contents
-rw-rw-r-- 1 1176 1176 1063 Jun 15 10:18 README...
  ...
  drwxr-sr-x 5 1176 1176 4096 Dec 19 2000 pool
  drwxr-sr-x 4 1176 1176 4096 Nov 17 2008 project
  drwxr-xr-x 3 1176 1176 4096 Oct 10 2012 tools
'226 Directory send OK.'
>>> ftp.retrbinary('RETR README', open('README', 'wb'))
'226 Transfer complete.'
>>> ftp.quit()
```

The module defines the following items:
class ftplib.FTP(host='', user='', passwd='', acct='', timeout=None, source_address=None)

Return a new instance of the FTP class. When host is given, the method call connect(host) is made. When user is given, additionally the method call login(user, passwd, acct) is made (where passwd and acct default to the empty string when not given). The optional timeout parameter specifies a timeout in seconds for blocking operations like the connection attempt (if is not specified, the global default timeout setting will be used). source_address is a 2-tuple (host, port) for the socket to bind to as its source address before connecting.

The FTP class supports the with statement, e.g.:

```python
>>> from ftplib import FTP
>>> with FTP("ftp1.at.proftpd.org") as ftp:
...     ftp.login()
...     ftp.dir()
... '230 Anonymous login ok, restrictions apply.'
   dr-xr-xr-x  9 ftp    ftp          154 May   6
   dr-xr-xr-x  9 ftp    ftp          154 May   6
   dr-xr-xr-x  5 ftp    ftp          4096 May  6
   dr-xr-xr-x  3 ftp    ftp           18 Jul  10
```  

*Changed in version 3.2:* Support for the with statement was added.

*Changed in version 3.3:* source_address parameter was added.

class ftplib.FTP_TLS(host='', user='', passwd='', acct='',
keyfile=None, certfile=None, context=None, timeout=None,
A FTP subclass which adds TLS support to FTP as described in RFC 4217. Connect as usual to port 21 implicitly securing the FTP control connection before authenticating. Securing the data connection requires the user to explicitly ask for it by calling the prot_p() method. context is a ssl.SSLContext object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security considerations for best practices.

keyfile and certfile are a legacy alternative to context – they can point to PEM-formatted private key and certificate chain files (respectively) for the SSL connection.

New in version 3.2.

Changed in version 3.3: source_address parameter was added.

Changed in version 3.4: The class now supports hostname check with ssl.SSLContext.check_hostname and Server Name Indication (see ssl.HAS_SNI).

Deprecated since version 3.6: keyfile and certfile are deprecated in favor of context. Please use ssl.SSLContext.load_cert_chain() instead, or let ssl.create_default_context() select the system’s trusted CA certificates for you.

Here’s a sample session using the FTP_TLS class:

```python
>>> ftps = FTP_TLS('ftp.pureftpd.org')
>>> ftps.login()
'230 Anonymous user logged in'
```
exception `ftplib.error_reply`
Exception raised when an unexpected reply is received from the server.

exception `ftplib.error_temp`
Exception raised when an error code signifying a temporary error (response codes in the range 400–499) is received.

exception `ftplib.error_perm`
Exception raised when an error code signifying a permanent error (response codes in the range 500–599) is received.

exception `ftplib.error_proto`
Exception raised when a reply is received from the server that does not fit the response specifications of the File Transfer Protocol, i.e. begin with a digit in the range 1–5.

`ftplib.all_errors`
The set of all exceptions (as a tuple) that methods of FTP instances may raise as a result of problems with the FTP connection (as opposed to programming errors made by the caller). This set includes the four exceptions listed above as well as OSError.

See also:
Module `netrc`
Parser for the `.netrc` file format. The file `.netrc` is typically
used by FTP clients to load user authentication information before prompting the user.
21.13.1. FTP Objects

Several methods are available in two flavors: one for handling text files and another for binary files. These are named for the command which is used followed by lines for the text version or binary for the binary version.

FTP instances have the following methods:

FTP.set_debuglevel(level)
Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

FTP.connect(host='', port=0, timeout=None, source_address=None)
Connect to the given host and port. The default port number is 21, as specified by the FTP protocol specification. It is rarely needed to specify a different port number. This function should be called only once for each instance; it should not be called at all if a host was given when the instance was created. All other methods can only be used after a connection has been made. The optional timeout parameter specifies a timeout in seconds for the connection attempt. If no timeout is passed, the global default timeout setting will be used. source_address is a 2-tuple (host, port) for the socket to bind to as its source address before connecting.

Changed in version 3.3: source_address parameter was added.
FTP. `getwelcome()`

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

FTP. `login(user='anonymous', passwd='', acct='')`  

Log in as the given `user`. The `passwd` and `acct` parameters are optional and default to the empty string. If no `user` is specified, it defaults to 'anonymous'. If `user` is 'anonymous', the default `passwd` is 'anonymous@'. This function should be called only once for each instance, after a connection has been established; it should not be called at all if a host and user were given when the instance was created. Most FTP commands are only allowed after the client has logged in. The `acct` parameter supplies “accounting information”; few systems implement this.

FTP. `abort()`  

Abort a file transfer that is in progress. Using this does not always work, but it’s worth a try.

FTP. `sendcmd(cmd)`  

Send a simple command string to the server and return the response string.

FTP. `voidcmd(cmd)`  

Send a simple command string to the server and handle the response. Return nothing if a response code corresponding to success (codes in the range 200–299) is received. Raise `error_reply` otherwise.

FTP. `retrbinary(cmd, callback, blocksize=8192, rest=None)`  

Retrieve a file in binary transfer mode. `cmd` should be an
appropriate RETR command: 'RETR filename'. The callback function is called for each block of data received, with a single bytes argument giving the data block. The optional blocksize argument specifies the maximum chunk size to read on the low-level socket object created to do the actual transfer (which will also be the largest size of the data blocks passed to callback). A reasonable default is chosen. rest means the same thing as in the transfercmd() method.

FTP. retrlines(cmd, callback=None)
Retrieve a file or directory listing in ASCII transfer mode. cmd should be an appropriate RETR command (see retrbinary()) or a command such as LIST or NLST (usually just the string 'LIST'). LIST retrieves a list of files and information about those files. NLST retrieves a list of file names. The callback function is called for each line with a string argument containing the line with the trailing CRLF stripped. The default callback prints the line to sys.stdout.

FTP. set_pasv(val)
Enable “passive” mode if val is true, otherwise disable passive mode. Passive mode is on by default.

FTP. storbinary(cmd, fp, blocksize=8192, callback=None, rest=None)
Store a file in binary transfer mode. cmd should be an appropriate STOR command: "STOR filename". fp is a file object (opened in binary mode) which is read until EOF using its read() method in blocks of size blocksize to provide the data to be stored. The blocksize argument defaults to 8192. callback is an optional single parameter callable that is called on each block of data after it is
sent. *rest* means the same thing as in the `transfercmd()` method.

*Changed in version 3.2: rest parameter added.*

**FTP. `storlines(cmd, fp, callback=None)`**

Store a file in ASCII transfer mode. *cmd* should be an appropriate STOR command (see `storbinary()`). Lines are read until EOF from the file object *fp* (opened in binary mode) using its `readline()` method to provide the data to be stored. *callback* is an optional single parameter callable that is called on each line after it is sent.

**FTP. `transfercmd(cmd, rest=None)`**

Initiate a transfer over the data connection. If the transfer is active, send an EPRT or PORT command and the transfer command specified by *cmd*, and accept the connection. If the server is passive, send an EPSV or PASV command, connect to it, and start the transfer command. Either way, return the socket for the connection.

If optional *rest* is given, a REST command is sent to the server, passing *rest* as an argument. *rest* is usually a byte offset into the requested file, telling the server to restart sending the file’s bytes at the requested offset, skipping over the initial bytes. Note however that RFC 959 requires only that *rest* be a string containing characters in the printable range from ASCII code 33 to ASCII code 126. The `transfercmd()` method, therefore, converts *rest* to a string, but no check is performed on the string’s contents. If the server does not recognize the REST command, an `error_reply` exception will be raised. If this happens, simply call `transfercmd()` without a *rest* argument.
FTP.\texttt{nttransfercmd}(\texttt{cmd}, \texttt{rest=None})

Like \texttt{transfercmd()}, but returns a tuple of the data connection and the expected size of the data. If the expected size could not be computed, \texttt{None} will be returned as the expected size. \texttt{cmd} and \texttt{rest} means the same thing as in \texttt{transfercmd()}.

FTP.\texttt{mlsd}(\texttt{path=""}, \texttt{facts=[]})

List a directory in a standardized format by using MLSD command (\texttt{RFC 3659}). If \texttt{path} is omitted the current directory is assumed. \texttt{facts} is a list of strings representing the type of information desired (e.g. ["type", "size", "perm"]). Return a generator object yielding a tuple of two elements for every file found in path. First element is the file name, the second one is a dictionary containing facts about the file name. Content of this dictionary might be limited by the \texttt{facts} argument but server is not guaranteed to return all requested facts.

\textit{New in version 3.3.}

FTP.\texttt{nlst}(\texttt{argument[...]}])

Return a list of file names as returned by the NLST command. The optional \texttt{argument} is a directory to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the NLST command.

\textbf{Note:} If your server supports the command, \texttt{mlsd()} offers a better API.

FTP.\texttt{dir}(\texttt{argument[...]}])

Produce a directory listing as returned by the LIST command, printing it to standard output. The optional \texttt{argument} is a directory
to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the `LIST` command. If the last argument is a function, it is used as a `callback` function as for `retrlines()`; the default prints to `sys.stdout`. This method returns `None`.

**Note:** If your server supports the command, `mlsd()` offers a better API.

FTP. **rename**(fromname, toname)

Rename file fromname on the server to toname.

FTP. **delete**(filename)

Remove the file named filename from the server. If successful, returns the text of the response, otherwise raises `error_perm` on permission errors or `error_reply` on other errors.

FTP. **cwd**(pathname)

Set the current directory on the server.

FTP. **mkd**(pathname)

Create a new directory on the server.

FTP. **pwd**( )

Return the pathname of the current directory on the server.

FTP. **rmd**(dirname)

Remove the directory named dirname on the server.

FTP. **size**(filename)

Request the size of the file named filename on the server. On success, the size of the file is returned as an integer, otherwise
None is returned. Note that the SIZE command is not standardized, but is supported by many common server implementations.

**FTP.quit()**
Send a QUIT command to the server and close the connection. This is the “polite” way to close a connection, but it may raise an exception if the server responds with an error to the QUIT command. This implies a call to the close() method which renders the FTP instance useless for subsequent calls (see below).

**FTP.close()**
Close the connection unilaterally. This should not be applied to an already closed connection such as after a successful call to quit(). After this call the FTP instance should not be used any more (after a call to close() or quit() you cannot reopen the connection by issuing another login() method).
21.13.2. FTP_TLS Objects

FTP_TLS class inherits from FTP, defining these additional objects:

FTP_TLS.ssl_version

The SSL version to use (defaults to ssl.PROTOCOL_SSLv23).

FTP_TLS.auth()

Set up a secure control connection by using TLS or SSL, depending on what is specified in the ssl_version attribute.

*Changed in version 3.4:* The method now supports hostname check with ssl.SSLContext.check_hostname and Server Name Indication (see ssl.HAS_SNI).

FTP_TLS.ccc()

Revert control channel back to plaintext. This can be useful to take advantage of firewalls that know how to handle NAT with non-secure FTP without opening fixed ports.

*New in version 3.3.*

FTP_TLS.prot_p()

Set up secure data connection.

FTP_TLS.prot_c()

Set up clear text data connection.
This module defines a class, `POP3`, which encapsulates a connection to a POP3 server and implements the protocol as defined in RFC 1939. The `POP3` class supports both the minimal and optional command sets from RFC 1939. The `POP3` class also supports the STLS command introduced in RFC 2595 to enable encrypted communication on an already established connection.

Additionally, this module provides a class `POP3_SSL`, which provides support for connecting to POP3 servers that use SSL as an underlying protocol layer.

Note that POP3, though widely supported, is obsolescent. The implementation quality of POP3 servers varies widely, and too many are quite poor. If your mailserver supports IMAP, you would be better off using the `imaplib.IMAP4` class, as IMAP servers tend to be better implemented.

The `poplib` module provides two classes:

```python
class poplib.POP3(host, port=POP3_PORT[, timeout])
```

This class implements the actual POP3 protocol. The connection is created when the instance is initialized. If `port` is omitted, the standard POP3 port (110) is used. The optional `timeout` parameter specifies a timeout in seconds for the connection attempt (if not
specified, the global default timeout setting will be used).

class poplib.POP3_SSL(host, port=POP3_SSL_PORT, keyfile=None, certfile=None, timeout=None, context=None)

This is a subclass of POP3 that connects to the server over an SSL encrypted socket. If port is not specified, 995, the standard POP3-over-SSL port is used. timeout works as in the POP3 constructor. context is an optional ssl.SSLContext object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security considerations for best practices.

keyfile and certfile are a legacy alternative to context - they can point to PEM-formatted private key and certificate chain files, respectively, for the SSL connection.

 Changed in version 3.2: context parameter added.

 Changed in version 3.4: The class now supports hostname check with ssl.SSLContext.check_hostname and Server Name Indication (see ssl.HAS_SNI).

 Deprecated since version 3.6: keyfile and certfile are deprecated in favor of context. Please use ssl.SSLContext.load_cert_chain() instead, or let ssl.create_default_context() select the system’s trusted CA certificates for you.

One exception is defined as an attribute of the poplib module:

exception poplib.error_proto

Exception raised on any errors from this module (errors from socket module are not caught). The reason for the exception is
passed to the constructor as a string.

See also:

Module **imaplib**
The standard Python IMAP module.

**Frequently Asked Questions About Fetchmail**
The FAQ for the **fetchmail** POP/IMAP client collects information on POP3 server variations and RFC noncompliance that may be useful if you need to write an application based on the POP protocol.
21.14.1. POP3 Objects

All POP3 commands are represented by methods of the same name, in lower-case; most return the response text sent by the server.

An POP3 instance has the following methods:

**POP3. `set_debuglevel(level)`**
Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

**POP3. `getwelcome()`**
Returns the greeting string sent by the POP3 server.

**POP3. `capa()`**
Query the server's capabilities as specified in RFC 2449. Returns a dictionary in the form `{ 'name': [ 'param'...] }`.

*New in version 3.4.*

**POP3. `user(username)`**
Send user command, response should indicate that a password is required.

**POP3. `pass_(password)`**
Send password, response includes message count and mailbox size. Note: the mailbox on the server is locked until `quit()` is called.
POP3. **apop**(user, secret)

Use the more secure APOP authentication to log into the POP3 server.

POP3. **rpop**(user)

Use RPOP authentication (similar to UNIX r-commands) to log into POP3 server.

POP3. **stat()**

Get mailbox status. The result is a tuple of 2 integers: (message count, mailbox size).

POP3. **list([which])**

Request message list, result is in the form (response, ['mesg_num octets', ...], octets). If which is set, it is the message to list.

POP3. **retr**(which)

Retrieve whole message number which, and set its seen flag. Result is in form (response, ['line', ...], octets).

POP3. **dele**(which)

Flag message number which for deletion. On most servers deletions are not actually performed until QUIT (the major exception is Eudora QPOP, which deliberately violates the RFCs by doing pending deletes on any disconnect).

POP3. **rset()**

Remove any deletion marks for the mailbox.

POP3. **noop()**

Do nothing. Might be used as a keep-alive.
POP3. **quit()**

Signoff: commit changes, unlock mailbox, drop connection.

POP3. **top**(which, howmuch)

Retrieves the message header plus *howmuch* lines of the message after the header of message number *which*. Result is in form *(response, ['line', ...], octets)*.

The POP3 TOP command this method uses, unlike the RETR command, doesn’t set the message’s seen flag; unfortunately, TOP is poorly specified in the RFCs and is frequently broken in off-brand servers. Test this method by hand against the POP3 servers you will use before trusting it.

POP3. **uidl**(which=None)

Return message digest (unique id) list. If *which* is specified, result contains the unique id for that message in the form *response mesgnum uid*, otherwise result is list *(response, ['mesgnum uid', ...], octets)*.

POP3. **utf8()**

Try to switch to UTF-8 mode. Returns the server response if successful, raises *error_proto* if not. Specified in RFC 6856.

*New in version 3.5.*

POP3. **stls**(context=None)

Start a TLS session on the active connection as specified in RFC 2595. This is only allowed before user authentication

*context* parameter is a *ssl.SSLContext* object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security
considerations for best practices.

This method supports hostname checking via \texttt{ssl\textunderscore SSLContext\textunderscore check\_hostname} and \textit{Server Name Indication} (see \texttt{ssl\textunderscore HAS\_SNI}).

\textit{New in version 3.4.}

Instances of \texttt{POP3\_SSL} have no additional methods. The interface of this subclass is identical to its parent.
21.14.2. POP3 Example

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```python
import getpass, poplib

M = poplib.POP3('localhost')
M.user(getpass.getuser())
M.pass_(getpass.getpass())
numMessages = len(M.list()[1])
for i in range(numMessages):
    for j in M.retr(i+1)[1]:
        print(j)
```

At the end of the module, there is a test section that contains a more extensive example of usage.
This module defines three classes, **IMAP4**, **IMAP4_SSL** and **IMAP4_stream**, which encapsulate a connection to an IMAP4 server and implement a large subset of the IMAP4rev1 client protocol as defined in **RFC 2060**. It is backward compatible with IMAP4 (**RFC 1730**) servers, but note that the STATUS command is not supported in IMAP4.

Three classes are provided by the `imaplib` module, **IMAP4** is the base class:

```python
class imaplib.IMAP4(host="", port=IMAP4_PORT)
```

This class implements the actual IMAP4 protocol. The connection is created and protocol version (IMAP4 or IMAP4rev1) is determined when the instance is initialized. If `host` is not specified, `''` (the local host) is used. If `port` is omitted, the standard IMAP4 port (143) is used.

The **IMAP4** class supports the `with` statement. When used like this, the IMAP4 **LOGOUT** command is issued automatically when the `with` statement exits. E.g.:

```python
>>> from imaplib import IMAP4
>>> with IMAP4("domain.org") as M:
...     M.noop()
...```
Changed in version 3.5: Support for the `with` statement was added.

Three exceptions are defined as attributes of the `IMAP4` class:

`exception IMAP4.error`

Exception raised on any errors. The reason for the exception is passed to the constructor as a string.

`exception IMAP4.abort`

IMAP4 server errors cause this exception to be raised. This is a sub-class of `IMAP4.error`. Note that closing the instance and instantiating a new one will usually allow recovery from this exception.

`exception IMAP4.readonly`

This exception is raised when a writable mailbox has its status changed by the server. This is a sub-class of `IMAP4.error`. Some other client now has write permission, and the mailbox will need to be re-opened to re-obtain write permission.

There’s also a subclass for secure connections:

`class imaplib.IMAP4_SSL(host='', port=IMAP4_SSL_PORT, keyfile=None, certfile=None, ssl_context=None)`

This is a subclass derived from `IMAP4` that connects over an SSL encrypted socket (to use this class you need a socket module that was compiled with SSL support). If `host` is not specified, '' (the local host) is used. If `port` is omitted, the standard IMAP4-over-SSL port (993) is used. `ssl_context` is a `ssl.SSLContext` object which
allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security considerations for best practices.

`keyfile` and `certfile` are a legacy alternative to `ssl_context` - they can point to PEM-formatted private key and certificate chain files for the SSL connection. Note that the `keyfile/certfile` parameters are mutually exclusive with `ssl_context`, a `ValueError` is raised if `keyfile/certfile` is provided along with `ssl_context`.

*Changed in version 3.3:* `ssl_context` parameter added.

*Changed in version 3.4:* The class now supports hostname check with `ssl.SSLContext.check_hostname` and Server Name Indication (see `ssl.HAS_SNI`).

*Deprecated since version 3.6:* `keyfile` and `certfile` are deprecated in favor of `ssl_context`. Please use `ssl.SSLContext.load_cert_chain()` instead, or let `ssl.create_default_context()` select the system's trusted CA certificates for you.

The second subclass allows for connections created by a child process:

```python
class imaplib.IMAP4_stream(command)
```

This is a subclass derived from `IMAP4` that connects to the `stdin/stdout` file descriptors created by passing `command` to `subprocess.Popen()`.

The following utility functions are defined:

```python
imaplib.Internaldate2tuple(datestr)
```
Parse an IMAP4 INTERNALDATE string and return corresponding local time. The return value is a time.struct_time tuple or None if the string has wrong format.

imaplib.Int2AP(num)
Converts an integer into a string representation using characters from the set [A .. P].

imaplib.ParseFlags(flagstr)
Converts an IMAP4 FLAGS response to a tuple of individual flags.

imaplib.Time2Internaldate(date_time)
Convert date_time to an IMAP4 INTERNALDATE representation. The return value is a string in the form: "DD-Mmm-YYYY HH:MM:SS +HHMM" (including double-quotes). The date_time argument can be a number (int or float) representing seconds since epoch (as returned by time.time()), a 9-tuple representing local time an instance of time.struct_time (as returned by time.localtime()), an aware instance of datetime.datetime, or a double-quoted string. In the last case, it is assumed to already be in the correct format.

Note that IMAP4 message numbers change as the mailbox changes; in particular, after an EXPUNGE command performs deletions the remaining messages are renumbered. So it is highly advisable to use UIDs instead, with the UID command.

At the end of the module, there is a test section that contains a more extensive example of usage.

See also: Documents describing the protocol, and sources and binaries for servers implementing it, can all be found at the
University of Washington’s *IMAP Information Center* (https://www.washington.edu/imap/).
21.15.1. IMAP4 Objects

All IMAP4rev1 commands are represented by methods of the same name, either upper-case or lower-case.

All arguments to commands are converted to strings, except for AUTHENTICATE, and the last argument to APPEND which is passed as an IMAP4 literal. If necessary (the string contains IMAP4 protocol-sensitive characters and isn’t enclosed with either parentheses or double quotes) each string is quoted. However, the password argument to the LOGIN command is always quoted. If you want to avoid having an argument string quoted (eg: the flags argument to STORE) then enclose the string in parentheses (eg: r'(\Deleted)').

Each command returns a tuple: (type, [data, ...]) where type is usually 'OK' or 'NO', and data is either the text from the command response, or mandated results from the command. Each data is either a string, or a tuple. If a tuple, then the first part is the header of the response, and the second part contains the data (ie: ‘literal’ value).

The message_set options to commands below is a string specifying one or more messages to be acted upon. It may be a simple message number (‘1’), a range of message numbers (‘2:4’), or a group of non-contiguous ranges separated by commas (‘1:3, 6:9’). A range can contain an asterisk to indicate an infinite upper bound (‘3:*’).

An IMAP4 instance has the following methods:

IMAP4.append(mailbox, flags, date_time, message)
    Append message to named mailbox.
**IMAP4. authenticate**(*mechanism, authobject*)

Authenticate command — requires response processing.

*mechanism* specifies which authentication mechanism is to be used - it should appear in the instance variable capabilities in the form AUTH=mechanism.

*authobject* must be a callable object:

```python
data = authobject(response)
```

It will be called to process server continuation responses; the *response* argument it is passed will be bytes. It should return bytes *data* that will be base64 encoded and sent to the server. It should return *None* if the client abort response * should be sent instead.

*Changed in version 3.5*: string usernames and passwords are now encoded to utf-8 instead of being limited to ASCII.

**IMAP4. check()**

Checkpoint mailbox on server.

**IMAP4. close()**

Close currently selected mailbox. Deleted messages are removed from writable mailbox. This is the recommended command before LOGOUT.

**IMAP4. copy**(*message_set, new_mailbox*)

Copy *message_set* messages onto end of *new_mailbox*.

**IMAP4. create**(*mailbox*)

Create new mailbox named *mailbox*. 
IMAP4. **delete*(mailbox)*
Delete old mailbox named *mailbox*.

IMAP4. **deleteacl*(mailbox, who)*
Delete the ACLs (remove any rights) set for who on mailbox.

IMAP4. **enable*(capability)*
Enable *capability* (see RFC 5161). Most capabilities do not need to be enabled. Currently only the **UTF8=ACCEPT** capability is supported (see RFC 6855).

*New in version 3.5:* The **enable()** method itself, and RFC 6855 support.

IMAP4. **expunge()**
Permanently remove deleted items from selected mailbox. Generates an **EXPUNGE** response for each deleted message. Returned data contains a list of **EXPUNGE** message numbers in order received.

IMAP4. **fetch**(message_set, message_parts)
Fetch (parts of) messages. *message_parts* should be a string of message part names enclosed within parentheses, eg: "(UID BODY[TEXT])". Returned data are tuples of message part envelope and data.

IMAP4. **getacl*(mailbox)*
Get the ACLs for *mailbox*. The method is non-standard, but is supported by the Cyrus server.

IMAP4. **getannotation**(mailbox, entry, attribute)
Retrieve the specified **ANNOTATIONs** for *mailbox*. The method is
non-standard, but is supported by the Cyrus server.

**IMAP4. `getquota(root)`**

Get the quota root's resource usage and limits. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

**IMAP4. `getquotaroot(mailbox)`**

Get the list of quota roots for the named mailbox. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

**IMAP4. `list([directory[, pattern]])`**

List mailbox names in directory matching pattern. directory defaults to the top-level mail folder, and pattern defaults to match anything. Returned data contains a list of LIST responses.

**IMAP4. `login(user, password)`**

Identify the client using a plaintext password. The password will be quoted.

**IMAP4. `login_cram_md5(user, password)`**

Force use of CRAM-MD5 authentication when identifying the client to protect the password. Will only work if the server CAPABILITY response includes the phrase AUTH=CRAM-MD5.

**IMAP4. `logout()`**

Shutdown connection to server. Returns server BYE response.

**IMAP4. `lsub(directory="", pattern="*")`**

List subscribed mailbox names in directory matching pattern. directory defaults to the top level directory and pattern defaults to match any mailbox. Returned data are tuples of message part envelope and data.
**IMAP4. myrights**(*mailbox*)
Show my ACLs for a mailbox (i.e. the rights that I have on mailbox).

**IMAP4. namespace()**
Returns IMAP namespaces as defined in RFC2342.

**IMAP4. noop()**
Send `NOOP` to server.

**IMAP4. open**(*host*, *port*)
Opens socket to *port* at *host*. This method is implicitly called by the IMAP4 constructor. The connection objects established by this method will be used in the `IMAP4.read()`, `IMAP4.readline()`, `IMAP4.send()`, and `IMAP4.shutdown()` methods. You may override this method.

**IMAP4. partial**(*message_num*, *message_part*, *start*, *length*)
Fetch truncated part of a message. Returned data is a tuple of message part envelope and data.

**IMAP4. proxyauth**(*user*)
Assume authentication as *user*. Allows an authorised administrator to proxy into any user’s mailbox.

**IMAP4. read**(*size*)
Reads *size* bytes from the remote server. You may override this method.

**IMAP4. readline()**
Reads one line from the remote server. You may override this method.
**IMAP4. *recent()***
Prompt server for an update. Returned data is *None* if no new messages, else value of **RECENT** response.

**IMAP4. *rename*(oldmailbox, newmailbox)**
Rename mailbox named *oldmailbox* to *newmailbox*.

**IMAP4. *response*(code)**
Return data for response *code* if received, or *None*. Returns the given code, instead of the usual type.

**IMAP4. *search*(charset, criterion[,...])**
Search mailbox for matching messages. *charset* may be *None*, in which case no **CHARSET** will be specified in the request to the server. The IMAP protocol requires that at least one criterion be specified; an exception will be raised when the server returns an error. *charset* must be *None* if the **UTF8=ACCEPT** capability was enabled using the **enable()** command.

Example:

```python
# M is a connected IMAP4 instance...
typ, msgnums = M.search(\None, 'FROM', '"LDJ"')
```

```python
# or:
typ, msgnums = M.search(\None, '(FROM "LDJ")')
```

**IMAP4. *select*(mailbox=\'INBOX\', readonly=False)**
Select a mailbox. Returned data is the count of messages in *mailbox* (**EXISTS** response). The default *mailbox* is \'INBOX\'. If the *readonly* flag is set, modifications to the mailbox are not allowed.
**IMAP4. `send(data)`**
Sends data to the remote server. You may override this method.

**IMAP4. `setacl(mailbox, who, what)`**
Set an ACL for `mailbox`. The method is non-standard, but is supported by the Cyrus server.

**IMAP4. `setannotation(mailbox, entry, attribute[, ...])`**
Set ANNOTATIONs for `mailbox`. The method is non-standard, but is supported by the Cyrus server.

**IMAP4. `setquota(root, limits)`**
Set the quota `root`'s resource `limits`. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

**IMAP4. `shutdown()`**
Close connection established in `open`. This method is implicitly called by `IMAP4.logout()`. You may override this method.

**IMAP4. `socket()`**
Returns socket instance used to connect to server.

**IMAP4. `sort(sort_criteria, charset, search_criterion[, ...])`**
The `sort` command is a variant of `search` with sorting semantics for the results. Returned data contains a space separated list of matching message numbers.

Sort has two arguments before the `search_criterion` argument(s); a parenthesized list of `sort_criteria`, and the searching `charset`. Note that unlike `search`, the searching `charset` argument is mandatory. There is also a `uid sort` command which corresponds to `sort`
the way that \texttt{uid search} corresponds to \texttt{search}. The \texttt{sort} command first searches the mailbox for messages that match the given searching criteria using the charset argument for the interpretation of strings in the searching criteria. It then returns the numbers of matching messages.

This is an \texttt{IMAP4rev1} extension command.

\texttt{IMAP4\_starttls(ssl\_context=None)}

Send a \texttt{STARTTLS} command. The \texttt{ssl\_context} argument is optional and should be a \texttt{ssl\_SSLContext} object. This will enable encryption on the IMAP connection. Please read \texttt{Security\_considerations} for best practices.

\textit{New in version 3.2.}

\textit{Changed in version 3.4:} The method now supports hostname check with \texttt{ssl\_SSLContext\_check\_hostname} and \textit{Server Name Indication} (see \texttt{ssl\_HAS\_SNI}).

\texttt{IMAP4\_status(mailbox, names)}

Request named status conditions for \texttt{mailbox}.

\texttt{IMAP4\_store(message\_set, command, flag\_list)}

Alters flag dispositions for messages in mailbox. \texttt{command} is specified by section 6.4.6 of \texttt{RFC 2060} as being one of “FLAGS”, “+FLAGS”, or “-FLAGS”, optionally with a suffix of “.SILENT”.

For example, to set the delete flag on all messages:

\begin{verbatim}
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    M.store(num, '+FLAGS', '\Deleted')
\end{verbatim}
M.expunge()

**Note:** Creating flags containing ‘]’ (for example: “[test]”) violates [RFC 3501](https://tools.ietf.org/html/rfc3501) (the IMAP protocol). However, imaplib has historically allowed creation of such tags, and popular IMAP servers, such as Gmail, accept and produce such flags. There are non-Python programs which also create such tags. Although it is an RFC violation and IMAP clients and servers are supposed to be strict, imaplib nonetheless continues to allow such tags to be created for backward compatibility reasons, and as of python 3.6, handles them if they are sent from the server, since this improves real-world compatibility.

**IMAP4. `subscribe(mailbox)`**

Subscribe to new mailbox.

**IMAP4. `thread(threading_algorithm, charset, search_criterion[, ...])`**

The `thread` command is a variant of `search` with threading semantics for the results. Returned data contains a space separated list of thread members.

Thread members consist of zero or more messages numbers, delimited by spaces, indicating successive parent and child.

Thread has two arguments before the `search_criterion` argument(s); a `threading_algorithm`, and the searching `charset`. Note that unlike `search`, the searching `charset` argument is mandatory. There is also a `uid thread` command which corresponds to `thread` the way that `uid search` corresponds to `search`. The `thread` command first searches the mailbox for messages that match the given searching criteria using the `charset` argument for the interpretation of strings in the searching criteria. It
then returns the matching messages threaded according to the specified threading algorithm.

This is an IMAP4rev1 extension command.

**IMAP4.** `uid(command, arg[, ...])`
Execute command args with messages identified by UID, rather than message number. Returns response appropriate to command. At least one argument must be supplied; if none are provided, the server will return an error and an exception will be raised.

**IMAP4.** `unsubscribe(mailbox)`
Unsubscribe from old mailbox.

**IMAP4.** `xatom(name[, ...])`
Allow simple extension commands notified by server in CAPABILITY response.

The following attributes are defined on instances of **IMAP4**:

**IMAP4.** `PROTOCOL_VERSION`
The most recent supported protocol in the CAPABILITY response from the server.

**IMAP4.** `debug`
Integer value to control debugging output. The initialize value is taken from the module variable `Debug`. Values greater than three trace each command.

**IMAP4.** `utf8_enabled`
Boolean value that is normally `False`, but is set to `True` if an `enable()` command is successfully issued for the `UTF8=ACCEPT`
capability.

New in version 3.5.
21.15.2. IMAP4 Example

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```python
import getpass, imaplib

M = imaplib.IMAP4()
M.login(getpass.getuser(), getpass.getpass())
M.select()
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    typ, data = M.fetch(num, '(RFC822)')
    print('Message %s
%s
' % (num, data[0][1]))
M.close()
M.logout()
```
21.16. nntpllib — NNTP protocol client

Source code: Lib/nntplib.py

This module defines the class `NNTP` which implements the client side of the Network News Transfer Protocol. It can be used to implement a news reader or poster, or automated news processors. It is compatible with `RFC 3977` as well as the older `RFC 977` and `RFC 2980`.

Here are two small examples of how it can be used. To list some statistics about a newsgroup and print the subjects of the last 10 articles:

```python
>>> s = nntplib.NNTP('news.gmane.org')
>>> resp, count, first, last, name = s.group('gmane.comp.python.committers')
>>> print('Group', name, 'has', count, 'articles, range', first, '-', last)
Group gmane.comp.python.committers has 1096 articles, range 1 - 1096
>>> resp, overviews = s.overview(last - 9, last)
>>> for id, over in overviews:
...     print(id, nntplib.decode_header(over['subject']))
...
1087 Re: Commit privileges for Łukasz Langa

1089 Re: 3.2 alpha 2 freeze
1090 Re: Commit privileges for Łukasz Langa
1091 Re: Commit privileges for Łukasz Langa
1092 Updated ssh key
1093 Re: Updated ssh key
1094 Re: Updated ssh key
1095 Hello fellow committers!
1096 Re: Hello fellow committers!
```
To post an article from a binary file (this assumes that the article has valid headers, and that you have right to post on the particular newsgroup):

```python
>>> s = nntplib.NNTP('news.gmane.org')
>>> f = open('article.txt', 'rb')
>>> s.post(f)
'240 Article posted successfully.'
>>> s.quit()
'205 Bye!'
```

The module itself defines the following classes:

```python
class nntplib.NNTP(host, port=119, user=None, password=None, readermode=None, usenetrc=False[, timeout])
```

Return a new `NNTP` object, representing a connection to the NNTP server running on host `host`, listening at port `port`. An optional `timeout` can be specified for the socket connection. If the optional `user` and `password` are provided, or if suitable credentials are present in `/netrc` and the optional flag `usenetrc` is true, the `AUTHINFO USER` and `AUTHINFO PASS` commands are used to identify and authenticate the user to the server. If the optional flag `readermode` is true, then a `mode reader` command is sent before authentication is performed. Reader mode is sometimes necessary if you are connecting to an NNTP server on the local machine and intend to call reader-specific commands, such as `group`. If you get unexpected `NNTPPermanentErrors`, you might need to set `readermode`. The `NNTP` class supports the `with` statement to unconditionally consume `OSError` exceptions and to close the
NNTP connection when done, e.g.:

```python
>>> from nntplib import NNTP
>>> with NNTP('news.gmane.org') as n:
...    n.group('gmane.comp.python.committers')
...    ('211 1755 1 1755 gmane.comp.python.committers',
>>> 
```

*Changed in version 3.2:* `usenetrc` is now `False` by default.

*Changed in version 3.3:* Support for the `with` statement was added.

```python
class nntplib.NNTP_SSL(host, port=563, user=None, password=None, ssl_context=None, readermode=None, usenetrc=False, [timeout])
```

Return a new `NNTP_SSL` object, representing an encrypted connection to the NNTP server running on host `host`, listening at port `port`. `NNTP_SSL` objects have the same methods as `NNTP` objects. If `port` is omitted, port 563 (NNTPS) is used. `ssl_context` is also optional, and is a `SSLCertContext` object. Please read `Security considerations` for best practices. All other parameters behave the same as for `NNTP`.

Note that SSL-on-563 is discouraged per `RFC 4642`, in favor of `STARTTLS` as described below. However, some servers only support the former.

*New in version 3.2.*

*Changed in version 3.4:* The class now supports hostname check with `ssl.SSLContext.check_hostname` and `Server Name
Indication (see `ssl.HAS_SNI`).

**exception** `nntplib.NNTPError`

Derived from the standard exception `Exception`, this is the base class for all exceptions raised by the `nntplib` module. Instances of this class have the following attribute:

**response**

The response of the server if available, as a `str` object.

**exception** `nntplib.NNTPReplyError`

Exception raised when an unexpected reply is received from the server.

**exception** `nntplib.NNTPTemporaryError`

Exception raised when a response code in the range 400–499 is received.

**exception** `nntplib.NNTPPermanentError`

Exception raised when a response code in the range 500–599 is received.

**exception** `nntplib.NNTPProtocolError`

Exception raised when a reply is received from the server that does not begin with a digit in the range 1–5.

**exception** `nntplib.NNTPDataError`

Exception raised when there is some error in the response data.
21.16.1. NNTP Objects

When connected, **NNTP** and **NNTP_SSL** objects support the following methods and attributes.

21.16.1.1. Attributes

**NNTP. nntp_version**

An integer representing the version of the NNTP protocol supported by the server. In practice, this should be 2 for servers advertising **RFC 3977** compliance and 1 for others.

*New in version 3.2.*

**NNTP. nntp_implementation**

A string describing the software name and version of the NNTP server, or **None** if not advertised by the server.

*New in version 3.2.*

21.16.1.2. Methods

The *response* that is returned as the first item in the return tuple of almost all methods is the server’s response: a string beginning with a three-digit code. If the server’s response indicates an error, the method raises one of the above exceptions.

Many of the following methods take an optional keyword-only argument *file*. When the *file* argument is supplied, it must be either a *file object* opened for binary writing, or the name of an on-disk file to be written to. The method will then write any data returned by the
server (except for the response line and the terminating dot) to the file; any list of lines, tuples or objects that the method normally returns will be empty.

Changed in version 3.2: Many of the following methods have been reworked and fixed, which makes them incompatible with their 3.1 counterparts.

**NNTP.** `quit()`  
Send a QUIT command and close the connection. Once this method has been called, no other methods of the NNTP object should be called.

**NNTP.** `getwelcome()`  
Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

**NNTP.** `getcapabilities()`  
Return the RFC 3977 capabilities advertised by the server, as a `dict` instance mapping capability names to (possibly empty) lists of values. On legacy servers which don’t understand the CAPABILITIES command, an empty dictionary is returned instead.

```python
>>> s = NNTP('news.gmane.org')
>>> 'POST' in s.getcapabilities()
True
```

*New in version 3.2.*

**NNTP.** `login(user=None, password=None, usenetrc=True)`  
Send AUTHINFO commands with the user name and password. If
user and password are None and usenetrc is true, credentials from ~/.netrc will be used if possible.

Unless intentionally delayed, login is normally performed during the NNTP object initialization and separately calling this function is unnecessary. To force authentication to be delayed, you must not set user or password when creating the object, and must set usenetrc to False.

New in version 3.2.

NNTP.starttls(ssl_context=None)
Send a STARTTLS command. This will enable encryption on the NNTP connection. The ssl_context argument is optional and should be a ssl.SSLContext object. Please read Security considerations for best practices.

Note that this may not be done after authentication information has been transmitted, and authentication occurs by default if possible during a NNTP object initialization. See NNTP.login() for information on suppressing this behavior.

New in version 3.2.

Changed in version 3.4: The method now supports hostname check with ssl.SSLContext.check_hostname and Server Name Indication (see ssl.HAS_SNI).

NNTP.newgroups(date, *, file=None)
Send a NEWGROUPS command. The date argument should be a datetime.date or datetime.datetime object. Return a pair (response, groups) where groups is a list representing the groups that are new since the given date. If file is supplied, though,
then groups will be empty.

```python
>>> from datetime import date, timedelta
>>> resp, groups = s.newgroups(date.today()) - timedelta
>>> len(groups)
85
>>> groups[0]
GroupInfo(group='gmane.network.tor.devel', last='4', first='1', flag='m')
```

**NNTP. newnews**(group, date, *, file=None)

Send a NEWNEWS command. Here, group is a group name or ' * ', and date has the same meaning as for newgroups(). Return a pair (response, articles) where articles is a list of message ids.

This command is frequently disabled by NNTP server administrators.

**NNTP. list**(group_pattern=None, *, file=None)

Send a LIST or LIST ACTIVE command. Return a pair (response, list) where list is a list of tuples representing all the groups available from this NNTP server, optionally matching the pattern string group_pattern. Each tuple has the form (group, last, first, flag), where group is a group name, last and first are the last and first article numbers, and flag usually takes one of these values:

- y: Local postings and articles from peers are allowed.
- m: The group is moderated and all postings must be approved.
- n: No local postings are allowed, only articles from peers.
- j: Articles from peers are filed in the junk group instead.
- x: No local postings, and articles from peers are ignored.
• =foo.bar: Articles are filed in the foo.bar group instead.

If flag has another value, then the status of the newsgroup should be considered unknown.

This command can return very large results, especially if group_pattern is not specified. It is best to cache the results offline unless you really need to refresh them.

*Changed in version 3.2:* group_pattern was added.

**NNTP.** descriptions(group_pattern)

Send a LIST NEWSGROUPS command, where group_pattern is a wildmat string as specified in [RFC 3977](https://tools.ietf.org/html/rfc3977) (it's essentially the same as DOS or UNIX shell wildcard strings). Return a pair (response, descriptions), where descriptions is a dictionary mapping group names to textual descriptions.

```python
>>> resp, desc = s.descriptions('gmane.comp.python.*
>>> len(desc)
295
>>> desc.popitem()
('gmane.comp.python.bio.general', 'BioPython discussion list (Moderated)')
```

**NNTP.** description(group)

Get a description for a single group group. If more than one group matches (if ‘group’ is a real wildmat string), return the first match. If no group matches, return an empty string.

This elides the response code from the server. If the response code is needed, use descriptions().

**NNTP.** group(name)
Send a `GROUP` command, where `name` is the group name. The group is selected as the current group, if it exists. Return a tuple `(response, count, first, last, name)` where `count` is the (estimated) number of articles in the group, `first` is the first article number in the group, `last` is the last article number in the group, and `name` is the group name.

NNTP. **over**(message_spec, *, file=None)

Send an `OVER` command, or an `XOVER` command on legacy servers. `message_spec` can be either a string representing a message id, or a `(first, last)` tuple of numbers indicating a range of articles in the current group, or a `(first, None)` tuple indicating a range of articles starting from `first` to the last article in the current group, or `None` to select the current article in the current group.

Return a pair `(response, overviews)`. `overviews` is a list of `(article_number, overview)` tuples, one for each article selected by `message_spec`. Each `overview` is a dictionary with the same number of items, but this number depends on the server. These items are either message headers (the key is then the lower-cased header name) or metadata items (the key is then the metadata name prepended with `"::"`). The following items are guaranteed to be present by the NNTP specification:

- the `subject`, `from`, `date`, `message-id` and `references` headers
- the `:bytes` metadata: the number of bytes in the entire raw article (including headers and body)
- the `:lines` metadata: the number of lines in the article body

The value of each item is either a string, or `None` if not present.
It is advisable to use the `decode_header()` function on header values when they may contain non-ASCII characters:

```python
>>> _, _, first, last, _ = s.group('gmane.comp.python.devel', resp, overviews = s.over((last, last))
>>> art_num, over = overviews[0]
>>> art_num
117216
>>> list(over.keys())
['xref', 'from', ':lines', ':bytes', 'references'
>>> over['from']
'=?UTF-8?B?Ik1hcnRpbB2LiBm7Z3aXMi=?= <martin@v.loewis.de>
>>> nntplib.decode_header(over['from'])
'Martin v. Löwis' <martin@v.loewis.de>
```
**NNTP.next()**

Send a NEXT command. Return as for `stat()`.

**NNTP.last()**

Send a LAST command. Return as for `stat()`.

**NNTP.article**(message_spec=None, *, file=None)

Send an ARTICLE command, where `message_spec` has the same meaning as for `stat()`. Return a tuple `(response, info)` where `info` is a `namedtuple` with three attributes `number`, `message_id` and `lines` (in that order). `number` is the article number in the group (or 0 if the information is not available), `message_id` the message id as a string, and `lines` a list of lines (without terminating newlines) comprising the raw message including headers and body.

```python
>>> resp, info = s.article('<20030112190404.GE29873@epoch.metaslash.com>
>>> info.number
0
>>> info.message_id
'<20030112190404.GE29873@epoch.metaslash.com>'
>>> len(info.lines)
65
>>> info.lines[0]
b'Path: main.gmane.org!not-for-mail'
>>> info.lines[1]
b'From: Neal Norwitz <neal@metaslash.com>'
>>> info.lines[-3:]
[b'There is a patch for 2.3 as well as 2.2.', b'
```

**NNTP.head**(message_spec=None, *, file=None)

Same as `article()`, but sends a HEAD command. The `lines`
returned (or written to file) will only contain the message headers, not the body.

**NNTP. body**(*message_spec=None, *, file=None*)

Same as **article()**, but sends a **BODY** command. The **lines** returned (or written to file) will only contain the message body, not the headers.

**NNTP. post**(*data*)

Post an article using the **POST** command. The **data** argument is either a **file object** opened for binary reading, or any iterable of bytes objects (representing raw lines of the article to be posted). It should represent a well-formed news article, including the required headers. The **post()** method automatically escapes lines beginning with \ and appends the termination line.

If the method succeeds, the server’s response is returned. If the server refuses posting, a **NNTPReplyError** is raised.

**NNTP. ihave**(*message_id, data*)

Send an **IHAVE** command. **message_id** is the id of the message to send to the server (enclosed in '<' and '>'). The **data** parameter and the return value are the same as for **post()**.

**NNTP. date()**

Return a pair **(response, date)**. **date** is a **datetime** object containing the current date and time of the server.

**NNTP. slave()**

Send a **SLAVE** command. Return the server's **response**.

**NNTP. set_debuglevel**(*level*)
Set the instance’s debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request or response. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the connection (including message text).

The following are optional NNTP extensions defined in RFC 2980. Some of them have been superseded by newer commands in RFC 3977.

**NNTP. `xhdr(hdr, str, *, file=None)`**

Send an `XHDR` command. The `hdr` argument is a header keyword, e.g. 'subject'. The `str` argument should have the form 'first-last' where `first` and `last` are the first and last article numbers to search. Return a pair `(response, list)`, where `list` is a list of pairs `(id, text)`, where `id` is an article number (as a string) and `text` is the text of the requested header for that article. If the `file` parameter is supplied, then the output of the `XHDR` command is stored in a file. If `file` is a string, then the method will open a file with that name, write to it then close it. If `file` is a file object, then it will start calling `write()` on it to store the lines of the command output. If `file` is supplied, then the returned `list` is an empty list.

**NNTP. `xover(start, end, *, file=None)`**

Send an `XOVER` command. `start` and `end` are article numbers delimiting the range of articles to select. The return value is the same of for `over()`. It is recommended to use `over()` instead, since it will automatically use the newer `OVER` command if available.
NNTP. `xpath(id)`

Return a pair `(resp, path)`, where `path` is the directory path to the article with message ID `id`. Most of the time, this extension is not enabled by NNTP server administrators.

*Deprecated since version 3.3:* The XPATH extension is not actively used.
21.16.2. Utility functions

The module also defines the following utility function:

```python
def decode_header(header_str)
    Decode a header value, un-escaping any escaped non-ASCII characters. `header_str` must be a `str` object. The unescaped value is returned. Using this function is recommended to display some headers in a human readable form:

```
21.17. **smtplib — SMTP protocol client**

**Source code:** Lib/smtplib.py

The **smtplib** module defines an SMTP client session object that can be used to send mail to any Internet machine with an SMTP or ESMTP listener daemon. For details of SMTP and ESMTP operation, consult RFC 821 (Simple Mail Transfer Protocol) and RFC 1869 (SMTP Service Extensions).

```python
class smtplib.SMTP(host='', port=0, local_hostname=None, [timeout, ]source_address=None)
```

An **SMTP** instance encapsulates an SMTP connection. It has methods that support a full repertoire of SMTP and ESMTP operations. If the optional host and port parameters are given, the **SMTP connect()** method is called with those parameters during initialization. If specified, **local_hostname** is used as the FQDN of the local host in the HELO/EHLO command. Otherwise, the local hostname is found using `socket.getfqdn()`. If the **connect()** call returns anything other than a success code, an **SMTPConnectError** is raised. The optional **timeout** parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). If the timeout expires, **socket.timeout** is raised. The optional **source_address** parameter allows binding to some specific source address in a machine with multiple network interfaces, and/or to some specific source TCP port. It takes a 2-tuple (host, port), for the socket to bind to as its source address.
before connecting. If omitted (or if host or port are '' and/or 0 respectively) the OS default behavior will be used.

For normal use, you should only require the initialization/connect, sendmail(), and quit() methods. An example is included below.

The SMTP class supports the with statement. When used like this, the SMTP QUIT command is issued automatically when the with statement exits. E.g.:

```python
>>> from smtplib import SMTP
>>> with SMTP("domain.org") as smtp:
...    smtp.noop()
... (250, b'Ok')

Changed in version 3.3: Support for the with statement was added.

Changed in version 3.3: source_address argument was added.

New in version 3.5: The SMTPUTF8 extension (RFC 6531) is now supported.

class smtplib.SMTP_SSL(host='', port=0, local_hostname=None, keyfile=None, certfile=None, [timeout, ]context=None, source_address=None)

An SMTP_SSL instance behaves exactly the same as instances of SMTP. SMTP_SSL should be used for situations where SSL is required from the beginning of the connection and using starttls() is not appropriate. If host is not specified, the local
host is used. If port is zero, the standard SMTP-over-SSL port (465) is used. The optional arguments local_hostname, timeout and source_address have the same meaning as they do in the SMTP class. context, also optional, can contain a SSLContext and allows configuring various aspects of the secure connection. Please read Security considerations for best practices.

keyfile and certfile are a legacy alternative to context, and can point to a PEM formatted private key and certificate chain file for the SSL connection.

Changed in version 3.3: context was added.

Changed in version 3.3: source_address argument was added.

Changed in version 3.4: The class now supports hostname check with ssl.SSLContext.check_hostname and Server Name Indication (see ssl.HAS_SNI).

Deprecated since version 3.6: keyfile and certfile are deprecated in favor of context. Please use ssl.SSLContext.load_cert_chain() instead, or let ssl.create_default_context() select the system’s trusted CA certificates for you.

class smtplib.LMTP(host='', port=LMTP_PORT,
local_hostname=None, source_address=None)

The LMTP protocol, which is very similar to ESMTP, is heavily based on the standard SMTP client. It’s common to use Unix sockets for LMTP, so our connect() method must support that as well as a regular host:port server. The optional arguments local_hostname and source_address have the same meaning as they do in the SMTP class. To specify a Unix socket, you must use
an absolute path for host, starting with a ‘/.

Authentication is supported, using the regular SMTP mechanism. When using a Unix socket, LMTP generally don’t support or require any authentication, but your mileage might vary.

A nice selection of exceptions is defined as well:

```python
exception smtplib.SMTPException
Subclass of OSError that is the base exception class for all the other exceptions provided by this module.

Changed in version 3.4: SMTPException became subclass of OSError
```

```python
exception smtplib.SMTPServerDisconnected
This exception is raised when the server unexpectedly disconnects, or when an attempt is made to use the SMTP instance before connecting it to a server.
```

```python
exception smtplib.SMTPResponseException
Base class for all exceptions that include an SMTP error code. These exceptions are generated in some instances when the SMTP server returns an error code. The error code is stored in the smtp_code attribute of the error, and the smtp_error attribute is set to the error message.
```

```python
exception smtplib.SMTPSenderRefused
Sender address refused. In addition to the attributes set by on all SMTPResponseException exceptions, this sets ‘sender’ to the string that the SMTP server refused.
```

```python
exception smtplib.SMTPRecipientsRefused
```
All recipient addresses refused. The errors for each recipient are accessible through the attribute recipients, which is a dictionary of exactly the same sort as `SMTP.sendmail()` returns.

*exception* `smtplib.SMTPDataError`

The SMTP server refused to accept the message data.

*exception* `smtplib.SMTPConnectError`

Error occurred during establishment of a connection with the server.

*exception* `smtplib.SMTPHeloError`

The server refused our `HELO` message.

*exception* `smtplib.SMTPNotSupportedError`

The command or option attempted is not supported by the server.

*New in version 3.5.*

*exception* `smtplib.SMTPAuthenticationError`

SMTP authentication went wrong. Most probably the server didn’t accept the username/password combination provided.

See also:

**RFC 821** - Simple Mail Transfer Protocol

Protocol definition for SMTP. This document covers the model, operating procedure, and protocol details for SMTP.

**RFC 1869** - SMTP Service Extensions

Definition of the ESMTP extensions for SMTP. This describes a framework for extending SMTP with new commands, supporting dynamic discovery of the commands provided by the server, and defines a few additional commands.
21.17.1. SMTP Objects

An `SMTP` instance has the following methods:

**SMTP. `set_debuglevel(level)`**
Set the debug output level. A value of 1 or `True` for `level` results in debug messages for connection and for all messages sent to and received from the server. A value of 2 for `level` results in these messages being timestamped.

*Changed in version 3.5: Added debuglevel 2.*

**SMTP. `docmd(cmd, args='')`**
Send a command `cmd` to the server. The optional argument `args` is simply concatenated to the command, separated by a space.

This returns a 2-tuple composed of a numeric response code and the actual response line (multiline responses are joined into one long line.)

In normal operation it should not be necessary to call this method explicitly. It is used to implement other methods and may be useful for testing private extensions.

If the connection to the server is lost while waiting for the reply, `SMTPServerDisconnected` will be raised.

**SMTP. `connect(host='localhost', port=0)`**
Connect to a host on a given port. The defaults are to connect to the local host at the standard SMTP port (25). If the hostname ends with a colon (`:`) followed by a number, that suffix will be stripped off and the number interpreted as the port number to use. This
method is automatically invoked by the constructor if a host is specified during instantiation. Returns a 2-tuple of the response code and message sent by the server in its connection response.

**SMTP. helo(name="")**

Identify yourself to the SMTP server using HELO. The hostname argument defaults to the fully qualified domain name of the local host. The message returned by the server is stored as the helo_resp attribute of the object.

In normal operation it should not be necessary to call this method explicitly. It will be implicitly called by the sendmail() when necessary.

**SMTP. ehlo(name="")**

Identify yourself to an ESMTP server using EHLO. The hostname argument defaults to the fully qualified domain name of the local host. Examine the response for ESMTP option and store them for use by has_extn(). Also sets several informational attributes: the message returned by the server is stored as the ehlo_resp attribute, does_esmtp is set to true or false depending on whether the server supports ESMTP, and esmtp_features will be a dictionary containing the names of the SMTP service extensions this server supports, and their parameters (if any).

Unless you wish to use has_extn() before sending mail, it should not be necessary to call this method explicitly. It will be implicitly called by sendmail() when necessary.

**SMTP.ehlo_or_helo_if_needed()**

This method call ehlo() and or helo() if there has been no previous EHLO or HELO command this session. It tries ESMTP
EHLO first.

SMTPHeloError
The server didn’t reply properly to the HELO greeting.

SMTP.\texttt{has_extn}(name)
Return \texttt{True} if \textit{name} is in the set of SMTP service extensions returned by the server, \texttt{False} otherwise. Case is ignored.

SMTP.\texttt{verify}(address)
Check the validity of an address on this server using SMTP VRFY. Returns a tuple consisting of code 250 and a full RFC 822 address (including human name) if the user address is valid. Otherwise returns an SMTP error code of 400 or greater and an error string.

\textbf{Note:} Many sites disable SMTP VRFY in order to foil spammers.

SMTP.\texttt{login}(user, password, *, initial_response_ok=True)
Log in on an SMTP server that requires authentication. The arguments are the username and the password to authenticate with. If there has been no previous EHLO or HELO command this session, this method tries ESMTP EHLO first. This method will return normally if the authentication was successful, or may raise the following exceptions:

SMTPHeloError
The server didn’t reply properly to the HELO greeting.

SMTPAuthenticationError
The server didn’t accept the username/password combination.

SMTPNotSupportedError
The \texttt{AUTH} command is not supported by the server.
SMTPException

No suitable authentication method was found.

Each of the authentication methods supported by smtplib are tried in turn if they are advertised as supported by the server. See auth() for a list of supported authentication methods.

initial_response_ok is passed through to auth().

Optional keyword argument initial_response_ok specifies whether, for authentication methods that support it, an “initial response” as specified in RFC 4954 can be sent along with the AUTH command, rather than requiring a challenge/response.

Changed in version 3.5: SMTPNotSupportedError may be raised, and the initial_response_ok parameter was added.

SMTP.auth(mechanism, authobject, *, initial_response_ok=True)

Issue an SMTP AUTH command for the specified authentication mechanism, and handle the challenge response via authobject.

mechanism specifies which authentication mechanism is to be used as argument to the AUTH command; the valid values are those listed in the auth element of esmtp_features.

authobject must be a callable object taking an optional single argument:

data = authobject(challenge=None)

If optional keyword argument initial_response_ok is true, authobject() will be called first with no argument. It can return the RFC 4954 “initial response” bytes which will be encoded and sent with the AUTH command as below. If the authobject()
does not support an initial response (e.g. because it requires a challenge), it should return None when called with challenge=None. If initial_response_ok is false, then authobject() will not be called first with None.

If the initial response check returns None, or if initial_response_ok is false, authobject() will be called to process the server's challenge response; the challenge argument it is passed will be a bytes. It should return bytes data that will be base64 encoded and sent to the server.

The SMTP class provides authobjects for the CRAM-MD5, PLAIN, and LOGIN mechanisms; they are named SMTP.auth_cram_md5, SMTP.auth_plain, and SMTP.auth_login respectively. They all require that the user and password properties of the SMTP instance are set to appropriate values.

User code does not normally need to call auth directly, but can instead call the login() method, which will try each of the above mechanisms in turn, in the order listed. auth is exposed to facilitate the implementation of authentication methods not (or not yet) supported directly by smtplib.

New in version 3.5.

SMTP.starttls(keyfile=None, certfile=None, context=None)
Put the SMTP connection in TLS (Transport Layer Security) mode. All SMTP commands that follow will be encrypted. You should then call ehlo() again.

If keyfile and certfile are provided, these are passed to the socket
module's `ssl()` function.

Optional `context` parameter is a `ssl.SSLContext` object; This is an alternative to using a keyfile and a certfile and if specified both `keyfile` and `certfile` should be None.

If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first.

**SMTPHeloError**

The server didn’t reply properly to the `HELO` greeting.

**SMTPNotSupportedError**

The server does not support the STARTTLS extension.

**RuntimeError**

SSL/TLS support is not available to your Python interpreter.

*Changed in version 3.3:* `context` was added.

*Changed in version 3.4:* The method now supports hostname check with `SSLContext.check_hostname` and `Server Name Indicator` (see `HAS_SNI`).

*Changed in version 3.5:* The error raised for lack of STARTTLS support is now the `SMTPNotSupportedError` subclass instead of the base `SMTPException`.

```python
SMTP.sendmail(from_addr, to_addrs, msg, mail_options=[], rcpt_options=[])
```

Send mail. The required arguments are an RFC 822 from-address string, a list of RFC 822 to-address strings (a bare string will be treated as a list with 1 address), and a message string. The caller may pass a list of ESMTP options (such as `8bitmime`) to be used
in MAIL_FROM commands as `mail_options`. ESMTP options (such as DSN commands) that should be used with all RCPT commands can be passed as `rcpt_options`. (If you need to use different ESMTP options to different recipients you have to use the low-level methods such as `mail()`, `rcpt()` and `data()` to send the message.)

**Note:** The `from_addr` and `to_addrs` parameters are used to construct the message envelope used by the transport agents. `sendmail` does not modify the message headers in any way.

`msg` may be a string containing characters in the ASCII range, or a byte string. A string is encoded to bytes using the ascii codec, and lone \r and \n characters are converted to \r\n characters. A byte string is not modified.

If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first. If the server does ESMTP, message size and each of the specified options will be passed to it (if the option is in the feature set the server advertises). If `EHLO` fails, `HELO` will be tried and ESMTP options suppressed.

This method will return normally if the mail is accepted for at least one recipient. Otherwise it will raise an exception. That is, if this method does not raise an exception, then someone should get your mail. If this method does not raise an exception, it returns a dictionary, with one entry for each recipient that was refused. Each entry contains a tuple of the SMTP error code and the accompanying error message sent by the server.

If `SMTPUTF8` is included in `mail_options`, and the server supports it, `from_addr` and `to_addrs` may contain non-ASCII characters.
This method may raise the following exceptions:

**SMTPRecipientsRefused**
All recipients were refused. Nobody got the mail. The recipients attribute of the exception object is a dictionary with information about the refused recipients (like the one returned when at least one recipient was accepted).

**SMTPHeloError**
The server didn’t reply properly to the HELO greeting.

**SMTPSenderRefused**
The server didn’t accept the from_addr.

**SMTPDataError**
The server replied with an unexpected error code (other than a refusal of a recipient).

**SMTPNotSupportedError**
SMTPUTF8 was given in the mail_options but is not supported by the server.

Unless otherwise noted, the connection will be open even after an exception is raised.

*Changed in version 3.2:* msg may be a byte string.

*Changed in version 3.5:* SMTPUTF8 support added, and SMTPNotSupportedError may be raised if SMTPUTF8 is specified but the server does not support it.

**SMTP.send_message**(msg, from_addr=None, to_addrs=None, mail_options=[], rcpt_options=[])  
This is a convenience method for calling sendmail() with the message represented by an email.message.Message object. The arguments have the same meaning as for sendmail(),
except that \textit{msg} is a \texttt{Message} object.

If \textit{from\_addr} is \texttt{None} or \textit{to\_addr} is \texttt{None}, \texttt{send\_message} fills those arguments with addresses extracted from the headers of \textit{msg} as specified in \texttt{RFC 5322}: \textit{from\_addr} is set to the \texttt{Sender} field if it is present, and otherwise to the \texttt{From} field. \textit{to\_addr} combines the values (if any) of the \texttt{To}, \texttt{Cc}, and \texttt{Bcc} fields from \textit{msg}. If exactly one set of \texttt{Resent-}\* headers appear in the message, the regular headers are ignored and the \texttt{Resent-}\* headers are used instead. If the message contains more than one set of \texttt{Resent-}\* headers, a \texttt{ValueError} is raised, since there is no way to unambiguously detect the most recent set of \texttt{Resent-} headers.

\texttt{send\_message} serializes \textit{msg} using \texttt{BytesGenerator} with \texttt{\r\n} as the \texttt{linesep}, and calls \texttt{sendmail()} to transmit the resulting message. Regardless of the values of \textit{from\_addr} and \textit{to\_addr}, \texttt{send\_message} does not transmit any \texttt{Bcc} or \texttt{Resent-Bcc} headers that may appear in \textit{msg}. If any of the addresses in \textit{from\_addr} and \textit{to\_addr} contain non-ASCII characters and the server does not advertise \texttt{SMTPUTF8} support, an \texttt{SMTPNotSupported} error is raised. Otherwise the \texttt{Message} is serialized with a clone of its \texttt{policy} with the \texttt{utf8} attribute set to \texttt{True}, and \texttt{SMTPUTF8} and \texttt{BODY=8BITMIME} are added to \texttt{mail\_options}.

\textit{New in version 3.2.}

\textit{New in version 3.5:} Support for internationalized addresses (\texttt{SMTPUTF8}).

\texttt{SMTP.quit()}

Terminate the SMTP session and close the connection. Return the
result of the SMTP QUIT command.

Low-level methods corresponding to the standard SMTP/ESMTP commands HELP, RSET, NOOP, MAIL, RCPT, and DATA are also supported. Normally these do not need to be called directly, so they are not documented here. For details, consult the module code.
21.17.2. SMTP Example

This example prompts the user for addresses needed in the message envelope (‘To’ and ‘From’ addresses), and the message to be delivered. Note that the headers to be included with the message must be included in the message as entered; this example doesn’t do any processing of the RFC 822 headers. In particular, the ‘To’ and ‘From’ addresses must be included in the message headers explicitly.

```python
import smtplib

def prompt(prompt):
    return input(prompt).strip()

fromaddr = prompt("From: ")
toaddrs = prompt("To: ").split()
print("Enter message, end with ^D (Unix) or ^Z (Windows):")

# Add the From: and To: headers at the start!
msg = ("From: %s\n\nTo: %s\n\n" % (fromaddr,", ".join(toaddrs)))

while True:
    try:
        line = input()
    except EOFError:
        break
    if not line:
        break
    msg = msg + line

print("Message length is", len(msg))

server = smtplib.SMTP('localhost')
server.set_debuglevel(1)
server.sendmail(fromaddr, toaddrs, msg)
```
server.quit()

**Note:** In general, you will want to use the `email` package’s features to construct an email message, which you can then send via `send_message()`; see `email: Examples`. 
This module offers several classes to implement SMTP (email) servers.

**See also:** The aiosmtpd package is a recommended replacement for this module. It is based on asyncio and provides a more straightforward API. smtpd should be considered deprecated.

Several server implementations are present; one is a generic do-nothing implementation, which can be overridden, while the other two offer specific mail-sending strategies.

Additionally the SMTPChannel may be extended to implement very specific interaction behaviour with SMTP clients.

The code supports RFC 5321, plus the RFC 1870 SIZE and RFC 6531 SMTPUTF8 extensions.
21.18.1. SMTPServer Objects

class smtpd.SMTPServer(localaddr, remoteaddr, data_size_limit=33554432, map=None, enable_SMTPUTF8=False, decode_data=False)

Create a new SMTPServer object, which binds to local address localaddr. It will treat remoteaddr as an upstream SMTP relayer. Both localaddr and remoteaddr should be a (host, port) tuple. The object inherits from asyncore.dispatcher, and so will insert itself into asyncore’s event loop on instantiation.

data_size_limit specifies the maximum number of bytes that will be accepted in a DATA command. A value of None or 0 means no limit.

map is the socket map to use for connections (an initially empty dictionary is a suitable value). If not specified the asyncore global socket map is used.

enable_SMTPUTF8 determines whether the SMTPUTF8 extension (as defined in RFC 6531) should be enabled. The default is False. When True, SMTPUTF8 is accepted as a parameter to the MAIL command and when present is passed to process_message() in the kwargs['mail_options'] list. decode_data and enable_SMTPUTF8 cannot be set to True at the same time.

decode_data specifies whether the data portion of the SMTP transaction should be decoded using UTF-8. When decode_data is False (the default), the server advertises the 8BITMIME extension (RFC 6152), accepts the BODY=8BITMIME parameter to
the MAIL command, and when present passes it to `process_message()` in the `kwargs['mail_options']` list. *decode_data* and *enable_SMTPUTF8* cannot be set to True at the same time.

**process_message**(peer, mailfrom, rcpttos, data, **kwargs)

Raise a `NotImplementedError` exception. Override this in subclasses to do something useful with this message. Whatever was passed in the constructor as *remoteaddr* will be available as the _remoteaddr_ attribute. `peer` is the remote host's address, *mailfrom* is the envelope originator, *rcpttos* are the envelope recipients and *data* is a string containing the contents of the e-mail (which should be in RFC 5321 format).

If the *decode_data* constructor keyword is set to True, the *data* argument will be a unicode string. If it is set to False, it will be a bytes object.

*kwargs* is a dictionary containing additional information. It is empty if *decode_data=True* was given as an init argument, otherwise it contains the following keys:

* mail_options:
  a list of all received parameters to the MAIL command (the elements are uppercase strings; example: ['BODY=8BITMIME', 'SMTPUTF8']).

* rcpt_options:
  same as *mail_options* but for the RCPT command. Currently no RCPT TO options are supported, so for now this will always be an empty list.

Implementations of `process_message` should use the
**kwargs signature to accept arbitrary keyword arguments, since future feature enhancements may add keys to the kwargs dictionary.

Return None to request a normal 250 Ok response; otherwise return the desired response string in RFC 5321 format.

channel_class

Override this in subclasses to use a custom SMTPChannel for managing SMTP clients.

New in version 3.4: The map constructor argument.

Changed in version 3.5: localaddr and remoteaddr may now contain IPv6 addresses.

New in version 3.5: The decode_data and enable_SMTPUTF8 constructor parameters, and the kwargs parameter to process_message() when decode_data is False.

Changed in version 3.6: decode_data is now False by default.
21.18.2. DebuggingServer Objects

class smtpd.DebuggingServer(localaddr, remoteaddr)

Create a new debugging server. Arguments are as per
SMTPServer. Messages will be discarded, and printed on stdout.
21.18.3. PureProxy Objects

class smtplib.PureProxy(localaddr, remoteaddr)

Create a new pure proxy server. Arguments are as per 
SMTPServer. Everything will be relayed to remoteaddr. Note that 
running this has a good chance to make you into an open relay, so 
please be careful.
21.18.4. MailmanProxy Objects

class smtpd.MailmanProxy(localaddr, remoteaddr)

Create a new pure proxy server. Arguments are as per SMTPServer. Everything will be relayed to remoteaddr, unless local mailman configurations knows about an address, in which case it will be handled via mailman. Note that running this has a good chance to make you into an open relay, so please be careful.
21.18.5. SMTPChannel Objects

```python
class smtplib.SMTPChannel(server, conn, addr,
data_size_limit=33554432, map=None, enable_SMTPUTF8=False,
decode_data=False)
```

Create a new `SMTPChannel` object which manages the communication between the server and a single SMTP client.

`conn` and `addr` are as per the instance variables described below.

`data_size_limit` specifies the maximum number of bytes that will be accepted in a `DATA` command. A value of `None` or `0` means no limit.

`enable_SMTPUTF8` determines whether the `SMTPUTF8` extension (as defined in **RFC 6531**) should be enabled. The default is `False`. `decode_data` and `enable_SMTPUTF8` cannot be set to `True` at the same time.

A dictionary can be specified in `map` to avoid using a global socket map.

`decode_data` specifies whether the data portion of the SMTP transaction should be decoded using UTF-8. The default is `False`. `decode_data` and `enable_SMTPUTF8` cannot be set to `True` at the same time.

To use a custom SMTPChannel implementation you need to override the `SMTPServer.channel_class` of your `SMTPServer`.

*Changed in version 3.5*: The `decode_data` and `enable_SMTPUTF8`
parameters were added.

*Changed in version 3.6:* `decode_data` is now `False` by default.

The `SMTPChannel` has the following instance variables:

**smtp_server**
- Holds the `SMTPServer` that spawned this channel.

**conn**
- Holds the socket object connecting to the client.

**addr**
- Holds the address of the client, the second value returned by `socket.accept`

**received_lines**
- Holds a list of the line strings (decoded using UTF-8) received from the client. The lines have their `
` line ending translated to `
`.

**smtp_state**
- Holds the current state of the channel. This will be either `COMMAND` initially and then `DATA` after the client sends a “DATA” line.

**seen_greeting**
- Holds a string containing the greeting sent by the client in its “HELO”.

**mailfrom**
- Holds a string containing the address identified in the “MAIL FROM:” line from the client.
**rcpttos**
Holds a list of strings containing the addresses identified in the “RCPT TO:” lines from the client.

**received_data**
Holds a string containing all of the data sent by the client during the DATA state, up to but not including the terminating "\r\n\r\n".

**fqdn**
Holds the fully-qualified domain name of the server as returned by `socket.getfqdn()`.

**peer**
Holds the name of the client peer as returned by `conn.getpeername()` where `conn` is `conn`.

The **SMTPChannel** operates by invoking methods named `smtp_<command>` upon reception of a command line from the client. Built into the base **SMTPChannel** class are methods for handling the following commands (and responding to them appropriately):

<table>
<thead>
<tr>
<th>Command</th>
<th>Action taken</th>
</tr>
</thead>
<tbody>
<tr>
<td>HELO</td>
<td>Accepts the greeting from the client and stores it in <code>seen_greeting</code>. Sets server to base command mode.</td>
</tr>
<tr>
<td>EHLO</td>
<td>Accepts the greeting from the client and stores it in <code>seen_greeting</code>. Sets server to extended command mode.</td>
</tr>
<tr>
<td>NOOP</td>
<td>Takes no action.</td>
</tr>
<tr>
<td>QUIT</td>
<td>Closes the connection cleanly.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>MAIL</td>
<td>Accepts the “MAIL FROM:” syntax and stores the supplied address as <code>mailfrom</code>. In extended command mode, accepts the RFC 1870 SIZE attribute and responds appropriately based on the value of <code>data_size_limit</code>.</td>
</tr>
<tr>
<td>RCPT</td>
<td>Accepts the “RCPT TO:” syntax and stores the supplied addresses in the <code>rcpttos</code> list.</td>
</tr>
<tr>
<td>RSET</td>
<td>Resets the <code>mailfrom</code>, <code>rcpttos</code>, and <code>received_data</code>, but not the greeting.</td>
</tr>
<tr>
<td>DATA</td>
<td>Sets the internal state to DATA and stores remaining lines from the client in <code>received_data</code> until the terminator <code>\r\n.\r\n</code> is received.</td>
</tr>
<tr>
<td>HELP</td>
<td>Returns minimal information on command syntax</td>
</tr>
<tr>
<td>VRFY</td>
<td>Returns code 252 (the server doesn’t know if the address is valid)</td>
</tr>
<tr>
<td>EXPN</td>
<td>Reports that the command is not implemented.</td>
</tr>
</tbody>
</table>
21.19. `telnetlib` — Telnet client

**Source code:** Lib/telnetlib.py

The `telnetlib` module provides a `Telnet` class that implements the Telnet protocol. See RFC 854 for details about the protocol. In addition, it provides symbolic constants for the protocol characters (see below), and for the telnet options. The symbolic names of the telnet options follow the definitions in `arpa/telnet.h`, with the leading `TELOPT_` removed. For symbolic names of options which are traditionally not included in `arpa/telnet.h`, see the module source itself.

The symbolic constants for the telnet commands are: IAC, DONT, DO, WONT, WILL, SE (Subnegotiation End), NOP (No Operation), DM (Data Mark), BRK (Break), IP (Interrupt process), AO (Abort output), AYT (Are You There), EC (Erase Character), EL (Erase Line), GA (Go Ahead), SB (Subnegotiation Begin).

```python
class telnetlib.Telnet(host=None, port=0[, timeout])
```

`Telnet` represents a connection to a Telnet server. The instance is initially not connected by default; the `open()` method must be used to establish a connection. Alternatively, the host name and optional port number can be passed to the constructor too, in which case the connection to the server will be established before the constructor returns. The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).
Do not reopen an already connected instance.

This class has many read_*() methods. Note that some of them raise E0FError when the end of the connection is read, because they can return an empty string for other reasons. See the individual descriptions below.

A Telnet object is a context manager and can be used in a with statement. When the with block ends, the close() method is called:

```python
>>> from telnetlib import Telnet
>>> with Telnet('localhost', 23) as tn:
...     tn.interact()
...```

*Changed in version 3.6:* Context manager support added

**See also:**

**RFC 854 - Telnet Protocol Specification**
Definition of the Telnet protocol.
21.19.1. Telnet Objects

Telnet instances have the following methods:

Telnet.\texttt{read\_until}(expected, timeout=\texttt{None})

Read until a given byte string, expected, is encountered or until timeout seconds have passed.

When no match is found, return whatever is available instead, possibly empty bytes. Raise E\texttt{OF}Error if the connection is closed and no cooked data is available.

Telnet.\texttt{read\_all}()

Read all data until EOF as bytes; block until connection closed.

Telnet.\texttt{read\_some}()

Read at least one byte of cooked data unless EOF is hit. Return b'' if EOF is hit. Block if no data is immediately available.

Telnet.\texttt{read\_very\_eager}()

Read everything that can be without blocking in I/O (eager).

Raise E\texttt{OF}Error if connection closed and no cooked data available. Return b'' if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

Telnet.\texttt{read\_eager}()

Read readily available data.

Raise E\texttt{OF}Error if connection closed and no cooked data available. Return b'' if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.
**Telnet**. `read_lazy()`  
Process and return data already in the queues (lazy).

Raise *EOFError* if connection closed and no data available. Return `b''` if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

**Telnet**. `read_very_lazy()`  
Return any data available in the cooked queue (very lazy).

Raise *EOFError* if connection closed and no data available. Return `b''` if no cooked data available otherwise. This method never blocks.

**Telnet**. `read_sb_data()`  
Return the data collected between a SB/SE pair (suboption begin/end). The callback should access these data when it was invoked with a SE command. This method never blocks.

**Telnet**. `open(host, port=0[, timeout])`  
Connect to a host. The optional second argument is the port number, which defaults to the standard Telnet port (23). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

Do not try to reopen an already connected instance.

**Telnet**. `msg(msg, *args)`  
Print a debug message when the debug level is $> 0$. If extra arguments are present, they are substituted in the message using the standard string formatting operator.
Telnet. `set_debuglevel(debuglevel)`
Set the debug level. The higher the value of `debuglevel`, the more debug output you get (on `sys.stdout`).

Telnet. `close()`
Close the connection.

Telnet. `get_socket()`
Return the socket object used internally.

Telnet. `fileno()`
Return the file descriptor of the socket object used internally.

Telnet. `write(buffer)`
Write a byte string to the socket, doubling any IAC characters. This can block if the connection is blocked. May raise `OSError` if the connection is closed.

   *Changed in version 3.3:* This method used to raise `socket.error`, which is now an alias of `OSError`.

Telnet. `interact()`
Interaction function, emulates a very dumb Telnet client.

Telnet. `mt_interact()`
Multithreaded version of `interact()`.

Telnet. `expect(list, timeout=None)`
Read until one from a list of a regular expressions matches.

The first argument is a list of regular expressions, either compiled (`regex objects`) or uncompiled (byte strings). The optional second argument is a timeout, in seconds; the default is to block
indefinitely.

Return a tuple of three items: the index in the list of the first regular expression that matches; the match object returned; and the bytes read up till and including the match.

If end of file is found and no bytes were read, raise `EOFError`. Otherwise, when nothing matches, return `(-1, None, data)` where `data` is the bytes received so far (may be empty bytes if a timeout happened).

If a regular expression ends with a greedy match (such as `.*`) or if more than one expression can match the same input, the results are non-deterministic, and may depend on the I/O timing.

`Telnet.set_option_negotiation_callback`\(\text{callback}\)\)

Each time a telnet option is read on the input flow, this `callback` (if set) is called with the following parameters: `callback(telnet socket, command (DO/DONT/WILL/WONT), option)`. No other action is done afterwards by telnetlib.
21.19.2. Telnet Example

A simple example illustrating typical use:

```python
import getpass
import telnetlib

HOST = "localhost"
user = input("Enter your remote account: ")
password = getpass.getpass()
	n = telnetlib.Telnet(HOST)
	n.read_until(b"login: ")
	n.write(user.encode('ascii') + b"\n")

if password:
    tn.read_until(b"Password: ")
    tn.write(password.encode('ascii') + b"\n")
	n.write(b"ls\n")
	n.write(b"exit\n")

print(tn.read_all().decode('ascii'))
```
21.20. **uuid** — UUID objects according to RFC 4122

**Source code:** Lib/uuid.py

This module provides immutable UUID objects (the UUID class) and the functions `uuid1()`, `uuid3()`, `uuid4()`, `uuid5()` for generating version 1, 3, 4, and 5 UUIDs as specified in RFC 4122.

If all you want is a unique ID, you should probably call `uuid1()` or `uuid4()`. Note that `uuid1()` may compromise privacy since it creates a UUID containing the computer’s network address. `uuid4()` creates a random UUID.

```python
class uuid.UUID(hex=None, bytes=None, bytes_le=None, fields=None, int=None, version=None)
```

Create a UUID from either a string of 32 hexadecimal digits, a string of 16 bytes as the `bytes` argument, a string of 16 bytes in little-endian order as the `bytes_le` argument, a tuple of six integers (32-bit `time_low`, 16-bit `time_mid`, 16-bit `time_hi_version`, 8-bit `clock_seq_hi_variant`, 8-bit `clock_seq_low`, 48-bit `node`) as the `fields` argument, or a single 128-bit integer as the `int` argument.

When a string of hex digits is given, curly braces, hyphens, and a URN prefix are all optional. For example, these expressions all yield the same UUID:

```
UUID('{{12345678-1234-5678-1234-567812345678}}')
UUID('12345678123456781234567812345678')
UUID('urn:uuid:12345678-1234-5678-1234-567812345678')
UUID(bytes=b'\x12\x34\x56\x78'*4)
```
Exactly one of *hex*, *bytes*, *bytes_le*, *fields*, or *int* must be given. The *version* argument is optional; if given, the resulting UUID will have its variant and version number set according to RFC 4122, overriding bits in the given *hex*, *bytes*, *bytes_le*, *fields*, or *int*.

Comparison of UUID objects are made by way of comparing their `UUID.int` attributes. Comparison with a non-UUID object raises a TypeError.

`str(uuid)` returns a string in the form `12345678-1234-5678-1234-567812345678` where the 32 hexadecimal digits represent the UUID.

**UUID** instances have these read-only attributes:

**UUID.** *bytes*

The UUID as a 16-byte string (containing the six integer fields in big-endian byte order).

**UUID.** *bytes_le*

The UUID as a 16-byte string (with `time_low`, `time_mid`, and `time_hi_version` in little-endian byte order).

**UUID.** *fields*

A tuple of the six integer fields of the UUID, which are also available as six individual attributes and two derived attributes:

<table>
<thead>
<tr>
<th>Field</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>time_low</td>
<td>the first 32 bits of the UUID</td>
</tr>
<tr>
<td>time_mid</td>
<td>the next 16 bits of the UUID</td>
</tr>
<tr>
<td>time_hi_version</td>
<td>the next 16 bits of the UUID</td>
</tr>
<tr>
<td>clock_seq_hi_variant</td>
<td>the next 8 bits of the UUID</td>
</tr>
<tr>
<td>clock_seq_low</td>
<td>the next 8 bits of the UUID</td>
</tr>
<tr>
<td>node</td>
<td>the last 48 bits of the UUID</td>
</tr>
<tr>
<td>time</td>
<td>the 60-bit timestamp</td>
</tr>
<tr>
<td>clock_seq</td>
<td>the 14-bit sequence number</td>
</tr>
</tbody>
</table>

**UUID. hex**

The UUID as a 32-character hexadecimal string.

**UUID. int**

The UUID as a 128-bit integer.

**UUID. urn**

The UUID as a URN as specified in RFC 4122.

**UUID. variant**

The UUID variant, which determines the internal layout of the UUID. This will be one of the constants `RESERVED_NCS`, `RFC_4122`, `RESERVED_MICROSOFT`, or `RESERVED_FUTURE`.

**UUID. version**

The UUID version number (1 through 5, meaningful only when the variant is `RFC_4122`).

The `uuid` module defines the following functions:

**uuid.getnode()**

Get the hardware address as a 48-bit positive integer. The first time
this runs, it may launch a separate program, which could be quite slow. If all attempts to obtain the hardware address fail, we choose a random 48-bit number with its eighth bit set to 1 as recommended in RFC 4122. “Hardware address” means the MAC address of a network interface, and on a machine with multiple network interfaces the MAC address of any one of them may be returned.

**uuid.uuid1**(node=None, clock_seq=None)
Generate a UUID from a host ID, sequence number, and the current time. If *node* is not given, `getnode()` is used to obtain the hardware address. If *clock_seq* is given, it is used as the sequence number; otherwise a random 14-bit sequence number is chosen.

**uuid.uuid3**(namespace, name)
Generate a UUID based on the MD5 hash of a namespace identifier (which is a UUID) and a name (which is a string).

**uuid.uuid4()**
Generate a random UUID.

**uuid.uuid5**(namespace, name)
Generate a UUID based on the SHA-1 hash of a namespace identifier (which is a UUID) and a name (which is a string).

The *uuid* module defines the following namespace identifiers for use with *uuid3()* or *uuid5()*.

**uuid.NAMESPACE_DNS**
When this namespace is specified, the *name* string is a fully-qualified domain name.

**uuid.NAMESPACE_URL**
When this namespace is specified, the *name* string is a URL.

**uuid.** `NAMESPACE_OID`

When this namespace is specified, the *name* string is an ISO OID.

**uuid.** `NAMESPACE_X500`

When this namespace is specified, the *name* string is an X.500 DN in DER or a text output format.

The `uuid` module defines the following constants for the possible values of the variant attribute:

**uuid.** `RESERVED_NCS`

Reserved for NCS compatibility.

**uuid.** `RFC_4122`

**uuid.** `RESERVED_MICROSOFT`

Reserved for Microsoft compatibility.

**uuid.** `RESERVED_FUTURE`

Reserved for future definition.

---

**See also:**

**RFC 4122** - A Universally Unique IDentifier (UUID) URN Namespace

This specification defines a Uniform Resource Name namespace for UUIDs, the internal format of UUIDs, and methods of generating UUIDs.
21.20.1. Example

Here are some examples of typical usage of the `uuid` module:

```python
>>> import uuid

>>> # make a UUID based on the host ID and current time
>>> uuid.uuid1()
UUID('a8098c1a-f86e-11da-bd1a-00112444be1e')

>>> # make a UUID using an MD5 hash of a namespace UUID and name
>>> uuid.uuid3(uuid.NAMESPACE_DNS, 'python.org')
UUID('6fa459ea-ee8a-3ca4-894e-db77e160355e')

>>> # make a random UUID
>>> uuid.uuid4()
UUID('16fd2706-8baf-433b-82eb-8c7fada847da')

>>> # make a UUID using a SHA-1 hash of a namespace UUID and name
>>> uuid.uuid5(uuid.NAMESPACE_DNS, 'python.org')
UUID('886313e1-3b8a-5372-9b90-0c9aee199e5d')

>>> # make a UUID from a string of hex digits (braces and hyphens ignored)
>>> x = uuid.UUID('{00010203-0405-0607-0809-0a0b0c0d0e0f}')

>>> # convert a UUID to a string of hex digits in standard form
>>> str(x)
'00010203-0405-0607-0809-0a0b0c0d0e0f'

>>> # get the raw 16 bytes of the UUID
>>> x.bytes
b'\x00\x01\x02\x03\x04\x05\x06\x07\x08\t\n\0b\0c\r
'

>>> # make a UUID from a 16-byte string
>>> uuid.UUID(bytes=x.bytes)
```
21. Internet Protocols and Support

**Source code:** Lib/socketserver.py

The `socketserver` module simplifies the task of writing network servers.

There are four basic concrete server classes:

```python
class socketserver.TCPServer(server_address, RequestHandlerClass, bind_and_activate=True)
```

This uses the Internet TCP protocol, which provides for continuous streams of data between the client and server. If `bind_and_activate` is true, the constructor automatically attempts to invoke `server_bind()` and `server_activate()`. The other parameters are passed to the `BaseServer` base class.

```python
class socketserver.UDPServer(server_address, RequestHandlerClass, bind_and_activate=True)
```

This uses datagrams, which are discrete packets of information that may arrive out of order or be lost while in transit. The parameters are the same as for `TCPServer`.

```python
class socketserver.UnixStreamServer(server_address, RequestHandlerClass, bind_and_activate=True)
class socketserver.UnixDatagramServer(server_address, RequestHandlerClass, bind_and_activate=True)
```

These more infrequently used classes are similar to the TCP and UDP classes, but use Unix domain sockets; they’re not available...
on non-Unix platforms. The parameters are the same as for
**TCP**Server.

These four classes process requests *synchronously*; each request
must be completed before the next request can be started. This isn’t
suitable if each request takes a long time to complete, because it
requires a lot of computation, or because it returns a lot of data which
the client is slow to process. The solution is to create a separate
process or thread to handle each request; the **ForkingMixIn** and
**ThreadingMixIn** mix-in classes can be used to support
asynchronous behaviour.

Creating a server requires several steps. First, you must create a
request handler class by subclassing the **BaseRequestHandler**
class and overriding its **handle()** method; this method will process
incoming requests. Second, you must instantiate one of the server
classes, passing it the server’s address and the request handler class.
It is recommended to use the server in a **with** statement. Then call
the **handle_request()** or **serve_forever()** method of the
server object to process one or many requests. Finally, call
**server_close()** to close the socket (unless you used a **with**
statement).

When inheriting from **ThreadingMixIn** for threaded connection
behavior, you should explicitly declare how you want your threads to
behave on an abrupt shutdown. The **ThreadingMixIn** class defines
an attribute **daemon_threads**, which indicates whether or not the
server should wait for thread termination. You should set the flag
explicitly if you would like threads to behave autonomously; the default
is **False**, meaning that Python will not exit until all threads created by
**ThreadingMixIn** have exited.
Server classes have the same external methods and attributes, no matter what network protocol they use.
21.21.1. Server Creation Notes

There are five classes in an inheritance diagram, four of which represent synchronous servers of four types:

```
+------------+          +------------------+
| BaseServer |          |                  |
+------------+          +------------------+
    |      +------------------+
    v      |                  |
+------------+          +------------------+
| TCPServer  |------->| UnixStreamServer |
+------------+          +------------------+
    |      +------------------+
    v      |                  |
+------------+          +------------------+
| UDPServer  |------->| UnixDatagramServer |
+------------+          +------------------+
```

Note that `UnixDatagramServer` derives from `UDPServer`, not from `UnixStreamServer` — the only difference between an IP and a Unix stream server is the address family, which is simply repeated in both Unix server classes.

```python
class socketserver.ForkingMixIn
class socketserver.ThreadingMixIn
```

Forking and threading versions of each type of server can be created using these mix-in classes. For instance, `ThreadingUDPServer` is created as follows:

```python
class ThreadingUDPServer(ThreadingMixIn, UDPServe
```
The mix-in class comes first, since it overrides a method defined in `UDPServer`. Setting the various attributes also changes the behavior of the underlying server mechanism.

`ForkingMixIn` and the Forking classes mentioned below are only available on POSIX platforms that support `fork()`.

```python
class socketserver.ForkingTCPServer
class socketserver.ForkingUDPServer
class socketserver.ThreadingTCPServer
class socketserver.ThreadingUDPServer
```

These classes are pre-defined using the mix-in classes.

To implement a service, you must derive a class from `BaseRequestHandler` and redefine its `handle()` method. You can then run various versions of the service by combining one of the server classes with your request handler class. The request handler class must be different for datagram or stream services. This can be hidden by using the handler subclasses `StreamRequestHandler` or `DatagramRequestHandler`.

Of course, you still have to use your head! For instance, it makes no sense to use a forking server if the service contains state in memory that can be modified by different requests, since the modifications in the child process would never reach the initial state kept in the parent process and passed to each child. In this case, you can use a threading server, but you will probably have to use locks to protect the integrity of the shared data.

On the other hand, if you are building an HTTP server where all data is stored externally (for instance, in the file system), a synchronous class will essentially render the service “deaf” while one request is being handled – which may be for a very long time if a client is slow to
receive all the data it has requested. Here a threading or forking server is appropriate.

In some cases, it may be appropriate to process part of a request synchronously, but to finish processing in a forked child depending on the request data. This can be implemented by using a synchronous server and doing an explicit fork in the request handler class `handle()` method.

Another approach to handling multiple simultaneous requests in an environment that supports neither threads nor `fork()` (or where these are too expensive or inappropriate for the service) is to maintain an explicit table of partially finished requests and to use `selectors` to decide which request to work on next (or whether to handle a new incoming request). This is particularly important for stream services where each client can potentially be connected for a long time (if threads or subprocesses cannot be used). See `asyncore` for another way to manage this.
21.21.2. Server Objects

```python
class socketserver.BaseServer(server_address, RequestHandlerClass)
```

This is the superclass of all Server objects in the module. It defines the interface, given below, but does not implement most of the methods, which is done in subclasses. The two parameters are stored in the respective `server_address` and `RequestHandlerClass` attributes.

**fileno()**

Return an integer file descriptor for the socket on which the server is listening. This function is most commonly passed to `selectors`, to allow monitoring multiple servers in the same process.

**handle_request()**

Process a single request. This function calls the following methods in order: `get_request()`, `verify_request()`, and `process_request()`. If the user-provided `handle()` method of the handler class raises an exception, the server's `handle_error()` method will be called. If no request is received within `timeout` seconds, `handle_timeout()` will be called and `handle_request()` will return.

**serve_forever**(poll_interval=0.5)

Handle requests until an explicit `shutdown()` request. Poll for shutdown every `poll_interval` seconds. Ignores the `timeout` attribute. It also calls `service_actions()`, which may be used by a subclass or mixin to provide actions specific to a
given service. For example, the ForkingMixIn class uses service_actions() to clean up zombie child processes.

*Changed in version 3.3:* Added service_actions call to the serve_forever method.

**service_actions()**
This is called in the serve_forever() loop. This method can be overridden by subclasses or mixin classes to perform actions specific to a given service, such as cleanup actions.

*New in version 3.3.*

**shutdown()**
Tell the serve_forever() loop to stop and wait until it does.

**server_close()**
Clean up the server. May be overridden.

**address_family**
The family of protocols to which the server’s socket belongs. Common examples are socket.AF_INET and socket.AF_UNIX.

**RequestHandlerClass**
The user-provided request handler class; an instance of this class is created for each request.

**server_address**
The address on which the server is listening. The format of addresses varies depending on the protocol family; see the documentation for the socket module for details. For Internet protocols, this is a tuple containing a string giving the address,
and an integer port number: ('127.0.0.1', 80), for example.

**socket**

The socket object on which the server will listen for incoming requests.

The server classes support the following class variables:

**allow_reuse_address**

Whether the server will allow the reuse of an address. This defaults to *False*, and can be set in subclasses to change the policy.

**request_queue_size**

The size of the request queue. If it takes a long time to process a single request, any requests that arrive while the server is busy are placed into a queue, up to *request_queue_size* requests. Once the queue is full, further requests from clients will get a “Connection denied” error. The default value is usually 5, but this can be overridden by subclasses.

**socket_type**

The type of socket used by the server; *socket.SOCK_STREAM* and *socket.SOCK_DGRAM* are two common values.

**timeout**

Timeout duration, measured in seconds, or *None* if no timeout is desired. If *handle_request()* receives no incoming requests within the timeout period, the *handle_timeout()* method is called.

There are various server methods that can be overridden by
subclasses of base server classes like `TCPServer`; these methods aren’t useful to external users of the server object.

**finish_request()**
Actually processes the request by instantiating `RequestHandlerClass` and calling its `handle()` method.

**get_request()**
Must accept a request from the socket, and return a 2-tuple containing the new socket object to be used to communicate with the client, and the client’s address.

**handle_error**(request, client_address)
This function is called if the `handle()` method of a `RequestHandlerClass` instance raises an exception. The default action is to print the traceback to standard error and continue handling further requests.

*Changed in version 3.6:* Now only called for exceptions derived from the `Exception` class.

**handle_timeout()**
This function is called when the `timeout` attribute has been set to a value other than `None` and the timeout period has passed with no requests being received. The default action for forking servers is to collect the status of any child processes that have exited, while in threading servers this method does nothing.

**process_request**(request, client_address)
Calls `finish_request()` to create an instance of the `RequestHandlerClass`. If desired, this function can create a
new process or thread to handle the request; the ForkingMixIn and ThreadingMixIn classes do this.

server_activate()
Called by the server’s constructor to activate the server. The default behavior for a TCP server just invokes listen() on the server’s socket. May be overridden.

server_bind()
Called by the server’s constructor to bind the socket to the desired address. May be overridden.

verify_request(request, client_address)
Must return a Boolean value; if the value is True, the request will be processed, and if it’s False, the request will be denied. This function can be overridden to implement access controls for a server. The default implementation always returns True.

Changed in version 3.6: Support for the context manager protocol was added. Exiting the context manager is equivalent to calling server_close().
21.21.3. Request Handler Objects

class socketserver.BaseRequestHandler

This is the superclass of all request handler objects. It defines the interface, given below. A concrete request handler subclass must define a new handle() method, and can override any of the other methods. A new instance of the subclass is created for each request.

setup()

Called before the handle() method to perform any initialization actions required. The default implementation does nothing.

handle()

This function must do all the work required to service a request. The default implementation does nothing. Several instance attributes are available to it; the request is available as self.request; the client address as self.client_address; and the server instance as self.server, in case it needs access to per-server information.

The type of self.request is different for datagram or stream services. For stream services, self.request is a socket object; for datagram services, self.request is a pair of string and socket.

finish()

Called after the handle() method to perform any clean-up actions required. The default implementation does nothing. If
setup() raises an exception, this function will not be called.

class socketserver.StreamRequestHandler
class socketserver.DatagramRequestHandler

These BaseRequestHandler subclasses override the setup() and finish() methods, and provide self.rfile and self.wfile attributes. The self.rfile and self.wfile attributes can be read or written, respectively, to get the request data or return data to the client.

The rfile attributes of both classes support the io.BufferedIOBase readable interface, and DatagramRequestHandler.wfile supports the io.BufferedIOBase writable interface.

Changed in version 3.6: StreamRequestHandler.wfile also supports the io.BufferedIOBase writable interface.
21.21.4. Examples

21.21.4.1. `socketserver.TCPServer` Example

This is the server side:

```python
import socketserver

class MyTCPHandler(socketserver.BaseRequestHandler):
    
    """
    The request handler class for our server.
    """
    
    def handle(self):
        
        # self.request is the TCP socket connected to the
        self.data = self.request.recv(1024).strip()
        print("{} wrote:".format(self.client_address))
        print(self.data)
        
        # just send back the same data, but upper-cased
        self.request.sendall(self.data.upper())

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999
    
    # Create the server, binding to localhost on port 9999
    with socketserver.TCPServer((HOST, PORT), MyTCPHandler):
        # Activate the server; this will keep running
        # interrupt the program with Ctrl-C
        server.serve_forever()
```
An alternative request handler class that makes use of streams (file-like objects that simplify communication by providing the standard file interface):

class MyTCPHandler(socketserver.StreamRequestHandler):
    def handle(self):
        # self.rfile is a file-like object created by the handler;
        # we can now use e.g. readline() instead of
        self.data = self.rfile.readline().strip()
        print("{} wrote:"
              .format(self.client_address))
        print(self.data)
        # Likewise, self.wfile is a file-like object
        # to the client
        self.wfile.write(self.data.upper())

The difference is that the `readline()` call in the second handler will call `recv()` multiple times until it encounters a newline character, while the single `recv()` call in the first handler will just return what has been sent from the client in one `sendall()` call.

This is the client side:

```python
import socket
import sys

HOST, PORT = "localhost", 9999
data = " ".join(sys.argv[1:])

# Create a socket (SOCK_STREAM means a TCP socket)
with socket.socket(socket.AF_INET, socket.SOCK_STREAM) as sock:
    # Connect to server and send data
    sock.connect((HOST, PORT))
    sock.sendall(bytes(data + "\n", "utf-8"))
```
# Receive data from the server and shut down
received = str(sock.recv(1024), "utf-8")

print("Sent: {}").format(data))
print("Received: {}").format(received))

The output of the example should look something like this:

**Server:**

```
$ python TCPServer.py
127.0.0.1 wrote:
b'hello world with TCP'
127.0.0.1 wrote:
b'python is nice'
```

**Client:**

```
$ python TCPClient.py hello world with TCP
Sent: hello world with TCP
Received: HELLO WORLD WITH TCP
$ python TCPClient.py python is nice
Sent: python is nice
Received: PYTHON IS NICE
```

21.21.4.2. `socketserver.UDPServer` Example

This is the server side:

```python
import socketserver

class MyUDPHandler(socketserver.BaseRequestHandler):
    ""
    This class works similar to the TCP handler class
```
self.request consists of a pair of data and client socket, and since there is no connection the client address must be given explicitly when sending data back via sendto().

```
def handle(self):
    data = self.request[0].strip()
    socket = self.request[1]
    print("{} wrote:").format(self.client_address)
    print(data)
    socket.sendto(data.upper(), self.client_address)

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999
    with socketserver.UDPServer((HOST, PORT), MyUDPHandler):
        server.serve_forever()
```

This is the client side:

```
import socket
import sys

HOST, PORT = "localhost", 9999
data = " ".join(sys.argv[1:])

# SOCK_DGRAM is the socket type to use for UDP sockets
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)

# As you can see, there is no connect() call; UDP has
# Instead, data is directly sent to the recipient via
sock.sendto(bytes(data + "\n", "utf-8"), (HOST, PORT))
received = str(sock.recv(1024), "utf-8")

print("Sent: {}".format(data))
print("Received: {}".format(received))
```
The output of the example should look exactly like for the TCP server
example.

21.21.4.3. Asynchronous Mixins
To build asynchronous handlers, use the ThreadingMixIn and
ForkingMixIn classes.
An example for the ThreadingMixIn class:
import socket
import threading
import socketserver
class ThreadedTCPRequestHandler(socketserver.BaseRequestHand
def handle(self):
data = str(self.request.recv(1024), 'ascii')
cur_thread = threading.current_thread()
response = bytes("{}: {}".format(cur_thread.
self.request.sendall(response)
class ThreadedTCPServer(socketserver.ThreadingMixIn,
pass
def client(ip, port, message):
with socket.socket(socket.AF_INET, socket.SOCK_STREAM
sock.connect((ip, port))
sock.sendall(bytes(message, 'ascii'))
response = str(sock.recv(1024), 'ascii')
print("Received: {}".format(response))
if __name__ == "__main__":
# Port 0 means to select an arbitrary unused port
HOST, PORT = "localhost", 0


server = ThreadedTCPServer((HOST, PORT), ThreadedTCPRequestHandler)

with server:
    ip, port = server.server_address

    # Start a thread with the server -- that thread will then start one more thread for each request
    server_thread = threading.Thread(target=server.serve_forever, daemon=True)
    server_thread.start()
    print("Server loop running in thread: ", server_thread)

    client(ip, port, "Hello World 1")
    client(ip, port, "Hello World 2")
    client(ip, port, "Hello World 3")

server.shutdown()

The output of the example should look something like this:

$ python ThreadedTCPServer.py
Server loop running in thread: Thread-1
Received: Thread-2: Hello World 1
Received: Thread-3: Hello World 2
Received: Thread-4: Hello World 3

The ForkingMixIn class is used in the same way, except that the server will spawn a new process for each request. Available only on POSIX platforms that support fork().
The Python Software Foundation is a non-profit corporation. Please donate.

Created using Sphinx 1.6.3.
### 21.22. **http.server** — HTTP servers

**Source code:** Lib/http/server.py

This module defines classes for implementing HTTP servers (Web servers).

One class, `HTTPServer`, is a `socketserver.TCPServer` subclass. It creates and listens at the HTTP socket, dispatching the requests to a handler. Code to create and run the server looks like this:

```python
def run(server_class=HTTPServer, handler_class=BaseHTTPRequestHandler, server_address=('', 8000)):
    httpd = server_class(server_address, handler_class)
    httpd.serve_forever()
```

**class** `http.server.HTTPServer(server_address, RequestHandlerClass)`

This class builds on the `TCPServer` class by storing the server address as instance variables named `server_name` and `server_port`. The server is accessible by the handler, typically through the handler’s server instance variable.

The `HTTPServer` must be given a `RequestHandlerClass` on instantiation, of which this module provides three different variants:

**class** `http.server.BaseHTTPRequestHandler(request, client_address, server)`
This class is used to handle the HTTP requests that arrive at the server. By itself, it cannot respond to any actual HTTP requests; it must be subclassed to handle each request method (e.g. GET or POST). `BaseHTTPRequestHandler` provides a number of class and instance variables, and methods for use by subclasses.

The handler will parse the request and the headers, then call a method specific to the request type. The method name is constructed from the request. For example, for the request method `SPAM`, the `do_SPAM()` method will be called with no arguments. All of the relevant information is stored in instance variables of the handler. Subclasses should not need to override or extend the `__init__()` method.

`BaseHTTPRequestHandler` has the following instance variables:

**client_address**
Contains a tuple of the form `(host, port)` referring to the client's address.

**server**
Contains the server instance.

**close_connection**
Boolean that should be set before `handle_one_request()` returns, indicating if another request may be expected, or if the connection should be shut down.

**requestline**
Contains the string representation of the HTTP request line. The terminating CRLF is stripped. This attribute should be set by `handle_one_request()`. If no valid request line was processed, it should be set to the empty string.
command
Contains the command (request type). For example, 'GET'.

path
Contains the request path.

request_version
Contains the version string from the request. For example, 'HTTP/1.0'.

headers
Holds an instance of the class specified by the MessageClass class variable. This instance parses and manages the headers in the HTTP request. The parse_headers() function from http.client is used to parse the headers and it requires that the HTTP request provide a valid RFC 2822 style header.

rfile
An io.BufferedIOBase input stream, ready to read from the start of the optional input data.

wfile
Contains the output stream for writing a response back to the client. Proper adherence to the HTTP protocol must be used when writing to this stream in order to achieve successful interoperation with HTTP clients.

Changed in version 3.6: This is an io.BufferedIOBase stream.

BaseHTTPRequestHandler has the following attributes:

server_version
Specifies the server software version. You may want to override this. The format is multiple whitespace-separated strings, where each string is of the form name[/version]. For example, 'BaseHTTP/0.2'.

**sys_version**

Contains the Python system version, in a form usable by the `version_string` method and the `server_version` class variable. For example, 'Python/1.4'.

**error_message_format**

Specifies a format string that should be used by `send_error()` method for building an error response to the client. The string is filled by default with variables from `responses` based on the status code that passed to `send_error()`.

**error_content_type**

Specifies the Content-Type HTTP header of error responses sent to the client. The default value is 'text/html'.

**protocol_version**

This specifies the HTTP protocol version used in responses. If set to 'HTTP/1.1', the server will permit HTTP persistent connections; however, your server must then include an accurate Content-Length header (using `send_header()`) in all of its responses to clients. For backwards compatibility, the setting defaults to 'HTTP/1.0'.

**MessageClass**

Specifies an `email.message.Message`-like class to parse HTTP headers. Typically, this is not overridden, and it defaults
to http.client.HTTPMessage.

**responses**
This attribute contains a mapping of error code integers to two-element tuples containing a short and long message. For example, \{code: (shortmessage, longmessage)\}. The *shortmessage* is usually used as the *message* key in an error response, and *longmessage* as the *explain* key. It is used by *send_response_only()* and *send_error()* methods.

A *BaseHTTPRequestHandler* instance has the following methods:

**handle()**
Calls *handle_one_request()* once (or, if persistent connections are enabled, multiple times) to handle incoming HTTP requests. You should never need to override it; instead, implement appropriate do_*()* methods.

**handle_one_request()**
This method will parse and dispatch the request to the appropriate do_*()* method. You should never need to override it.

**handle_expect_100()**
When a HTTP/1.1 compliant server receives an *Expect: 100-continue* request header it responds back with a 100 *Continue* followed by 200 *OK* headers. This method can be overridden to raise an error if the server does not want the client to continue. For e.g. server can chose to send 417 *Expectation Failed* as a response header and return False.
New in version 3.2.

**send_error**(code, message=None, explain=None)
Sends and logs a complete error reply to the client. The numeric `code` specifies the HTTP error code, with `message` as an optional, short, human readable description of the error. The `explain` argument can be used to provide more detailed information about the error; it will be formatted using the `error_message_format` attribute and emitted, after a complete set of headers, as the response body. The `responses` attribute holds the default values for `message` and `explain` that will be used if no value is provided; for unknown codes the default value for both is the string `??`. The body will be empty if the method is HEAD or the response code is one of the following: 1xx, 204 No Content, 205 Reset Content, 304 Not Modified.

*Changed in version 3.4:* The error response includes a Content-Length header. Added the `explain` argument.

**send_response**(code, message=None)
Adds a response header to the headers buffer and logs the accepted request. The HTTP response line is written to the internal buffer, followed by `Server` and `Date` headers. The values for these two headers are picked up from the `version_string()` and `date_time_string()` methods, respectively. If the server does not intend to send any other headers using the `send_header()` method, then `send_response()` should be followed by an `end_headers()` call.

*Changed in version 3.3:* Headers are stored to an internal buffer
and `end_headers()` needs to be called explicitly.

**send_header** *(keyword, value)*

Adds the HTTP header to an internal buffer which will be written to the output stream when either `end_headers()` or `flush_headers()` is invoked. *keyword* should specify the header keyword, with *value* specifying its value. Note that, after the send_header calls are done, `end_headers()` MUST BE called in order to complete the operation.

*Changed in version 3.2:* Headers are stored in an internal buffer.

**send_response_only** *(code, message=None)*

Sends the response header only, used for the purposes when 100 Continue response is sent by the server to the client. The headers not buffered and sent directly the output stream. If the *message* is not specified, the HTTP message corresponding the response *code* is sent.

*New in version 3.2.*

**end_headers()**

Adds a blank line (indicating the end of the HTTP headers in the response) to the headers buffer and calls `flush_headers()`.

*Changed in version 3.2:* The buffered headers are written to the output stream.

**flush_headers()**

Finally send the headers to the output stream and flush the internal headers buffer.
New in version 3.3.

**log_request**(code='-', size='-')

Logs an accepted (successful) request. *code* should specify the numeric HTTP code associated with the response. If a size of the response is available, then it should be passed as the *size* parameter.

**log_error**(...)

Logs an error when a request cannot be fulfilled. By default, it passes the message to **log_message()**, so it takes the same arguments (*format* and additional values).

**log_message**(format, ...)

Logs an arbitrary message to `sys.stderr`. This is typically overridden to create custom error logging mechanisms. The *format* argument is a standard printf-style format string, where the additional arguments to **log_message()** are applied as inputs to the formatting. The client ip address and current date and time are prefixed to every message logged.

**version_string()**

Returns the server software’s version string. This is a combination of the *server_version* and *sys_version* attributes.

**date_time_string**(timestamp=None)

Returns the date and time given by *timestamp* (which must be *None* or in the format returned by `time.time()`), formatted for a message header. If *timestamp* is omitted, it uses the current date and time.
The result looks like 'Sun, 06 Nov 1994 08:49:37 GMT'.

log_date_time_string()
Returns the current date and time, formatted for logging.

address_string()
Returns the client address.

*Changed in version 3.3:* Previously, a name lookup was performed. To avoid name resolution delays, it now always returns the IP address.

class http.server.SimpleHTTPRequestHandler(request, client_address, server)
This class serves files from the current directory and below, directly mapping the directory structure to HTTP requests.

A lot of the work, such as parsing the request, is done by the base class BaseHTTPRequestHandler. This class implements the do_GET() and do_HEAD() functions.

The following are defined as class-level attributes of SimpleHTTPRequestHandler:

server_version
This will be "SimpleHTTP/" + __version__, where __version__ is defined at the module level.

extensions_map
A dictionary mapping suffixes into MIME types. The default is signified by an empty string, and is considered to be application/octet-stream. The mapping is used case-insensitively, and so should contain only lower-cased keys.
The SimpleHTTPRequestHandler class defines the following methods:

**do_HEAD()**

This method serves the 'HEAD' request type: it sends the headers it would send for the equivalent GET request. See the do_GET() method for a more complete explanation of the possible headers.

**do_GET()**

The request is mapped to a local file by interpreting the request as a path relative to the current working directory.

If the request was mapped to a directory, the directory is checked for a file named index.html or index.htm (in that order). If found, the file's contents are returned; otherwise a directory listing is generated by calling the list_directory() method. This method uses os.listdir() to scan the directory, and returns a 404 error response if the listdir() fails.

If the request was mapped to a file, it is opened and the contents are returned. Any OSError exception in opening the requested file is mapped to a 404, 'File not found' error. Otherwise, the content type is guessed by calling the guess_type() method, which in turn uses the extensions_map variable.

A 'Content-type:' header with the guessed content type is output, followed by a 'Content-Length:' header with the file's size and a 'Last-Modified:' header with the file's modification time.
Then follows a blank line signifying the end of the headers, and then the contents of the file are output. If the file's MIME type starts with `text/` the file is opened in text mode; otherwise binary mode is used.

For example usage, see the implementation of the `test()` function invocation in the `http.server` module.

The `SimpleHTTPRequestHandler` class can be used in the following manner in order to create a very basic webserver serving files relative to the current directory:

```python
import http.server
import socketserver

PORT = 8000

Handler = http.server.SimpleHTTPRequestHandler

with socketserver.TCPServer(('', PORT), Handler) as httpd:
    print("serving at port", PORT)
    httpd.serve_forever()
```

`http.server` can also be invoked directly using the `-m` switch of the interpreter with a `port number` argument. Similar to the previous example, this serves files relative to the current directory:

```bash
python -m http.server 8000
```

By default, server binds itself to all interfaces. The option `-b/--bind` specifies a specific address to which it should bind. For example, the following command causes the server to bind to localhost only:
New in version 3.4: `--bind` argument was introduced.

class http.server.CGIHTTPRequestHandler(request, client_address, server)

This class is used to serve either files or output of CGI scripts from the current directory and below. Note that mapping HTTP hierarchic structure to local directory structure is exactly as in SimpleHTTPRequestHandler.

**Note:** CGI scripts run by the CGIHTTPRequestHandler class cannot execute redirects (HTTP code 302), because code 200 (script output follows) is sent prior to execution of the CGI script. This pre-empts the status code.

The class will however, run the CGI script, instead of serving it as a file, if it guesses it to be a CGI script. Only directory-based CGI are used — the other common server configuration is to treat special extensions as denoting CGI scripts.

The `do_GET()` and `do_HEAD()` functions are modified to run CGI scripts and serve the output, instead of serving files, if the request leads to somewhere below the `cgi_directories` path.

The CGIHTTPRequestHandler defines the following data member:

**cgi_directories**

This defaults to `[/cgi-bin/, /htbin/]` and describes directories to treat as containing CGI scripts.

The CGIHTTPRequestHandler defines the following method:
**do_POST()**

This method serves the 'POST' request type, only allowed for CGI scripts. Error 501, “Can only POST to CGI scripts”, is output when trying to POST to a non-CGI url.

Note that CGI scripts will be run with UID of user nobody, for security reasons. Problems with the CGI script will be translated to error 403.

**CGIHTTPRequestHandler** can be enabled in the command line by passing the --cgi option:

```
python -m http.server --cgi 8000
```
21.23. **http.cookies** — HTTP state management

**Source code:** Lib/http/cookies.py

The `http.cookies` module defines classes for abstracting the concept of cookies, an HTTP state management mechanism. It supports both simple string-only cookies, and provides an abstraction for having any serializable data-type as cookie value.

The module formerly strictly applied the parsing rules described in the [RFC 2109](https://tools.ietf.org/html/rfc2109) and [RFC 2068](https://tools.ietf.org/html/rfc2068) specifications. It has since been discovered that MSIE 3.0x doesn’t follow the character rules outlined in those specs and also many current day browsers and servers have relaxed parsing rules when comes to Cookie handling. As a result, the parsing rules used are a bit less strict.

The character set, `string.ascii_letters`, `string.digits` and `!#$%&'*+-.^_`~:: denote the set of valid characters allowed by this module in Cookie name (as key).

**Changed in version 3.3:** Allowed ‘:’ as a valid Cookie name character.

**Note:** On encountering an invalid cookie, `CookieError` is raised, so if your cookie data comes from a browser you should always prepare for invalid data and catch `CookieError` on parsing.

```python
exception http.cookies.CookieError

Exception failing because of RFC 2109 invalidity: incorrect
```
attributes, incorrect Set-Cookie header, etc.

```python
class http.cookies.BaseCookie([input])
```

This class is a dictionary-like object whose keys are strings and whose values are `Morsel` instances. Note that upon setting a key to a value, the value is first converted to a `Morsel` containing the key and the value.

If `input` is given, it is passed to the `load()` method.

```python
class http.cookies.SimpleCookie([input])
```

This class derives from `BaseCookie` and overrides `value_decode()` and `value_encode()` to be the identity and `str()` respectively.

---

**See also:**

**Module http.cookiejar**

HTTP cookie handling for web clients. The `http.cookiejar` and `http.cookies` modules do not depend on each other.

**RFC 2109 - HTTP State Management Mechanism**

This is the state management specification implemented by this module.
21.23.1. Cookie Objects

BaseCookie.value_decode(val)
Return a decoded value from a string representation. Return value can be any type. This method does nothing in BaseCookie — it exists so it can be overridden.

BaseCookie.value_encode(val)
Return an encoded value. val can be any type, but return value must be a string. This method does nothing in BaseCookie — it exists so it can be overridden.

In general, it should be the case that value_encode() and value_decode() are inverses on the range of value_decode.

BaseCookie.output(attrs=None, header='Set-Cookie:', sep='
')
Return a string representation suitable to be sent as HTTP headers. attrs and header are sent to each Morsel's output() method. sep is used to join the headers together, and is by default the combination '
' (CRLF).

BaseCookie.js_output(attrs=None)
Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP headers was sent.

The meaning for attrs is the same as in output().

BaseCookie.load(rawdata)
If rawdata is a string, parse it as an HTTP_COOKIE and add the values found there as Morsels. If it is a dictionary, it is equivalent
for k, v in rawdata.items():
    cookie[k] = v
21.23.2. Morsel Objects

```python
class http.cookies.Morsel
```

Abstract a key/value pair, which has some RFC 2109 attributes.

Morsels are dictionary-like objects, whose set of keys is constant — the valid RFC 2109 attributes, which are

- `expires`
- `path`
- `comment`
- `domain`
- `max-age`
- `secure`
- `version`
- `httponly`

The attribute `httponly` specifies that the cookie is only transferred in HTTP requests, and is not accessible through JavaScript. This is intended to mitigate some forms of cross-site scripting.

The keys are case-insensitive and their default value is `'`

*Changed in version 3.5*: `__eq__()` now takes `key` and `value` into account.

```python
Morsel.value
```

The value of the cookie.

*Deprecated since version 3.5*: assigning to `value`; use `set()` instead.
Morsel. **coded_value**

The encoded value of the cookie — this is what should be sent.

*Deprecated since version 3.5:* assigning to `coded_value`; use `set()` instead.

Morsel. **key**

The name of the cookie.

*Deprecated since version 3.5:* assigning to `key`; use `set()` instead.

Morsel. **set(key, value, coded_value)**

Set the `key`, `value` and `coded_value` attributes.

*Deprecated since version 3.5:* The undocumented `LegalChars` parameter is ignored and will be removed in a future version.

Morsel. **isReservedKey(K)**

Whether `K` is a member of the set of keys of a Morsel.

Morsel. **output(** *attrs=None, header='Set-Cookie:'*)**

Return a string representation of the Morsel, suitable to be sent as an HTTP header. By default, all the attributes are included, unless `attrs` is given, in which case it should be a list of attributes to use. `header` is by default "Set-Cookie:"

Morsel. **js_output(** *attrs=None*)**

Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP header was sent.

The meaning for `attrs` is the same as in `output()`.
Morsel. **OutputString**(*attrs=None*)

Return a string representing the Morsel, without any surrounding HTTP or JavaScript.

The meaning for *attrs* is the same as in *output()*.

Morsel. **update**(values)

Update the values in the Morsel dictionary with the values in the dictionary *values*. Raise an error if any of the keys in the *values* dict is not a valid RFC 2109 attribute.

*Changed in version 3.5*: an error is raised for invalid keys.

Morsel. **copy**(value)

Return a shallow copy of the Morsel object.

*Changed in version 3.5*: return a Morsel object instead of a dict.

Morsel. **setdefault**(key, *value=None*)

Raise an error if key is not a valid RFC 2109 attribute, otherwise behave the same as *dict.setdefault()*.
21.23.3. Example

The following example demonstrates how to use the `http.cookies` module.

```python
>>> from http import cookies
>>> C = cookies.SimpleCookie()
>>> C["fig"] = "newton"
>>> C["sugar"] = "wafer"
>>> print(C)  # generate HTTP headers
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> print(C.output())  # same thing
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> C = cookies.SimpleCookie()
>>> C["rocky"] = "road"
>>> C["rocky"]["path"] = "/cookie"
>>> print(C.output(header="Cookie:"))
Cookie: rocky=road; Path=/cookie
>>> print(C.output(attrs=[], header="Cookie:"))
Cookie: rocky=road
>>> C = cookies.SimpleCookie()
>>> C.load("chips=ahoy; vienna=finger")  # load from
>>> print(C)
Set-Cookie: chips=ahoy
Set-Cookie: vienna=finger
>>> C = cookies.SimpleCookie()
>>> C.load('keebler="E=everybody; L="Loves\"; fudge"
>>> print(C)
Set-Cookie: keebler="E=everybody; L="Loves"; fudge
>>> C = cookies.SimpleCookie()
>>> C["oreo"] = "doublestuff"
>>> C["oreo"]["path"] = "/"
>>> print(C)
```
Set-Cookie: oreo=doublestuff; Path=/
>>> C = cookies.SimpleCookie()
>>> C['twix'] = "none for you"
>>> C['twix'].value
'none for you'
>>> C = cookies.SimpleCookie()
>>> C['number'] = 7  # equivalent to C['number'] = str(7)
>>> C['string'] = "seven"
>>> C['number'].value
'7'
>>> C['string'].value
'seven'
>>> print(C)
Set-Cookie: number=7
Set-Cookie: string=seven
The `http.cookiejar` module defines classes for automatic handling of HTTP cookies. It is useful for accessing web sites that require small pieces of data – *cookies* – to be set on the client machine by an HTTP response from a web server, and then returned to the server in later HTTP requests.

Both the regular Netscape cookie protocol and the protocol defined by [RFC 2965](https://www.rfc-editor.org/rfc/rfc2965) are handled. RFC 2965 handling is switched off by default. [RFC 2109](https://www.rfc-editor.org/rfc/rfc2109) cookies are parsed as Netscape cookies and subsequently treated either as Netscape or RFC 2965 cookies according to the ‘policy’ in effect. Note that the great majority of cookies on the Internet are Netscape cookies. `http.cookiejar` attempts to follow the de-facto Netscape cookie protocol (which differs substantially from that set out in the original Netscape specification), including taking note of the `max-age` and `port` cookie-attributes introduced with RFC 2965.

**Note:** The various named parameters found in `Set-Cookie` and `Set-Cookie2` headers (eg. `domain` and `expires`) are conventionally referred to as *attributes*. To distinguish them from Python attributes, the documentation for this module uses the term *cookie-attribute* instead.

The module defines the following exception:
exception http.cookiejar.LoadError

Instances of FileCookieJar raise this exception on failure to load cookies from a file. LoadError is a subclass of OSError.

*Changed in version 3.3:* LoadError was made a subclass of OSError instead of IOError.

The following classes are provided:

**class** http.cookiejar.CookieJar(policy=None)

*policy* is an object implementing the CookiePolicy interface.

The CookieJar class stores HTTP cookies. It extracts cookies from HTTP requests, and returns them in HTTP responses. CookieJar instances automatically expire contained cookies when necessary. Subclasses are also responsible for storing and retrieving cookies from a file or database.

**class** http.cookiejar.FileCookieJar(filename, delayload=None, policy=None)

*policy* is an object implementing the CookiePolicy interface. For the other arguments, see the documentation for the corresponding attributes.

A CookieJar which can load cookies from, and perhaps save cookies to, a file on disk. Cookies are NOT loaded from the named file until either the load() or revert() method is called. Subclasses of this class are documented in section FileCookieJar subclasses and co-operation with web browsers.

**class** http.cookiejar.CookiePolicy

This class is responsible for deciding whether each cookie should be accepted from / returned to the server.
class http.cookiejar.DefaultCookiePolicy(blocked_domains=None, allowed_domains=None, netscape=True, rfc2965=False, rfc2109_as_netscape=None, hide_cookie2=False, strict_domain=False, strict_rfc2965_unverifiable=True, strict_ns_unverifiable=False, strict_ns_domain=http.cookiejar.DefaultCookiePolicy.DomainLiberal, strict_ns_set_initial_dollar=False, strict_ns_set_path=False)

Constructor arguments should be passed as keyword arguments only. `blocked_domains` is a sequence of domain names that we never accept cookies from, nor return cookies to. `allowed_domains` if not `None`, this is a sequence of the only domains for which we accept and return cookies. For all other arguments, see the documentation for `CookiePolicy` and `DefaultCookiePolicy` objects.

`DefaultCookiePolicy` implements the standard accept / reject rules for Netscape and RFC 2965 cookies. By default, RFC 2109 cookies (ie. cookies received in a `Set-Cookie` header with a version cookie-attribute of 1) are treated according to the RFC 2965 rules. However, if RFC 2965 handling is turned off or `rfc2109_as_netscape` is `True`, RFC 2109 cookies are ‘downgraded’ by the `CookieJar` instance to Netscape cookies, by setting the version attribute of the `Cookie` instance to 0. `DefaultCookiePolicy` also provides some parameters to allow some fine-tuning of policy.

class http.cookiejar.Cookie

This class represents Netscape, RFC 2109 and RFC 2965 cookies. It is not expected that users of `http.cookiejar` construct their own `Cookie` instances. Instead, if necessary, call `make_cookies()` on a `CookieJar` instance.
See also:

**Module urllib.request**
URL opening with automatic cookie handling.

**Module http.cookies**
HTTP cookie classes, principally useful for server-side code. The http.cookiejar and http.cookies modules do not depend on each other.

https://curl.haxx.se/rfc/cookie_spec.html
The specification of the original Netscape cookie protocol. Though this is still the dominant protocol, the ‘Netscape cookie protocol’ implemented by all the major browsers (and http.cookiejar) only bears a passing resemblance to the one sketched out in cookie_spec.html.

**RFC 2109 - HTTP State Management Mechanism**
Obsoleted by RFC 2965. Uses Set-Cookie with version=1.

**RFC 2965 - HTTP State Management Mechanism**
The Netscape protocol with the bugs fixed. Uses Set-Cookie2 in place of Set-Cookie. Not widely used.

http://kristol.org/cookie/errata.html
Unfinished errata to RFC 2965.

**RFC 2964 - Use of HTTP State Management**

CookieJar objects support the iterator protocol for iterating over contained Cookie objects.

CookieJar has the following methods:

CookieJar.\texttt{add\_cookie\_header}(\texttt{request})
Add correct Cookie header to request.

If policy allows (ie. the rfc2965 and hide_cookie2 attributes of the CookieJar’s CookiePolicy instance are true and false respectively), the Cookie2 header is also added when appropriate.

The \texttt{request} object (usually a \texttt{urllib.request..Request} instance) must support the methods \texttt{get\_full\_url()}, \texttt{get\_host()}, \texttt{get\_type()}, \texttt{unverifiable()}, \texttt{has\_header()}, \texttt{get\_header()}, \texttt{header\_items()}, \texttt{add\_unredirected\_header()} and \texttt{origin\_req\_host} attribute as documented by \texttt{urllib.request}.

\textit{Changed in version 3.3: request object needs origin\_req\_host attribute. Dependency on a deprecated method get\_origin\_req\_host()} has been removed.

CookieJar.\texttt{extract\_cookies}(\texttt{response}, \texttt{request})
Extract cookies from HTTP response and store them in the CookieJar, where allowed by policy.

The CookieJar will look for allowable Set-Cookie and Set-
Cookie2 headers in the \textit{response} argument, and store cookies as appropriate (subject to the \texttt{CookiePolicy.set\_ok()} method's approval).

The \textit{response} object (usually the result of a call to \texttt{urllib.request.urlopen()}, or similar) should support an \texttt{info()} method, which returns an \texttt{email.message.Message} instance.

The \textit{request} object (usually a \texttt{urllib.request.Request} instance) must support the methods \texttt{get\_full\_url()}, \texttt{get\_host()}, \texttt{unverifiable()}, \texttt{origin\_req\_host} attribute, as documented by \texttt{urllib.request}. The request is used to set default values for cookie-attributes as well as for checking that the cookie is allowed to be set.

\textit{Changed in version 3.3}: \textit{request} object needs \texttt{origin\_req\_host} attribute. Dependency on a deprecated method \texttt{get\_origin\_req\_host()} has been removed.

\texttt{CookieJar.set\_policy(\textit{policy})}

Set the \texttt{CookiePolicy} instance to be used.

\texttt{CookieJar.make\_cookies(\textit{response}, \textit{request})}

Return sequence of \texttt{Cookie} objects extracted from \textit{response} object.

See the documentation for \texttt{extract\_cookies()} for the interfaces required of the \textit{response} and \textit{request} arguments.

\texttt{CookieJar.set\_cookie\_if\_ok(\textit{cookie}, \textit{request})}

Set a \texttt{Cookie} if policy says it's OK to do so.
CookieJar.**set_cookie**(cookie)

Set a Cookie, without checking with policy to see whether or not it should be set.

CookieJar.**clear**([domain[, path[, name]]])

Clear some cookies.

If invoked without arguments, clear all cookies. If given a single argument, only cookies belonging to that domain will be removed. If given two arguments, cookies belonging to the specified domain and URL path are removed. If given three arguments, then the cookie with the specified domain, path and name is removed.

Raises **KeyError** if no matching cookie exists.

CookieJar.**clear_session_cookies**()

Discard all session cookies.

Discards all contained cookies that have a true discard attribute (usually because they had either no max-age or expires cookie-attribute, or an explicit discard cookie-attribute). For interactive browsers, the end of a session usually corresponds to closing the browser window.

Note that the save() method won’t save session cookies anyway, unless you ask otherwise by passing a true ignore_discard argument.

**FileCookieJar** implements the following additional methods:

FileCookieJar.**save**(filename=None, ignore_discard=False, ignore_expires=False)

Save cookies to a file.
This base class raises `NotImplementedError`. Subclasses may leave this method unimplemented.

`filename` is the name of file in which to save cookies. If `filename` is not specified, `self.filename` is used (whose default is the value passed to the constructor, if any); if `self.filename` is `None`, `ValueError` is raised.

`ignore_discard`: save even cookies set to be discarded.  
`ignore_expires`: save even cookies that have expired

The file is overwritten if it already exists, thus wiping all the cookies it contains. Saved cookies can be restored later using the `load()` or `revert()` methods.

FileCookieJar. **load**( `filename=None, ignore_discard=False, ignore_expires=False` )  
Load cookies from a file.

Old cookies are kept unless overwritten by newly loaded ones.

Arguments are as for `save()`.

The named file must be in the format understood by the class, or `LoadError` will be raised. Also, `OSError` may be raised, for example if the file does not exist.

*Changed in version 3.3*: `IOError` used to be raised, it is now an alias of `OSError`.

FileCookieJar. **revert**( `filename=None, ignore_discard=False, ignore_expires=False` )  
Clear all cookies and reload cookies from a saved file.
revert() can raise the same exceptions as load(). If there is a failure, the object's state will not be altered.

FileCookieJar instances have the following public attributes:

FileCookieJar.filename
Filename of default file in which to keep cookies. This attribute may be assigned to.

FileCookieJar.delayload
If true, load cookies lazily from disk. This attribute should not be assigned to. This is only a hint, since this only affects performance, not behaviour (unless the cookies on disk are changing). A CookieJar object may ignore it. None of the FileCookieJar classes included in the standard library lazily loads cookies.
21.24.2. FileCookieJar subclasses and cooperation with web browsers

The following CookieJar subclasses are provided for reading and writing.

```python
class http.cookiejar.MozillaCookieJar(filename, delayload=None, policy=None)

A FileCookieJar that can load from and save cookies to disk in the Mozilla cookies.txt file format (which is also used by the Lynx and Netscape browsers).
```

**Note:** This loses information about RFC 2965 cookies, and also about newer or non-standard cookie-attributes such as port.

**Warning:** Back up your cookies before saving if you have cookies whose loss / corruption would be inconvenient (there are some subtleties which may lead to slight changes in the file over a load / save round-trip).

Also note that cookies saved while Mozilla is running will get clobbered by Mozilla.

```python
class http.cookiejar.LWPCookieJar(filename, delayload=None, policy=None)

A FileCookieJar that can load from and save cookies to disk in format compatible with the libwww-perl library's Set-Cookie3 file format. This is convenient if you want to store cookies in a human-readable file.
```
21.24.3. CookiePolicy Objects

Objects implementing the `CookiePolicy` interface have the following methods:

**CookiePolicy.set_ok(cookie, request)**

Return boolean value indicating whether cookie should be accepted from server.

*cookie* is a `Cookie` instance. *request* is an object implementing the interface defined by the documentation for `CookieJar.extract_cookies()`.

**CookiePolicy.return_ok(cookie, request)**

Return boolean value indicating whether cookie should be returned to server.

*cookie* is a `Cookie` instance. *request* is an object implementing the interface defined by the documentation for `CookieJar.add_cookie_header()`.

**CookiePolicy.domain_return_ok(domain, request)**

Return false if cookies should not be returned, given cookie domain.

This method is an optimization. It removes the need for checking every cookie with a particular domain (which might involve reading many files). Returning true from `domain_return_ok()` and `path_return_ok()` leaves all the work to `return_ok()`.

If `domain_return_ok()` returns true for the cookie domain, `path_return_ok()` is called for the cookie path. Otherwise,
path_return_ok() and return_ok() are never called for that cookie domain. If path_return_ok() returns true, return_ok() is called with the Cookie object itself for a full check. Otherwise, return_ok() is never called for that cookie path.

Note that domain_return_ok() is called for every cookie domain, not just for the request domain. For example, the function might be called with both "example.com" and "www.example.com" if the request domain is "www.example.com". The same goes for path_return_ok().

The request argument is as documented for return_ok().

CookiePolicy.path_return_ok(path, request)

Return false if cookies should not be returned, given cookie path.

See the documentation for domain_return_ok().

In addition to implementing the methods above, implementations of the CookiePolicy interface must also supply the following attributes, indicating which protocols should be used, and how. All of these attributes may be assigned to.

CookiePolicy.netscape

Implement Netscape protocol.

CookiePolicy.rfc2965

Implement RFC 2965 protocol.

CookiePolicy.hide_cookie2

Don’t add Cookie2 header to requests (the presence of this header indicates to the server that we understand RFC 2965 cookies).
The most useful way to define a `CookiePolicy` class is by subclassing from `DefaultCookiePolicy` and overriding some or all of the methods above. `CookiePolicy` itself may be used as a ‘null policy’ to allow setting and receiving any and all cookies (this is unlikely to be useful).
21.24.4. DefaultCookiePolicy Objects

Implements the standard rules for accepting and returning cookies.

Both RFC 2965 and Netscape cookies are covered. RFC 2965 handling is switched off by default.

The easiest way to provide your own policy is to override this class and call its methods in your overridden implementations before adding your own additional checks:

```python
import http.cookiejar

class MyCookiePolicy(http.cookiejar.DefaultCookiePolicy):
    def set_ok(self, cookie, request):
        if not http.cookiejar.DefaultCookiePolicy.set_ok(self, cookie, request):
            return False
        if i_dont_want_to_store_this_cookie(cookie):
            return False
        return True
```

In addition to the features required to implement the `CookiePolicy` interface, this class allows you to block and allow domains from setting and receiving cookies. There are also some strictness switches that allow you to tighten up the rather loose Netscape protocol rules a little bit (at the cost of blocking some benign cookies).

A domain blacklist and whitelist is provided (both off by default). Only domains not in the blacklist and present in the whitelist (if the whitelist is active) participate in cookie setting and returning. Use the `blocked_domains` constructor argument, and `blocked_domains()` and `set_blocked_domains()` methods (and the corresponding argument and methods for `allowed_domains`). If you set a whitelist,
you can turn it off again by setting it to None.

Domains in block or allow lists that do not start with a dot must equal the cookie domain to be matched. For example, "example.com" matches a blacklist entry of "example.com", but "www.example.com" does not. Domains that do start with a dot are matched by more specific domains too. For example, both "www.example.com" and "www.coyote.example.com" match ".example.com" (but "example.com" itself does not). IP addresses are an exception, and must match exactly. For example, if blocked_domains contains "192.168.1.2" and ".168.1.2", 192.168.1.2 is blocked, but 193.168.1.2 is not.

DefaultCookiePolicy implements the following additional methods:

DefaultCookiePolicy.blocked_domains()

  Return the sequence of blocked domains (as a tuple).

DefaultCookiePolicy.set_blocked_domains(blocked_domains)

  Set the sequence of blocked domains.

DefaultCookiePolicy.is_blocked(domain)

  Return whether domain is on the blacklist for setting or receiving cookies.

DefaultCookiePolicy.allowed_domains()

  Return None, or the sequence of allowed domains (as a tuple).

DefaultCookiePolicy.set_allowed_domains(allowed_domains)

  Set the sequence of allowed domains, or None.
DefaultCookiePolicy.is_not_allowed(domain)

Return whether domain is not on the whitelist for setting or receiving cookies.

DefaultCookiePolicy instances have the following attributes, which are all initialised from the constructor arguments of the same name, and which may all be assigned to.

DefaultCookiePolicy.rfc2109_as_netscape

If true, request that the CookieJar instance downgrade RFC 2109 cookies (ie. cookies received in a Set-Cookie header with a version cookie-attribute of 1) to Netscape cookies by setting the version attribute of the Cookie instance to 0. The default value is None, in which case RFC 2109 cookies are downgraded if and only if RFC 2965 handling is turned off. Therefore, RFC 2109 cookies are downgraded by default.

General strictness switches:

DefaultCookiePolicy.strict_domain

Don’t allow sites to set two-component domains with country-code top-level domains like .co.uk, .gov.uk, .co.nz,etc. This is far from perfect and isn’t guaranteed to work!

RFC 2965 protocol strictness switches:

DefaultCookiePolicy.strict_rfc2965_unverifiable

Follow RFC 2965 rules on unverifiable transactions (usually, an unverifiable transaction is one resulting from a redirect or a request for an image hosted on another site). If this is false, cookies are never blocked on the basis of verifiability

Netscape protocol strictness switches:
**DefaultCookiePolicy. strict\_ns\_unverifiable**

Apply RFC 2965 rules on unverifiable transactions even to Netscape cookies.

**DefaultCookiePolicy. strict\_ns\_domain**

Flags indicating how strict to be with domain-matching rules for Netscape cookies. See below for acceptable values.

**DefaultCookiePolicy. strict\_ns\_set\_initial\_dollar**

Ignore cookies in Set-Cookie: headers that have names starting with '\$'.

**DefaultCookiePolicy. strict\_ns\_set\_path**

Don't allow setting cookies whose path doesn't path-match request URI.

---

**Strict\_ns\_domain** is a collection of flags. Its value is constructed by or-ing together (for example, DomainStrictNoDots|DomainStrictNonDomain means both flags are set).

**DefaultCookiePolicy. DomainStrictNoDots**

When setting cookies, the ‘host prefix’ must not contain a dot (eg. www.foo.bar.com can’t set a cookie for .bar.com, because www.foo contains a dot).

**DefaultCookiePolicy. DomainStrictNonDomain**

Cookies that did not explicitly specify a domain cookie-attribute can only be returned to a domain equal to the domain that set the cookie (eg. spam.example.com won’t be returned cookies from example.com that had no domain cookie-attribute).

**DefaultCookiePolicy. DomainRFC2965Match**
When setting cookies, require a full RFC 2965 domain-match.

The following attributes are provided for convenience, and are the most useful combinations of the above flags:

DefaultCookiePolicy. **DomainLiberal**
- Equivalent to 0 (ie. all of the above Netscape domain strictness flags switched off).

DefaultCookiePolicy. **DomainStrict**
- Equivalent to `DomainStrictNoDots|DomainStrictNonDomain`. 
21.24.5. Cookie Objects

Cookie instances have Python attributes roughly corresponding to the standard cookie-attributes specified in the various cookie standards. The correspondence is not one-to-one, because there are complicated rules for assigning default values, because the max-age and expires cookie-attributes contain equivalent information, and because RFC 2109 cookies may be ‘downgraded’ by http.cookiejar from version 1 to version 0 (Netscape) cookies.

Assignment to these attributes should not be necessary other than in rare circumstances in a CookiePolicy method. The class does not enforce internal consistency, so you should know what you’re doing if you do that.

Cookie.**version**

Integer or None. Netscape cookies have version 0. RFC 2965 and RFC 2109 cookies have a version cookie-attribute of 1. However, note that http.cookiejar may 'downgrade' RFC 2109 cookies to Netscape cookies, in which case version is 0.

Cookie.**name**

Cookie name (a string).

Cookie.**value**

Cookie value (a string), or None.

Cookie.**port**

String representing a port or a set of ports (eg. ‘80’, or ‘80,8080’), or None.

Cookie.**path**
Cookie path (a string, eg. '/acme/rocket_launchers').

Cookie. **secure**
*True* if cookie should only be returned over a secure connection.

Cookie. **expires**
Integer expiry date in seconds since epoch, or *None*. See also the *is_expired()* method.

Cookie. **discard**
*True* if this is a session cookie.

Cookie. **comment**
String comment from the server explaining the function of this cookie, or *None*.

Cookie. **comment_url**
URL linking to a comment from the server explaining the function of this cookie, or *None*.

Cookie. **rfc2109**
*True* if this cookie was received as an RFC 2109 cookie (ie. the cookie arrived in a *Set-Cookie* header, and the value of the Version cookie-attribute in that header was 1). This attribute is provided because *http.cookiejar* may 'downgrade' RFC 2109 cookies to Netscape cookies, in which case *version* is 0.

Cookie. **port_specified**
*True* if a port or set of ports was explicitly specified by the server (in the *Set-Cookie / Set-Cookie2* header).

Cookie. **domain_specified**
True if a domain was explicitly specified by the server.

Cookie. `domain_initial_dot`
True if the domain explicitly specified by the server began with a dot (').

Cookies may have additional non-standard cookie-attributes. These may be accessed using the following methods:

Cookie. `has_nonstandard_attr(name)`
Return true if cookie has the named cookie-attribute.

Cookie. `get_nonstandard_attr(name, default=None)`
If cookie has the named cookie-attribute, return its value. Otherwise, return `default`.

Cookie. `set_nonstandard_attr(name, value)`
Set the value of the named cookie-attribute.

The Cookie class also defines the following method:

Cookie. `is_expired(now=None)`
True if cookie has passed the time at which the server requested it should expire. If `now` is given (in seconds since the epoch), return whether the cookie has expired at the specified time.
21.24.6. Examples

The first example shows the most common usage of `http.cookiejar`:

```python
import http.cookiejar, urllib.request
cj = http.cookiejar.CookieJar()
opener = urllib.request.build_opener(urllib.request.
r = opener.open("http://example.com/")
```

This example illustrates how to open a URL using your Netscape, Mozilla, or Lynx cookies (assumes Unix/Netscape convention for location of the cookies file):

```python
import os, http.cookiejar, urllib.request
cj = http.cookiejar.MozillaCookieJar()
cj.load(os.path.join(os.path.expanduser("~"), ".nets
opener = urllib.request.build_opener(urllib.request.
r = opener.open("http://example.com/")
```

The next example illustrates the use of `DefaultCookiePolicy`. Turn on RFC 2965 cookies, be more strict about domains when setting and returning Netscape cookies, and block some domains from setting cookies or having them returned:

```python
import urllib.request
from http.cookiejar import CookieJar, DefaultCookiePolicy
policy = DefaultCookiePolicy(
    rfc2965=True, strict_ns_domain=Policy.DomainStri
    blocked_domains=["ads.net", ".ads.net"]
)cj = CookieJar(policy)
opener = urllib.request.build_opener(urllib.request.
```
r = opener.open("http://example.com/")
21.25. xmlrpc — XMLRPC server and client modules

XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get back structured data.

xmlrpc is a package that collects server and client modules implementing XML-RPC. The modules are:

- xmlrpc.client
- xmlrpc.server
21.26. `xmlrpc.client` — XML-RPC client access

Source code: `Lib/xmlrpc/client.py`

XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP(S) as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get back structured data. This module supports writing XML-RPC client code; it handles all the details of translating between conformable Python objects and XML on the wire.

Warning: The `xmlrpc.client` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

*Changed in version 3.5:* For HTTPS URIs, `xmlrpc.client` now performs all the necessary certificate and hostname checks by default.

```python
class xmlrpc.client.ServerProxy(uri, transport=None, encoding=None, verbose=False, allow_none=False, use_datetime=False, use_builtin_types=False, *, context=None)
```

*Changed in version 3.3:* The `use_builtin_types` flag was added.

A `ServerProxy` instance is an object that manages communication with a remote XML-RPC server. The required first argument is a URI (Uniform Resource Indicator), and will normally be the URL of the server. The optional second argument is a transport factory instance; by default it is an internal
SafeTransport instance for https: URLs and an internal HTTP Transport instance otherwise. The optional third argument is an encoding, by default UTF-8. The optional fourth argument is a debugging flag.

The following parameters govern the use of the returned proxy instance. If *allow_none* is true, the Python constant `None` will be translated into XML; the default behaviour is for `None` to raise a `TypeError`. This is a commonly-used extension to the XML-RPC specification, but isn’t supported by all clients and servers; see [http://ontosys.com/xml-rpc/extensions.php](http://ontosys.com/xml-rpc/extensions.php) for a description. The *use_builtin_types* flag can be used to cause date/time values to be presented as `datetime.datetime` objects and binary data to be presented as `bytes` objects; this flag is false by default. `datetime.datetime`, `bytes` and `bytearray` objects may be passed to calls. The obsolete *use_datetime* flag is similar to *use_builtin_types* but it applies only to date/time values.

Both the HTTP and HTTPS transports support the URL syntax extension for HTTP Basic Authentication: [http://user:pass@host:port/path](http://user:pass@host:port/path). The *user:pass* portion will be base64-encoded as an HTTP ‘Authorization’ header, and sent to the remote server as part of the connection process when invoking an XML-RPC method. You only need to use this if the remote server requires a Basic Authentication user and password. If an HTTPS URL is provided, *context* may be `ssl.SSLContext` and configures the SSL settings of the underlying HTTPS connection.

The returned instance is a proxy object with methods that can be used to invoke corresponding RPC calls on the remote server. If the remote server supports the introspection API, the proxy can
also be used to query the remote server for the methods it supports (service discovery) and fetch other server-associated metadata.

Types that are conformable (e.g. that can be marshalled through XML), include the following (and except where noted, they are unmarshalled as the same Python type):

<table>
<thead>
<tr>
<th>XML-RPC type</th>
<th>Python type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>bool</td>
</tr>
<tr>
<td>int, i1, i2, i4, i8 or biginteger</td>
<td>int in range from -2147483648 to 2147483647. Values get the <code>&lt;int&gt;</code> tag.</td>
</tr>
<tr>
<td>double or float</td>
<td>float. Values get the <code>&lt;double&gt;</code> tag.</td>
</tr>
<tr>
<td>string</td>
<td>str</td>
</tr>
<tr>
<td>array</td>
<td>list or tuple containing conformable elements. Arrays are returned as lists.</td>
</tr>
<tr>
<td>struct</td>
<td>dict. Keys must be strings, values may be any conformable type. Objects of user-defined classes can be passed in; only their <code>__dict__</code> attribute is transmitted.</td>
</tr>
<tr>
<td>dateTime.iso8601</td>
<td>DateTime or datetime.datetime. Returned type depends on values of <code>use_builtin_types</code> and <code>use_datetime</code> flags.</td>
</tr>
<tr>
<td>base64</td>
<td>Binary, bytes or bytearray. Returned type depends on the value of the <code>use_builtin_types</code> flag.</td>
</tr>
<tr>
<td>nil</td>
<td>The None constant. Passing is allowed only if <code>allow_none</code> is true.</td>
</tr>
<tr>
<td>bigdecimal</td>
<td>decimal.Decimal. Returned type</td>
</tr>
</tbody>
</table>
This is the full set of data types supported by XML-RPC. Method calls may also raise a special Fault instance, used to signal XML-RPC server errors, or ProtocolError used to signal an error in the HTTP/HTTPS transport layer. Both Fault and ProtocolError derive from a base class called Error. Note that the xmlrpc client module currently does not marshal instances of subclasses of built-in types.

When passing strings, characters special to XML such as `<`, `>`, and `&` will be automatically escaped. However, it's the caller's responsibility to ensure that the string is free of characters that aren't allowed in XML, such as the control characters with ASCII values between 0 and 31 (except, of course, tab, newline and carriage return); failing to do this will result in an XML-RPC request that isn't well-formed XML. If you have to pass arbitrary bytes via XML-RPC, use bytes or bytearray classes or the Binary wrapper class described below.

Server is retained as an alias for ServerProxy for backwards compatibility. New code should use ServerProxy.

*Changed in version 3.5:* Added the context argument.

*Changed in version 3.6:* Added support of type tags with prefixes (e.g. ex:nil). Added support of unmarshalling additional types used by Apache XML-RPC implementation for numerics: i1, i2, i8, biginteger, float and bigdecimal. See http://ws.apache.org/xmlrpc/types.html for a description.

**See also:**
XML-RPC HOWTO
A good description of XML-RPC operation and client software in several languages. Contains pretty much everything an XML-RPC client developer needs to know.

XML-RPC Introspection
Describes the XML-RPC protocol extension for introspection.

XML-RPC Specification
The official specification.

Unofficial XML-RPC Errata
Fredrik Lundh’s “unofficial errata, intended to clarify certain details in the XML-RPC specification, as well as hint at ‘best practices’ to use when designing your own XML-RPC implementations.”

A `ServerProxy` instance has a method corresponding to each remote procedure call accepted by the XML-RPC server. Calling the method performs an RPC, dispatched by both name and argument signature (e.g. the same method name can be overloaded with multiple argument signatures). The RPC finishes by returning a value, which may be either returned data in a conformant type or a `Fault` or `ProtocolError` object indicating an error.

Servers that support the XML introspection API support some common methods grouped under the reserved `system` attribute:

`ServerProxy.system.listMethods()`

This method returns a list of strings, one for each (non-system) method supported by the XML-RPC server.

`ServerProxy.system.methodSignature(name)`

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns an array of possible signatures for this method. A signature is an array of types. The first of these types is the return type of the method, the rest are parameters.

Because multiple signatures (ie. overloading) is permitted, this method returns a list of signatures rather than a singleton.

Signatures themselves are restricted to the top level parameters expected by a method. For instance if a method expects one array of structs as a parameter, and it returns a string, its signature is simply “string, array”. If it expects three integers and returns a string, its signature is “string, int, int, int”.

If no signature is defined for the method, a non-array value is returned. In Python this means that the type of the returned value will be something other than list.

ServerProxy.system\textbf{.methodHelp(name)}

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns a documentation string describing the use of that method. If no such string is available, an empty string is returned. The documentation string may contain HTML markup.

\textit{Changed in version 3.5:} Instances of ServerProxy support the context manager protocol for closing the underlying transport.

A working example follows. The server code:

```python
from xmlrpc.server import SimpleXMLRPCServer
def is_even(n):
    return n % 2 == 0

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(is_even, "is_even")
server.serve_forever()
```

The client code for the preceding server:

```python
import xmlrpc.client

with xmlrpc.client.ServerProxy("http://localhost:8000") as proxy:
    print("3 is even: %s" % str(proxy.is_even(3)))
    print("100 is even: %s" % str(proxy.is_even(100)))
```
21.26.2. DateTime Objects

*class xmlrpc.client.**DateTime***

This class may be initialized with seconds since the epoch, a time tuple, an ISO 8601 time/date string, or a `datetime.datetime` instance. It has the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

**decode**(string)

Accept a string as the instance's new time value.

**encode**(out)

Write the XML-RPC encoding of this **DateTime** item to the `out` stream object.

It also supports certain of Python's built-in operators through rich comparison and **__repr__()** methods.

A working example follows. The server code:

```python
import datetime
from xmlrpc.server import SimpleXMLRPCServer
import xmlrpc.client

def today():
    today = datetime.datetime.today()
    return xmlrpc.client.DateTime(today)

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(today, "today")
server.serve_forever()
```
The client code for the preceding server:

```python
import xmlrpc.client
import datetime

proxy = xmlrpc.client.ServerProxy("http://localhost:")

today = proxy.today()
# convert the ISO8601 string to a datetime object
converted = datetime.datetime.strptime(today.value,
print("Today: %s" % converted.strftime("%d.%m.%Y, %H:%M")
```
21.26.3. Binary Objects

class xmlrpc.client.Binary

This class may be initialized from bytes data (which may include NULs). The primary access to the content of a Binary object is provided by an attribute:

data

The binary data encapsulated by the Binary instance. The data is provided as a bytes object.

Binary objects have the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

decode(bytes)

Accept a base64 bytes object and decode it as the instance's new data.

encode(out)

Write the XML-RPC base 64 encoding of this binary item to the out stream object.

The encoded data will have newlines every 76 characters as per RFC 2045 section 6.8, which was the de facto standard base64 specification when the XML-RPC spec was written.

It also supports certain of Python’s built-in operators through __eq__() and __ne__() methods.

Example usage of the binary objects. We’re going to transfer an image over XMLRPC:
from xmlrpc.server import SimpleXMLRPCServer
import xmlrpc.client

def python_logo():
    with open("python_logo.jpg", "rb") as handle:
        return xmlrpc.client.Binary(handle.read())

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(python_logo, 'python_logo')

server.serve_forever()

The client gets the image and saves it to a file:

import xmlrpc.client

proxy = xmlrpc.client.ServerProxy("http://localhost:
with open("fetched_python_logo.jpg", "wb") as handle:
    handle.write(proxy.python_logo().data)
21.26.4. Fault Objects

`class xmlrpc.client.Fault`

A `Fault` object encapsulates the content of an XML-RPC fault tag. Fault objects have the following attributes:

- **faultCode**
  A string indicating the fault type.

- **faultString**
  A string containing a diagnostic message associated with the fault.

In the following example we’re going to intentionally cause a `Fault` by returning a complex type object. The server code:

```python
from xmlrpc.server import SimpleXMLRPCServer

# A marshalling error is going to occur because we're returning a complex number
def add(x, y):
    return x+y+0j

s = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
s.register_function(add, 'add')
s.serve_forever()
```

The client code for the preceding server:

```python
import xmlrpc.client
```
proxy = xmlrpc.client.ServerProxy("http://localhost:
try:
    proxy.add(2, 5)
except xmlrpc.client.Fault as err:
    print("A fault occurred")
    print("Fault code: %d" % err.faultCode)
    print("Fault string: %s" % err.faultString)
21.26.5. ProtocolError Objects

class xmlrpc.client.ProtocolError

A ProtocolError object describes a protocol error in the underlying transport layer (such as a 404 ‘not found’ error if the server named by the URI does not exist). It has the following attributes:

url
The URI or URL that triggered the error.

errcode
The error code.

errmsg
The error message or diagnostic string.

headers
A dict containing the headers of the HTTP/HTTPS request that triggered the error.

In the following example we’re going to intentionally cause a ProtocolError by providing an invalid URI:

```python
import xmlrpc.client

# create a ServerProxy with a URI that doesn't respond
proxy = xmlrpc.client.ServerProxy("http://google.com/")

try:
    proxy.some_method()
except xmlrpc.client.ProtocolError as err:
    print("A protocol error occurred")
```
print("URL: %s" % err.url)
print("HTTP/HTTPS headers: %s" % err.headers)
print("Error code: %d" % err.errcode)
print("Error message: %s" % err.errmsg)
21.26.6. MultiCall Objects

The MultiCall object provides a way to encapsulate multiple calls to a remote server into a single request [1].

class xmlrpc.client.MultiCall(server)

Create an object used to boxcar method calls. server is the eventual target of the call. Calls can be made to the result object, but they will immediately return None, and only store the call name and parameters in the MultiCall object. Calling the object itself causes all stored calls to be transmitted as a single system.multicall request. The result of this call is a generator; iterating over this generator yields the individual results.

A usage example of this class follows. The server code:

```python
from xmlrpc.server import SimpleXMLRPCServer

def add(x, y):
    return x + y

def subtract(x, y):
    return x - y

def multiply(x, y):
    return x * y

def divide(x, y):
    return x // y

# A simple server with simple arithmetic functions
server = SimpleXMLRPCServer(('localhost', 8000))
print("Listening on port 8000...")
server.register_multicall_functions()
```
server.register_function(add, 'add')
server.register_function(subtract, 'subtract')
server.register_function(multiply, 'multiply')
server.register_function(divide, 'divide')
server.serve_forever()

The client code for the preceding server:

```python
import xmlrpc.client

multicall = xmlrpc.client.MultiCall(proxy)
multicall.add(7, 3)
multicall.subtract(7, 3)
multicall.multiply(7, 3)
multicall.divide(7, 3)
result = multicall()

print("7+3=%d, 7-3=%d, 7*3=%d, 7//3=%d" % tuple(result))
```
21.26.7. Convenience Functions

```
xmlrpc.client.dumps(params, methodname=None, methodresponse=None, encoding=None, allow_none=False)
```

Convert `params` into an XML-RPC request or into a response if `methodresponse` is true. `params` can be either a tuple of arguments or an instance of the `Fault` exception class. If `methodresponse` is true, only a single value can be returned, meaning that `params` must be of length 1. `encoding`, if supplied, is the encoding to use in the generated XML; the default is UTF-8. Python’s `None` value cannot be used in standard XML-RPC; to allow using it via an extension, provide a true value for `allow_none`.

```
xmlrpc.client.loads(data, use_datetime=False, use_builtin_types=False)
```

Convert an XML-RPC request or response into Python objects, a `(params, methodname)`. `params` is a tuple of argument; `methodname` is a string, or `None` if no method name is present in the packet. If the XML-RPC packet represents a fault condition, this function will raise a `Fault` exception. The `use_builtin_types` flag can be used to cause date/time values to be presented as `datetime.datetime` objects and binary data to be presented as `bytes` objects; this flag is false by default.

The obsolete `use_datetime` flag is similar to `use_builtin_types` but it applies only to date/time values.

*Changed in version 3.3:* The `use_builtin_types` flag was added.

```python
# simple test program (from the XML-RPC specification)
from xmlrpc.client import ServerProxy, Error

# server = ServerProxy("http://localhost:8000") # local
with ServerProxy("http://betty.userland.com") as proxy:
    print(proxy)

    try:
        print(proxy.examples.getStateName(41))
    except Error as v:
        print("ERROR", v)
```

To access an XML-RPC server through a HTTP proxy, you need to define a custom transport. The following example shows how:

```python
import http.client
import xmlrpc.client

class ProxiedTransport(xmlrpc.client.Transport):
    def set_proxy(self, host, port=None, headers=None):
        self.proxy = host, port
        self.proxy_headers = headers

    def make_connection(self, host):
        connection = http.client.HTTPConnection(*self._set_tunnel(host, headers=self.proxy_headers)
        self._connection = host, connection
        return connection

transport = ProxiedTransport()
```
transport.set_proxy('proxy-server', 8080)
s
server = xmlrpc.client.ServerProxy('http://betty.use

print(server.examples.getStateName(41))
21.26.9. Example of Client and Server Usage

See SimpleXMLRPCServer Example.

Footnotes

[1] This approach has been first presented in a discussion on xmlrpc.com.
21.27. xmlrpc.server — Basic XML-RPC servers

Source code: Lib/xmlrpc/server.py

The xmlrpc.server module provides a basic server framework for XML-RPC servers written in Python. Servers can either be free standing, using SimpleXMLRPCServer, or embedded in a CGI environment, using CGIXMLRPCRequestHandler.

Warning: The xmlrpc.server module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

class xmlrpc.server.SimpleXMLRPCServer(addr, requestHandler=SimpleXMLRPCRequestHandler, logRequests=True, allow_none=False, encoding=None, bind_and_activate=True, use_builtin_types=False)

Create a new server instance. This class provides methods for registration of functions that can be called by the XML-RPC protocol. The requestHandler parameter should be a factory for request handler instances; it defaults to SimpleXMLRPCRequestHandler. The addr and requestHandler parameters are passed to the socketserver.TCPServer constructor. If logRequests is true (the default), requests will be logged; setting this parameter to false will turn off logging. The allow_none and encoding parameters are passed on to xmlrpc.client and control the XML-RPC responses that will be returned from the server. The bind_and_activate parameter
controls whether server_bind() and server_activate() are called immediately by the constructor; it defaults to true. Setting it to false allows code to manipulate the allow_reuse_address class variable before the address is bound. The use_builtin_types parameter is passed to the loads() function and controls which types are processed when date/times values or binary data are received; it defaults to false.

*Changed in version 3.3:* The use_builtin_types flag was added.

```python
class xmlrpc.server.CGIXMLRPCRequestHandler(allow_none=False, encoding=None, use_builtin_types=False)

Create a new instance to handle XML-RPC requests in a CGI environment. The allow_none and encoding parameters are passed on to xmlrpc.client and control the XML-RPC responses that will be returned from the server. The use_builtin_types parameter is passed to the loads() function and controls which types are processed when date/times values or binary data are received; it defaults to false.

*Changed in version 3.3:* The use_builtin_types flag was added.

```python
class xmlrpc.server.SimpleXMLRPCRequestHandler

Create a new request handler instance. This request handler supports POST requests and modifies logging so that the logRequests parameter to the SimpleXMLRPCServer constructor parameter is honored.
21.27.1. SimpleXMLRPCServer Objects

The `SimpleXMLRPCServer` class is based on `socketserver.TCPServer` and provides a means of creating simple, stand alone XML-RPC servers.

`SimpleXMLRPCServer.register_function(function, name=None)`

Register a function that can respond to XML-RPC requests. If `name` is given, it will be the method name associated with `function`, otherwise `function.__name__` will be used. `name` can be either a normal or Unicode string, and may contain characters not legal in Python identifiers, including the period character.

`SimpleXMLRPCServer.register_instance(instance, allow_dotted_names=False)`

Register an object which is used to expose method names which have not been registered using `register_function()`. If `instance` contains a `_dispatch()` method, it is called with the requested method name and the parameters from the request. Its API is `def _dispatch(self, method, params)` (note that `params` does not represent a variable argument list). If it calls an underlying function to perform its task, that function is called as `func(*params)`, expanding the parameter list. The return value from `_dispatch()` is returned to the client as the result. If `instance` does not have a `_dispatch()` method, it is searched for an attribute matching the name of the requested method.

If the optional `allow_dotted_names` argument is true and the instance does not have a `_dispatch()` method, then if the requested method name contains periods, each component of the
method name is searched for individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

**Warning:** Enabling the `allow_dotted_names` option allows intruders to access your module’s global variables and may allow intruders to execute arbitrary code on your machine. Only use this option on a secure, closed network.

`SimpleXMLRPCServer.register_introspection_functions()`

Registers the XML-RPC introspection functions `system.listMethods`, `system.methodHelp` and `system.methodSignature`.

`SimpleXMLRPCServer.register_multicall_functions()`

Registers the XML-RPC multicall function `system.multicall`.

`SimpleXMLRPCRequestHandler.rpc_paths`  
An attribute value that must be a tuple listing valid path portions of the URL for receiving XML-RPC requests. Requests posted to other paths will result in a 404 “no such page” HTTP error. If this tuple is empty, all paths will be considered valid. The default value is `('/', '/RPC2')`.

### 21.27.1.1. SimpleXMLRPCServer Example

Server code:

```python
from xmlrpc.server import SimpleXMLRPCServer
from xmlrpc.server import SimpleXMLRPCRequestHandler
```
# Restrict to a particular path.
class RequestHandler(SimpleXMLRPCRequestHandler):
    rpc_paths = ('/RPC2',)

# Create server
with SimpleXMLRPCServer(('localhost', 8000),
    requestHandler=RequestHandler):
    server.register_introspection_functions()

    # Register pow() function; this will use the value of
    # pow.__name__ as the name, which is just 'pow'.
    server.register_function(pow)

    # Register a function under a different name
    def adder_function(x, y):
        return x + y
    server.register_function(adder_function, 'add')

    # Register an instance; all the methods of the instance
    # published as XML-RPC methods (in this case, just
    # 'mul').
    class MyFuncs:
        def mul(self, x, y):
            return x * y
    server.register_instance(MyFuncs())

    # Run the server's main loop
    server.serve_forever()

The following client code will call the methods made available by the preceding server:

```python
import xmlrpc.client

s = xmlrpc.client.ServerProxy('http://localhost:8000')
print(s.pow(2, 3))  # Returns 2**3 = 8
```
print(s.add(2,3))  # Returns 5
print(s.mul(5,2))  # Returns 5*2 = 10

# Print list of available methods
print(s.system.listMethods())

The following example included in the Lib/xmlrpc/server.py module shows a server allowing dotted names and registering a multicall function.

**Warning:** Enabling the *allow_dotted_names* option allows intruders to access your module’s global variables and may allow intruders to execute arbitrary code on your machine. Only use this example only within a secure, closed network.

```python
import datetime

class ExampleService:
    def getData(self):
        return '42'

    class currentTime:
        @staticmethod
        def getCurrentTime():
            return datetime.datetime.now()

with SimpleXMLRPCServer(('localhost', 8000)) as server:
    server.register_function(pow)
    server.register_function(lambda x,y: x+y, 'add')
    server.register_instance(ExampleService(), allow_dotted_names=True)
    server.register_multicall_functions()
    print('Serving XML-RPC on localhost port 8000')
    try:
        server.serve_forever()
```
```python
except KeyboardInterrupt:
    print("\nKeyboard interrupt received, exiting.")
sys.exit(0)
```

This ExampleService demo can be invoked from the command line:

```
python -m xmlrpc.server
```

The client that interacts with the above server is included in `Lib/xmlrpc/client.py`:

```python
server = ServerProxy("http://localhost:8000")
try:
    print(server.currentTime.getCurrentTime())
except Error as v:
    print("ERROR", v)

multi = MultiCall(server)
multi.getData()
multi.pow(2, 9)
multi.add(1, 2)
try:
    for response in multi():
        print(response)
except Error as v:
    print("ERROR", v)
```

This client which interacts with the demo XMLRPC server can be invoked as:

```
python -m xmlrpc.client
```
21.27.2. CGIXMLRPCRequestHandler

The CGIXMLRPCRequestHandler class can be used to handle XML-RPC requests sent to Python CGI scripts.

CGIXMLRPCRequestHandler.register_function(function, name=None)

Register a function that can respond to XML-RPC requests. If name is given, it will be the method name associated with function, otherwise function.__name__ will be used. name can be either a normal or Unicode string, and may contain characters not legal in Python identifiers, including the period character.

CGIXMLRPCRequestHandler.register_instance(instance)

Register an object which is used to expose method names which have not been registered using register_function(). If instance contains a _dispatch() method, it is called with the requested method name and the parameters from the request; the return value is returned to the client as the result. If instance does not have a _dispatch() method, it is searched for an attribute matching the name of the requested method; if the requested method name contains periods, each component of the method name is searched for individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

CGIXMLRPCRequestHandler.register_introspection_functions

Register the XML-RPC introspection functions system.listMethods, system.methodHelp and system.methodSignature.
CGIXMLRPCRequestHandler.register_multicall_function:
Register the XML-RPC multicall function system.multicall.

CGIXMLRPCRequestHandler.handle_request(request_text=None)
Handle an XML-RPC request. If request_text is given, it should be
the POST data provided by the HTTP server, otherwise the
contents of stdin will be used.

Example:

class MyFuncs:
    def mul(self, x, y):
        return x * y

handler = CGIXMLRPCRequestHandler()
handler.register_function(pow)
handler.register_function(lambda x, y: x+y, 'add')
handler.register_introspection_functions()
handler.register_instance(MyFuncs())
handler.handle_request()
21.27.3. Documenting XMLRPC server

These classes extend the above classes to serve HTML documentation in response to HTTP GET requests. Servers can either be free standing, using `DocXMLRPCServer`, or embedded in a CGI environment, using `DocCGIXMLRPCRequestHandler`.

```python
class xmlrpc.server.DocXMLRPCServer(addr,
    requestHandler=DocXMLRPCRequestHandler, logRequests=True,
    allow_none=False, encoding=None, bind_and_activate=True,
    use_builtin_types=True)

Create a new server instance. All parameters have the same meaning as for SimpleXMLRPCServer; requestHandler defaults to DocXMLRPCRequestHandler.

Changed in version 3.3: The use_builtin_types flag was added.
```

```python
class xmlrpc.server.DocCGIXMLRPCRequestHandler

Create a new instance to handle XML-RPC requests in a CGI environment.
```

```python
class xmlrpc.server.DocXMLRPCRequestHandler

Create a new request handler instance. This request handler supports XML-RPC POST requests, documentation GET requests, and modifies logging so that the logRequests parameter to the DocXMLRPCServer constructor parameter is honored.
```
21.27.4. DocXMLRPCServer Objects

The DocXMLRPCServer class is derived from SimpleXMLRPCServer and provides a means of creating self-documenting, stand alone XML-RPC servers. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

DocXMLRPCServer.set_server_title(server_title)
Set the title used in the generated HTML documentation. This title will be used inside the HTML "title" element.

DocXMLRPCServer.set_server_name(server_name)
Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a "h1" element.

DocXMLRPCServer.set_server_documentation(server_doc)
Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.
21.27.5. DocCGIXMLRPCRequestHandler

The DocCGIXMLRPCRequestHandler class is derived from CGIXMLRPCRequestHandler and provides a means of creating self-documenting, XML-RPC CGI scripts. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

DocCGIXMLRPCRequestHandler.set_server_title(server_title)
Set the title used in the generated HTML documentation. This title will be used inside the HTML “title” element.

DocCGIXMLRPCRequestHandler.set_server_name(server_name)
Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a “h1” element.

DocCGIXMLRPCRequestHandler.set_server_documentation(server_documentation)
Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.
21.28. **ipaddress** — IPv4/IPv6 manipulation library

**Source code:** Lib/ipaddress.py

`ipaddress` provides the capabilities to create, manipulate and operate on IPv4 and IPv6 addresses and networks.

The functions and classes in this module make it straightforward to handle various tasks related to IP addresses, including checking whether or not two hosts are on the same subnet, iterating over all hosts in a particular subnet, checking whether or not a string represents a valid IP address or network definition, and so on.

This is the full module API reference—for an overview and introduction, see An introduction to the ipaddress module.

*New in version 3.3.*
21.28.1. Convenience factory functions

The `ipaddress` module provides factory functions to conveniently create IP addresses, networks and interfaces:

**ipaddress.**`ip_address(address)`

Return an `IPv4Address` or `IPv6Address` object depending on the IP address passed as argument. Either IPv4 or IPv6 addresses may be supplied; integers less than 2**32 will be considered to be IPv4 by default. A `ValueError` is raised if `address` does not represent a valid IPv4 or IPv6 address.

```python
>>> ipaddress.ip_address('192.168.0.1')
IPv4Address('192.168.0.1')
>>> ipaddress.ip_address('2001:db8::')
IPv6Address('2001:db8::')
```

**ipaddress.**`ip_network(address, strict=True)`

Return an `IPv4Network` or `IPv6Network` object depending on the IP address passed as argument. `address` is a string or integer representing the IP network. Either IPv4 or IPv6 networks may be supplied; integers less than 2**32 will be considered to be IPv4 by default. `strict` is passed to `IPv4Network` or `IPv6Network` constructor. A `ValueError` is raised if `address` does not represent a valid IPv4 or IPv6 address, or if the network has host bits set.

```python
>>> ipaddress.ip_network('192.168.0.0/28')
IPv4Network('192.168.0.0/28')
```

**ipaddress.**`ip_interface(address)`

Return an `IPv4Interface` or `IPv6Interface` object depending
on the IP address passed as argument. *address* is a string or integer representing the IP address. Either IPv4 or IPv6 addresses may be supplied; integers less than $2^{**32}$ will be considered to be IPv4 by default. A *ValueError* is raised if *address* does not represent a valid IPv4 or IPv6 address.

One downside of these convenience functions is that the need to handle both IPv4 and IPv6 formats means that error messages provide minimal information on the precise error, as the functions don't know whether the IPv4 or IPv6 format was intended. More detailed error reporting can be obtained by calling the appropriate version specific class constructors directly.
21.28.2. IP Addresses

21.28.2.1. Address objects

The IPv4Address and IPv6Address objects share a lot of common attributes. Some attributes that are only meaningful for IPv6 addresses are also implemented by IPv4Address objects, in order to make it easier to write code that handles both IP versions correctly.

```python
class ipaddress.IPv4Address(address)

Construct an IPv4 address. An AddressValueError is raised if address is not a valid IPv4 address.

The following constitutes a valid IPv4 address:

1. A string in decimal-dot notation, consisting of four decimal integers in the inclusive range 0–255, separated by dots (e.g. 192.168.0.1). Each integer represents an octet (byte) in the address. Leading zeroes are tolerated only for values less than 8 (as there is no ambiguity between the decimal and octal interpretations of such strings).
2. An integer that fits into 32 bits.
3. An integer packed into a bytes object of length 4 (most significant octet first).
```

```python
>>> ipaddress.IPv4Address('192.168.0.1')
IPv4Address('192.168.0.1')
>>> ipaddress.IPv4Address(3232235521)
IPv4Address('192.168.0.1')
>>> ipaddress.IPv4Address(b'\xC0\xA8\x00\x01')
IPv4Address('192.168.0.1')
```
The appropriate version number: 4 for IPv4, 6 for IPv6.

**max_prefixlen**

The total number of bits in the address representation for this version: 32 for IPv4, 128 for IPv6.

The prefix defines the number of leading bits in an address that are compared to determine whether or not an address is part of a network.

**compressed**

**exploded**

The string representation in dotted decimal notation. Leading zeroes are never included in the representation.

As IPv4 does not define a shorthand notation for addresses with octets set to zero, these two attributes are always the same as `str(addr)` for IPv4 addresses. Exposing these attributes makes it easier to write display code that can handle both IPv4 and IPv6 addresses.

**packed**

The binary representation of this address - a `bytes` object of the appropriate length (most significant octet first). This is 4 bytes for IPv4 and 16 bytes for IPv6.

**reverse_pointer**

The name of the reverse DNS PTR record for the IP address, e.g.:

```python
>>> ipaddress.ip_address("127.0.0.1").reverse_pointer
'1.0.0.127.in-addr.arpa'
>>> ipaddress.ip_address("2001:db8::1").reverse_pointer
'1001:0db8:0000:0000:0000:0000:0000:0001.in-addr.arpa'
```
This is the name that could be used for performing a PTR lookup, not the resolved hostname itself.

*New in version 3.5.*

**is_multicast**

True if the address is reserved for multicast use. See [RFC 3171](https://tools.ietf.org/html/rfc3171) (for IPv4) or [RFC 2373](https://tools.ietf.org/html/rfc2373) (for IPv6).

**is_private**

True if the address is allocated for private networks. See [iana-ipv4-special-registry](https://www.iana.org/assignments/ipv4-special-registry) (for IPv4) or [iana-ipv6-special-registry](https://www.iana.org/assignments/ipv6-special-registry) (for IPv6).

**is_global**

True if the address is allocated for public networks. See [iana-ipv4-special-registry](https://www.iana.org/assignments/ipv4-special-registry) (for IPv4) or [iana-ipv6-special-registry](https://www.iana.org/assignments/ipv6-special-registry) (for IPv6).

*New in version 3.4.*

**is_unspecified**

**is_reserved**

True if the address is otherwise IETF reserved.

**is_loopback**

True if this is a loopback address. See [RFC 3330](https://tools.ietf.org/html/rfc3330) (for IPv4) or [RFC 2373](https://tools.ietf.org/html/rfc2373) (for IPv6).
is_link_local

True if the address is reserved for link-local usage. See RFC 3927.

class ipaddress.IPv6Address(address)

Construct an IPv6 address. An AddressValueError is raised if address is not a valid IPv6 address.

The following constitutes a valid IPv6 address:

1. A string consisting of eight groups of four hexadecimal digits, each group representing 16 bits. The groups are separated by colons. This describes an exploded (longhand) notation. The string can also be compressed (shorthand notation) by various means. See RFC 4291 for details. For example, "0000:0000:0000:0000:0000:0abc:0007:0def" can be compressed to "::abc:7:def".
2. An integer that fits into 128 bits.
3. An integer packed into a bytes object of length 16, big-endian.

>>> ipaddress.IPv6Address('2001:db8::1000')
IPv6Address('2001:db8::1000')

compressed

The short form of the address representation, with leading zeroes in groups omitted and the longest sequence of groups consisting entirely of zeroes collapsed to a single empty group.

This is also the value returned by str(addr) for IPv6 addresses.

exploded

The long form of the address representation, with all leading
zeroes and groups consisting entirely of zeroes included.

For the following attributes, see the corresponding documentation of the `IPv4Address` class:

- packed
- reverse_pointer
- version
- max_prefixlen
- is_multicast
- is_private
- is_global
- is_unspecified
- is_reserved
- is_loopback
- is_link_local
  
  New in version 3.4: is_global

- is_site_local
  
  True if the address is reserved for site-local usage. Note that the site-local address space has been deprecated by RFC 3879. Use `is_private` to test if this address is in the space of unique local addresses as defined by RFC 4193.

- ipv4_mapped
  
  For addresses that appear to be IPv4 mapped addresses (starting with `::FFFF/96`), this property will report the
embedded IPv4 address. For any other address, this property will be None.

**sixtofour**

For addresses that appear to be 6to4 addresses (starting with 2002::/16) as defined by RFC 3056, this property will report the embedded IPv4 address. For any other address, this property will be None.

**teredo**

For addresses that appear to be Teredo addresses (starting with 2001::/32) as defined by RFC 4380, this property will report the embedded (server, client) IP address pair. For any other address, this property will be None.

### 21.28.2.2. Conversion to Strings and Integers

To interoperate with networking interfaces such as the socket module, addresses must be converted to strings or integers. This is handled using the `str()` and `int()` builtin functions:

```python
>>> str(ipaddress.IPv4Address('192.168.0.1'))
'192.168.0.1'
>>> int(ipaddress.IPv4Address('192.168.0.1'))
3232235521
>>> str(ipaddress.IPv6Address '::1')
'::1'
>>> int(ipaddress.IPv6Address '::1')
1
```

### 21.28.2.3. Operators
Address objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

21.28.2.3.1. Comparison operators

Address objects can be compared with the usual set of comparison operators. Some examples:

```python
>>> IPv4Address('127.0.0.2') > IPv4Address('127.0.0.1')
True
>>> IPv4Address('127.0.0.2') == IPv4Address('127.0.0.1')
False
>>> IPv4Address('127.0.0.2') != IPv4Address('127.0.0.1')
True
```

21.28.2.3.2. Arithmetic operators

Integers can be added to or subtracted from address objects. Some examples:

```python
>>> IPv4Address('127.0.0.2') + 3
IPv4Address('127.0.0.5')
>>> IPv4Address('127.0.0.2') - 3
IPv4Address('126.255.255.255')
>>> IPv4Address('255.255.255.255') + 1
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ipaddress.AddressValueError: 4294967296 (>= 2**32)
```

Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ipaddress.AddressValueError: 4294967296 (>= 2**32)

21.28.3. IP Network definitions

The IPv4Network and IPv6Network objects provide a mechanism for defining and inspecting IP network definitions. A network definition consists of a mask and a network address, and as such defines a range of IP addresses that equal the network address when masked (binary AND) with the mask. For example, a network definition with the mask `255.255.255.0` and the network address `192.168.1.0` consists of IP addresses in the inclusive range `192.168.1.0` to `192.168.1.255`.

21.28.3.1. Prefix, net mask and host mask

There are several equivalent ways to specify IP network masks. A prefix `/<nbbits>` is a notation that denotes how many high-order bits are set in the network mask. A net mask is an IP address with some number of high-order bits set. Thus the prefix `/24` is equivalent to the net mask `255.255.255.0` in IPv4, or `ffff:ff00::` in IPv6. In addition, a host mask is the logical inverse of a net mask, and is sometimes used (for example in Cisco access control lists) to denote a network mask. The host mask equivalent to `/24` in IPv4 is `0.0.0.255`.

21.28.3.2. Network objects

All attributes implemented by address objects are implemented by network objects as well. In addition, network objects implement additional attributes. All of these are common between IPv4Network and IPv6Network, so to avoid duplication they are only documented for IPv4Network.
class ipaddress.**IPv4Network**(address, strict=True)

Construct an IPv4 network definition. address can be one of the following:

1. A string consisting of an IP address and an optional mask, separated by a slash (/). The IP address is the network address, and the mask can be either a single number, which means it’s a *prefix*, or a string representation of an IPv4 address. If it’s the latter, the mask is interpreted as a *net mask* if it starts with a non-zero field, or as a *host mask* if it starts with a zero field. If no mask is provided, it’s considered to be */32*.

   For example, the following address specifications are equivalent:
   
   192.168.1.0/24, 192.168.1.0/255.255.255.0 and 192.168.1.0/0.0.0.255.

2. An integer that fits into 32 bits. This is equivalent to a single-address network, with the network address being address and the mask being */32*.

3. An integer packed into a `bytes` object of length 4, big-endian. The interpretation is similar to an integer address.

4. A two-tuple of an address description and a netmask, where the address description is either a string, a 32-bits integer, a 4-bytes packed integer, or an existing IPv4Address object; and the netmask is either an integer representing the prefix length (e.g. 24) or a string representing the prefix mask (e.g. 255.255.255.0).

   An `AddressValueError` is raised if address is not a valid IPv4
address. A **NetmaskValueError** is raised if the mask is not valid for an IPv4 address.

If *strict* is *True* and host bits are set in the supplied address, then **ValueError** is raised. Otherwise, the host bits are masked out to determine the appropriate network address.

Unless stated otherwise, all network methods accepting other network/address objects will raise **TypeError** if the argument’s IP version is incompatible to `self`.

*Changed in version 3.5:* Added the two-tuple form for the *address* constructor parameter.

**version**

**max_prefixlen**

Refer to the corresponding attribute documentation in `IPv4Address`.

**is_multicast**

**is_private**

**is_unspecified**

**is_reserved**

**is_loopback**

**is_link_local**

These attributes are true for the network as a whole if they are true for both the network address and the broadcast address.

**network_address**

The network address for the network. The network address and
the prefix length together uniquely define a network.

**broadcast_address**

The broadcast address for the network. Packets sent to the broadcast address should be received by every host on the network.

**hostmask**

The host mask, as a string.

**with_prefixlen**

**compressed**

**exploded**

A string representation of the network, with the mask in prefix notation.

**with_prefixlen** and **compressed** are always the same as `str(network)`. **exploded** uses the exploded form the network address.

**with_netmask**

A string representation of the network, with the mask in net mask notation.

**with_hostmask**

A string representation of the network, with the mask in host mask notation.

**num_addresses**

The total number of addresses in the network.

**prefixlen**
Length of the network prefix, in bits.

**hosts()**

Returns an iterator over the usable hosts in the network. The usable hosts are all the IP addresses that belong to the network, except the network address itself and the network broadcast address.

```python
>>> list(ip_network('192.0.2.0/29').hosts())
[IPv4Address('192.0.2.1'), IPv4Address('192.0.2.2'), IPv4Address('192.0.2.3'), IPv4Address('192.0.2.4'), IPv4Address('192.0.2.5'), IPv4Address('192.0.2.6')]
```

**overlaps(other)**

True if this network is partly or wholly contained in other or other is wholly contained in this network.

**address_exclude(network)**

Computes the network definitions resulting from removing the given network from this one. Returns an iterator of network objects. Raises **ValueError** if network is not completely contained in this network.

```python
>>> n1 = ip_network('192.0.2.0/28')
>>> n2 = ip_network('192.0.2.1/32')
>>> list(n1.address_exclude(n2))
[IPv4Network('192.0.2.8/29'), IPv4Network('192.0.2.4/30'), IPv4Network('192.0.2.2/31'), IPv4Network('192.0.2.0/32')]
```

**subnets(prefixlen_diff=1, new_prefix=None)**

The subnets that join to make the current network definition, depending on the argument values. **prefixlen_diff** is the amount
our prefix length should be increased by. new_prefix is the desired new prefix of the subnets; it must be larger than our prefix. One and only one of prefixlen_diff and new_prefix must be set. Returns an iterator of network objects.

```python
generated_text = ">>> list(ip_network('192.0.2.0/24').subnets(()))
[IPv4Network('192.0.2.0/25'), IPv4Network('192.0.2.128/25')]
>>> list(ip_network('192.0.2.0/24').subnets(prefixlen_diff=1))
[IPv4Network('192.0.2.0/25'), IPv4Network('192.0.2.128/25'), IPv4Network('192.0.2.192/25')]
>>> list(ip_network('192.0.2.0/24').subnets(new_prefix='192.0.2.0/25'))
Traceback (most recent call last):
  File "<stdin>" , line 1, in <module>
    raise ValueError('new prefix must be longer')
ValueError: new prefix must be longer
>>> list(ip_network('192.0.2.0/24').subnets(new_prefix='192.0.2.128/25'))
[IPv4Network('192.0.2.0/25'), IPv4Network('192.0.2.128/25'), IPv4Network('192.0.2.192/25')]
```

**supernet**(prefixlen_diff=1, new_prefix=None)

The supernet containing this network definition, depending on the argument values. prefixlen_diff is the amount our prefix length should be decreased by. new_prefix is the desired new prefix of the supernet; it must be smaller than our prefix. One and only one of prefixlen_diff and new_prefix must be set. Returns a single network object.

```python
generated_text = ">>> ip_network('192.0.2.0/24').supernet()
IPv4Network('192.0.2.0/23')
>>> ip_network('192.0.2.0/24').supernet(prefixlen_diff=1)
IPv4Network('192.0.0.0/22')
>>> ip_network('192.0.2.0/24').supernet(new_prefix='192.0.2.0/25')
Traceback (most recent call last):
  File "<stdin>" , line 1, in <module>
    raise ValueError('new prefix must be longer')
ValueError: new prefix must be longer"
```
**compare_networks**(other)

Compare this network to other. In this comparison only the network addresses are considered; host bits aren’t. Returns either -1, 0 or 1.

```python
>>> ip_network('192.0.2.1/32').compare_networks(ip_network('192.0.2.1/32'))
-1  
>>> ip_network('192.0.2.1/32').compare_networks(ip_network('192.0.2.1/32'))
1  
>>> ip_network('192.0.2.1/32').compare_networks(ip_network('192.0.2.1/32'))
0
```

**class ipaddress.IPv6Network**(address, strict=True)

Construct an IPv6 network definition. address can be one of the following:

1. A string consisting of an IP address and an optional mask, separated by a slash (/). The IP address is the network address, and the mask can be either a single number, which means it’s a prefix, or a string representation of an IPv6 address. If it's the latter, the mask is interpreted as a net mask. If no mask is provided, it's considered to be /128.

   For example, the following address specifications are equivalent:

   2001:db00::0/24 and 2001:db00::0/ffff:ff00:.

2. An integer that fits into 128 bits. This is equivalent to a single-address network, with the network address being address and the mask being /128.
3. An integer packed into a `bytes` object of length 16, big-endian. The interpretation is similar to an integer `address`.

4. A two-tuple of an address description and a netmask, where the address description is either a string, a 128-bits integer, a 16-bytes packed integer, or an existing IPv6Address object; and the netmask is an integer representing the prefix length.

An `AddressValueError` is raised if `address` is not a valid IPv6 address. A `NetmaskValueError` is raised if the mask is not valid for an IPv6 address.

If `strict` is `True` and host bits are set in the supplied address, then `ValueError` is raised. Otherwise, the host bits are masked out to determine the appropriate network address.

`Changed in version 3.5: Added the two-tuple form for the address constructor parameter.`

is_site_local
    These attribute is true for the network as a whole if it is true for both the network address and the broadcast address

21.28.3.3. Operators
Network objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

21.28.3.3.1. Logical operators

Network objects can be compared with the usual set of logical operators, similarly to address objects.

21.28.3.3.2. Iteration

Network objects can be iterated to list all the addresses belonging to the network. For iteration, all hosts are returned, including unusable hosts (for usable hosts, use the hosts() method). An example:

```python
>>> for addr in IPv4Network('192.0.2.0/28):
...     addr
... IPv4Address('192.0.2.0')
IPv4Address('192.0.2.1')
IPv4Address('192.0.2.2')
IPv4Address('192.0.2.3')
IPv4Address('192.0.2.4')
IPv4Address('192.0.2.5')
IPv4Address('192.0.2.6')
IPv4Address('192.0.2.7')
IPv4Address('192.0.2.8')
IPv4Address('192.0.2.9')
IPv4Address('192.0.2.10')
IPv4Address('192.0.2.11')
IPv4Address('192.0.2.12')
IPv4Address('192.0.2.13')
IPv4Address('192.0.2.14')
IPv4Address('192.0.2.15')
```
21.28.3.3.3. Networks as containers of addresses

Network objects can act as containers of addresses. Some examples:

```python
>>> IPv4Network('192.0.2.0/28')[0]
IPv4Address('192.0.2.0')
>>> IPv4Network('192.0.2.0/28')[15]
IPv4Address('192.0.2.15')
>>> IPv4Address('192.0.2.6') in IPv4Network('192.0.2.0/28')
True
>>> IPv4Address('192.0.3.6') in IPv4Network('192.0.2.0/28')
False
```
21.28.4. Interface objects

**class ipaddress.**IPv4Interface**(address)**

Construct an IPv4 interface. The meaning of *address* is as in the constructor of IPv4Network, except that arbitrary host addresses are always accepted.

*IPv4Interface* is a subclass of *IPv4Address*, so it inherits all the attributes from that class. In addition, the following attributes are available:

**ip**

The address (*IPv4Address*) without network information.

```python
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.ip
IPv4Address('192.0.2.5')
```

**network**

The network (*IPv4Network*) this interface belongs to.

```python
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.network
IPv4Network('192.0.2.0/24')
```

**with_prefixlen**

A string representation of the interface with the mask in prefix notation.

```python
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_prefixlen
'192.0.2.5/24'
```
**with_netmask**

A string representation of the interface with the network as a net mask.

```python
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_netmask
'192.0.2.5/255.255.255.0'
```

**with_hostmask**

A string representation of the interface with the network as a host mask.

```python
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_hostmask
'192.0.2.5/0.0.0.255'
```

**class **ipaddress.IPv6Interface**(address)**

Construct an IPv6 interface. The meaning of `address` is as in the constructor of `IPv6Network`, except that arbitrary host addresses are always accepted.

`IPv6Interface` is a subclass of `IPv6Address`, so it inherits all the attributes from that class. In addition, the following attributes are available:

- `ip`
- `network`
- `with_prefixlen`
- `with_netmask`
- `with_hostmask`

Refer to the corresponding attribute documentation in
IPv4Interface.
21.28.5. Other Module Level Functions

The module also provides the following module level functions:

\[ \text{ipaddress}. \, \texttt{v4\_int\_to\_packed}(\textit{address}) \]

Represent an address as 4 packed bytes in network (big-endian) order. \textit{address} is an integer representation of an IPv4 IP address. A \texttt{ValueError} is raised if the integer is negative or too large to be an IPv4 IP address.

\[
>>> \text{ipaddress.ip\_address}(3221225985) \\
\text{IPv4Address('192.0.2.1')} \\
>>> \text{ipaddress.v4\_int\_to\_packed}(3221225985) \\
b'\xc0\x00\x02\x01'
\]

\[ \text{ipaddress}. \, \texttt{v6\_int\_to\_packed}(\textit{address}) \]

Represent an address as 16 packed bytes in network (big-endian) order. \textit{address} is an integer representation of an IPv6 IP address. A \texttt{ValueError} is raised if the integer is negative or too large to be an IPv6 IP address.

\[ \text{ipaddress}. \, \texttt{summarize\_address\_range}(\textit{first}, \textit{last}) \]

Return an iterator of the summarized network range given the first and last IP addresses. \textit{first} is the first \texttt{IPv4Address} or \texttt{IPv6Address} in the range and \textit{last} is the last \texttt{IPv4Address} or \texttt{IPv6Address} in the range. A \texttt{TypeError} is raised if \textit{first} or \textit{last} are not IP addresses or are not of the same version. A \texttt{ValueError} is raised if \textit{last} is not greater than \textit{first} or if \textit{first} address version is not 4 or 6.

\[
>>> \text{[ipaddr for ipaddr in ipaddress.summarize_add} \\
\text{... \)} ipaddress.IPv4Address('192.0.2.0'),} \]
ipaddress.collapse_addresses(addresses)
Return an iterator of the collapsed IPv4Network or IPv6Network objects. addresses is an iterator of IPv4Network or IPv6Network objects. A TypeError is raised if addresses contains mixed version objects.

>>> [ipaddr for ipaddr in ...
ipaddress.collapse_addresses([ipaddress.IPv4Network('192.0.2.128/25')])]
[IPv4Network('192.0.2.0/24')]

ipaddress.get_mixed_type_key(obj)
Return a key suitable for sorting between networks and addresses. Address and Network objects are not sortable by default; they're fundamentally different, so the expression:

IPv4Address('192.0.2.0') <= IPv4Network('192.0.2.0')

doesn't make sense. There are some times however, where you may wish to have ipaddress sort these anyway. If you need to do this, you can use this function as the key argument to sorted().

obj is either a network or address object.
21.28.6. Custom Exceptions

To support more specific error reporting from class constructors, the module defines the following exceptions:

```python
exception ipaddress.AddressValueError(ValueError)
    Any value error related to the address.

exception ipaddress.NetmaskValueError(ValueError)
    Any value error related to the netmask.
```
22. Multimedia Services

The modules described in this chapter implement various algorithms or interfaces that are mainly useful for multimedia applications. They are available at the discretion of the installation. Here’s an overview:

- **22.1. audioop** — Manipulate raw audio data
- **22.2. aifc** — Read and write AIFF and AIFC files
- **22.3. sunau** — Read and write Sun AU files
  - **22.3.1. AU_read Objects**
  - **22.3.2. AU_write Objects**
- **22.4. wave** — Read and write WAV files
  - **22.4.1. Wave_read Objects**
  - **22.4.2. Wave_write Objects**
- **22.5. chunk** — Read IFF chunked data
- **22.6. colorsys** — Conversions between color systems
- **22.7. imghdr** — Determine the type of an image
- **22.8. sndhdr** — Determine type of sound file
- **22.9. ossaudiodev** — Access to OSS-compatible audio devices
  - **22.9.1. Audio Device Objects**
  - **22.9.2. Mixer Device Objects**
22.1. audioop — Manipulate raw audio data

The `audioop` module contains some useful operations on sound fragments. It operates on sound fragments consisting of signed integer samples 8, 16, 24 or 32 bits wide, stored in bytes-like objects. All scalar items are integers, unless specified otherwise.

*Changed in version 3.4:* Support for 24-bit samples was added. All functions now accept any bytes-like object. String input now results in an immediate error.

This module provides support for a-LAW, u-LAW and Intel/DVI ADPCM encodings.

A few of the more complicated operations only take 16-bit samples, otherwise the sample size (in bytes) is always a parameter of the operation.

The module defines the following variables and functions:

- `exception audioop.error`
  
  This exception is raised on all errors, such as unknown number of bytes per sample, etc.

- `audioop.add(fragment1, fragment2, width)`
  
  Return a fragment which is the addition of the two samples passed as parameters. `width` is the sample width in bytes, either 1, 2, 3 or 4. Both fragments should have the same length. Samples are truncated in case of overflow.
audioop.\texttt{adpcm2lin}(\texttt{adpcmfragment}, \texttt{width}, \texttt{state})

Decode an Intel/DVI ADPCM coded fragment to a linear fragment. See the description of \texttt{lin2adpcm()} for details on ADPCM coding. Return a tuple (\texttt{sample}, \texttt{newstate}) where the sample has the width specified in \texttt{width}.

audioop.\texttt{alaw2lin}(\texttt{fragment}, \texttt{width})

Convert sound fragments in a-LAW encoding to linearly encoded sound fragments. a-LAW encoding always uses 8 bits samples, so \texttt{width} refers only to the sample width of the output fragment here.

audioop.\texttt{avg}(\texttt{fragment}, \texttt{width})

Return the average over all samples in the fragment.

audioop.\texttt{avgpp}(\texttt{fragment}, \texttt{width})

Return the average peak-peak value over all samples in the fragment. No filtering is done, so the usefulness of this routine is questionable.

audioop.\texttt{bias}(\texttt{fragment}, \texttt{width}, \texttt{bias})

Return a fragment that is the original fragment with a bias added to each sample. Samples wrap around in case of overflow.

audioop.\texttt{byteswap}(\texttt{fragment}, \texttt{width})

“Byteswap” all samples in a fragment and returns the modified fragment. Converts big-endian samples to little-endian and vice versa.

\textit{New in version 3.4.}

audioop.\texttt{cross}(\texttt{fragment}, \texttt{width})

Return the number of zero crossings in the fragment passed as an argument.
audioop.\texttt{findfactor}(\texttt{fragment}, \texttt{reference})

Return a factor $F$ such that \texttt{rms(add(fragment, mul(reference, -F)))} is minimal, i.e., return the factor with which you should multiply \texttt{reference} to make it match as well as possible to \texttt{fragment}. The fragments should both contain 2-byte samples.

The time taken by this routine is proportional to \texttt{len(fragment)}.

audioop.\texttt{findfit}(\texttt{fragment}, \texttt{reference})

Try to match \texttt{reference} as well as possible to a portion of \texttt{fragment} (which should be the longer fragment). This is (conceptually) done by taking slices out of \texttt{fragment}, using \texttt{findfactor()} to compute the best match, and minimizing the result. The fragments should both contain 2-byte samples. Return a tuple \texttt{(offset, factor)} where \texttt{offset} is the (integer) offset into \texttt{fragment} where the optimal match started and \texttt{factor} is the (floating-point) factor as per \texttt{findfactor()}.

audioop.\texttt{findmax}(\texttt{fragment}, \texttt{length})

Search \texttt{fragment} for a slice of length \texttt{length} samples (not bytes!) with maximum energy, i.e., return $i$ for which \texttt{rms(fragment[i*2:(i+length)*2])} is maximal. The fragments should both contain 2-byte samples.

The routine takes time proportional to \texttt{len(fragment)}.

audioop.\texttt{getsample}(\texttt{fragment}, \texttt{width}, \texttt{index})

Return the value of sample \texttt{index} from the fragment.

audioop.\texttt{lin2adpcm}(\texttt{fragment}, \texttt{width}, \texttt{state})
Convert samples to 4 bit Intel/DVI ADPCM encoding. ADPCM coding is an adaptive coding scheme, whereby each 4 bit number is the difference between one sample and the next, divided by a (varying) step. The Intel/DVI ADPCM algorithm has been selected for use by the IMA, so it may well become a standard.

`state` is a tuple containing the state of the coder. The coder returns a tuple `(adpcmfrag, newstate)`, and the `newstate` should be passed to the next call of `lin2adpcm()`. In the initial call, `None` can be passed as the state. `adpcmfrag` is the ADPCM coded fragment packed 2 4-bit values per byte.

`audioop.lin2alaw(fragment, width)`

Convert samples in the audio fragment to a-LAW encoding and return this as a bytes object. a-LAW is an audio encoding format whereby you get a dynamic range of about 13 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

`audioop.lin2lin(fragment, width, newwidth)`

Convert samples between 1-, 2-, 3- and 4-byte formats.

**Note:** In some audio formats, such as .WAV files, 16, 24 and 32 bit samples are signed, but 8 bit samples are unsigned. So when converting to 8 bit wide samples for these formats, you need to also add 128 to the result:

```
new_frames = audioop.lin2lin(frames, old_width,
new_frames = audioop.bias(new_frames, 1, 128)
```

The same, in reverse, has to be applied when converting from 8 to 16, 24 or 32 bit width samples.
audioop.\texttt{lin2ulaw}(\textit{fragment}, \textit{width})

Convert samples in the audio fragment to u-LAW encoding and return this as a bytes object. u-LAW is an audio encoding format whereby you get a dynamic range of about 14 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

audioop.\texttt{max}(\textit{fragment}, \textit{width})

Return the maximum of the absolute value of all samples in a fragment.

audioop.\texttt{maxpp}(\textit{fragment}, \textit{width})

Return the maximum peak-peak value in the sound fragment.

audioop.\texttt{minmax}(\textit{fragment}, \textit{width})

Return a tuple consisting of the minimum and maximum values of all samples in the sound fragment.

audioop.\texttt{mul}(\textit{fragment}, \textit{width}, \textit{factor})

Return a fragment that has all samples in the original fragment multiplied by the floating-point value \textit{factor}. Samples are truncated in case of overflow.

audioop.\texttt{ratecv}(\textit{fragment}, \textit{width}, \textit{nchannels}, \textit{inrate}, \textit{outrate},
\textit{state}[,, \textit{weightA}[,, \textit{weightB}]])

Convert the frame rate of the input fragment.

\textit{state} is a tuple containing the state of the converter. The converter returns a tuple \texttt{(newfragment, newstate)}, and \textit{newstate} should be passed to the next call of \texttt{ratecv()}. The initial call should pass \texttt{None} as the state.

The \textit{weightA} and \textit{weightB} arguments are parameters for a simple
digital filter and default to 1 and 0 respectively.

audioop.\texttt{reverse}(\textit{fragment, width})
Reverse the samples in a fragment and returns the modified fragment.

audioop.\texttt{rms}(\textit{fragment, width})
Return the root-mean-square of the fragment, i.e. \(\sqrt{\text{sum}(S_i^2)/n}\).
This is a measure of the power in an audio signal.

audioop.\texttt{tomono}(\textit{fragment, width, ifactor, rfactor})
Convert a stereo fragment to a mono fragment. The left channel is multiplied by \textit{ifactor} and the right channel by \textit{rfactor} before adding the two channels to give a mono signal.

audioop.\texttt{tostereo}(\textit{fragment, width, ifactor, rfactor})
Generate a stereo fragment from a mono fragment. Each pair of samples in the stereo fragment are computed from the mono sample, whereby left channel samples are multiplied by \textit{ifactor} and right channel samples by \textit{rfactor}.

audioop.\texttt{ulaw2lin}(\textit{fragment, width})
Convert sound fragments in u-LAW encoding to linearly encoded sound fragments. u-LAW encoding always uses 8 bits samples, so \textit{width} refers only to the sample width of the output fragment here.

Note that operations such as \texttt{mul()} or \texttt{max()} make no distinction between mono and stereo fragments, i.e. all samples are treated equal. If this is a problem the stereo fragment should be split into two mono fragments first and recombined later. Here is an example of how to do that:
def mul_stereo(sample, width, lfactor, rfactor):
    lsample = audioop.tomono(sample, width, 1, 0)
    rsample = audioop.tomono(sample, width, 0, 1)
    lsample = audioop.mul(lsample, width, lfactor)
    rsample = audioop.mul(rsample, width, rfactor)
    lsample = audioop.tostereo(lsample, width, 1, 0)
    rsample = audioop.tostereo(rsample, width, 0, 1)
    return audioop.add(lsample, rsample, width)

If you use the ADPCM coder to build network packets and you want your protocol to be stateless (i.e. to be able to tolerate packet loss) you should not only transmit the data but also the state. Note that you should send the initial state (the one you passed to lin2adpcm()) along to the decoder, not the final state (as returned by the coder). If you want to use struct.Struct to store the state in binary you can code the first element (the predicted value) in 16 bits and the second (the delta index) in 8.

The ADPCM coders have never been tried against other ADPCM coders, only against themselves. It could well be that I misinterpreted the standards in which case they will not be interoperable with the respective standards.

The find*() routines might look a bit funny at first sight. They are primarily meant to do echo cancellation. A reasonably fast way to do this is to pick the most energetic piece of the output sample, locate that in the input sample and subtract the whole output sample from the input sample:

def echocancel(outputdata, inputdata):
    pos = audioop.findmax(outputdata, 800)  # one
    out_test = outputdata[pos*2:]
    in_test = inputdata[pos*2:]
```python
ipos, factor = audioop.findfit(in_test, out_test)
# Optional (for better cancellation):
# factor = audioop.findfactor(in_test[ipos*2:ipos*2+len(out_test)],
# out_test)
prefill = '\\0'*(pos+ipos)*2
postfill = '\\0'*(len(inputdata)-len(prefill)-len(outputdata))
outputdata = prefill + audioop.mul(outputdata, 2)
return audioop.add(inputdata, outputdata, 2)
```
22.2. aifc — Read and write AIFF and AIFC files

Source code: Lib/aifc.py

This module provides support for reading and writing AIFF and AIFF-C files. AIFF is Audio Interchange File Format, a format for storing digital audio samples in a file. AIFF-C is a newer version of the format that includes the ability to compress the audio data.

Audio files have a number of parameters that describe the audio data. The sampling rate or frame rate is the number of times per second the sound is sampled. The number of channels indicate if the audio is mono, stereo, or quadro. Each frame consists of one sample per channel. The sample size is the size in bytes of each sample. Thus a frame consists of \texttt{nchannels} * \texttt{samplesize} bytes, and a second's worth of audio consists of \texttt{nchannels} * \texttt{samplesize} * \texttt{framerate} bytes.

For example, CD quality audio has a sample size of two bytes (16 bits), uses two channels (stereo) and has a frame rate of 44,100 frames/second. This gives a frame size of 4 bytes (2*2), and a second's worth occupies 2*2*44100 bytes (176,400 bytes).

Module \texttt{aifc} defines the following function:

\texttt{aifc.open(file, mode=\texttt{None})}

Open an AIFF or AIFF-C file and return an object instance with methods that are described below. The argument \texttt{file} is either a string naming a file or a \texttt{file object}. \texttt{mode} must be \texttt{'r'} or \texttt{\texttt{rb}'}
when the file must be opened for reading, or 'w' or 'wb' when the file must be opened for writing. If omitted, file.mode is used if it exists, otherwise 'rb' is used. When used for writing, the file object should be seekable, unless you know ahead of time how many samples you are going to write in total and use writeframesraw() and setnframes(). The open() function may be used in a with statement. When the with block completes, the close() method is called.

*Changed in version 3.4:* Support for the with statement was added.

Objects returned by open() when a file is opened for reading have the following methods:

aifc.getnchannels()
Return the number of audio channels (1 for mono, 2 for stereo).

aifc.getsampwidth()
Return the size in bytes of individual samples.

aifc.getframerate()
Return the sampling rate (number of audio frames per second).

aifc.getnframes()
Return the number of audio frames in the file.

aifc.getcomptype()
Return a bytes array of length 4 describing the type of compression used in the audio file. For AIFF files, the returned value is b'NONE'.

aifc.getcompname()
Return a bytes array convertible to a human-readable description of the type of compression used in the audio file. For AIFF files, the returned value is \texttt{b'not compressed'}.

\texttt{aifc.getparams()}

Returns a \texttt{namedtuple()} \texttt{(nchannels, sampwidth, framerate, nframes, comptype, compname)}, equivalent to output of the get\texttt{*}() methods.

\texttt{aifc.getmarkers()}

Return a list of markers in the audio file. A marker consists of a tuple of three elements. The first is the mark ID (an integer), the second is the mark position in frames from the beginning of the data (an integer), the third is the name of the mark (a string).

\texttt{aifc.getmark(id)}

Return the tuple as described in getmarkers() for the mark with the given \texttt{id}.

\texttt{aifc.readframes(nframes)}

Read and return the next \texttt{nframes} frames from the audio file. The returned data is a string containing for each frame the uncompressed samples of all channels.

\texttt{aifc.rewind()}

Rewind the read pointer. The next readframes() will start from the beginning.

\texttt{aifc.setpos(pos)}

Seek to the specified frame number.

\texttt{aifc.tell()}
Return the current frame number.

**aifc.close()**

Close the AIFF file. After calling this method, the object can no longer be used.

Objects returned by **open()** when a file is opened for writing have all the above methods, except for **readframes()** and **setpos()**. In addition the following methods exist. The get*() methods can only be called after the corresponding set*() methods have been called. Before the first **writeframes()** or **writeframesraw()**, all parameters except for the number of frames must be filled in.

**aifc.aiff()**

Create an AIFF file. The default is that an AIFF-C file is created, unless the name of the file ends in ' .aiff ' in which case the default is an AIFF file.

**aifc.aifc()**

Create an AIFF-C file. The default is that an AIFF-C file is created, unless the name of the file ends in ' .aiff ' in which case the default is an AIFF file.

**aifc.setnchannels(nchannels)**

Specify the number of channels in the audio file.

**aifc.setsampwidth(width)**

Specify the size in bytes of audio samples.

**aifc.setframerate(rate)**

Specify the sampling frequency in frames per second.

**aifc.setnframes(nframes)**
Specify the number of frames that are to be written to the audio file. If this parameter is not set, or not set correctly, the file needs to support seeking.

**aifc.setcomptype(type, name)**

Specify the compression type. If not specified, the audio data will not be compressed. In AIFF files, compression is not possible. The name parameter should be a human-readable description of the compression type as a bytes array, the type parameter should be a bytes array of length 4. Currently the following compression types are supported: b'NONE', b'ULAW', b'ALAW', b'G722'.

**aifc.setparams(nchannels, sampwidth, framerate, comptype, compname)**

Set all the above parameters at once. The argument is a tuple consisting of the various parameters. This means that it is possible to use the result of a `getparams()` call as argument to `setparams()`.

**aifc.setmark(id, pos, name)**

Add a mark with the given id (larger than 0), and the given name at the given position. This method can be called at any time before `close()`.

**aifc.tell()**

Return the current write position in the output file. Useful in combination with `setmark()`.

**aifc.writeframes(data)**

Write data to the output file. This method can only be called after the audio file parameters have been set.
**Changed in version 3.4:** Any bytes-like object is now accepted.

`aifc.writeframesraw(data)`

Like `writeframes()`, except that the header of the audio file is not updated.

**Changed in version 3.4:** Any bytes-like object is now accepted.

`aifc.close()`

Close the AIFF file. The header of the file is updated to reflect the actual size of the audio data. After calling this method, the object can no longer be used.
22.3. **sunau** — Read and write Sun AU files

**Source code:** Lib/sunau.py

The **sunau** module provides a convenient interface to the Sun AU sound format. Note that this module is interface-compatible with the modules **aifc** and **wave**.

An audio file consists of a header followed by the data. The fields of the header are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>magic word</td>
<td>The four bytes <code>.snd</code></td>
</tr>
<tr>
<td>header size</td>
<td>Size of the header, including info, in bytes.</td>
</tr>
<tr>
<td>data size</td>
<td>Physical size of the data, in bytes.</td>
</tr>
<tr>
<td>encoding</td>
<td>Indicates how the audio samples are encoded.</td>
</tr>
<tr>
<td>sample rate</td>
<td>The sampling rate.</td>
</tr>
<tr>
<td># of channels</td>
<td>The number of channels in the samples.</td>
</tr>
<tr>
<td>info</td>
<td>ASCII string giving a description of the audio file (padded with null bytes)</td>
</tr>
</tbody>
</table>

Apart from the info field, all header fields are 4 bytes in size. They are all 32-bit unsigned integers encoded in big-endian byte order.

The **sunau** module defines the following functions:

sunau.open(*file*, *mode*)
If `file` is a string, open the file by that name, otherwise treat it as a seekable file-like object. `mode` can be any of

```
'r'

Read only mode.

'w'

Write only mode.

```

Note that it does not allow read/write files.

A `mode` of `'r'` returns an AU_read object, while a `mode` of `'w'` or `'wb'` returns an AU_write object.

```
sunau.openfp(file, mode)
```

A synonym for `open()`, maintained for backwards compatibility.

The `sunau` module defines the following exception:

```
exception sunau.Error

An error raised when something is impossible because of Sun AU specs or implementation deficiency.
```

The `sunau` module defines the following data items:

```
sunau.AUDIO_FILE_MAGIC

An integer every valid Sun AU file begins with, stored in big-endian form. This is the string `.snd` interpreted as an integer.

sunau.AUDIO_FILE_ENCODING_MULAW_8
sunau.AUDIO_FILE_ENCODING_LINEAR_8
sunau.AUDIO_FILE_ENCODING_LINEAR_16
sunau.AUDIO_FILE_ENCODING_LINEAR_24
sunau.AUDIO_FILE_ENCODING_LINEAR_32
sunau.AUDIO_FILE_ENCODING_ALAW_8
```
Values of the encoding field from the AU header which are supported by this module.

sunau.\texttt{AUDIO\_FILE\_ENCODING\_FLOAT}
sunau.\texttt{AUDIO\_FILE\_ENCODING\_DOUBLE}
sunau.\texttt{AUDIO\_FILE\_ENCODING\_ADPCM\_G721}
sunau.\texttt{AUDIO\_FILE\_ENCODING\_ADPCM\_G722}
sunau.\texttt{AUDIO\_FILE\_ENCODING\_ADPCM\_G723\_3}
sunau.\texttt{AUDIO\_FILE\_ENCODING\_ADPCM\_G723\_5}

Additional known values of the encoding field from the AU header, but which are not supported by this module.
22.3.1. AU_read Objects

AU_read objects, as returned by `open()` above, have the following methods:

`AU_read.close()`
Close the stream, and make the instance unusable. (This is called automatically on deletion.)

`AU_read.getnchannels()`
Returns number of audio channels (1 for mono, 2 for stereo).

`AU_read.getsampwidth()`
Returns sample width in bytes.

`AU_read.getframerate()`
Returns sampling frequency.

`AU_read.getnframes()`
Returns number of audio frames.

`AU_read.getcomptype()`
Returns compression type. Supported compression types are 'ULAW', 'ALAW' and 'NONE'.

`AU_read.getcompname()`
Human-readable version of `getcomptype()`. The supported types have the respective names 'CCITT G.711 u-law', 'CCITT G.711 A-law' and 'not compressed'.

`AU_read.getparams()`
Returns a `namedtuple()` (nchannels, sampwidth,
framerate, nframes, comptype, compname), equivalent to output of the get*() methods.

**AU_read**. **readframes**(n)
Reads and returns at most n frames of audio, as a bytes object. The data will be returned in linear format. If the original data is in u-LAW format, it will be converted.

**AU_read**. **rewind**()
Rewind the file pointer to the beginning of the audio stream.

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

**AU_read**. **setpos**(pos)
Set the file pointer to the specified position. Only values returned from tell() should be used for pos.

**AU_read**. **tell**()
Return current file pointer position. Note that the returned value has nothing to do with the actual position in the file.

The following two functions are defined for compatibility with the aifc, and don’t do anything interesting.

**AU_read**. **getmarkers**()
Returns None.

**AU_read**. **getmark**(id)
Raise an error.
22.3.2. AU_write Objects

AU_write objects, as returned by `open()` above, have the following methods:

- **AU_write.setnchannels(n)**
  Set the number of channels.

- **AU_write.setsampwidth(n)**
  Set the sample width (in bytes.)

  *Changed in version 3.4: Added support for 24-bit samples.*

- **AU_write.setframerate(n)**
  Set the frame rate.

- **AU_write.setnframes(n)**
  Set the number of frames. This can be later changed, when and if more frames are written.

- **AU_write.setcomptype(type, name)**
  Set the compression type and description. Only 'NONE' and 'ULAW' are supported on output.

- **AU_write.setparams(tupled)**
  The *tupled* should be (nchannels, sampwidth, framerate, nframes, comptype, compname), with values valid for the set*() methods. Set all parameters.

- **AU_write.tell()**
  Return current position in the file, with the same disclaimer for the AU_read.tell() and AU_read.setpos() methods.
AU_write.writeframesraw(data)
Write audio frames, without correcting nframes.

*Changed in version 3.4:* Any bytes-like object is now accepted.

AU_write.writeframes(data)
Write audio frames and make sure nframes is correct.

*Changed in version 3.4:* Any bytes-like object is now accepted.

AU_write.close()
Make sure nframes is correct, and close the file.

This method is called upon deletion.

Note that it is invalid to set any parameters after calling writeframes() or writeframesraw().
22.4. wave — Read and write WAV files

Source code: Lib/wave.py

The wave module provides a convenient interface to the WAV sound format. It does not support compression/decompression, but it does support mono/stereo.

The wave module defines the following function and exception:

```
wave.open(file, mode=None)
```

If `file` is a string, open the file by that name, otherwise treat it as a file-like object. `mode` can be:

- `'rb'`  
  Read only mode.
- `'wb'`  
  Write only mode.

Note that it does not allow read/write WAV files.

A `mode` of `'rb'` returns a `Wave_read` object, while a `mode` of `'wb'` returns a `Wave_write` object. If `mode` is omitted and a file-like object is passed as `file`, `file.mode` is used as the default value for `mode`.

If you pass in a file-like object, the wave object will not close it when its `close()` method is called; it is the caller’s responsibility to close the file object.
The `open()` function may be used in a `with` statement. When the
`with` block completes, the `Wave_read.close()` or
`Wave_write.close()` method is called.

*Changed in version 3.4:* Added support for unseekable files.

```
wave.openfp(file, mode)
```

A synonym for `open()`, maintained for backwards compatibility.

```
exception wave.Error
```

An error raised when something is impossible because it violates
the WAV specification or hits an implementation deficiency.
22.4.1. Wave_read Objects

Wave_read objects, as returned by open(), have the following methods:

Wave_read.close()
    Close the stream if it was opened by wave, and make the instance unusable. This is called automatically on object collection.

Wave_read.getnchannels()
    Returns number of audio channels (1 for mono, 2 for stereo).

Wave_read.getsampwidth()
    Returns sample width in bytes.

Wave_read.getframerate()
    Returns sampling frequency.

Wave_read.getnframes()
    Returns number of audio frames.

Wave_read.getcomptype()
    Returns compression type ('NONE' is the only supported type).

Wave_read.getcompname()
    Human-readable version of getcomptype(). Usually 'not compressed' parallels 'NONE'.

Wave_read.getparams()
    Returns a namedtuple(nchannels, sampwidth, framerate, nframes, comptype, compname), equivalent to
output of the get*() methods.

Wave_read.readframes(n)
Reads and returns at most n frames of audio, as a bytes object.

Wave_read.rewind()
Rewind the file pointer to the beginning of the audio stream.

The following two methods are defined for compatibility with the aifc module, and don’t do anything interesting.

Wave_read.getmarkers()
Returns None.

Wave_read.getmark(id)
Raise an error.

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

Wave_read.setpos(pos)
Set the file pointer to the specified position.

Wave_read.tell()
Return current file pointer position.
22.4.2. Wave_write Objects

For seekable output streams, the wave header will automatically be updated to reflect the number of frames actually written. For unseekable streams, the nframes value must be accurate when the first frame data is written. An accurate nframes value can be achieved either by calling setnframes() or setparams() with the number of frames that will be written before close() is called and then using writeframesraw() to write the frame data, or by calling writeframes() with all of the frame data to be written. In the latter case writeframes() will calculate the number of frames in the data and set nframes accordingly before writing the frame data.

Wave_write objects, as returned by open(), have the following methods:

*Changed in version 3.4:* Added support for unseekable files.

Wave_write.close()

Make sure nframes is correct, and close the file if it was opened by wave. This method is called upon object collection. It will raise an exception if the output stream is not seekable and nframes does not match the number of frames actually written.

Wave_write.setnchannels(n)

Set the number of channels.

Wave_write.setsampwidth(n)

Set the sample width to n bytes.

Wave_write.setframerate(n)
Set the frame rate to \( n \).

*Changed in version 3.2:* A non-integral input to this method is rounded to the nearest integer.

Wave_write.setnframes\((n)\)

Set the number of frames to \( n \). This will be changed later if the number of frames actually written is different (this update attempt will raise an error if the output stream is not seekable).

Wave_write.setcomptype\((type, name)\)

Set the compression type and description. At the moment, only compression type **NONE** is supported, meaning no compression.

Wave_write.setparams\((tuple)\)

The tuple should be \((nchannels, sampwidth, framerate, nframes, comptype, compname)\), with values valid for the set*() methods. Sets all parameters.

Wave_write.tell\()\)

Return current position in the file, with the same disclaimer for the Wave_read.tell\() and Wave_read.setpos\() methods.

Wave_write.writeframesraw\((data)\)

Write audio frames, without correcting \( nframes \).

*Changed in version 3.4:* Any bytes-like object is now accepted.

Wave_write.writeframes\((data)\)

Write audio frames and make sure \( nframes \) is correct. It will raise an error if the output stream is not seekable and the total number of frames that have been written after \( data \) has been written does not match the previously set value for \( nframes \).
Changed in version 3.4: Any bytes-like object is now accepted.

Note that it is invalid to set any parameters after calling writeframes() or writeframesraw(), and any attempt to do so will raise wave.Error.
22.5. **chunk** — Read IFF chunked data

**Source code:** Lib/chunk.py

This module provides an interface for reading files that use EA IFF 85 chunks. [1] This format is used in at least the Audio Interchange File Format (AIFF/AIFF-C) and the Real Media File Format (RMFF). The WAVE audio file format is closely related and can also be read using this module.

A chunk has the following structure:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Length</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>Chunk ID</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Size of chunk in big-endian byte order, not including the header</td>
</tr>
<tr>
<td>8</td>
<td>n</td>
<td>Data bytes, where n is the size given in the preceding field</td>
</tr>
<tr>
<td>8 + n</td>
<td>0 or 1</td>
<td>Pad byte needed if n is odd and chunk alignment is used</td>
</tr>
</tbody>
</table>

The ID is a 4-byte string which identifies the type of chunk.

The size field (a 32-bit value, encoded using big-endian byte order) gives the size of the chunk data, not including the 8-byte header.

Usually an IFF-type file consists of one or more chunks. The proposed usage of the **Chunk** class defined here is to instantiate an instance at
the start of each chunk and read from the instance until it reaches the end, after which a new instance can be instantiated. At the end of the file, creating a new instance will fail with an EOFError exception.

```python
class chunk. Chunk(file, align=True, bigendian=True, inclheader=False)
```

Class which represents a chunk. The file argument is expected to be a file-like object. An instance of this class is specifically allowed. The only method that is needed is read(). If the methods seek() and tell() are present and don’t raise an exception, they are also used. If these methods are present and raise an exception, they are expected to not have altered the object. If the optional argument align is true, chunks are assumed to be aligned on 2-byte boundaries. If align is false, no alignment is assumed. The default value is true. If the optional argument bigendian is false, the chunk size is assumed to be in little-endian order. This is needed for WAVE audio files. The default value is true. If the optional argument inclheader is true, the size given in the chunk header includes the size of the header. The default value is false.

A Chunk object supports the following methods:

- **getname()**
  Returns the name (ID) of the chunk. This is the first 4 bytes of the chunk.

- **getsize()**
  Returns the size of the chunk.

- **close()**
  Close and skip to the end of the chunk. This does not close the underlying file.
The remaining methods will raise `OSError` if called after the `close()` method has been called. Before Python 3.3, they used to raise `IOError`, now an alias of `OSError`.

**isatty()**

Returns `False`.

**seek(pos, whence=0)**

Set the chunk's current position. The `whence` argument is optional and defaults to `0` (absolute file positioning); other values are `1` (seek relative to the current position) and `2` (seek relative to the file's end). There is no return value. If the underlying file does not allow seek, only forward seeks are allowed.

**tell()**

Return the current position into the chunk.

**read(size=-1)**

Read at most `size` bytes from the chunk (less if the read hits the end of the chunk before obtaining `size` bytes). If the `size` argument is negative or omitted, read all data until the end of the chunk. An empty bytes object is returned when the end of the chunk is encountered immediately.

**skip()**

Skip to the end of the chunk. All further calls to `read()` for the chunk will return `b''`. If you are not interested in the contents of the chunk, this method should be called so that the file points to the start of the next chunk.

**Footnotes**

[1]
22.6. colorsys — Conversions between color systems

Source code: Lib/colors.py

The colorsys module defines bidirectional conversions of color values between colors expressed in the RGB (Red Green Blue) color space used in computer monitors and three other coordinate systems: YIQ, HLS (Hue Lightness Saturation) and HSV (Hue Saturation Value). Coordinates in all of these color spaces are floating point values. In the YIQ space, the Y coordinate is between 0 and 1, but the I and Q coordinates can be positive or negative. In all other spaces, the coordinates are all between 0 and 1.

The colorsys module defines the following functions:

colorsys.rgb_to_yiq(r, g, b)
   Convert the color from RGB coordinates to YIQ coordinates.

colorsys.yiq_to_rgb(y, i, q)
   Convert the color from YIQ coordinates to RGB coordinates.

colorsys.rgb_to_hls(r, g, b)
   Convert the color from RGB coordinates to HLS coordinates.

colorsys.hls_to_rgb(h, l, s)
Convert the color from HLS coordinates to RGB coordinates.

colorsys. **rgb_to_hsv**(*r*, *g*, *b*)

Convert the color from RGB coordinates to HSV coordinates.

colorsys. **hsv_to_rgb**(*h*, *s*, *v*)

Convert the color from HSV coordinates to RGB coordinates.

Example:

```python
>>> import colorsys
>>> colorsys.rgb_to_hsv(0.2, 0.4, 0.4)
(0.5, 0.5, 0.4)
>>> colorsys.hsv_to_rgb(0.5, 0.5, 0.4)
(0.2, 0.4, 0.4)
```
22.7. **imghdr** — Determine the type of an image

**Source code:** Lib/imghdr.py

The `imghdr` module determines the type of image contained in a file or byte stream.

The `imghdr` module defines the following function:

```python
imghdr.what(filename, h=None)
```

Tests the image data contained in the file named by `filename`, and returns a string describing the image type. If optional `h` is provided, the `filename` is ignored and `h` is assumed to contain the byte stream to test.

*Changed in version 3.6:* Accepts a [path-like object](https://docs.python.org/3/glossary.html#term-path-like-object).

The following image types are recognized, as listed below with the return value from `what()`:

<table>
<thead>
<tr>
<th>Value</th>
<th>Image format</th>
</tr>
</thead>
<tbody>
<tr>
<td>'rgb'</td>
<td>SGI ImgLib Files</td>
</tr>
<tr>
<td>'gif'</td>
<td>GIF 87a and 89a Files</td>
</tr>
<tr>
<td>'pbm'</td>
<td>Portable Bitmap Files</td>
</tr>
<tr>
<td>'pgm'</td>
<td>Portable Graymap Files</td>
</tr>
<tr>
<td>'ppm'</td>
<td>Portable Pixmap Files</td>
</tr>
<tr>
<td>'tiff'</td>
<td>TIFF Files</td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>'rast'</td>
<td>Sun Raster Files</td>
</tr>
<tr>
<td>'xbm'</td>
<td>X Bitmap Files</td>
</tr>
<tr>
<td>'jpeg'</td>
<td>JPEG data in JFIF or Exif formats</td>
</tr>
<tr>
<td>'bmp'</td>
<td>BMP files</td>
</tr>
<tr>
<td>'png'</td>
<td>Portable Network Graphics</td>
</tr>
<tr>
<td>'webp'</td>
<td>WebP files</td>
</tr>
<tr>
<td>'exr'</td>
<td>OpenEXR Files</td>
</tr>
</tbody>
</table>

New in version 3.5: The exr and webp formats were added.

You can extend the list of file types `imghdr` can recognize by appending to this variable:

`imghdr.tests`

A list of functions performing the individual tests. Each function takes two arguments: the byte-stream and an open file-like object. When `what()` is called with a byte-stream, the file-like object will be `None`.

The test function should return a string describing the image type if the test succeeded, or `None` if it failed.

Example:

```python
>>> import imghdr
>>> imghdr.what('bass.gif')
'gif'
```
22.8. sndhdr — Determine type of sound file

**Source code:** Lib/sndhdr.py

The `sndhdr` provides utility functions which attempt to determine the type of sound data which is in a file. When these functions are able to determine what type of sound data is stored in a file, they return a `namedtuple()`, containing five attributes: (filetype, framerate, nchannels, nframes, sampwidth). The value for `type` indicates the data type and will be one of the strings 'aifc', 'aiff', 'au', 'hcom', 'sndr', 'sndt', 'voc', 'wav', '8svx', 'sb', 'ub', or 'ul'. The `sampling_rate` will be either the actual value or 0 if unknown or difficult to decode. Similarly, `channels` will be either the number of channels or 0 if it cannot be determined or if the value is difficult to decode. The value for `frames` will be either the number of frames or -1. The last item in the tuple, `bits_per_sample`, will either be the sample size in bits or 'A' for A-LAW or 'U' for u-LAW.

```python
sndhdr.whathdr(filename)
```

Determines the type of sound data stored in a file `filename` using `whathdr()`. If it succeeds, returns a namedtuple as described above, otherwise None is returned.

*Changed in version 3.5:* Result changed from a tuple to a namedtuple.
header. The name of the file is given by `filename`. This function returns a namedtuple as described above on success, or `None`.

*Changed in version 3.5:* Result changed from a tuple to a namedtuple.
22.9. **ossaudiodev** — Access to OSS-compatible audio devices

This module allows you to access the OSS (Open Sound System) audio interface. OSS is available for a wide range of open-source and commercial Unices, and is the standard audio interface for Linux and recent versions of FreeBSD.

*Changed in version 3.3:* Operations in this module now raise `OSError` where `IOError` was raised.

**See also:**

**Open Sound System Programmer’s Guide**
the official documentation for the OSS C API

The module defines a large number of constants supplied by the OSS device driver; see `<sys/soundcard.h>` on either Linux or FreeBSD for a listing.

`ossaudiodev` defines the following variables and functions:

```plaintext
exception oxaudiodev.OSSAudioError
  This exception is raised on certain errors. The argument is a string describing what went wrong.

  (If `ossaudiodev` receives an error from a system call such as open(), write(), or ioctl(), it raises `OSError`. Errors detected directly by `ossaudiodev` result in `OSSAudioError`.)
```
ossaudiodev.open

ossaudiodev.open(device, mode)

Open an audio device and return an OSS audio device object. This object supports many file-like methods, such as read(), write(), and fileno() (although there are subtle differences between conventional Unix read/write semantics and those of OSS audio devices). It also supports a number of audio-specific methods; see below for the complete list of methods.

device is the audio device filename to use. If it is not specified, this module first looks in the environment variable AUDIODEV for a device to use. If not found, it falls back to /dev/dsp.

mode is one of 'r' for read-only (record) access, 'w' for write-only (playback) access and 'rw' for both. Since many sound cards only allow one process to have the recorder or player open at a time, it is a good idea to open the device only for the activity needed. Further, some sound cards are half-duplex: they can be opened for reading or writing, but not both at once.

Note the unusual calling syntax: the first argument is optional, and the second is required. This is a historical artifact for compatibility with the older linuxaudiodev module which ossaudiodev supersedes.

ossaudiodev.openmixer([device])

Open a mixer device and return an OSS mixer device object. device is the mixer device filename to use. If it is not specified, this module first looks in the environment variable MIXERDEV for a
device to use. If not found, it falls back to /dev/mixer.
22.9.1. Audio Device Objects

Before you can write to or read from an audio device, you must call three methods in the correct order:

1. `setfmt()` to set the output format
2. `channels()` to set the number of channels
3. `speed()` to set the sample rate

Alternately, you can use the `setparameters()` method to set all three audio parameters at once. This is more convenient, but may not be as flexible in all cases.

The audio device objects returned by `open()` define the following methods and (read-only) attributes:

`oss_audio_device.close()`

Explicitly close the audio device. When you are done writing to or reading from an audio device, you should explicitly close it. A closed device cannot be used again.

`oss_audio_device.fileno()`

Return the file descriptor associated with the device.

`oss_audio_device.read(size)`

Read `size` bytes from the audio input and return them as a Python string. Unlike most Unix device drivers, OSS audio devices in blocking mode (the default) will block `read()` until the entire requested amount of data is available.

`oss_audio_device.write(data)`

Write a bytes-like object `data` to the audio device and return the
number of bytes written. If the audio device is in blocking mode (the default), the entire data is always written (again, this is different from usual Unix device semantics). If the device is in non-blocking mode, some data may not be written — see `writeall()`.

*Changed in version 3.5:*Writable bytes-like object is now accepted.

```python
text
oss_audio_device.writeall(data)
```

Write a bytes-like object `data` to the audio device: waits until the audio device is able to accept data, writes as much data as it will accept, and repeats until `data` has been completely written. If the device is in blocking mode (the default), this has the same effect as `write(); writeall()` is only useful in non-blocking mode. Has no return value, since the amount of data written is always equal to the amount of data supplied.

*Changed in version 3.5:*Writable bytes-like object is now accepted.

*Changed in version 3.2:* Audio device objects also support the context management protocol, i.e. they can be used in a `with` statement.

The following methods each map to exactly one ioctl() system call. The correspondence is obvious: for example, `setfmt()` corresponds to the `SNDCTL_DSP_SETFMT` ioctl, and `sync()` to `SNDCTL_DSP_SYNC` (this can be useful when consulting the OSS documentation). If the underlying ioctl() fails, they all raise `OSError`.

```python
text
oss_audio_device.nonblock()
```

Put the device into non-blocking mode. Once in non-blocking mode, there is no way to return it to blocking mode.

```python
text
oss_audio_device.getfmts()
```
Return a bitmask of the audio output formats supported by the soundcard. Some of the formats supported by OSS are:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFMT_MU_LAW</td>
<td>a logarithmic encoding (used by Sun .au files and /dev/audio)</td>
</tr>
<tr>
<td>AFMT_A_LAW</td>
<td>a logarithmic encoding</td>
</tr>
<tr>
<td>AFMT_HM</td>
<td>a 4:1 compressed format defined by the Interactive Multimedia Association</td>
</tr>
<tr>
<td>AFMT_U8</td>
<td>Unsigned, 8-bit audio</td>
</tr>
<tr>
<td>AFMT_S16_LE</td>
<td>Signed, 16-bit audio, little-endian byte order (as used by Intel processors)</td>

<tr>
<td>AFMT_S16_BE</td>
<td>Signed, 16-bit audio, big-endian byte order (as used by 68k, PowerPC, Sparc)</td>
</tr>
<tr>
<td>AFMT_S8</td>
<td>Signed, 8 bit audio</td>
</tr>
<tr>
<td>AFMT_U16_LE</td>
<td>Unsigned, 16-bit little-endian audio</td>
</tr>
<tr>
<td>AFMT_U16_BE</td>
<td>Unsigned, 16-bit big-endian audio</td>
</tr>
</tbody>
</table>

Consult the OSS documentation for a full list of audio formats, and note that most devices support only a subset of these formats. Some older devices only support AFMT_U8; the most common format used today is AFMT_S16_LE.

**oss_audio_device.setfmt(format)**

Try to set the current audio format to *format*—see **getfmts()** for a list. Returns the audio format that the device was set to, which may not be the requested format. May also be used to return the current audio format—do this by passing an “audio format” of AFMT_QUERY.
oss_audio_device.channels(nchannels)
Set the number of output channels to nchannels. A value of 1 indicates monophonic sound, 2 stereophonic. Some devices may have more than 2 channels, and some high-end devices may not support mono. Returns the number of channels the device was set to.

oss_audio_device.speed(samplerate)
Try to set the audio sampling rate to samplerate samples per second. Returns the rate actually set. Most sound devices don’t support arbitrary sampling rates. Common rates are:

<table>
<thead>
<tr>
<th>Rate</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8000</td>
<td>default rate for /dev/audio</td>
</tr>
<tr>
<td>11025</td>
<td>speech recording</td>
</tr>
<tr>
<td>22050</td>
<td></td>
</tr>
<tr>
<td>44100</td>
<td>CD quality audio (at 16 bits/sample and 2 channels)</td>
</tr>
<tr>
<td>96000</td>
<td>DVD quality audio (at 24 bits/sample)</td>
</tr>
</tbody>
</table>

oss_audio_device.sync()
Wait until the sound device has played every byte in its buffer. (This happens implicitly when the device is closed.) The OSS documentation recommends closing and re-opening the device rather than using sync().

oss_audio_device.reset()
Immediately stop playing or recording and return the device to a state where it can accept commands. The OSS documentation recommends closing and re-opening the device after calling.
reset().

oss_audio_device.post()

Tell the driver that there is likely to be a pause in the output, making it possible for the device to handle the pause more intelligently. You might use this after playing a spot sound effect, before waiting for user input, or before doing disk I/O.

The following convenience methods combine several ioctlS, or one ioctl and some simple calculations.

oss_audio_device.setparameters(format, nchannels, samplerate[, strict=False])

Set the key audio sampling parameters—sample format, number of channels, and sampling rate—in one method call. format, nchannels, and samplerate should be as specified in the setfmt(), channels(), and speed() methods. If strict is true, setparameters() checks to see if each parameter was actually set to the requested value, and raises OSSAudioError if not. Returns a tuple (format, nchannels, samplerate) indicating the parameter values that were actually set by the device driver (i.e., the same as the return values of setfmt(), channels(), and speed()).

For example,

```
(fmt, channels, rate) = dsp.setparameters(fmt, ch
```

is equivalent to

```
fmt = dsp.setfmt(fmt)
channels = dsp.channels(channels)
```
rate = dsp.rate(rate)

oss_audio_device.bufsize()
Returns the size of the hardware buffer, in samples.

oss_audio_device.obufcount()
Returns the number of samples that are in the hardware buffer yet to be played.

oss_audio_device.obuffree()
Returns the number of samples that could be queued into the hardware buffer to be played without blocking.

Audio device objects also support several read-only attributes:

oss_audio_device.closed
Boolean indicating whether the device has been closed.

oss_audio_device.name
String containing the name of the device file.

oss_audio_device.mode
The I/O mode for the file, either "r", "rw", or "w".
22.9.2. Mixer Device Objects

The mixer object provides two file-like methods:

oss_mixer_device.close()

This method closes the open mixer device file. Any further attempts to use the mixer after this file is closed will raise an OSError.

oss_mixer_device.fileno()

Returns the file handle number of the open mixer device file.

*Changed in version 3.2:* Mixer objects also support the context management protocol.

The remaining methods are specific to audio mixing:

oss_mixer_device.controls()

This method returns a bitmask specifying the available mixer controls ("Control" being a specific mixable "channel", such as SOUND_MIXER_PCM or SOUND_MIXER_SYNTH). This bitmask indicates a subset of all available mixer controls—the SOUND_MIXER_* constants defined at module level. To determine if, for example, the current mixer object supports a PCM mixer, use the following Python code:

```python
mixer=ossaudiodev.openmixer()
if mixer.controls() & (1 << ossaudiodev.SOUND_MIXER_PCM):
    # PCM is supported
    ... code ...
```

For most purposes, the SOUND_MIXER_VOLUME (master volume) and SOUND_MIXER_PCM controls should suffice—but code that
uses the mixer should be flexible when it comes to choosing mixer controls. On the Gravis Ultrasound, for example, `SOUND_MIXER_VOLUME` does not exist.

`oss_mixer_device.stereocontrols()`
Returns a bitmask indicating stereo mixer controls. If a bit is set, the corresponding control is stereo; if it is unset, the control is either monophonic or not supported by the mixer (use in combination with `controls()` to determine which).

See the code example for the `controls()` function for an example of getting data from a bitmask.

`oss_mixer_device.reccontrols()`
Returns a bitmask specifying the mixer controls that may be used to record. See the code example for `controls()` for an example of reading from a bitmask.

`oss_mixer_device.get(control)`
Returns the volume of a given mixer control. The returned volume is a 2-tuple `(left_volume, right_volume)`. Volumes are specified as numbers from 0 (silent) to 100 (full volume). If the control is monophonic, a 2-tuple is still returned, but both volumes are the same.

Raises `OSSAudioError` if an invalid control is specified, or `OSError` if an unsupported control is specified.

`oss_mixer_device.set(control, (left, right))`
Sets the volume for a given mixer control to `(left, right)`. `left` and `right` must be ints and between 0 (silent) and 100 (full volume). On success, the new volume is returned as a 2-tuple.
Note that this may not be exactly the same as the volume specified, because of the limited resolution of some soundcard's mixers.

 Raises **OSSAudioError** if an invalid mixer control was specified, or if the specified volumes were out-of-range.

 **oss_mixer_device.get_recsrc()**

 This method returns a bitmask indicating which control(s) are currently being used as a recording source.

 **oss_mixer_device.set_recsrc(bitmask)**

 Call this function to specify a recording source. Returns a bitmask indicating the new recording source (or sources) if successful; raises **OSError** if an invalid source was specified. To set the current recording source to the microphone input:

```python
mixer.setrecsrc (1 << ossaudiodev.SOUND_MIXER_MIC)
```

23. Internationalization

The modules described in this chapter help you write software that is independent of language and locale by providing mechanisms for selecting a language to be used in program messages or by tailoring output to match local conventions.

The list of modules described in this chapter is:

- 23.1. gettext — Multilingual internationalization services
  - 23.1.1. GNU gettext API
  - 23.1.2. Class-based API
    - 23.1.2.1. The NullTranslations class
    - 23.1.2.2. The GNUTranslations class
    - 23.1.2.3. Solaris message catalog support
    - 23.1.2.4. The Catalog constructor
  - 23.1.3. Internationalizing your programs and modules
    - 23.1.3.1. Localizing your module
    - 23.1.3.2. Localizing your application
    - 23.1.3.3. Changing languages on the fly
    - 23.1.3.4. Deferred translations
  - 23.1.4. Acknowledgements
- 23.2. locale — Internationalization services
  - 23.2.1. Background, details, hints, tips and caveats
  - 23.2.2. For extension writers and programs that embed Python
  - 23.2.3. Access to message catalogs
23.1. gettext — Multilingual internationalization services

Source code: Lib/gettext.py

The gettext module provides internationalization (I18N) and localization (L10N) services for your Python modules and applications. It supports both the GNU gettext message catalog API and a higher level, class-based API that may be more appropriate for Python files. The interface described below allows you to write your module and application messages in one natural language, and provide a catalog of translated messages for running under different natural languages.

Some hints on localizing your Python modules and applications are also given.
23.1.1. GNU gettext API

The `gettext` module defines the following API, which is very similar to the GNU `gettext` API. If you use this API you will affect the translation of your entire application globally. Often this is what you want if your application is monolingual, with the choice of language dependent on the locale of your user. If you are localizing a Python module, or if your application needs to switch languages on the fly, you probably want to use the class-based API instead.

`gettext.bindtextdomain(domain, localedir=None)`

Bind the `domain` to the locale directory `localedir`. More concretely, `gettext` will look for binary `.mo` files for the given domain using the path (on Unix):
```
localedir/language/LC_MESSAGES/domain.mo
```
where `languages` is searched for in the environment variables `LANGUAGE`, `LC_ALL`, `LC_MESSAGES`, and `LANG` respectively.

If `localedir` is omitted or `None`, then the current binding for `domain` is returned. [1]

`gettext.bind_textdomain_codeset(domain, codeset=None)`

Bind the `domain` to `codeset`, changing the encoding of byte strings returned by the `lgettext()`, `ldgettext()`, `lngettext()` and `ldngettext()` functions. If `codeset` is omitted, then the current binding is returned.

`gettext.textdomain(domain=None)`

Change or query the current global domain. If `domain` is `None`, then the current global domain is returned, otherwise the global
domain is set to *domain*, which is returned.

**gettext** *(message)*

Return the localized translation of *message*, based on the current global domain, language, and locale directory. This function is usually aliased as `_()` in the local namespace (see examples below).

**gettext** *(domain, message)*

Like *gettext()*, but look the message up in the specified *domain*.

**gettext** *(singular, plural, n)*

Like *gettext()*, but consider plural forms. If a translation is found, apply the plural formula to *n*, and return the resulting message (some languages have more than two plural forms). If no translation is found, return *singular* if *n* is 1; return *plural* otherwise.

The Plural formula is taken from the catalog header. It is a C or Python expression that has a free variable *n*; the expression evaluates to the index of the plural in the catalog. See the GNU gettext documentation for the precise syntax to be used in .po files and the formulas for a variety of languages.

**gettext** *(domain, singular, plural, n)*

Like *ngettext()*, but look the message up in the specified *domain*.

**gettext** *(message)*

**gettext** *(domain, message)*

**gettext** *(singular, plural, n)*
gettext.\texttt{ldgettext}(\textit{domain}, \textit{singular}, \textit{plural}, \textit{n})

Equivalent to the corresponding functions without the \texttt{l} prefix (\texttt{gettext()}, \texttt{dgettext()}, \texttt{ngettext()} and \texttt{dngettext()}), but the translation is returned as a byte string encoded in the preferred system encoding if no other encoding was explicitly set with \texttt{bind_textdomain_codeset()}.

\begin{Shaded}
\begin{Verbatim}
\textbf{Warning:} These functions should be avoided in Python 3, because they return encoded bytes. It's much better to use alternatives which return Unicode strings instead, since most Python applications will want to manipulate human readable text as strings instead of bytes. Further, it's possible that you may get unexpected Unicode-related exceptions if there are encoding problems with the translated strings. It is possible that the \texttt{l*()} functions will be deprecated in future Python versions due to their inherent problems and limitations.
\end{Verbatim}
\end{Shaded}

Note that GNU \texttt{gettext} also defines a \texttt{dcgettext()} method, but this was deemed not useful and so it is currently unimplemented.

Here's an example of typical usage for this API:

\begin{Verbatim}
import gettext
ggettext.bindtextdomain('myapplication', '/path/to/my
gettext.textdomain('myapplication')
_ = gettext.gettext
# ...
print(_('This is a translatable string.'))
\end{Verbatim}
23.1.2. Class-based API

The class-based API of the gettext module gives you more flexibility and greater convenience than the GNU gettext API. It is the recommended way of localizing your Python applications and modules. gettext defines a “translations” class which implements the parsing of GNU .mo format files, and has methods for returning strings. Instances of this “translations” class can also install themselves in the built-in namespace as the function _( ).

```
gettext.find(domain, localedir=None, languages=None, all=False)
```

This function implements the standard .mo file search algorithm. It takes a domain, identical to what textdomain() takes. Optional localedir is as in bindtextdomain() Optional languages is a list of strings, where each string is a language code.

If localedir is not given, then the default system locale directory is used. [2] If languages is not given, then the following environment variables are searched: LANGUAGE, LC_ALL, LC_MESSAGES, and LANG. The first one returning a non-empty value is used for the languages variable. The environment variables should contain a colon separated list of languages, which will be split on the colon to produce the expected list of language code strings.

find() then expands and normalizes the languages, and then iterates through them, searching for an existing file built of these components:

```
localedir/language/LC_MESSAGES/domain.mo
```
The first such file name that exists is returned by `find()`. If no such file is found, then `None` is returned. If `all` is given, it returns a list of all file names, in the order in which they appear in the languages list or the environment variables.

```
gettext.translation(domain, localedir=None,
languages=None, class_=None, fallback=False, codeset=None)
```

Return a Translations instance based on the `domain`, `localedir`, and `languages`, which are first passed to `find()` to get a list of the associated `.mo` file paths. Instances with identical `.mo` file names are cached. The actual class instantiated is either `class_` if provided, otherwise `GNUTranslations`. The class's constructor must take a single `file object` argument. If provided, `codeset` will change the charset used to encode translated strings in the `lgettext()` and `lngettext()` methods.

If multiple files are found, later files are used as fallbacks for earlier ones. To allow setting the fallback, `copy.copy()` is used to clone each translation object from the cache; the actual instance data is still shared with the cache.

If no `.mo` file is found, this function raises `OSError` if `fallback` is false (which is the default), and returns a `NullTranslations` instance if `fallback` is true.

*Changed in version 3.3:* `IOError` used to be raised instead of `OSError`.

```
gettext.install(domain, localedir=None, codeset=None, names=None)
```

This installs the function `_()` in Python's builtins namespace, based on `domain`, `localedir`, and `codeset` which are passed to the
function translation().

For the names parameter, please see the description of the translation object's install() method.

As seen below, you usually mark the strings in your application that are candidates for translation, by wrapping them in a call to the _() function, like this:

```python
print(_('This string will be translated.'))
```

For convenience, you want the _() function to be installed in Python's builtins namespace, so it is easily accessible in all modules of your application.

### 23.1.2.1. The NullTranslations class

Translation classes are what actually implement the translation of original source file message strings to translated message strings. The base class used by all translation classes is NullTranslations; this provides the basic interface you can use to write your own specialized translation classes. Here are the methods of NullTranslations:

```python
class gettext.NullTranslations(fp=None)
```

Takes an optional file object fp, which is ignored by the base class. Initializes “protected” instance variables _info and _charset which are set by derived classes, as well as _fallback, which is set through add_fallback(). It then calls self._parse(fp) if fp is not None.

```python
_parse(fp)
```
No-op’d in the base class, this method takes file object \( fp \), and reads the data from the file, initializing its message catalog. If you have an unsupported message catalog file format, you should override this method to parse your format.

**add_fallback**(*fallback*)

Add *fallback* as the fallback object for the current translation object. A translation object should consult the fallback if it cannot provide a translation for a given message.

**gettext**(*message*)

If a fallback has been set, forward **gettext()** to the fallback. Otherwise, return *message*. Overridden in derived classes.

**ngettext**(*singular, plural, n*)

If a fallback has been set, forward **ngettext()** to the fallback. Otherwise, return *singular* if \( n \) is 1; return *plural* otherwise. Overridden in derived classes.

**lgettext**(*message*)

**lngettext**(*singular, plural, n*)

Equivalent to **gettext()** and **ngettext()**, but the translation is returned as a byte string encoded in the preferred system encoding if no encoding was explicitly set with **set_output_charset()**. Overridden in derived classes.

**Warning:** These methods should be avoided in Python 3. See the warning for the **lgettext()** function.

**info()**

Return the “protected” \_info variable.
charset()
    Return the encoding of the message catalog file.

output_charset()
    Return the encoding used to return translated messages in lgettext() and lngettext().

set_output_charset(charset)
    Change the encoding used to return translated messages.

install(names=None)
    This method installs gettext() into the built-in namespace, binding it to _.

    If the names parameter is given, it must be a sequence containing the names of functions you want to install in the builtins namespace in addition to _.(). Supported names are 'gettext', 'ngettext', 'lgettext' and 'lngettext'.

    Note that this is only one way, albeit the most convenient way, to make the _() function available to your application. Because it affects the entire application globally, and specifically the built-in namespace, localized modules should never install _(). Instead, they should use this code to make _() available to their module:

    ```python
    import gettext
t = gettext.translation('mymodule', ...)
_ = t.gettext
    ```

    This puts _() only in the module's global namespace and so only affects calls within this module.
23.1.2.2. The **GNUTranslations** class

The `gettext` module provides one additional class derived from `NullTranslations`: `GNUTranslations`. This class overrides `_parse()` to enable reading GNU `gettext` format `.mo` files in both big-endian and little-endian format.

`GNUTranslations` parses optional meta-data out of the translation catalog. It is convention with GNU `gettext` to include meta-data as the translation for the empty string. This meta-data is in RFC 822-style key: value pairs, and should contain the Project-Id-Version key. If the key Content-Type is found, then the charset property is used to initialize the “protected” `_charset` instance variable, defaulting to `None` if not found. If the charset encoding is specified, then all message ids and message strings read from the catalog are converted to Unicode using this encoding, else ASCII encoding is assumed.

Since message ids are read as Unicode strings too, all `*gettext()` methods will assume message ids as Unicode strings, not byte strings.

The entire set of key/value pairs are placed into a dictionary and set as the “protected” `_info` instance variable.

If the `.mo` file’s magic number is invalid, the major version number is unexpected, or if other problems occur while reading the file, instantiating a `GNUTranslations` class can raise `OSError`.

**class gettext.GNUTranslations**

The following methods are overridden from the base class implementation:
**gettext**(message)

Look up the *message* id in the catalog and return the corresponding message string, as a Unicode string. If there is no entry in the catalog for the *message* id, and a fallback has been set, the look up is forwarded to the fallback's **gettext()** method. Otherwise, the *message* id is returned.

**ngettext**(singular, plural, n)

Do a plural-forms lookup of a message id. *singular* is used as the message id for purposes of lookup in the catalog, while *n* is used to determine which plural form to use. The returned message string is a Unicode string.

If the message id is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback's **ngettext()** method. Otherwise, when *n* is 1 *singular* is returned, and *plural* is returned in all other cases.

Here is an example:

```python
n = len(os.listdir('.'))
cat = GNUTranslations(somefile)
message = cat.ngettext(
    'There is %(num)d file in this directory',
    'There are %(num)d files in this directory',
    n) % {'num': n}
```

**lgettext**(message)

**lngettext**(singular, plural, n)

Equivalent to **gettext()** and **ngettext()**, but the translation is returned as a byte string encoded in the preferred system encoding if no encoding was explicitly set with
set_output_charset().

Warning: These methods should be avoided in Python 3. See the warning for the lgettext() function.

23.1.2.3. Solaris message catalog support

The Solaris operating system defines its own binary .mo file format, but since no documentation can be found on this format, it is not supported at this time.

23.1.2.4. The Catalog constructor

GNOME uses a version of the gettext module by James Henstridge, but this version has a slightly different API. Its documented usage was:

```python
import gettext
cat = gettext.Catalog(domain, localizedir)
_ = cat.gettext
print(_('hello world'))
```

For compatibility with this older module, the function Catalog() is an alias for the translation() function described above.

One difference between this module and Henstridge’s: his catalog objects supported access through a mapping API, but this appears to be unused and so is not currently supported.
23.1.3. Internationalizing your programs and modules

Internationalization (I18N) refers to the operation by which a program is made aware of multiple languages. Localization (L10N) refers to the adaptation of your program, once internationalized, to the local language and cultural habits. In order to provide multilingual messages for your Python programs, you need to take the following steps:

1. prepare your program or module by specially marking translatable strings
2. run a suite of tools over your marked files to generate raw messages catalogs
3. create language specific translations of the message catalogs
4. use the `gettext` module so that message strings are properly translated

In order to prepare your code for I18N, you need to look at all the strings in your files. Any string that needs to be translated should be marked by wrapping it in `_(...)` — that is, a call to the function `_()`. For example:

```python
filename = 'mylog.txt'
message = _( 'writing a log message' )
fp = open( filename, 'w' )
fp.write(message)
fp.close()
```

In this example, the string `'writing a log message'` is marked as a candidate for translation, while the strings `'mylog.txt'` and `'w'` are not.
There are a few tools to extract the strings meant for translation. The original GNU gettext only supported C or C++ source code but its extended version xgettext scans code written in a number of languages, including Python, to find strings marked as translatable. Babel is a Python internationalization library that includes a pybabel script to extract and compile message catalogs. François Pinard's program called xpot does a similar job and is available as part of his po-utils package.

(Python also includes pure-Python versions of these programs, called pygettext.py and msgfmt.py; some Python distributions will install them for you. pygettext.py is similar to xgettext, but only understands Python source code and cannot handle other programming languages such as C or C++. pygettext.py supports a command-line interface similar to xgettext; for details on its use, run pygettext.py --help. msgfmt.py is binary compatible with GNU msgfmt. With these two programs, you may not need the GNU gettext package to internationalize your Python applications.)

xgettext, pygettext, and similar tools generate .po files that are message catalogs. They are structured human-readable files that contain every marked string in the source code, along with a placeholder for the translated versions of these strings.

Copies of these .po files are then handed over to the individual human translators who write translations for every supported natural language. They send back the completed language-specific versions as a <language-name>.po file that's compiled into a machine-readable .mo binary catalog file using the msgfmt program. The .mo files are used by the gettext module for the actual translation processing at run-time.
How you use the `gettext` module in your code depends on whether you are internationalizing a single module or your entire application. The next two sections will discuss each case.

23.1.3.1. Localizing your module

If you are localizing your module, you must take care not to make global changes, e.g. to the built-in namespace. You should not use the GNU `gettext` API but instead the class-based API.

Let's say your module is called “spam” and the module's various natural language translation `.mo` files reside in `/usr/share/locale` in GNU `gettext` format. Here's what you would put at the top of your module:

```python
import gettext
t = gettext.translation('spam', '/usr/share/locale')
_ = t.gettext
```

23.1.3.2. Localizing your application

If you are localizing your application, you can install the `__()` function globally into the built-in namespace, usually in the main driver file of your application. This will let all your application-specific files just use `__('...')` without having to explicitly install it in each file.

In the simple case then, you need only add the following bit of code to the main driver file of your application:

```python
import gettext
gettext.install('myapplication')
```
If you need to set the locale directory, you can pass it into the `install()` function:

```python
import gettext
ggettext.install('myapplication', '/usr/share/locale')
```

### 23.1.3.3. Changing languages on the fly

If your program needs to support many languages at the same time, you may want to create multiple translation instances and then switch between them explicitly, like so:

```python
import gettext

lang1 = gettext.translation('myapplication', languages=['en']
lang2 = gettext.translation('myapplication', languages=['es']
lang3 = gettext.translation('myapplication', languages=['fr']

# start by using language1
lang1.install()

# ... time goes by, user selects language 2
lang2.install()

# ... more time goes by, user selects language 3
lang3.install()
```

### 23.1.3.4. Deferred translations

In most coding situations, strings are translated where they are coded. Occasionally however, you need to mark strings for translation, but defer actual translation until later. A classic example is:
Here, you want to mark the strings in the `animals` list as being translatable, but you don’t actually want to translate them until they are printed.

Here is one way you can handle this situation:

```python
animals = ['mollusk', 'albatross', 'rat', 'penguin', 'python', ]

# ...
for a in animals:
    print(a)
```

This works because the dummy definition of `() simply returns the string unchanged. And this dummy definition will temporarily override any definition of `() in the built-in namespace (until the del command). Take care, though if you have a previous definition of `() in the local namespace.
Note that the second use of `_()` will not identify “a” as being translatable to the `gettext` program, because the parameter is not a string literal.

Another way to handle this is with the following example:

```python
def N_(message): return message

animals = [N_('mollusk'),
           N_('albatross'),
           N_('rat'),
           N_('penguin'),
           N_('python'), ]

# ...
for a in animals:
    print(_(a))
```

In this case, you are marking translatable strings with the function `N_()`, which won’t conflict with any definition of `_()`. However, you will need to teach your message extraction program to look for translatable strings marked with `N_()`. `xgettext`, `pygettext`, `pybabel extract`, and `xpot` all support this through the use of the `-k` command-line switch. The choice of `N_()` here is totally arbitrary; it could have just as easily been `MarkThisStringForTranslation()`.
23.1.4. Acknowledgements

The following people contributed code, feedback, design suggestions, previous implementations, and valuable experience to the creation of this module:

- Peter Funk
- James Henstridge
- Juan David Ibáñez Palomar
- Marc-André Lemburg
- Martin von Löwis
- François Pinard
- Barry Warsaw
- Gustavo Niemeyer

Footnotes

The default locale directory is system dependent; for example, on RedHat Linux it is `/usr/share/locale`, but on Solaris it is `/usr/lib/locale`. The `gettext` module does not try to support these system dependent defaults; instead its default is `sys.prefix/share/locale`. For this reason, it is always best to call `bindtextdomain()` with an explicit absolute path at the start of your application.

[1] See the footnote for `bindtextdomain()` above.
23.2. **locale** —
Internationalization services

**Source code:** [Lib/locale.py](#)

The `locale` module opens access to the POSIX locale database and functionality. The POSIX locale mechanism allows programmers to deal with certain cultural issues in an application, without requiring the programmer to know all the specifics of each country where the software is executed.

The `locale` module is implemented on top of the `_locale` module, which in turn uses an ANSI C locale implementation if available.

The `locale` module defines the following exception and functions:

**exception** `locale.Error`

Exception raised when the locale passed to `setlocale()` is not recognized.

**locale.setlocale(category, locale=None)**

If `locale` is given and not `None`, `setlocale()` modifies the locale setting for the `category`. The available categories are listed in the data description below. `locale` may be a string, or an iterable of two strings (language code and encoding). If it's an iterable, it's converted to a locale name using the locale aliasing engine. An empty string specifies the user's default settings. If the modification of the locale fails, the exception `Error` is raised. If successful, the new locale setting is returned.
If `locale` is omitted or `None`, the current setting for `category` is returned.

`setlocale()` is not thread-safe on most systems. Applications typically start with a call of

```python
import locale
locale.setlocale(locale.LC_ALL, '')
```

This sets the locale for all categories to the user’s default setting (typically specified in the LANG environment variable). If the locale is not changed thereafter, using multithreading should not cause problems.

`locale.localeconv()`

Returns the database of the local conventions as a dictionary. This dictionary has the following strings as keys:

<table>
<thead>
<tr>
<th>Category</th>
<th>Key</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>LC_NUMERIC</td>
<td>'decimal_point'</td>
<td>Decimal point character.</td>
</tr>
<tr>
<td></td>
<td>'grouping'</td>
<td>Sequence of numbers specifying which relative positions the 'thousands_sep' is expected. This sequence is terminated with CHAR_MAX further grouping is performed. If the sequence terminates with a</td>
</tr>
<tr>
<td><strong>LC_MONETARY</strong></td>
<td>'int_curr_symbol'</td>
<td>International currency symbol.</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td></td>
<td>'currency_symbol'</td>
<td>Local currency symbol.</td>
</tr>
<tr>
<td></td>
<td>'p_cs_precedes/n_cs_precedes'</td>
<td>Whether the currency symbol precedes the value (for positive resp. negative values).</td>
</tr>
<tr>
<td></td>
<td>'p_sep_by_space/n_sep_by_space'</td>
<td>Whether the currency symbol is separated from the value (for positive resp. negative values).</td>
</tr>
<tr>
<td></td>
<td>'mon_decimal_point'</td>
<td>Decimal point used for monetary values.</td>
</tr>
<tr>
<td></td>
<td>'frac_digits'</td>
<td>Number of fractional digits used in local formatting of monetary values.</td>
</tr>
<tr>
<td></td>
<td>'int_frac_digits'</td>
<td>Number of fractional digits used in international formatting of monetary values.</td>
</tr>
<tr>
<td></td>
<td>'mon_thousands_sep'</td>
<td>Group separator used for monetary value.</td>
</tr>
</tbody>
</table>
'mon_grouping'
Equivalent to 'grouping' for monetary values.

'positive_sign'
Symbol used to annotate a positive monetary value.

'negative_sign'
Symbol used to annotate a negative monetary value.

'p_sign_posn/n_sign_posn'
The position of the sign (for positive resp. negative values), see below.

All numeric values can be set to `CHAR_MAX` to indicate that there is no value specified in this locale.

The possible values for 'p_sign_posn' and 'n_sign_posn' are given below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Currency and value are surrounded by parentheses.</td>
</tr>
<tr>
<td>1</td>
<td>The sign should precede the value and currency symbol.</td>
</tr>
<tr>
<td>2</td>
<td>The sign should follow the value and currency symbol.</td>
</tr>
<tr>
<td>3</td>
<td>The sign should immediately precede the value.</td>
</tr>
<tr>
<td>4</td>
<td>The sign should immediately follow the value.</td>
</tr>
<tr>
<td>CHAR_MAX</td>
<td>Nothing is specified in this locale.</td>
</tr>
</tbody>
</table>
Return some locale-specific information as a string. This function is not available on all systems, and the set of possible options might also vary across platforms. The possible argument values are numbers, for which symbolic constants are available in the locale module.

The `nl_langinfo()` function accepts one of the following keys. Most descriptions are taken from the corresponding description in the GNU C library.

**locale.CODESET**

Get a string with the name of the character encoding used in the selected locale.

**locale.D_T_FMT**

Get a string that can be used as a format string for `time.strftime()` to represent date and time in a locale-specific way.

**locale.D_FMT**

Get a string that can be used as a format string for `time.strftime()` to represent a date in a locale-specific way.

**locale.T_FMT**

Get a string that can be used as a format string for `time.strftime()` to represent a time in a locale-specific way.

**locale.T_FMT_AMPM**

Get a format string for `time.strftime()` to represent time in the am/pm format.
**DAY_1 . . . DAY_7**

Get the name of the n-th day of the week.

*Note:* This follows the US convention of DAY_1 being Sunday, not the international convention (ISO 8601) that Monday is the first day of the week.

**ABDAY_1 . . . ABDAY_7**

Get the abbreviated name of the n-th day of the week.

**MON_1 . . . MON_12**

Get the name of the n-th month.

**ABMON_1 . . . ABMON_12**

Get the abbreviated name of the n-th month.

locale. **RADIIXCHAR**

Get the radix character (decimal dot, decimal comma, etc.).

locale. **THOUSEP**

Get the separator character for thousands (groups of three digits).

locale. **YESEXPR**

Get a regular expression that can be used with the regex function to recognize a positive response to a yes/no question.

*Note:* The expression is in the syntax suitable for the regex() function from the C library, which might differ from the syntax used in re.

locale. **NOEXPR**

Get a regular expression that can be used with the regex(3)
function to recognize a negative response to a yes/no question.

**locale.** **CRNCYSTR**

Get the currency symbol, preceded by “-” if the symbol should appear before the value, “+” if the symbol should appear after the value, or “.” if the symbol should replace the radix character.

**locale.** **ERA**

Get a string that represents the era used in the current locale.

Most locales do not define this value. An example of a locale which does define this value is the Japanese one. In Japan, the traditional representation of dates includes the name of the era corresponding to the then-emperor’s reign.

Normally it should not be necessary to use this value directly. Specifying the E modifier in their format strings causes the `time.strftime()` function to use this information. The format of the returned string is not specified, and therefore you should not assume knowledge of it on different systems.

**locale.** **ERA_D_T_FMT**

Get a format string for `time.strftime()` to represent date and time in a locale-specific era-based way.

**locale.** **ERA_D_FMT**

Get a format string for `time.strftime()` to represent a date in a locale-specific era-based way.

**locale.** **ERA_T_FMT**

Get a format string for `time.strftime()` to represent a time in a locale-specific era-based way.
locale.**ALT_DIGITS**

Get a representation of up to 100 values used to represent the values 0 to 99.

locale.**getdefaultlocale**([envvars])

Tries to determine the default locale settings and returns them as a tuple of the form (language code, encoding).

According to POSIX, a program which has not called `setlocale(LC_ALL, '')` runs using the portable 'C' locale. Calling `setlocale(LC_ALL, '')` lets it use the default locale as defined by the LANG variable. Since we do not want to interfere with the current locale setting we thus emulate the behavior in the way described above.

To maintain compatibility with other platforms, not only the LANG variable is tested, but a list of variables given as envvars parameter. The first found to be defined will be used. envvars defaults to the search path used in GNU gettext; it must always contain the variable name 'LANG'. The GNU gettext search path contains 'LC_ALL', 'LC_CTYPE', 'LANG' and 'LANGUAGE', in that order.

Except for the code 'C', the language code corresponds to RFC 1766. **language code** and **encoding** may be None if their values cannot be determined.

locale.**getlocale**(category=LC_CTYPE)

Returns the current setting for the given locale category as sequence containing **language code**, **encoding**. category may be one of the LC_* values except LC_ALL. It defaults to LC_CTYPE.
Except for the code 'C', the language code corresponds to RFC 1766. Language code and encoding may be None if their values cannot be determined.

locale.getpreferredencoding(do_setlocale=True)
Return the encoding used for text data, according to user preferences. User preferences are expressed differently on different systems, and might not be available programmatically on some systems, so this function only returns a guess.

On some systems, it is necessary to invoke setlocale() to obtain the user preferences, so this function is not thread-safe. If invoking setlocale is not necessary or desired, do_setlocale should be set to False.

locale.normalize(localename)
Returns a normalized locale code for the given locale name. The returned locale code is formatted for use with setlocale(). If normalization fails, the original name is returned unchanged.

If the given encoding is not known, the function defaults to the default encoding for the locale code just like setlocale().

locale.resetlocale(category=LC_ALL)
Sets the locale for category to the default setting.

The default setting is determined by calling getdefaultlocale(). category defaults to LC_ALL.

locale.strcoll(string1, string2)
Compares two strings according to the current LC_COLLATE setting. As any other compare function, returns a negative, or a
positive value, or 0, depending on whether string1 collates before or after string2 or is equal to it.

locale.strxfrm(string)
Transforms a string to one that can be used in locale-aware comparisons. For example, strxfrm(s1) < strxfrm(s2) is equivalent to strcoll(s1, s2) < 0. This function can be used when the same string is compared repeatedly, e.g. when collating a sequence of strings.

locale.format(format, val, grouping=False, monetary=False)
Formats a number val according to the current LC_NUMERIC setting. The format follows the conventions of the % operator. For floating point values, the decimal point is modified if appropriate. If grouping is true, also takes the grouping into account.

If monetary is true, the conversion uses monetary thousands separator and grouping strings.

Please note that this function will only work for exactly one %char specifier. For whole format strings, use format_string().

locale.format_string(format, val, grouping=False)
Processes formatting specifiers as in format % val, but takes the current locale settings into account.

locale.currency(val, symbol=True, grouping=False, international=False)
Formats a number val according to the current LC_MONETARY settings.

The returned string includes the currency symbol if symbol is true, which is the default. If grouping is true (which is not the default),
grouping is done with the value. If international is true (which is not the default), the international currency symbol is used.

Note that this function will not work with the ‘C’ locale, so you have to set a locale via setlocale() first.

locale.\texttt{str}(float)

Formats a floating point number using the same format as the built-in function \texttt{str(float)}, but takes the decimal point into account.

locale.\texttt{delocalize}(string)

Converts a string into a normalized number string, following the LC_NUMERIC settings.

\textit{New in version 3.5.}

locale.\texttt{atof}(string)

Converts a string to a floating point number, following the LC_NUMERIC settings.

locale.\texttt{atoi}(string)

Converts a string to an integer, following the LC_NUMERIC conventions.

locale.\texttt{LC\_CTYPE}

Locale category for the character type functions. Depending on the settings of this category, the functions of module \texttt{string} dealing with case change their behaviour.

locale.\texttt{LC\_COLLATE}

Locale category for sorting strings. The functions \texttt{strcoll()} and \texttt{strxfrm()} of the \texttt{locale} module are affected.
locale.**LC_TIME**
Locale category for the formatting of time. The function `time.strftime()` follows these conventions.

locale.**LC_MONETARY**
Locale category for formatting of monetary values. The available options are available from the `localeconv()` function.

locale.**LC_MESSAGES**
Locale category for message display. Python currently does not support application specific locale-aware messages. Messages displayed by the operating system, like those returned by `os.strerror()` might be affected by this category.

locale.**LC_NUMERIC**
Locale category for formatting numbers. The functions `format()`, `atoi()`, `atof()` and `str()` of the `locale` module are affected by that category. All other numeric formatting operations are not affected.

locale.**LC_ALL**
Combination of all locale settings. If this flag is used when the locale is changed, setting the locale for all categories is attempted. If that fails for any category, no category is changed at all. When the locale is retrieved using this flag, a string indicating the setting for all categories is returned. This string can be later used to restore the settings.

locale.**CHAR_MAX**
This is a symbolic constant used for different values returned by `localeconv()`.

Example:
```python
>>> import locale

# get current locale
>>> loc = locale.getlocale()

# use German locale; name might vary with platform
>>> locale.setlocale(locale.LC_ALL, 'de_DE')

# compare a string containing an umlaut
>>> locale.strcoll('f\xe4n', 'foo')

# use user's preferred locale
>>> locale.setlocale(locale.LC_ALL, '')

# use default (C) locale
>>> locale.setlocale(locale.LC_ALL, 'C')

# restore saved locale
>>> locale.setlocale(locale.LC_ALL, loc)
```
23.2.1. Background, details, hints, tips and caveats

The C standard defines the locale as a program-wide property that may be relatively expensive to change. On top of that, some implementation are broken in such a way that frequent locale changes may cause core dumps. This makes the locale somewhat painful to use correctly.

Initially, when a program is started, the locale is the C locale, no matter what the user’s preferred locale is. There is one exception: the LC_CTYPE category is changed at startup to set the current locale encoding to the user’s preferred locale encoding. The program must explicitly say that it wants the user’s preferred locale settings for other categories by calling `setlocale(LC_ALL, '')`.

It is generally a bad idea to call `setlocale()` in some library routine, since as a side effect it affects the entire program. Saving and restoring it is almost as bad: it is expensive and affects other threads that happen to run before the settings have been restored.

If, when coding a module for general use, you need a locale independent version of an operation that is affected by the locale (such as certain formats used with `time.strftime()`), you will have to find a way to do it without using the standard library routine. Even better is convincing yourself that using locale settings is okay. Only as a last resort should you document that your module is not compatible with non-C locale settings.

The only way to perform numeric operations according to the locale is to use the special functions defined by this module: `atof()`, `atoi()`,
There is no way to perform case conversions and character classifications according to the locale. For (Unicode) text strings these are done according to the character value only, while for byte strings, the conversions and classifications are done according to the ASCII value of the byte, and bytes whose high bit is set (i.e., non-ASCII bytes) are never converted or considered part of a character class such as letter or whitespace.
23.2.2. For extension writers and programs that embed Python

Extension modules should never call `setlocale()`, except to find out what the current locale is. But since the return value can only be used portably to restore it, that is not very useful (except perhaps to find out whether or not the locale is C).

When Python code uses the `locale` module to change the locale, this also affects the embedding application. If the embedding application doesn't want this to happen, it should remove the `_locale` extension module (which does all the work) from the table of built-in modules in the `config.c` file, and make sure that the `_locale` module is not accessible as a shared library.
23.2.3. Access to message catalogs

The locale module exposes the C library's gettext interface on systems that provide this interface. It consists of the functions `gettext()`, `dgettext()`, `dcgettext()`, `textdomain()`, `bindtextdomain()`, and `bind_textdomain_codeset()`. These are similar to the same functions in the `gettext` module, but use the C library's binary format for message catalogs, and the C library's search algorithms for locating message catalogs.

Python applications should normally find no need to invoke these functions, and should use `gettext` instead. A known exception to this rule are applications that link with additional C libraries which internally invoke `gettext()` or `dcgettext()`. For these applications, it may be necessary to bind the text domain, so that the libraries can properly locate their message catalogs.
24. Program Frameworks

The modules described in this chapter are frameworks that will largely dictate the structure of your program. Currently the modules described here are all oriented toward writing command-line interfaces.

The full list of modules described in this chapter is:

  - 24.3.3. Improved Compatibility with Shells
24.1. **turtle** — Turtle graphics

**Source code:** [Lib/turtle.py](#)
24.1.1. Introduction

Turtle graphics is a popular way for introducing programming to kids. It was part of the original Logo programming language developed by Wally Feurzig and Seymour Papert in 1966.

Imagine a robotic turtle starting at (0, 0) in the x-y plane. After an `import turtle`, give it the command `turtle.forward(15)`, and it moves (on-screen!) 15 pixels in the direction it is facing, drawing a line as it moves. Give it the command `turtle.right(25)`, and it rotates in-place 25 degrees clockwise.

By combining together these and similar commands, intricate shapes and pictures can easily be drawn.

The `turtle` module is an extended reimplementation of the same-named module from the Python standard distribution up to version Python 2.5.

It tries to keep the merits of the old turtle module and to be (nearly) 100% compatible with it. This means in the first place to enable the learning programmer to use all the commands, classes and methods interactively when using the module from within IDLE run with the `-n` switch.

The turtle module provides turtle graphics primitives, in both object-
oriented and procedure-oriented ways. Because it uses tkinter for the underlying graphics, it needs a version of Python installed with Tk support.

The object-oriented interface uses essentially two+two classes:

1. The TurtleScreen class defines graphics windows as a playground for the drawing turtles. Its constructor needs a tkinter.Canvas or a ScrolledCanvas as argument. It should be used when turtle is used as part of some application.

   The function Screen() returns a singleton object of a TurtleScreen subclass. This function should be used when turtle is used as a standalone tool for doing graphics. As a singleton object, inheriting from its class is not possible.

   All methods of TurtleScreen/Screen also exist as functions, i.e. as part of the procedure-oriented interface.

2. RawTurtle (alias: RawPen) defines Turtle objects which draw on a TurtleScreen. Its constructor needs a Canvas, ScrolledCanvas or TurtleScreen as argument, so the RawTurtle objects know where to draw.

   Derived from RawTurtle is the subclass Turtle (alias: Pen), which draws on “the” Screen instance which is automatically created, if not already present.

   All methods of RawTurtle/Turtle also exist as functions, i.e. part of
the procedure-oriented interface.

The procedural interface provides functions which are derived from the methods of the classes `Screen` and `Turtle`. They have the same names as the corresponding methods. A screen object is automatically created whenever a function derived from a Screen method is called. An (unnamed) turtle object is automatically created whenever any of the functions derived from a Turtle method is called.

To use multiple turtles on a screen one has to use the object-oriented interface.

**Note:** In the following documentation the argument list for functions is given. Methods, of course, have the additional first argument `self` which is omitted here.
24.1.2. Overview of available Turtle and Screen methods

24.1.2.1. Turtle methods

Turtle motion
   Move and draw

   forward() | fd()
   backward() | bk() | back()
   right() | rt()
   left() | lt()
   goto() | setpos() | setposition()
   setx()
   sety()
   setheading() | seth()
   home()
   circle()
   dot()
   stamp()
   clearstamp()
   clearstamps()
   undo()
   speed()

Tell Turtle's state

   position() | pos()
   towards()
   xcor()
   ycor()
   heading()
   distance()
Setting and measurement

\texttt{degrees()}
\texttt{radians()}

Pen control

Drawing state

\texttt{pendown()} | \texttt{pd()} | \texttt{down()}
\texttt{penup()} | \texttt{pu()} | \texttt{up()}
\texttt{pensize()} | \texttt{width()}
\texttt{pen()}
\texttt{isdown()}

Color control

\texttt{color()}
\texttt{pencolor()}
\texttt{fillcolor()}

Filling

\texttt{filling()}
\texttt{begin_fill()}
\texttt{end_fill()}

More drawing control

\texttt{reset()}
\texttt{clear()}
\texttt{write()}

Turtle state

Visibility

\texttt{showturtle()} | \texttt{st()}
hideturtle() | ht()
isvisible()

Appearance

shape()
resizemode()
shapesize() | turtlesize()
shearfactor()
settiltangle()
tiltangle()
tilt()
shapetransform()
get_shapespoly()

Using events

onclick()
onrelease()
odrag()

Special Turtle methods

begin_poly()
end_poly()
get_poly()
clone()
getturtle() | getpen()
getscreen()
setundobuffer()
undobufferentries()

24.1.2.2. Methods of TurtleScreen/Screen

Window control
bgcolor()
bgpic()
clear() | clearsreen()
reset() | resetscreen()
screensize()
setworldcoordinates()

Animation control

delay()
tracer()
update()

Using screen events

listen()
onkey() | onkeyrelease()
onkeypress()
onclick() | onscreencluck()
ontimer()
mainloop() | done()

Settings and special methods

mode()
colormode()
getcanvas()
getshapes()
register_shape() | addshape()
turtles()
window_height()
window_width()

Input methods

textinput()
numinput()

Methods specific to Screen

bye()
exitonclick()
setup()
title()
24.1.3. Methods of RawTurtle/Turtle and corresponding functions

Most of the examples in this section refer to a Turtle instance called turtle.

24.1.3.1. Turtle motion

turtle.**forward**(distance)
turtle.**fd**(distance)

**Parameters:**
- **distance** – a number (integer or float)

Move the turtle forward by the specified distance, in the direction the turtle is headed.

```python
>>> turtle.position()
(0.00,0.00)
>>> turtle.forward(25)
>>> turtle.position()
(25.00,0.00)
>>> turtle.forward(-75)
>>> turtle.position()
(-50.00,0.00)
```

turtle.**back**(distance)
turtle.**bk**(distance)
turtle.**backward**(distance)

**Parameters:**
- **distance** – a number

Move the turtle backward by distance, opposite to the direction the turtle is headed. Do not change the turtle's heading.
turtle.\texttt{\textbf{right}}(angle)
turtle.\texttt{rt}(angle)

\begin{quote}
\textbf{Parameters:} \hspace{1cm} angle – a number (integer or float)
\end{quote}

Turn turtle right by \textit{angle} units. (Units are by default degrees, but can be set via the \texttt{degrees()} and \texttt{radians()} functions.) Angle orientation depends on the turtle mode, see \texttt{mode()}.

\begin{verbatim}
>>> turtle.position()
(0.00,0.00)
>>> turtle.backward(30)
>>> turtle.position()
(-30.00,0.00)
\end{verbatim}

turtle.\texttt{\textbf{left}}(angle)
turtle.\texttt{lt}(angle)

\begin{quote}
\textbf{Parameters:} \hspace{1cm} angle – a number (integer or float)
\end{quote}

Turn turtle left by \textit{angle} units. (Units are by default degrees, but can be set via the \texttt{degrees()} and \texttt{radians()} functions.) Angle orientation depends on the turtle mode, see \texttt{mode()}.

\begin{verbatim}
>>> turtle.position()
(0.00,0.00)
>>> turtle.backward(30)
>>> turtle.position()
(-30.00,0.00)
\end{verbatim}

\begin{verbatim}
>>> turtle.left(45)
>>> turtle.position()
(-30.00,30.00)
>>> turtle.right(45)
>>> turtle.position()
(-30.00,0.00)
\end{verbatim}
turtle.\texttt{goto}(x, y=None)
turtle.\texttt{setpos}(x, y=None)
turtle.\texttt{setposition}(x, y=None)

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>• x – a number or a pair/vector of numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• y – a number or None</td>
</tr>
</tbody>
</table>

If y is None, x must be a pair of coordinates or a Vec2D (e.g. as returned by \texttt{pos()}).

Move turtle to an absolute position. If the pen is down, draw line. Do not change the turtle's orientation.

```python
>>> tp = turtle.pos()
>>> tp
turtle.setpos(60, 30)
>>> turtle.pos()
(60.00, 30.00)
>>> turtle.setpos((20, 80))
>>> turtle.pos()
(20.00, 80.00)
>>> turtle.setpos(tp)
>>> turtle.pos()
(0.00, 0.00)
```

turtle.\texttt{setx}(x)

| Parameters: | x – a number (integer or float) |

Set the turtle's first coordinate to \( x \), leave second coordinate unchanged.

```python
>>> turtle.position()
(0.00, 240.00)
>>> turtle.setx(10)
```
turtle.sety(\textit{y})

**Parameters:** \textit{y} – a number (integer or float)

Set the turtle’s second coordinate to \textit{y}, leave first coordinate unchanged.

```python
>>> turtle.position()
(10.00, 240.00)
>>> turtle.sety(-10)
>>> turtle.position()
(0.00, -10.00)
```

turtle.setheading(\textit{to\_angle})
turtle.seth(\textit{to\_angle})

**Parameters:** \textit{to\_angle} – a number (integer or float)

Set the orientation of the turtle to \textit{to\_angle}. Here are some common directions in degrees:

<table>
<thead>
<tr>
<th>standard mode</th>
<th>logo mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - east</td>
<td>0 - north</td>
</tr>
<tr>
<td>90 - north</td>
<td>90 - east</td>
</tr>
<tr>
<td>180 - west</td>
<td>180 - south</td>
</tr>
<tr>
<td>270 - south</td>
<td>270 - west</td>
</tr>
</tbody>
</table>

```python
>>> turtle.setheading(90)
>>> turtle.heading()
90.0
```
turtle.**home()**

Move turtle to the origin – coordinates (0,0) – and set its heading to its start-orientation (which depends on the mode, see `mode()`).

```python
>>> turtle.heading()
90.0
>>> turtle.position()
(0.00,-10.00)
>>> turtle.home()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
```

turtle.**circle**(radius, extent=None, steps=None)

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>radius</td>
<td>a number</td>
</tr>
<tr>
<td>extent</td>
<td>a number (or None)</td>
</tr>
<tr>
<td>steps</td>
<td>an integer (or None)</td>
</tr>
</tbody>
</table>

Draw a circle with given `radius`. The center is `radius` units left of the turtle; `extent` – an angle – determines which part of the circle is drawn. If `extent` is not given, draw the entire circle. If `extent` is not a full circle, one endpoint of the arc is the current pen position. Draw the arc in counterclockwise direction if `radius` is positive, otherwise in clockwise direction. Finally the direction of the turtle is changed by the amount of `extent`.

As the circle is approximated by an inscribed regular polygon, `steps` determines the number of steps to use. If not given, it will be calculated automatically. May be used to draw regular polygons.

```python
>>> turtle.home()
>>> turtle.position()
```
turtle.**dot**(*size=None, *color*)

**Parameters:**
- **size** – an integer $\geq 1$ (if given)
- **color** – a colorstring or a numeric color tuple

Draw a circular dot with diameter *size*, using *color*. If *size* is not given, the maximum of pensize+4 and 2*pensize* is used.

```python
>>> turtle.home()
>>> turtle.dot()
>>> turtle.fd(50); turtle.dot(20, "blue"); turtle
>>> turtle.position()
(100.00,-0.00)
>>> turtle.heading()
0.0
```

turtle.**stamp**()

Stamp a copy of the turtle shape onto the canvas at the current turtle position. Return a stamp_id for that stamp, which can be used to delete it by calling clearstamp(stamp_id).
```python
>>> turtle.color("blue")
>>> turtle.stamp()
11
>>> turtle.fd(50)
```

turtle.**clearstamp**(stampid)

**Parameters:**
- **stampid** – an integer, must be return value of previous `stamp()` call

Delete stamp with given `stampid`.

```python
>>> turtle.position()
(150.00, -0.00)
>>> turtle.color("blue")
>>> astamp = turtle.stamp()
>>> turtle.fd(50)
>>> turtle.position()
(200.00, -0.00)
>>> turtle.clearstamp(astamp)
>>> turtle.position()
(200.00, -0.00)
```

turtle.**clearstamps**(n=None)

**Parameters:**
- **n** – an integer (or None)

Delete all or first/last n of turtle's stamps. If n is None, delete all stamps, if n > 0 delete first n stamps, else if n < 0 delete last n stamps.

```python
>>> for i in range(8):
...      turtle.stamp(); turtle.fd(30)
13
14
15
```
turtle.

```
>>> turtle.clearstamps(2)
>>> turtle.clearstamps(-2)
>>> turtle.clearstamps()
```

turtle. `undo()`

Undo (repeatedly) the last turtle action(s). Number of available undo actions is determined by the size of the undobuffer.

```
>>> for i in range(4):
...     turtle.fd(50); turtle.lt(80)
...
>>> for i in range(8):
...     turtle.undo()
```

turtle. `speed(speed=None)`

**Parameters:**

| speed       | an integer in the range 0..10 or a speedstring (see below) |

Set the turtle's speed to an integer value in the range 0..10. If no argument is given, return current speed.

If input is a number greater than 10 or smaller than 0.5, speed is set to 0. Speedstrings are mapped to speedvalues as follows:

- “fastest”: 0
- “fast”: 10
- “normal”: 6
- “slow”: 3
- “slowest”: 1
Speeds from 1 to 10 enforce increasingly faster animation of line drawing and turtle turning.

Attention: speed = 0 means that no animation takes place. forward/back makes turtle jump and likewise left/right make the turtle turn instantly.

```
>>> turtle.speed()
3
>>> turtle.speed('normal')
>>> turtle.speed()
6
>>> turtle.speed(9)
>>> turtle.speed()
9
```

24.1.3.2. Tell Turtle’s state

turtle.

```
position()
p

pos()

pos()

(440.00, -0.00)
```

turtle.

```
towards(x, y=None)

Parameters:

- x – a number or a pair/vector of numbers or a turtle instance
- y – a number if x is a number, else None

Return the angle between the line from turtle position to position specified by (x,y), the vector or the other turtle. This depends on the turtle’s start orientation which depends on the mode -
“standard”/"world" or “logo”.

```
>>> turtle.goto(10, 10)
>>> turtle.towards(0,0)
225.0
```

turtle.**xcor**()
Return the turtle's x coordinate.

```
>>> turtle.home()
>>> turtle.left(50)
>>> turtle.forward(100)
>>> turtle.pos()
(64.28,76.60)
>>> print(round(turtle.xcor(), 5))
64.27876
```

turtle.**ycor**()
Return the turtle's y coordinate.

```
>>> turtle.home()
>>> turtle.left(60)
>>> turtle.forward(100)
>>> print(turtle.pos())
(50.00,86.60)
>>> print(round(turtle.ycor(), 5))
86.60254
```

turtle.**heading**()
Return the turtle's current heading (value depends on the turtle mode, see **mode**()).

```
>>> turtle.home()
>>> turtle.left(67)
>>> turtle.heading()
```
turtle.distance\(x, y=\text{None}\)

**Parameters:**
- \(x\) – a number or a pair/vector of numbers or a turtle instance
- \(y\) – a number if \(x\) is a number, else \(\text{None}\)

Return the distance from the turtle to \((x, y)\), the given vector, or the given other turtle, in turtle step units.

```python
>>> turtle.home()
>>> turtle.distance(30, 40)
50.0
>>> turtle.distance((30, 40))
50.0
>>> joe = Turtle()
>>> joe.forward(77)
>>> turtle.distance(joe)
77.0
```

### 24.1.3.3. Settings for measurement

turtle.\textbf{degrees}(\textit{fullcircle}=360.0)

**Parameters:** \textit{fullcircle} – a number

Set angle measurement units, i.e. set number of “degrees” for a full circle. Default value is 360 degrees.

```python
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.heading()
90.0
```

Change angle measurement unit to grad (also known
grade, or gradian and equals 1/100-th of the right angle.

```python
>>> turtle.degrees(400.0)
>>> turtle.headings()
100.0
>>> turtle.degrees(360)
```  
```python
>>> turtle.headings()
90.0
```  
```python
>>> turtle.radians()
```  
```python
turtle.radians()
```

Set the angle measurement units to radians. Equivalent to `degrees(2*math.pi)`.

```python
>>> turtle.home()
```  
```python
>>> turtle.left(90)
```  
```python
>>> turtle.headings()
90.0
```  
```python
>>> turtle.radians()
```  
```python
>>> turtle.headings()
1.5707963267948966
```

### 24.1.3.4. Pen control

#### 24.1.3.4.1. Drawing state

```python
turtle.pendown()
turtle.pd()
turtle.down()
```

Pull the pen down – drawing when moving.

```python
turtle.penup()
turtle.pu()
turtle.up()
```

Pull the pen up – no drawing when moving.
turtle.pensize(width=None)
turtle.width(width=None)

Parameters:
width – a positive number

Set the line thickness to width or return it. If resizemode is set to “auto” and turtleshape is a polygon, that polygon is drawn with the same line thickness. If no argument is given, the current pensize is returned.

```python
>>> turtle.pensize()
1
>>> turtle.pensize(10)  # from here on lines of
turtle.pen(pen=None, **pendict)

Parameters:
- pen – a dictionary with some or all of the below listed keys
- pendict – one or more keyword-arguments with the below listed keys as keywords

Return or set the pen’s attributes in a “pen-dictionary” with the following key/value pairs:

- “shown”: True/False
- “pendown”: True/False
- “pencolor”: color-string or color-tuple
- “fillcolor”: color-string or color-tuple
- “pensize”: positive number
- “speed”: number in range 0..10
- “resizemode”: “auto” or “user” or “noresize”
- “stretchfactor”: (positive number, positive number)
- “outline”: positive number
- “tilt”: number
This dictionary can be used as argument for a subsequent call to \texttt{pen()} to restore the former pen-state. Moreover one or more of these attributes can be provided as keyword-arguments. This can be used to set several pen attributes in one statement.

```python
>>> turtle.pen(fillcolor="black", pencolor="red",
>>> sorted(turtle.pen().items())
[('fillcolor', 'black'), ('outline', 1), ('pencol ('pendown', True), ('pensize', 10), ('resizemode ('shearfactor', 0.0), ('shown', True), ('speed', ('stretchfactor', (1.0, 1.0)), ('tilt', 0.0))
>>> penstate=turtle.pen()
>>> turtle.color("yellow", ")
>>> turtle.penup()
>>> sorted(turtle.pen().items())[3]
[('fillcolor', ''), ('outline', 1), ('pencolor', )
>>> turtle.pen(penstate, fillcolor="green")
>>> sorted(turtle.pen().items())[3]
[('fillcolor', 'green'), ('outline', 1), ('pencol...
```

turtle.\texttt{isdown()}

Return \texttt{True} if pen is down, \texttt{False} if it's up.

```python
>>> turtle.penup()
>>> turtle.isdown()
False
>>> turtle.pendown()
>>> turtle.isdown()
True
```

24.1.3.4.2. Color control

turtle.\texttt{pencolor(*args)}

Return or set the pencolor.
Four input formats are allowed:

**pencolor()**
Return the current pencolor as color specification string or as a tuple (see example). May be used as input to another color/pencolor/fillcolor call.

**pencolor(colorstring)**
Set pencolor to *colorstring*, which is a Tk color specification string, such as "red", "yellow", or "#33cc8c".

**pencolor((r, g, b))**
Set pencolor to the RGB color represented by the tuple of *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode, where colormode is either 1.0 or 255 (see *colormode()*).

**pencolor(*r*, *g*, *b)**
Set pencolor to the RGB color represented by *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode.

If turtleshape is a polygon, the outline of that polygon is drawn with the newly set pencolor.

```python
>>> colormode()
1.0
>>> turtle.pencolor()
'red'
>>> turtle.pencolor("brown")
>>> turtle.pencolor()
'brown'
>>> tup = (0.2, 0.8, 0.55)
>>> turtle.pencolor(tup)
>>> turtle.pencolor()
(0.2, 0.8, 0.5490196078431373)
>>> colormode(255)
>>> turtle.pencolor()
(51.0, 204.0, 140.0)
```
turtle. **fillcolor(**args**)

Return or set the fillcolor.

Four input formats are allowed:

**fillcolor()**

Return the current fillcolor as color specification string, possibly in tuple format (see example). May be used as input to another color/pencolor/fillcolor call.

**fillcolor(colorstring)**

Set fillcolor to *colorstring*, which is a Tk color specification string, such as "red", "yellow", or "#33cc8c".

**fillcolor((r, g, b))**

Set fillcolor to the RGB color represented by the tuple of *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode, where colormode is either 1.0 or 255 (see colormode()).

**fillcolor(r, g, b)**

Set fillcolor to the RGB color represented by *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode.

If turtleshape is a polygon, the interior of that polygon is drawn with the newly set fillcolor.

```python
>>> turtle.fillcolor("violet")
>>> turtle.fillcolor()
'violet'
>>> col = turtle.pencolor()
>>> col
(50.0, 193.0, 143.0)
```
turtle.color(*args)
Return or set pencolor and fillcolor.

Several input formats are allowed. They use 0 to 3 arguments as follows:

color()  
Return the current pencolor and the current fillcolor as a pair of 
color specification strings or tuples as returned by pencolor() and fillcolor().

color(colorstring), color((r, g, b)), color(r, g, b)  
Inputs as in pencolor(), set both, fillcolor and pencolor, to 
the given value.

color(colorstring1, colorstring2),  
color((r1, g1, b1), (r2, g2, b2))  
Equivalent to pencolor(colorstring1) and 
fillcolor(colorstring2) and analogously if the 
other input format is used.

If turtleshape is a polygon, outline and interior of that polygon is 
drawn with the newly set colors.

>>> turtle.fillcolor(col)  
>>> turtle.fillcolor()  
(50.0, 193.0, 143.0)  
>>> turtle.fillcolor('#ffffff')  
>>> turtle.fillcolor()  
(255.0, 255.0, 255.0)  

>>> turtle.color("red", "green")  
>>> turtle.color()  
('red', 'green')  
>>> color("#285078", "#a0c8f0")
See also: Screen method `colormode()`.

24.1.3.4.3. Filling

`turtle.filling()`

Return `fillstate` (`True` if filling, `False` otherwise).

```python
>>> turtle.begin_fill()
>>> if turtle.filling():
...     turtle.pensize(5)
...     else:
...     turtle.pensize(3)
```

`turtle.begin_fill()`

To be called just before drawing a shape to be filled.

`turtle.end_fill()`

Fill the shape drawn after the last call to `begin_fill()`.

```python
>>> turtle.color("black", "red")
>>> turtle.begin_fill()
>>> turtle.circle(80)
>>> turtle.end_fill()
```

24.1.3.4.4. More drawing control

`turtle.reset()`

Delete the turtle's drawings from the screen, re-center the turtle and set variables to the default values.
turtle.goto(0,-22)
turtle.left(100)
turtle.position()
(0.00,-22.00)
turtle.heading()
100.0
turtle.reset()
turtle.position()
(0.00,0.00)
turtle.heading()
0.0

turtle.clear()
Delete the turtle’s drawings from the screen. Do not move turtle. State and position of the turtle as well as drawings of other turtles are not affected.

turtle.write(arg, move=False, align="left", font=("Arial", 8, "normal"))

Parameters:
- **arg** – object to be written to the TurtleScreen
- **move** – True/False
- **align** – one of the strings “left”, “center” or right”
- **font** – a triple (fontname, fontsize, fonttype)

Write text - the string representation of **arg** - at the current turtle position according to **align** (“left”, “center” or right”) and with the given font. If **move** is true, the pen is moved to the bottom-right corner of the text. By default, **move** is False.

turtle.write("Home = ", True, align="center")
turtle.write((0,0), True)
24.1.3.5. Turtle state

24.1.3.5.1. Visibility

turtle. hideturtle()
turtle. ht()

Make the turtle invisible. It’s a good idea to do this while you’re in the middle of doing some complex drawing, because hiding the turtle speeds up the drawing observably.

```python
>>> turtle.hideturtle()
```

turtle. showturtle()
turtle. st()

Make the turtle visible.

```python
>>> turtle.showturtle()
```

turtle. isvisible()

Return True if the Turtle is shown, False if it’s hidden.

```python
>>> turtle.hideturtle()
>>> turtle.isvisible()
False
>>> turtle.showturtle()
>>> turtle.isvisible()
True
```

24.1.3.5.2. Appearance

turtle. shape(name=None)

Parameters: name – a string which is a valid shapename
Set turtle shape to shape with given name or, if name is not given, return name of current shape. Shape with name must exist in the TurtleScreen's shape dictionary. Initially there are the following polygon shapes: “arrow”, “turtle”, “circle”, “square”, “triangle”, “classic”. To learn about how to deal with shapes see Screen method register_shape().

```python
>>> turtle.shape()
'classic'
>>> turtle.shape("turtle")
>>> turtle.shape()
'turtle'
```

turtle.resizemode(rmode=None)

| Parameters: | rmode – one of the strings “auto”, “user”, “noresize” |

Set resizemode to one of the values: “auto”, “user”, “noresize”. If rmode is not given, return current resizemode. Different resizemodes have the following effects:

- “auto”: adapts the appearance of the turtle corresponding to the value of pensize.
- “user”: adapts the appearance of the turtle according to the values of stretchfactor and outlinewidth (outline), which are set by shapesize().
- “noresize”: no adaption of the turtle’s appearance takes place.

resizemode("user") is called by shapesize() when used with arguments.

```python
>>> turtle.resizemode()
'noresize'
>>> turtle.resizemode("auto")
```
turtle.shapesize(stretch_wid=None, stretch_len=None, outline=None)
turtle.turtlesize(stretch_wid=None, stretch_len=None, outline=None)

**Parameters:**
- `stretch_wid` – positive number
- `stretch_len` – positive number
- `outline` – positive number

Return or set the pen's attributes x/y-stretchfactors and/or outline. Set resizemode to “user”. If and only if resizemode is set to “user”, the turtle will be displayed stretched according to its stretchfactors: `stretch_wid` is stretchfactor perpendicular to its orientation, `stretch_len` is stretchfactor in direction of its orientation, `outline` determines the width of the shapes's outline.

```python
>>> turtle.shapesize()
(1.0, 1.0, 1)
>>> turtle.resizemode("user")
>>> turtle.shapesize(5, 5, 12)
>>> turtle.shapesize()
(5, 5, 12)
>>> turtle.shapesize(outline=8)
>>> turtle.shapesize()
(5, 5, 8)
```

turtle.shearfactor(shear=None)

**Parameters:**
- `shear` – number (optional)

Set or return the current shearfactor. Shear the turtleshape according to the given shearfactor shear, which is the tangent of
the shear angle. Do \textit{not} change the turtle's heading (direction of movement). If shear is not given: return the current shear factor, i.e. the tangent of the shear angle, by which lines parallel to the heading of the turtle are sheared.

```python
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.shearfactor(0.5)
>>> turtle.shearfactor()
0.5
```

\textbf{turtle.\texttt{tilt}(angle)}

\textbf{Parameters:} \hspace{1em} \texttt{angle} – a number

Rotate the turtleshape by \texttt{angle} from its current tilt-angle, but do \textit{not} change the turtle's heading (direction of movement).

```python
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.tilt(30)
>>> turtle.fd(50)
>>> turtle.tilt(30)
>>> turtle.fd(50)
```

\textbf{turtle.\texttt{settiltangle}(angle)}

\textbf{Parameters:} \hspace{1em} \texttt{angle} – a number

Rotate the turtleshape to point in the direction specified by \texttt{angle}, regardless of its current tilt-angle. \textit{Do not} change the turtle's heading (direction of movement).

```python
>>> turtle.reset()
>>> turtle.shape("circle")
```
```python
>>> turtle.shapesize(5, 2)
>>> turtle.settiltangle(45)
>>> turtle.fd(50)
>>> turtle.settiltangle(-45)
>>> turtle.fd(50)
```

*Deprecated since version 3.1.*

**turtle.tiltangle**(angle=None)

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>angle – a number (optional)</th>
</tr>
</thead>
</table>

Set or return the current tilt-angle. If angle is given, rotate the turtleshape to point in the direction specified by angle, regardless of its current tilt-angle. Do *not* change the turtle's heading (direction of movement). If angle is not given: return the current tilt-angle, i.e. the angle between the orientation of the turtleshape and the heading of the turtle (its direction of movement).

```python
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5, 2)
>>> turtle.tilt(45)
>>> turtle.tiltangle()
45.0
```

**turtle.shapetransform**(t11=None, t12=None, t21=None, t22=None)

| Parameters: |
|-------------|----------------------------|
| t11 – a number (optional) |
| t12 – a number (optional) |
| t21 – a number (optional) |
| t22 – a number (optional) |

Set or return the current transformation matrix of the turtle shape.
If none of the matrix elements are given, return the transformation matrix as a tuple of 4 elements. Otherwise set the given elements and transform the turtleshape according to the matrix consisting of first row t11, t12 and second row t21, 22. The determinant t11 * t22 - t12 * t21 must not be zero, otherwise an error is raised. Modify stretchfactor, shearfactor and tiltangle according to the given matrix.

```python
>>> turtle = Turtle()
>>> turtle.shape("square")
>>> turtle.shapesize(4, 2)
>>> turtle.shearfactor(-0.5)
>>> turtle.shapetransform()
(4.0, -1.0, -0.0, 2.0)
```

**turtle.get_shapepoly()**

Return the current shape polygon as tuple of coordinate pairs. This can be used to define a new shape or components of a compound shape.

```python
>>> turtle.shape("square")
>>> turtle.shapetransform(4, -1, 0, 2)
>>> turtle.get_shapepoly()
((50, -20), (30, 20), (-50, 20), (-30, -20))
```

### 24.1.3.6. Using events

**turtle.onclick**(fun, btn=1, add=None)

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults
to 1 (left mouse button)

- **add** – **True** or **False** – if **True**, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-click events on this turtle. If *fun* is None, existing bindings are removed. Example for the anonymous turtle, i.e. the procedural way:

```python
>>> def turn(x, y):
...     left(180)
>>> onclick(turn)  # Now clicking into the turtle
>>> onclick(None)  # event-binding will be removed
```

**turtle.onrelease**(*fun*, *btn=1*, *add=None*)

**Parameters:**

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – **True** or **False** – if **True**, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-button-release events on this turtle. If *fun* is None, existing bindings are removed.

```python
>>> class MyTurtle(Turtle):
...     def glow(self, x, y):
...         self.fillcolor("red")
...     def unglow(self, x, y):
...         self.fillcolor("")
```
turtle = MyTurtle()
>>> turtle.onclick(turtle.glow) # clicking on
turtle.onrelease(turtle.unglow) # releasing t

turtle.ondrag(fun, btn=1, add=None)

Parameters:

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – True or False – if True, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-move events on this turtle. If *fun* is None, existing bindings are removed.

Remark: Every sequence of mouse-move-events on a turtle is preceded by a mouse-click event on that turtle.

>>> turtle.ondrag(turtle.goto)

Subsequently, clicking and dragging the Turtle will move it across the screen thereby producing handdrawings (if pen is down).

### 24.1.3.7. Special Turtle methods

turtle.begin_poly()

Start recording the vertices of a polygon. Current turtle position is first vertex of polygon.

turtle.end_poly()
Stop recording the vertices of a polygon. Current turtle position is last vertex of polygon. This will be connected with the first vertex.

turtle. `get_poly()`

Return the last recorded polygon.

```python
>>> turtle.home()
>>> turtle.begin_poly()
>>> turtle.fd(100)
>>> turtle.left(20)
>>> turtle.fd(30)
>>> turtle.left(60)
>>> turtle.fd(50)
>>> turtle.end_poly()
>>> p = turtle.get_poly()
>>> register_shape("myFavouriteShape", p)
```

turtle. `clone()`

Create and return a clone of the turtle with same position, heading and turtle properties.

```python
>>> mick = Turtle()
>>> joe = mick.clone()
```

turtle. `getturtle()`

turtle. `getpen()`

Return the Turtle object itself. Only reasonable use: as a function to return the “anonymous turtle”:

```python
>>> pet = getturtle()
>>> pet.fd(50)
>>> pet
<turtle.Turtle object at 0x...>
```
turtle.\texttt{getscreen()}

Return the \textit{TurtleScreen} object the turtle is drawing on. TurtleScreen methods can then be called for that object.

\begin{verbatim}
>>> ts = turtle.getscreen()
>>> ts
<title:_Screen object at 0x...>
>>> ts.bgcolor("pink")
\end{verbatim}

turtle.\texttt{setundobuffer(size)}

\begin{center}
\textbf{Parameters:} size – an integer or \texttt{None}
\end{center}

Set or disable undobuffer. If \texttt{size} is an integer an empty undobuffer of given size is installed. \texttt{size} gives the maximum number of turtle actions that can be undone by the \texttt{undo()} method/function. If \texttt{size} is \texttt{None}, the undobuffer is disabled.

\begin{verbatim}
>>> turtle.setundobuffer(42)
\end{verbatim}

turtle.\texttt{undobufferentries()}

Return number of entries in the undobuffer.

\begin{verbatim}
>>> while undobufferentries():
...     undo()
\end{verbatim}

24.1.3.8. Compound shapes

To use compound turtle shapes, which consist of several polygons of different color, you must use the helper class \texttt{Shape} explicitly as described below:

1. Create an empty Shape object of type “compound”.
2. Add as many components to this object as desired, using the `addcomponent()` method.

For example:

```python
>>> s = Shape("compound")
>>> poly1 = ((0,0),(10,-5),(0,10),(-10,-5))
>>> s.addcomponent(poly1, "red", "blue")
>>> poly2 = ((0,0),(10,-5),(-10,-5))
>>> s.addcomponent(poly2, "blue", "red")
```

3. Now add the Shape to the Screen’s shapelist and use it:

```python
>>> register_shape("myshape", s)
>>> shape("myshape")
```

**Note:** The `Shape` class is used internally by the `register_shape()` method in different ways. The application programmer has to deal with the Shape class only when using compound shapes like shown above!
24.1.4. Methods of TurtleScreen/Screen and corresponding functions

Most of the examples in this section refer to a TurtleScreen instance called `screen`.

24.1.4.1. Window control

turtle. bgcolor(*args)

Parameters: 

| Parameters: | args – a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers |

Set or return background color of the TurtleScreen.

```python
>>> screen.bgcolor("orange")
'orange'
>>> screen.bgcolor()
(128.0, 0.0, 128.0)
```

turtle. bgpic(picname=None)

Parameters: 

| Parameters: | picname – a string, name of a gif-file or "nopic", or None |

Set background image or return name of current background image. If `picname` is a filename, set the corresponding image as background. If `picname` is "nopic", delete background image, if present. If `picname` is None, return the filename of the current background image.
turtle\texttt{.clear()}
turtle\texttt{.clearscreen()}

Delete all drawings and all turtles from the TurtleScreen. Reset the now empty TurtleScreen to its initial state: white background, no background image, no event bindings and tracing on.

\textbf{Note: } This TurtleScreen method is available as a global function only under the name \texttt{clearscreen}. The global function \texttt{clear} is a different one derived from the Turtle method \texttt{clear}.

turtle\texttt{.reset()}
turtle\texttt{.resetscreen()}

Reset all Turtles on the Screen to their initial state.

\textbf{Note: } This TurtleScreen method is available as a global function only under the name \texttt{resetscreen}. The global function \texttt{reset} is another one derived from the Turtle method \texttt{reset}.

turtle\texttt{.screensize}(\texttt{canvwidth=}, \texttt{canvheight=}, \texttt{bg=})

\textbf{Parameters:}

\begin{itemize}
  \item \texttt{canvwidth} – positive integer, new width of canvas in pixels
  \item \texttt{canvheight} – positive integer, new height of canvas in pixels
  \item \texttt{bg} – colorstring or color-tuple, new
If no arguments are given, return current (canvaswidth, canvashight). Else resize the canvas the turtles are drawing on. Do not alter the drawing window. To observe hidden parts of the canvas, use the scrollbars. With this method, one can make visible those parts of a drawing which were outside the canvas before.

```python
>>> screen.screensize()
(400, 300)
>>> screen.screensize(2000, 1500)
>>> screen.screensize()
(2000, 1500)
```

e.g. to search for an erroneously escaped turtle ;-)

```python
turtle.setworldcoordinates(llx, lly, urx, ury)
```

<table>
<thead>
<tr>
<th>Parameters:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>llx</strong> – a number, x-coordinate of lower left corner of canvas</td>
</tr>
<tr>
<td>• <strong>lly</strong> – a number, y-coordinate of lower left corner of canvas</td>
</tr>
<tr>
<td>• <strong>urx</strong> – a number, x-coordinate of upper right corner of canvas</td>
</tr>
<tr>
<td>• <strong>ury</strong> – a number, y-coordinate of upper right corner of canvas</td>
</tr>
</tbody>
</table>

Set up user-defined coordinate system and switch to mode “world” if necessary. This performs a `screen.reset()`. If mode “world” is already active, all drawings are redrawn according to the new coordinates.

**ATTENTION**: in user-defined coordinate systems angles may appear distorted.
>>> screen.reset()
>>> screen.setworldcoordinates(-50,-7.5,50,7.5)
>>> for _ in range(72):
...    left(10)
...
>>> for _ in range(8):
...    left(45); fd(2)  # a regular octagon

24.1.4.2. Animation control

turtle.**delay**(delay=None)

**Parameters:**

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>delay</th>
<th>positive integer</th>
</tr>
</thead>
</table>

Set or return the drawing *delay* in milliseconds. (This is approximately the time interval between two consecutive canvas updates.) The longer the drawing delay, the slower the animation.

Optional argument:

```python
>>> screen.delay()
10
>>> screen.delay(5)
>>> screen.delay()
5
```

turtle.**tracer**(n=None, delay=None)

**Parameters:**

- **n** – nonnegative integer
- **delay** – nonnegative integer

Turn turtle animation on/off and set delay for update drawings. If *n* is given, only each *n*-th regular screen update is really performed. (Can be used to accelerate the drawing of complex graphics.) When called without arguments, returns the currently stored value
of n. Second argument sets delay value (see `delay()`).

```python
>>> screen.tracer(8, 25)
>>> dist = 2
>>> for i in range(200):
...    fd(dist)
...    rt(90)
...    dist += 2
```

turtle.**update()**

Perform a TurtleScreen update. To be used when tracer is turned off.

See also the RawTurtle/Turtle method `speed()`.

### 24.1.4.3. Using screen events

**turtle.**listen(*xdummy=None, ydummy=None*)

Set focus on TurtleScreen (in order to collect key-events). Dummy arguments are provided in order to be able to pass `listen()` to the onclick method.

**turtle.**onkey(*fun, key*)
**turtle.**onkeyrelease(*fun, key*)

**Parameters:**

- **fun** – a function with no arguments or `None`
- **key** – a string: key (e.g. “a”) or key-symbol (e.g. “space”)

Bind `fun` to key-release event of `key`. If `fun` is `None`, event bindings are removed. Remark: in order to be able to register key-events, TurtleScreen must have the focus. (See method `listen()`.)
turtle.onkeypress(fun, key=None)

Parameters:
- **fun** – a function with no arguments or `None`
- **key** – a string: key (e.g. “a”) or key-symbol (e.g. “space”)

Bind `fun` to key-press event of `key` if `key` is given, or to any key-press-event if no `key` is given. Remark: in order to be able to register key-events, TurtleScreen must have focus. (See method `listen()`.)

turtle.onclick(fun, btn=1, add=None)
turtle.onscreenclick(fun, btn=1, add=None)

Parameters:
- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – `True` or `False` – if `True`, a new binding will be added, otherwise it will replace a former binding
Bind *fun* to mouse-click events on this screen. If *fun* is *None*, existing bindings are removed.

Example for a TurtleScreen instance named *screen* and a Turtle instance named *turtle*:

```python
>>> screen.onclick(turtle.goto)  # Subsequently clicking into the TurtleScreen will make the turtle move to the clicked point.
>>> screen.onclick(None)        # remove event binding again
```

**Note:** This TurtleScreen method is available as a global function only under the name `onscreenclick`. The global function `onclick` is another one derived from the Turtle method `onclick`.

```python
turtle.ontimer(fun, t=0)
```

**Parameters:**
- *fun* – a function with no arguments
- *t* – a number $\geq 0$

Install a timer that calls *fun* after *t* milliseconds.

```python
>>> running = True
>>> def f():
...     if running:
...         fd(50)
...         lt(60)
...     screen.ontimer(f, 250)
>>> f()  # makes the turtle march around
>>> running = False
```

```python
turtle.mainloop()
turtle.done()
```
Starts event loop - calling Tkinter's mainloop function. Must be the last statement in a turtle graphics program. Must not be used if a script is run from within IDLE in -n mode (No subprocess) - for interactive use of turtle graphics.

```python
>>> screen.mainloop()
```

### 24.1.4.4. Input methods

**turtle.** `textinput` *(title, prompt)*

**Parameters:**
- `title` – string
- `prompt` – string

Pop up a dialog window for input of a string. Parameter title is the title of the dialog window, prompt is a text mostly describing what information to input. Return the string input. If the dialog is canceled, return `None`.

```python
>>> screen.textinput("NIM", "Name of first player:")
```

**turtle.** `numinput` *(title, prompt, default=None, minval=None, maxval=None)*

**Parameters:**
- `title` – string
- `prompt` – string
- `default` – number (optional)
- `minval` – number (optional)
- `maxval` – number (optional)

Pop up a dialog window for input of a number. title is the title of the dialog window, prompt is a text mostly describing what numerical information to input. default: default value, minval: minimum value
for input, maxval: maximum value for input The number input must be in the range minval .. maxval if these are given. If not, a hint is issued and the dialog remains open for correction. Return the number input. If the dialog is canceled, return None.

```
>>> screen.numinput("Poker", "Your stakes:", 1000
```

24.1.4.5. Settings and special methods

turtle. **mode**(mode=None)

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>mode – one of the strings “standard”, “logo” or “world”</th>
</tr>
</thead>
</table>

Set turtle mode (“standard”, “logo” or “world”) and perform reset. If mode is not given, current mode is returned.

Mode “standard” is compatible with old `turtle`. Mode “logo” is compatible with most Logo turtle graphics. Mode “world” uses user-defined “world coordinates”. **Attention:** in this mode angles appear distorted if x/y unit-ratio doesn’t equal 1.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Initial turtle heading</th>
<th>positive angles</th>
</tr>
</thead>
<tbody>
<tr>
<td>“standard”</td>
<td>to the right (east)</td>
<td>counterclockwise</td>
</tr>
<tr>
<td>“logo”</td>
<td>upward (north)</td>
<td>clockwise</td>
</tr>
</tbody>
</table>

```
>>> mode("logo")  # resets turtle heading to nor
```

```
>>> mode()
'logo'
```

turtle. **colormode**(cmode=None)
Parameters:  
cmode – one of the values 1.0 or 255

Return the colormode or set it to 1.0 or 255. Subsequently r, g, b values of color triples have to be in the range 0..cmode.

```python
c>>> screen.colormode(1)
c>>> turtle.pencolor(240, 160, 80)
TurtleGraphicsError: bad color sequence: (240, 16
```

`turtle.getcanvas()`  
Return the Canvas of this TurtleScreen. Useful for insiders who know what to do with a Tkinter Canvas.

```python
c>>> cv = screen.getcanvas()
c>>> cv
<turtle.ScrolledCanvas object ...>
```

`turtle.getshapes()`  
Return a list of names of all currently available turtle shapes.

```python
c>>> screen.getshapes()
['arrow', 'blank', 'circle', ..., 'turtle']
```

`turtle.register_shape(name, shape=None)`  
turtle.addshape(name, shape=None)  
There are three different ways to call this function:
1. *name* is the name of a gif-file and *shape* is `None`: Install the corresponding image shape.

```python
>>> screen.register_shape("turtle.gif")
```

**Note:** Image shapes *do not* rotate when turning the turtle, so they do not display the heading of the turtle!

2. *name* is an arbitrary string and *shape* is a tuple of pairs of coordinates: Install the corresponding polygon shape.

```python
>>> screen.register_shape("triangle", ((5,-3),
```

3. *name* is an arbitrary string and *shape* is a (compound) *Shape* object: Install the corresponding compound shape.

Add a turtle shape to TurtleScreen's shapelist. Only thusly registered shapes can be used by issuing the command `shape(shapename)`.

```python
turtle.turtles()
Return the list of turtles on the screen.
```

```python
>>> for turtle in screen.turtles():
...     turtle.color("red")
```

```python
turtle.window_height()
Return the height of the turtle window.
```

```python
>>> screen.window_height()
480
```

```python
turtle.window_width()
```
24.1.4.6. Methods specific to Screen, not inherited from TurtleScreen

turtle.**bye**()

Shut the turtle graphics window.

turtle.**exitonclick**()

Bind **bye()** method to mouse clicks on the Screen.

If the value “using_IDLE” in the configuration dictionary is False (default value), also enter mainloop. Remark: If IDLE with the -n switch (no subprocess) is used, this value should be set to True in *turtle.cfg*. In this case IDLE’s own mainloop is active also for the client script.

turtle.**setup**(width=_CFG["width"], height=_CFG["height"],
startx=_CFG["leftright"], starty=_CFG["topbottom"])

Set the size and position of the main window. Default values of arguments are stored in the configuration dictionary and can be changed via a *turtle.cfg* file.

- **width** – if an integer, a size in pixels, if a float, a fraction of the screen; default is 50% of screen
- **height** – if an integer, the height in pixels, if a float, a fraction of the screen; default is 75% of screen
Parameters:

- **startx** – if positive, starting position in pixels from the left edge of the screen, if negative from the right edge, if `None`, center window horizontally
- **starty** – if positive, starting position in pixels from the top edge of the screen, if negative from the bottom edge, if `None`, center window vertically

```python
>>> screen.setup (width=200, height=200, startx=0)
>>>                      # sets window to 200x200 pixels,
>>> screen.setup(width=.75, height=0.5, startx=None)
>>>                      # sets window to 75% of screen b
```

`turtle.title(titlestring)`

Parameters:

- **titlestring** – a string that is shown in the titlebar of the turtle graphics window

Set title of turtle window to *titlestring*.

```python
>>> screen.title("Welcome to the turtle zoo!")
```
24.1.5. Public classes

class turtle.RawTurtle(canvas)

class turtle.RawPen(canvas)

| Parameters: | canvas – a tkinter.Canvas, a ScrolledCanvas or a TurtleScreen |

Create a turtle. The turtle has all methods described above as “methods of Turtle/RawTurtle”.

class turtle.Turtle

Subclass of RawTurtle, has the same interface but draws on a default Screen object created automatically when needed for the first time.

class turtle.TurtleScreen(cv)

| Parameters: | cv – a tkinter.Canvas |

Provides screen oriented methods like setbg() etc. that are described above.

class turtle.Screen

Subclass of TurtleScreen, with four methods added.

class turtle.ScrolledCanvas(master)

| Parameters: | master – some Tkinter widget to contain the ScrolledCanvas, i.e. a Tkinter-canvas with scrollbars added |

Used by class Screen, which thus automatically provides a ScrolledCanvas as playground for the turtles.
class turtle. **Shape**(type\_\_, data)

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type_</td>
<td>one of the strings “polygon”, “image”, “compound”</td>
</tr>
</tbody>
</table>

Data structure modeling shapes. The pair (type\_, data) must follow this specification:

<table>
<thead>
<tr>
<th>type_</th>
<th>data</th>
</tr>
</thead>
<tbody>
<tr>
<td>“polygon”</td>
<td>a polygon-tuple, i.e. a tuple of pairs of coordinates</td>
</tr>
<tr>
<td>“image”</td>
<td>an image (in this form only used internally!)</td>
</tr>
<tr>
<td>“compound”</td>
<td>None (a compound shape has to be constructed using the addcomponent() method)</td>
</tr>
</tbody>
</table>

**addcomponent**(poly, fill, outline=None)

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>poly</td>
<td>a polygon, i.e. a tuple of pairs of numbers</td>
</tr>
<tr>
<td>fill</td>
<td>a color the poly will be filled with</td>
</tr>
<tr>
<td>outline</td>
<td>a color for the poly’s outline (if given)</td>
</tr>
</tbody>
</table>

Example:

```python
>>> poly = ((0, 0), (10, -5), (0, 10), (-10, -5))
>>> s = Shape("compound")
>>> s.addcomponent(poly, "red", "blue")
>>> # ... add more components and then use register_shape()
```

See Compound shapes.

class turtle. **Vec2D**(x, y)

A two-dimensional vector class, used as a helper class for implementing turtle graphics. May be useful for turtle graphics.
programs too. Derived from tuple, so a vector is a tuple!

Provides (for $a, b$ vectors, $k$ number):

- $a + b$ vector addition
- $a - b$ vector subtraction
- $a \times b$ inner product
- $k \times a$ and $a \times k$ multiplication with scalar
- $\text{abs}(a)$ absolute value of $a$
- $a.\text{rotate}(\text{angle})$ rotation
24.1.6. Help and configuration

24.1.6.1. How to use help

The public methods of the Screen and Turtle classes are documented extensively via docstrings. So these can be used as online-help via the Python help facilities:

- When using IDLE, tooltips show the signatures and first lines of the docstrings of typed in function-/method calls.
- Calling `help()` on methods or functions displays the docstrings:

```python
>>> help(Screen.bgcolor)
Help on method bgcolor in module turtle:

bcolor(self, *args) unbound turtle.Screen method
    Set or return backgroundcolor of the TurtleScreen.

    Arguments (if given): a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers.

>>> screenbgcolor("orange")
>>> screenbgcolor()
"orange"
>>> screenbgcolor(0.5,0,0.5)
>>> screenbgcolor()
"#800080"

>>> help(Turtle.penup)
Help on method penup in module turtle:

penup(self) unbound turtle.Turtle method
    Pull the pen up -- no drawing when moving.
```
Aliases: penup | pu | up

No argument

>>> turtle.penup()

- The docstrings of the functions which are derived from methods have a modified form:

>>> help(bgcolor)
Help on function bgcolor in module turtle:

bgcolor(*args)
   Set or return backgroundcolor of the TurtleScreen.

   Arguments (if given): a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers.

Example::

   >>> bgcolor("orange")
   >>> bgcolor()
   "orange"
   >>> bgcolor(0.5,0,0.5)
   >>> bgcolor()
   "#800080"

>>> help(penup)
Help on function penup in module turtle:

penup()
   Pull the pen up -- no drawing when moving.

   Aliases: penup | pu | up
No argument

Example:
>>> penup()

These modified docstrings are created automatically together with the function definitions that are derived from the methods at import time.

24.1.6.2. Translation of docstrings into different languages

There is a utility to create a dictionary the keys of which are the method names and the values of which are the docstrings of the public methods of the classes Screen and Turtle.

turtle.write_docstringdict(filename="turtle_docstringdict"

Parameters: filename – a string, used as filename

Create and write docstring-dictionary to a Python script with the given filename. This function has to be called explicitly (it is not used by the turtle graphics classes). The docstring dictionary will be written to the Python script filename.py. It is intended to serve as a template for translation of the docstrings into different languages.

If you (or your students) want to use turtle with online help in your native language, you have to translate the docstrings and save the resulting file as e.g. turtle_docstringdict_german.py.

If you have an appropriate entry in your turtle.cfg file this dictionary will be read in at import time and will replace the original English docstrings.
At the time of this writing there are docstring dictionaries in German and in Italian. (Requests please to glingl@aon.at.)

24.1.6.3. How to configure Screen and Turtles

The built-in default configuration mimics the appearance and behaviour of the old turtle module in order to retain best possible compatibility with it.

If you want to use a different configuration which better reflects the features of this module or which better fits to your needs, e.g. for use in a classroom, you can prepare a configuration file `turtle.cfg` which will be read at import time and modify the configuration according to its settings.

The built-in configuration would correspond to the following `turtle.cfg`:

```plaintext
width = 0.5
height = 0.75
leftright = None
topbottom = None
canvwidth = 400
canvheight = 300
mode = standard
colormode = 1.0
delay = 10
undobuffersize = 1000
shape = classic
pencolor = black
fillcolor = black
resizemode = nosize
visible = True
language = english
exampleturtle = turtle
examplescreen = screen
```
Short explanation of selected entries:

- The first four lines correspond to the arguments of the `Screen.setup()` method.
- Line 5 and 6 correspond to the arguments of the method `Screen.screensize()`.
- `shape` can be any of the built-in shapes, e.g: arrow, turtle, etc. For more info try `help(shape)`.
- If you want to use no fillcolor (i.e. make the turtle transparent), you have to write `fillcolor = ""` (but all nonempty strings must not have quotes in the cfg-file).
- If you want to reflect the turtle its state, you have to use `resizemode = auto`.
- If you set e.g. `language = italian` the docstringdict `turtle_docstringdict_italian.py` will be loaded at import time (if present on the import path, e.g. in the same directory as `turtle`.
- The entries `exampleturtle` and `examplescreen` define the names of these objects as they occur in the docstrings. The transformation of method-docstrings to function-docstrings will delete these names from the docstrings.
- `using_IDLE`: Set this to True if you regularly work with IDLE and its -n switch (“no subprocess”). This will prevent `exitonclick()` to enter the mainloop.

There can be a `turtle.cfg` file in the directory where `turtle` is stored and an additional one in the current working directory. The latter will override the settings of the first one.

The `Lib/turtledemo` directory contains a `turtle.cfg` file. You can study it as an example and see its effects when running the
demos (preferably not from within the demo-viewer).
24.1.7. *turtledemo* — Demo scripts

The *turtledemo* package includes a set of demo scripts. These scripts can be run and viewed using the supplied demo viewer as follows:

```python
python -m turtledemo
```

Alternatively, you can run the demo scripts individually. For example,

```python
python -m turtledemo.bytedesign
```

The *turtledemo* package directory contains:

- A demo viewer `__main__.py` which can be used to view the source code of the scripts and run them at the same time.
- Multiple scripts demonstrating different features of the *turtle* module. Examples can be accessed via the Examples menu. They can also be run standalone.
- A *turtle.cfg* file which serves as an example of how to write and use such files.

The demo scripts are:

<table>

Have fun!
24.1.8. Changes since Python 2.6

- The methods `Turtle.tracer()`, `Turtle.window_width()` and `Turtle.window_height()` have been eliminated. Methods with these names and functionality are now available only as methods of `Screen`. The functions derived from these remain available. (In fact already in Python 2.6 these methods were merely duplications of the corresponding `TurtleScreen/Screen-methods`.)
- The method `Turtle.fill()` has been eliminated. The behaviour of `begin_fill()` and `end_fill()` have changed slightly: now every filling-process must be completed with an `end_fill()` call.
- A method `Turtle.filling()` has been added. It returns a boolean value: `True` if a filling process is under way, `False` otherwise. This behaviour corresponds to a `fill()` call without arguments in Python 2.6.
24.1.9. Changes since Python 3.0

- The methods `Turtle.shearfactor()`, `Turtle.shapetransform()` and `Turtle.get_shapepoly()` have been added. Thus the full range of regular linear transforms is now available for transforming turtle shapes. `Turtle.tiltangle()` has been enhanced in functionality: it now can be used to get or set the tiltangle. `Turtle.settiltangle()` has been deprecated.

- The method `Screen.onkeypress()` has been added as a complement to `Screen.onkey()` which in fact binds actions to the keyrelease event. Accordingly the latter has got an alias: `Screen.onkeyrelease()`.

- The method `Screen.mainloop()` has been added. So when working only with Screen and Turtle objects one must not additionally import `mainloop()` anymore.

- Two input methods has been added `Screen.textinput()` and `Screen.numinput()`. These popup input dialogs and return strings and numbers respectively.

- Two example scripts `tdemo_nim.py` and `tdemo_round_dance.py` have been added to the `Lib/turtledemo` directory.
The `Cmd` class provides a simple framework for writing line-oriented command interpreters. These are often useful for test harnesses, administrative tools, and prototypes that will later be wrapped in a more sophisticated interface.

```python
class cmd.Cmd(completekey='tab', stdin=None, stdout=None)
```

A `Cmd` instance or subclass instance is a line-oriented interpreter framework. There is no good reason to instantiate `Cmd` itself; rather, it's useful as a superclass of an interpreter class you define yourself in order to inherit `Cmd`'s methods and encapsulate action methods.

The optional argument `completekey` is the `readline` name of a completion key; it defaults to `Tab`. If `completekey` is not `None` and `readline` is available, command completion is done automatically.

The optional arguments `stdin` and `stdout` specify the input and output file objects that the `Cmd` instance or subclass instance will use for input and output. If not specified, they will default to `sys.stdin` and `sys.stdout`.

If you want a given `stdin` to be used, make sure to set the instance's `use_rawinput` attribute to `False`, otherwise `stdin` will
be ignored.
24.2.1. Cmd Objects

A `Cmd` instance has the following methods:

```
Cmd.cmdloop(intro=None)
```

Repeatedly issue a prompt, accept input, parse an initial prefix off the received input, and dispatch to action methods, passing them the remainder of the line as argument.

The optional argument is a banner or intro string to be issued before the first prompt (this overrides the `intro` class attribute).

If the `readline` module is loaded, input will automatically inherit bash-like history-list editing (e.g. `Control-P` scrolls back to the last command, `Control-N` forward to the next one, `Control-F` moves the cursor to the right non-destructively, `Control-B` moves the cursor to the left non-destructively, etc.).

An end-of-file on input is passed back as the string `'EOF'`.

An interpreter instance will recognize a command name `foo` if and only if it has a method `do_foo()`. As a special case, a line beginning with the character `?' is dispatched to the method `do_help()`. As another special case, a line beginning with the character `!' is dispatched to the method `do_shell()` (if such a method is defined).

This method will return when the `postcmd()` method returns a true value. The `stop` argument to `postcmd()` is the return value from the command's corresponding `do_*()` method.

If completion is enabled, completing commands will be done
automatically, and completing of commands args is done by calling complete_foo() with arguments text, line, begidx, and endidx. text is the string prefix we are attempting to match: all returned matches must begin with it. line is the current input line with leading whitespace removed, begidx and endidx are the beginning and ending indexes of the prefix text, which could be used to provide different completion depending upon which position the argument is in.

All subclasses of Cmd inherit a predefined do_help(). This method, called with an argument 'bar', invokes the corresponding method help_bar(), and if that is not present, prints the docstring of do_bar(), if available. With no argument, do_help() lists all available help topics (that is, all commands with corresponding help_*() methods or commands that have docstrings), and also lists any undocumented commands.

Cmd.onecmd(str)

Interpret the argument as though it had been typed in response to the prompt. This may be overridden, but should not normally need to be; see the precmd() and postcmd() methods for useful execution hooks. The return value is a flag indicating whether interpretation of commands by the interpreter should stop. If there is a do_*() method for the command str, the return value of that method is returned, otherwise the return value from the default() method is returned.

Cmd.emptyline()

Method called when an empty line is entered in response to the prompt. If this method is not overridden, it repeats the last nonempty command entered.
**Cmd. **\texttt{default(line)}

Method called on an input line when the command prefix is not recognized. If this method is not overridden, it prints an error message and returns.

**Cmd. **\texttt{completesdefault(text, line, begidx, endidx)}

Method called to complete an input line when no command-specific \texttt{complete_*()} method is available. By default, it returns an empty list.

**Cmd. **\texttt{precmd(line)}

Hook method executed just before the command line \texttt{line} is interpreted, but after the input prompt is generated and issued. This method is a stub in \texttt{Cmd}; it exists to be overridden by subclasses. The return value is used as the command which will be executed by the \texttt{onecmd()} method; the \texttt{precmd()} implementation may re-write the command or simply return \texttt{line} unchanged.

**Cmd. **\texttt{postcmd(stop, line)}

Hook method executed just after a command dispatch is finished. This method is a stub in \texttt{Cmd}; it exists to be overridden by subclasses. \texttt{line} is the command line which was executed, and \texttt{stop} is a flag which indicates whether execution will be terminated after the call to \texttt{postcmd()}; this will be the return value of the \texttt{onecmd()} method. The return value of this method will be used as the new value for the internal flag which corresponds to \texttt{stop}; returning false will cause interpretation to continue.

**Cmd. **\texttt{preloop()}

Hook method executed once when \texttt{cmdloop()} is called. This method is a stub in \texttt{Cmd}; it exists to be overridden by subclasses.
Cmd. **postloop()**

Hook method executed once when `cmdloop()` is about to return. This method is a stub in Cmd; it exists to be overridden by subclasses.

Instances of **Cmd** subclasses have some public instance variables:

**Cmd. prompt**

The prompt issued to solicit input.

**Cmd. identchars**

The string of characters accepted for the command prefix.

**Cmd. lastcmd**

The last nonempty command prefix seen.

**Cmd. cmdqueue**

A list of queued input lines. The cmdqueue list is checked in `cmdloop()` when new input is needed; if it is nonempty, its elements will be processed in order, as if entered at the prompt.

**Cmd. intro**

A string to issue as an intro or banner. May be overridden by giving the `cmdloop()` method an argument.

**Cmd. doc_header**

The header to issue if the help output has a section for documented commands.

**Cmd. misc_header**

The header to issue if the help output has a section for miscellaneous help topics (that is, there are `help_*()` methods
without corresponding do_*( ) methods).

Cmd. **undoc_header**
The header to issue if the help output has a section for undocumented commands (that is, there are do_*( ) methods without corresponding help_*( ) methods).

Cmd. **ruler**
The character used to draw separator lines under the help-message headers. If empty, no ruler line is drawn. It defaults to `='.

Cmd. **use_rawinput**
A flag, defaulting to true. If true, cmdloop() uses input() to display a prompt and read the next command; if false, sys.stdout.write() and sys.stdin.readline() are used. (This means that by importing readline, on systems that support it, the interpreter will automatically support Emacs-like line editing and command-history keystrokes.)
24.2.2. Cmd Example

The `cmd` module is mainly useful for building custom shells that let a user work with a program interactively.

This section presents a simple example of how to build a shell around a few of the commands in the `turtle` module.

Basic turtle commands such as `forward()` are added to a `Cmd` subclass with method named `do_forward()`. The argument is converted to a number and dispatched to the turtle module. The docstring is used in the help utility provided by the shell.

The example also includes a basic record and playback facility implemented with the `precmd()` method which is responsible for converting the input to lowercase and writing the commands to a file. The `do_playback()` method reads the file and adds the recorded commands to the `cmdqueue` for immediate playback:

```python
import cmd, sys
from turtle import *

class TurtleShell(cmd.Cmd):
    intro = 'Welcome to the turtle shell. Type help or ? to list commands.'
    prompt = '(turtle) '
    file = None

    # ---- basic turtle commands ----
    def do_forward(self, arg):
        'Move the turtle forward by the specified distance: FORWARD 10'
        forward(*parse(arg))
    def do_right(self, arg):
        'Turn turtle right by given number of degrees: RIGHT 20'
```

right(*parse(arg))

def do_left(self, arg):
    'Turn turtle left by given number of degrees'
    left(*parse(arg))

def do_goto(self, arg):
    'Move turtle to an absolute position with changing orientation'
    goto(*parse(arg))

def do_home(self, arg):
    'Return turtle to the home position: HOME'
    home()

def do_circle(self, arg):
    'Draw circle with given radius and options except angle'
    circle(*parse(arg))

def do_position(self, arg):
    'Print the current turtle position: POSITION'
    print('Current position is %d %d
          ' % position)

def do_heading(self, arg):
    'Print the current turtle heading in degrees'
    print('Current heading is %d
          ' % (heading()))

def do_color(self, arg):
    'Set the color: COLOR BLUE'
    color(arg.lower())

def do_undo(self, arg):
    'Undo (repeatedly) the last turtle action(s)'

def do_reset(self, arg):
    'Clear the screen and return turtle to center'
    reset()

def do_bye(self, arg):
    'Stop recording, close the turtle window, and exit'
    print('Thank you for using Turtle')
    self.close()
    bye()
    return True

# ----- record and playback -----

def do_record(self, arg):
    'Save future commands to filename: RECORD rose.cmd'
def do_playback(self, arg):
    'Playback commands from a file: PLAYBACK rose.cmd'
    self.close()
    with open(arg) as f:
        self.cmdqueue.extend(f.read().splitlines)

def precmd(self, line):
    line = line.lower()
    if self.file and 'playback' not in line:
        print(line, file=self.file)
    return line

def close(self):
    if self.file:
        self.file.close()
    self.file = None

def parse(arg):
    'Convert a series of zero or more numbers to an argument tuple'
    return tuple(map(int, arg.split()))

if __name__ == '__main__':
    TurtleShell().cmdloop()

Here is a sample session with the turtle shell showing the help functions, using blank lines to repeat commands, and the simple record and playback facility:

Welcome to the turtle shell. Type help or ? to list commands.
(turtle) ?

Documented commands (type help <topic>):
-----------------------------------------
by color goto home playback record right circle forward heading left position reset undo
(turtle) help forward
Move the turtle forward by the specified distance:
(turtle) record spiral.cmd
(turtle) position
Current position is 0 0

(turtle) heading
Current heading is 0

(turtle) reset
(turtle) circle 20
(turtle) right 30
(turtle) circle 40
(turtle) right 30
(turtle) circle 60
(turtle) right 30
(turtle) circle 80
(turtle) right 30
(turtle) circle 100
(turtle) right 30
(turtle) circle 120
(turtle) right 30
(turtle) circle 120
(turtle) heading
Current heading is 180

(turtle) forward 100
(turtle)
(turtle) right 90
(turtle) forward 100
(turtle)
(turtle) right 90
(turtle) forward 400
(turtle) right 90
(turtle) forward 500
(turtle) right 90
(turtle) forward 400
(turtle) right 90
(turtle) forward 300
(turtle) playback spiral.cmd
Current position is 0 0

Current heading is 0

Current heading is 180

(turtle) bye
Thank you for using Turtle
24.3. **shlex** — Simple lexical analysis

**Source code:** Lib/shlex.py

The *shlex* class makes it easy to write lexical analyzers for simple syntaxes resembling that of the Unix shell. This will often be useful for writing minilanguages, (for example, in run control files for Python applications) or for parsing quoted strings.

The *shlex* module defines the following functions:

**shlex.split** *(s, comments=False, posix=True)*

Split the string *s* using shell-like syntax. If *comments* is *False* (the default), the parsing of comments in the given string will be disabled (setting the *commenters* attribute of the *shlex* instance to the empty string). This function operates in POSIX mode by default, but uses non-POSIX mode if the *posix* argument is false.

**Note:** Since the *split()* function instantiates a *shlex* instance, passing None for *s* will read the string to split from standard input.

**shlex.quote** *(s)*

Return a shell-escaped version of the string *s*. The returned value is a string that can safely be used as one token in a shell command line, for cases where you cannot use a list.

This idiom would be unsafe:
quote() lets you plug the security hole:

```python
>>> command = 'ls -l {}' . format(quote(filename))
>>> print(command)
ls -l 'somefile; rm -rf ~'
>>> remote_command = 'ssh home {}' . format(quote(command))
>>> print(remote_command)
ssh home 'ls -l """somefile; rm -rf ~"""'
```

The quoting is compatible with UNIX shells and with `split()`:

```python
>>> remote_command = split(remote_command)
>>> remote_command
['ssh', 'home', 'ls -l 'somefile; rm -rf ~']
>>> command = split(remote_command[-1])
>>> command
['ls', '-l', 'somefile; rm -rf ~']
```

New in version 3.3.

The `shlex` module defines the following class:

```python
class shlex . shlex ( instream=None, infile=None, posix=False, punctuation_chars=False )
```

A `shlex` instance or subclass instance is a lexical analyzer object. The initialization argument, if present, specifies where to read characters from. It must be a file-/stream-like object with `read()` and `readline()` methods, or a string. If no argument is given,
input will be taken from `sys.stdin`. The second optional argument is a filename string, which sets the initial value of the `in_file` attribute. If the `in_stream` argument is omitted or equal to `sys.stdin`, this second argument defaults to “stdin”. The `posix` argument defines the operational mode: when `posix` is not true (default), the `shlex` instance will operate in compatibility mode. When operating in POSIX mode, `shlex` will try to be as close as possible to the POSIX shell parsing rules. The `punctuation_chars` argument provides a way to make the behaviour even closer to how real shells parse. This can take a number of values: the default value, `False`, preserves the behaviour seen under Python 3.5 and earlier. If set to `True`, then parsing of the characters `();<>|&` is changed: any run of these characters (considered punctuation characters) is returned as a single token. If set to a non-empty string of characters, those characters will be used as the punctuation characters. Any characters in the `word_chars` attribute that appear in `punctuation_chars` will be removed from `word_chars`. See Improved Compatibility with Shells for more information.

*Changed in version 3.6:* The `punctuation_chars` parameter was added.

### See also:

**Module configparser**

Parser for configuration files similar to the Windows `.ini` files.
24.3.1. shlex Objects

A shlex instance has the following methods:

```
shlex.get_token()
```

Return a token. If tokens have been stacked using `push_token()`, pop a token off the stack. Otherwise, read one from the input stream. If reading encounters an immediate end-of-file, `eof` is returned (the empty string (`''`) in non-POSIX mode, and `None` in POSIX mode).

```
shlex.push_token(str)
```

Push the argument onto the token stack.

```
shlex.read_token()
```

Read a raw token. Ignore the pushback stack, and do not interpret source requests. (This is not ordinarily a useful entry point, and is documented here only for the sake of completeness.)

```
shlex.sourcehook(filename)
```

When shlex detects a source request (see `source` below) this method is given the following token as argument, and expected to return a tuple consisting of a filename and an open file-like object.

Normally, this method first strips any quotes off the argument. If the result is an absolute pathname, or there was no previous source request in effect, or the previous source was a stream (such as `sys.stdin`), the result is left alone. Otherwise, if the result is a relative pathname, the directory part of the name of the file immediately before it on the source inclusion stack is prepended (this behavior is like the way the C preprocessor handles
The result of the manipulations is treated as a filename, and returned as the first component of the tuple, with `open()` called on it to yield the second component. (Note: this is the reverse of the order of arguments in instance initialization!)

This hook is exposed so that you can use it to implement directory search paths, addition of file extensions, and other namespace hacks. There is no corresponding ‘close’ hook, but a shlex instance will call the `close()` method of the sourced input stream when it returns EOF.

For more explicit control of source stacking, use the `push_source()` and `pop_source()` methods.

```python
shlex.push_source(newstream, newfile=None)
```

Push an input source stream onto the input stack. If the filename argument is specified it will later be available for use in error messages. This is the same method used internally by the `sourcehook()` method.

```python
shlex.pop_source()
```

Pop the last-pushed input source from the input stack. This is the same method used internally when the lexer reaches EOF on a stacked input stream.

```python
shlex.error_leader(infile=None, lineno=None)
```

This method generates an error message leader in the format of a Unix C compiler error label; the format is `'"%s", line %d: '`, where the `%%s` is replaced with the name of the current source file and the `%d` with the current input line number (the optional
arguments can be used to override these).

This convenience is provided to encourage shlex users to generate error messages in the standard, parseable format understood by Emacs and other Unix tools.

Instances of shlex subclasses have some public instance variables which either control lexical analysis or can be used for debugging:

shlex.commenters
The string of characters that are recognized as comment beginners. All characters from the comment beginner to end of line are ignored. Includes just '#' by default.

shlex.wordchars
The string of characters that will accumulate into multi-character tokens. By default, includes all ASCII alphanumerics and underscore. In POSIX mode, the accented characters in the Latin-1 set are also included. If punctuation_chars is not empty, the characters ~-./*?=, which can appear in filename specifications and command line parameters, will also be included in this attribute, and any characters which appear in punctuation_chars will be removed from wordchars if they are present there.

shlex.whitespace
Characters that will be considered whitespace and skipped. Whitespace bounds tokens. By default, includes space, tab, linefeed and carriage-return.

shlex.escape
Characters that will be considered as escape. This will be only used in POSIX mode, and includes just '\' by default.
shlex.**quotes**
Characters that will be considered string quotes. The token accumulates until the same quote is encountered again (thus, different quote types protect each other as in the shell.) By default, includes ASCII single and double quotes.

shlex.**escapedquotes**
Characters in quotes that will interpret escape characters defined in escape. This is only used in POSIX mode, and includes just '\'' by default.

shlex.**whitespace_split**
If True, tokens will only be split in whitespaces. This is useful, for example, for parsing command lines with shlex, getting tokens in a similar way to shell arguments. If this attribute is True, punctuation_chars will have no effect, and splitting will happen only on whitespaces. When using punctuation_chars, which is intended to provide parsing closer to that implemented by shells, it is advisable to leave whitespace_split as False (the default value).

shlex.**infil**
The name of the current input file, as initially set at class instantiation time or stacked by later source requests. It may be useful to examine this when constructing error messages.

shlex.**instream**
The input stream from which this shlex instance is reading characters.

shlex.**source**
This attribute is None by default. If you assign a string to it, that
string will be recognized as a lexical-level inclusion request similar to the `source` keyword in various shells. That is, the immediately following token will be opened as a filename and input will be taken from that stream until EOF, at which point the `close()` method of that stream will be called and the input source will again become the original input stream. Source requests may be stacked any number of levels deep.

**shlex.** **debug**

If this attribute is numeric and 1 or more, a `shlex` instance will print verbose progress output on its behavior. If you need to use this, you can read the module source code to learn the details.

**shlex.** **lineno**

Source line number (count of newlines seen so far plus one).

**shlex.** **token**

The token buffer. It may be useful to examine this when catching exceptions.

**shlex.** **eof**

Token used to determine end of file. This will be set to the empty string (`''`), in non-POSIX mode, and to `None` in POSIX mode.

**shlex.** **punctuation_chars**

Characters that will be considered punctuation. Runs of punctuation characters will be returned as a single token. However, note that no semantic validity checking will be performed: for example, ‘>>>’ could be returned as a token, even though it may not be recognised as such by shells.

*New in version 3.6.*
24.3.2. Parsing Rules

When operating in non-POSIX mode, `shlex` will try to obey to the following rules.

- Quote characters are not recognized within words (Do\"Not\"Separate is parsed as the single word Do\"Not\"Separate);
- Escape characters are not recognized;
- Enclosing characters in quotes preserve the literal value of all characters within the quotes;
- Closing quotes separate words ("Do\"Separate is parsed as "Do" and Separate);
- If `whitespace_split` is False, any character not declared to be a word character, whitespace, or a quote will be returned as a single-character token. If it is True, `shlex` will only split words in whitespaces;
- EOF is signaled with an empty string ('');
- It's not possible to parse empty strings, even if quoted.

When operating in POSIX mode, `shlex` will try to obey to the following parsing rules.

- Quotes are stripped out, and do not separate words ("Do\"Not\"Separate" is parsed as the single word DoNotSeparate);
- Non-quoted escape characters (e.g. '\\') preserve the literal value of the next character that follows;
- Enclosing characters in quotes which are not part of escapedquotes (e.g. "'"') preserve the literal value of all characters within the quotes;
- Enclosing characters in quotes which are part of
escapedquotes (e.g. `"'`) preserves the literal value of all characters within the quotes, with the exception of the characters mentioned in escape. The escape characters retain its special meaning only when followed by the quote in use, or the escape character itself. Otherwise the escape character will be considered a normal character.

- EOF is signaled with a None value;
- Quoted empty strings (`'`') are allowed.
24.3.3. Improved Compatibility with Shells

New in version 3.6.

The `shlex` class provides compatibility with the parsing performed by common Unix shells like bash, dash, and sh. To take advantage of this compatibility, specify the `punctuation_chars` argument in the constructor. This defaults to `False`, which preserves pre-3.6 behaviour. However, if it is set to `True`, then parsing of the characters `();<>|&` is changed: any run of these characters is returned as a single token. While this is short of a full parser for shells (which would be out of scope for the standard library, given the multiplicity of shells out there), it does allow you to perform processing of command lines more easily than you could otherwise. To illustrate, you can see the difference in the following snippet:

```python
>>> import shlex
>>> text = "a && b; c && d || e; f >'abc'; (def \"ghi\")'
>>> list(shlex.shlex(text))
["a", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",", ",
example:

```python
>>> import shlex
>>> s = shlex.shlex("a & b || c", punctuation_chars=list(s)
['a', '&', '|', 'b', 'c']
```

**Note:** When `punctuation_chars` is specified, the `wordchars` attribute is augmented with the characters `~./*?=`. That is because these characters can appear in file names (including wildcards) and command-line arguments (e.g. `--color=auto`). Hence:

```python
>>> import shlex
>>> s = shlex.shlex('~/a & b-c --color=auto || d
... punctuation_chars=True)
>>> list(s)
['~/a', '&', 'b-c', '--color=auto', '|', 'd', '*
```

For best effect, `punctuation_chars` should be set in conjunction with `posix=True`. (Note that `posix=False` is the default for `shlex`.)
25. Graphical User Interfaces with Tk

Tk/Tcl has long been an integral part of Python. It provides a robust and platform independent windowing toolkit, that is available to Python programmers using the `tkinter` package, and its extension, the `tkinter.tix` and the `tkinter.ttk` modules.

The `tkinter` package is a thin object-oriented layer on top of Tcl/Tk. To use `tkinter`, you don’t need to write Tcl code, but you will need to consult the Tk documentation, and occasionally the Tcl documentation. `tkinter` is a set of wrappers that implement the Tk widgets as Python classes. In addition, the internal module `_tkinter` provides a threadsafe mechanism which allows Python and Tcl to interact.

`tkinter`'s chief virtues are that it is fast, and that it usually comes bundled with Python. Although its standard documentation is weak, good material is available, which includes: references, tutorials, a book and others. `tkinter` is also famous for having an outdated look and feel, which has been vastly improved in Tk 8.5. Nevertheless, there are many other GUI libraries that you could be interested in. For more information about alternatives, see the Other Graphical User Interface Packages section.

25.1. **tkinter** — Python interface to Tcl/Tk

**Source code:** `Lib/tkinter/__init__.py`

The **tkinter** package (“Tk interface”) is the standard Python interface to the Tk GUI toolkit. Both Tk and **tkinter** are available on most Unix platforms, as well as on Windows systems. (Tk itself is not part of Python; it is maintained at ActiveState.) You can check that **tkinter** is properly installed on your system by running `python -m tkinter` from the command line; this should open a window demonstrating a simple Tk interface.

**Python and Tkinter Programming**
25.1.1. Tkinter Modules

Most of the time, `tkinter` is all you really need, but a number of additional modules are available as well. The Tk interface is located in a binary module named `_tkinter`. This module contains the low-level interface to Tk, and should never be used directly by application programmers. It is usually a shared library (or DLL), but might in some cases be statically linked with the Python interpreter.

In addition to the Tk interface module, `tkinter` includes a number of Python modules, `tkinter.constants` being one of the most important. Importing `tkinter` will automatically import `tkinter.constants`, so, usually, to use Tkinter all you need is a simple import statement:

```python
import tkinter
```

Or, more often:

```python
from tkinter import *
```

class tkinter.Tk(screenName=None, baseName=None, className='Tk', useTk=1)

The `Tk` class is instantiated without arguments. This creates a toplevel widget of Tk which usually is the main window of an application. Each instance has its own associated Tcl interpreter.

tkinter.Tcl(screenName=None, baseName=None, className='Tk', useTk=0)

The `Tcl()` function is a factory function which creates an object much like that created by the `Tk` class, except that it does not
initialize the Tk subsystem. This is most often useful when driving
the Tcl interpreter in an environment where one doesn’t want to
create extraneous toplevel windows, or where one cannot (such as
Unix/Linux systems without an X server). An object created by the
Tcl() object can have a Toplevel window created (and the Tk
subsystem initialized) by calling its loadtk() method.

Other modules that provide Tk support include:

tkinter.scrolledtext
Text widget with a vertical scroll bar built in.
tkinter.colorchooser
Dialog to let the user choose a color.
tkinter.commondialog
Base class for the dialogs defined in the other modules listed here.
tkinter.filedialog
Common dialogs to allow the user to specify a file to open or save.
tkinter.font
Utilities to help work with fonts.
tkinter.messagebox
Access to standard Tk dialog boxes.
tkinter.simpledialog
Basic dialogs and convenience functions.
tkinter.dnd
Drag-and-drop support for tkinter. This is experimental and
should become deprecated when it is replaced with the Tk DND.
turtle
Turtle graphics in a Tk window.
25.1.2. Tkinter Life Preserver

This section is not designed to be an exhaustive tutorial on either Tk or Tkinter. Rather, it is intended as a stop gap, providing some introductory orientation on the system.

Credits:

- Tk was written by John Ousterhout while at Berkeley.
- Tkinter was written by Steen Lumholt and Guido van Rossum.
- This Life Preserver was written by Matt Conway at the University of Virginia.
- The HTML rendering, and some liberal editing, was produced from a FrameMaker version by Ken Manheimer.
- Fredrik Lundh elaborated and revised the class interface descriptions, to get them current with Tk 4.2.
- Mike Clarkson converted the documentation to LaTeX, and compiled the User Interface chapter of the reference manual.

25.1.2.1. How To Use This Section

This section is designed in two parts: the first half (roughly) covers background material, while the second half can be taken to the keyboard as a handy reference.

When trying to answer questions of the form “how do I do blah”, it is often best to find out how to do”blah” in straight Tk, and then convert this back into the corresponding `tkinter` call. Python programmers can often guess at the correct Python command by looking at the Tk documentation. This means that in order to use Tkinter, you will have to know a little bit about Tk. This document can’t fulfill that role, so the best we can do is point you to the best documentation that exists.
Here are some hints:

- The authors strongly suggest getting a copy of the Tk man pages. Specifically, the man pages in the manN directory are most useful. The man3 man pages describe the C interface to the Tk library and thus are not especially helpful for script writers.
- Addison-Wesley publishes a book called Tcl and the Tk Toolkit by John Ousterhout (ISBN 0-201-63337-X) which is a good introduction to Tcl and Tk for the novice. The book is not exhaustive, and for many details it defers to the man pages.
- tkinter/__init__.py is a last resort for most, but can be a good place to go when nothing else makes sense.

### 25.1.2.2. A Simple Hello World Program

```python
import tkinter as tk

class Application(tk.Frame):
    def __init__(self, master=None):
        super().__init__(master)
        self.pack()
        self.create_widgets()
```
def create_widgets(self):
    self.hi_there = tk.Button(self)
    self.hi_there['text'] = "Hello World\n(click me)"
    self.hi_there['command'] = self.say_hi
    self.hi_there.pack(side="top")

    self.quit = tk.Button(self, text="QUIT", fg=
                               command=root.destroy)
    self.quit.pack(side="bottom")

def say_hi(self):
    print("hi there, everyone!")

root = tk.Tk()
app = Application(master=root)
app.mainloop()
25.1.3. A (Very) Quick Look at Tcl/Tk

The class hierarchy looks complicated, but in actual practice, application programmers almost always refer to the classes at the very bottom of the hierarchy.

Notes:

- These classes are provided for the purposes of organizing certain functions under one namespace. They aren’t meant to be instantiated independently.
- The Tk class is meant to be instantiated only once in an application. Application programmers need not instantiate one explicitly, the system creates one whenever any of the other classes are instantiated.
- The Widget class is not meant to be instantiated, it is meant only for subclassing to make “real” widgets (in C++, this is called an ‘abstract class’).

To make use of this reference material, there will be times when you will need to know how to read short passages of Tk and how to identify the various parts of a Tk command. (See section Mapping Basic Tk into Tkinter for the tkinter equivalents of what’s below.)

Tk scripts are Tcl programs. Like all Tcl programs, Tk scripts are just lists of tokens separated by spaces. A Tk widget is just its class, the options that help configure it, and the actions that make it do useful things.

To make a widget in Tk, the command is always of the form:

```
classCommand newPathname options
```
**classCommand**

denotes which kind of widget to make (a button, a label, a menu...)

**newPathname**
is the new name for this widget. All names in Tk must be unique. To help enforce this, widgets in Tk are named with *pathnames*, just like files in a file system. The top level widget, the *root*, is called (period) and children are delimited by more periods. For example, `.myApp.controlPanel.okButton` might be the name of a widget.

**options**
configure the widget's appearance and in some cases, its behavior. The options come in the form of a list of flags and values. Flags are preceded by a ‘-‘, like Unix shell command flags, and values are put in quotes if they are more than one word.

For example:

```
button .fred -fg red -text "hi there"
```

Once created, the pathname to the widget becomes a new command. This new *widget command* is the programmer's handle for getting the new widget to perform some *action*. In C, you'd express this as `someAction(fred, someOptions)`, in C++, you would express this as `fred.someAction(someOptions)`, and in Tk, you say:

```
.fred someAction someOptions
```

Note that the object name, `.fred`, starts with a dot.
As you’d expect, the legal values for `someAction` will depend on the widget’s class: `.fred disable` works if fred is a button (fred gets greyed out), but does not work if fred is a label (disabling of labels is not supported in Tk).

The legal values of `someOptions` is action dependent. Some actions, like `disable`, require no arguments, others, like a text-entry box’s `delete` command, would need arguments to specify what range of text to delete.
25.1.4. Mapping Basic Tk into Tkinter

Class commands in Tk correspond to class constructors in Tkinter.

```python
button .fred        ===>  fred = Button()
```

The master of an object is implicit in the new name given to it at creation time. In Tkinter, masters are specified explicitly.

```python
button .panel.fred  ===>  fred = Button(panel)
```

The configuration options in Tk are given in lists of hyphenated tags followed by values. In Tkinter, options are specified as keyword-arguments in the instance constructor, and keyword-args for configure calls or as instance indices, in dictionary style, for established instances. See section Setting Options on setting options.

```python
button .fred -fg red  ===>  fred = Button(panel)
.fred configure -fg red  ===>  fred["fg"] = red
OR ==>  fred.config(fg=
```

In Tk, to perform an action on a widget, use the widget name as a command, and follow it with an action name, possibly with arguments (options). In Tkinter, you call methods on the class instance to invoke actions on the widget. The actions (methods) that a given widget can perform are listed in `tkinter/__init__.py`.

```python
.fred invoke        ===>  fred.invoke()
```

To give a widget to the packer (geometry manager), you call pack with optional arguments. In Tkinter, the Pack class holds all this
functionality, and the various forms of the pack command are implemented as methods. All widgets in tkinter are subclassed from the Packer, and so inherit all the packing methods. See the tkinter.tix module documentation for additional information on the Form geometry manager.

```python
pack .fred -side left ===> fred.pack(side='left'
```
25.1.5. How Tk and Tkinter are Related

From the top down:

Your App Here (Python)
   A Python application makes a tkinter call.

tkinter (Python Package)
   This call (say, for example, creating a button widget), is implemented in the tkinter package, which is written in Python. This Python function will parse the commands and the arguments and convert them into a form that makes them look as if they had come from a Tk script instead of a Python script.

ltkinter (C)
   These commands and their arguments will be passed to a C function in the _tkinter - note the underscore - extension module.

Tk Widgets (C and Tcl)
   This C function is able to make calls into other C modules, including the C functions that make up the Tk library. Tk is implemented in C and some Tcl. The Tcl part of the Tk widgets is used to bind certain default behaviors to widgets, and is executed once at the point where the Python tkinter package is imported. (The user never sees this stage).

Tk (C)
   The Tk part of the Tk Widgets implement the final mapping to ...

Xlib (C)
   the Xlib library to draw graphics on the screen.
25.1.6. Handy Reference

25.1.6.1. Setting Options

Options control things like the color and border width of a widget. Options can be set in three ways:

At object creation time, using keyword arguments

```python
fred = Button(self, fg="red", bg="blue")
```

After object creation, treating the option name like a dictionary index

```python
fred["fg"] = "red"
fred["bg"] = "blue"
```

Use the config() method to update multiple attrs subsequent to object creation

```python
fred.config(fg="red", bg="blue")
```

For a complete explanation of a given option and its behavior, see the Tk man pages for the widget in question.

Note that the man pages list “STANDARD OPTIONS” and “WIDGET SPECIFIC OPTIONS” for each widget. The former is a list of options that are common to many widgets, the latter are the options that are idiosyncratic to that particular widget. The Standard Options are documented on the `options(3)` man page.

No distinction between standard and widget-specific options is made in this document. Some options don’t apply to some kinds of widgets. Whether a given widget responds to a particular option depends on the class of the widget; buttons have a `command` option, labels do not.
The options supported by a given widget are listed in that widget's man page, or can be queried at runtime by calling the `config()` method without arguments, or by calling the `keys()` method on that widget. The return value of these calls is a dictionary whose key is the name of the option as a string (for example, 'relief') and whose values are 5-tuples.

Some options, like bg are synonyms for common options with long names (bg is shorthand for “background”). Passing the `config()` method the name of a shorthand option will return a 2-tuple, not 5-tuple. The 2-tuple passed back will contain the name of the synonym and the “real” option (such as ('bg', 'background')).

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>option name</td>
<td>'relief'</td>
</tr>
<tr>
<td>1</td>
<td>option name for database lookup</td>
<td>'relief'</td>
</tr>
<tr>
<td>2</td>
<td>option class for database lookup</td>
<td>'Relief'</td>
</tr>
<tr>
<td>3</td>
<td>default value</td>
<td>'raised'</td>
</tr>
<tr>
<td>4</td>
<td>current value</td>
<td>'groove'</td>
</tr>
</tbody>
</table>

Example:

```python
>>> print(fred.config())
{'relief': ('relief', 'relief', 'Relief', 'raised', 'groove')}
```

Of course, the dictionary printed will include all the options available and their values. This is meant only as an example.

25.1.6.2. The Packer
The packer is one of Tk’s geometry-management mechanisms. Geometry managers are used to specify the relative positioning of the positioning of widgets within their container - their mutual master. In contrast to the more cumbersome placer (which is used less commonly, and we do not cover here), the packer takes qualitative relationship specification - above, to the left of, filling, etc - and works everything out to determine the exact placement coordinates for you.

The size of any master widget is determined by the size of the “slave widgets” inside. The packer is used to control where slave widgets appear inside the master into which they are packed. You can pack widgets into frames, and frames into other frames, in order to achieve the kind of layout you desire. Additionally, the arrangement is dynamically adjusted to accommodate incremental changes to the configuration, once it is packed.

Note that widgets do not appear until they have had their geometry specified with a geometry manager. It’s a common early mistake to leave out the geometry specification, and then be surprised when the widget is created but nothing appears. A widget will appear only after it has had, for example, the packer’s pack() method applied to it.

The pack() method can be called with keyword-option/value pairs that control where the widget is to appear within its container, and how it is to behave when the main application window is resized. Here are some examples:

```python
fred.pack()  # defaults to side =
fred.pack(side="left")
fred.pack(expand=1)
```

25.1.6.3. Packer Options
For more extensive information on the packer and the options that it can take, see the man pages and page 183 of John Ousterhout's book.

**anchor**
Anchor type. Denotes where the packer is to place each slave in its parcel.

**expand**
Boolean, \( 0 \) or \( 1 \).

**fill**
Legal values: 'x', 'y', 'both', 'none'.

**ipadx** and **ipady**
A distance - designating internal padding on each side of the slave widget.

**padx** and **pady**
A distance - designating external padding on each side of the slave widget.

**side**
Legal values are: 'left', 'right', 'top', 'bottom'.

### 25.1.6.4. Coupling Widget Variables

The current-value setting of some widgets (like text entry widgets) can be connected directly to application variables by using special options. These options are `variable`, `textvariable`, `onvalue`, `offvalue`, and `value`. This connection works both ways: if the variable changes for any reason, the widget it’s connected to will be updated to reflect the new value.

Unfortunately, in the current implementation of `tkinter` it is not possible to hand over an arbitrary Python variable to a widget through
a variable or textvariable option. The only kinds of variables for which this works are variables that are subclassed from a class called Variable, defined in tkinter.

There are many useful subclasses of Variable already defined: StringVar, IntVar, DoubleVar, and BooleanVar. To read the current value of such a variable, call the get() method on it, and to change its value you call the set() method. If you follow this protocol, the widget will always track the value of the variable, with no further intervention on your part.

For example:

```python
class App(Frame):
    def __init__(self, master=None):
        super().__init__(master)
        self.pack()

        self.entrythingy = Entry()
        self.entrythingy.pack()

        # here is the application variable
        self.contents = StringVar()
        # set it to some value
        self.contents.set("this is a variable")
        # tell the entry widget to watch this variable
        self.entrythingy["textvariable"] = self.contents

        # and here we get a callback when the user hits return
        # we will have the program print out the value of the application variable when the user hits return
        self.entrythingy.bind('<Key-Return>',
            def print_contents(self, event):
```

```python
def print_contents(self, event):
```
25.1.6.5. The Window Manager

In Tk, there is a utility command, `wm`, for interacting with the window manager. Options to the `wm` command allow you to control things like titles, placement, icon bitmaps, and the like. In `tkinter`, these commands have been implemented as methods on the `Wm` class. Toplevel widgets are subclassed from the `Wm` class, and so can call the `Wm` methods directly.

To get at the toplevel window that contains a given widget, you can often just refer to the widget's master. Of course if the widget has been packed inside of a frame, the master won’t represent a toplevel window. To get at the toplevel window that contains an arbitrary widget, you can call the `_root()` method. This method begins with an underscore to denote the fact that this function is part of the implementation, and not an interface to Tk functionality.

Here are some examples of typical usage:

```python
import tkinter as tk

class App(tk.Frame):
    def __init__(self, master=None):
        super().__init__(master)
        self.pack()

# create the application
myapp = App()
```
25.1.6.6. Tk Option Data Types

anchor
Legal values are points of the compass: "n", "ne", "e", "se", "s", "sw", "w", "nw", and also "center".

bitmap
There are eight built-in, named bitmaps: 'error', 'gray25', 'gray50', 'hourglass', 'info', 'questhead', 'question', 'warning'. To specify an X bitmap filename, give the full path to the file, preceded with an @, as in "@/usr/contrib(bitmap/gumby.bit)".

boolean
You can pass integers 0 or 1 or the strings "yes" or "no".

callback
This is any Python function that takes no arguments. For example:

```python
def print_it():
    print("hi there")
fred["command"] = print_it
```

color
Colors can be given as the names of X colors in the rgb.txt file, or as strings representing RGB values in 4 bit: "#RGB", 8 bit: "#RRRGGGBB", 12 bit "#RRRGGGGBBB", or 16 bit

cursor
The standard X cursor names from `cursorfont.h` can be used, without the `XC_` prefix. For example to get a hand cursor (`XC_hand2`), use the string "hand2". You can also specify a bitmap and mask file of your own. See page 179 of Ousterhout's book.

distance
Screen distances can be specified in either pixels or absolute distances. Pixels are given as numbers and absolute distances as strings, with the trailing character denoting units: c for centimetres, i for inches, m for millimetres, p for printer's points. For example, 3.5 inches is expressed as "3.5i".

font
Tk uses a list font name format, such as `{courier 10 bold}`. Font sizes with positive numbers are measured in points; sizes with negative numbers are measured in pixels.

geometry
This is a string of the form `widthxheight`, where width and height are measured in pixels for most widgets (in characters for widgets displaying text). For example: `fred["geometry"] = "200x100"`.

justify
Legal values are the strings: "left", "center", "right", and "fill".

region
This is a string with four space-delimited elements, each of which is a legal distance (see above). For example: "2 3 4 5" and "3i 2i 4.5i 2i" and "3c 2c 4c 10.43c" are all legal regions.
relief
Determined what the border style of a widget will be. Legal values are: "raised", "sunken", "flat", "groove", and "ridge".

scrollcommand
This is almost always the set() method of some scrollbar widget, but can be any widget method that takes a single argument.

wrap:
Must be one of: "none", "char", or "word".

25.1.6.7. Bindings and Events

The bind method from the widget command allows you to watch for certain events and to have a callback function trigger when that event type occurs. The form of the bind method is:

```python
def bind(self, sequence, func, add=' '):
```

where:

sequence
is a string that denotes the target kind of event. (See the bind man page and page 201 of John Ousterhout's book for details).

func
is a Python function, taking one argument, to be invoked when the event occurs. An Event instance will be passed as the argument. (Functions deployed this way are commonly known as callbacks.)

add
is optional, either '' or '+'. Passing an empty string denotes that this binding is to replace any other bindings that this event is associated with. Passing a '+' means that this function is to be added to the list of functions bound to this event type.
For example:

```python
def turn_red(self, event):
    event.widget['activeforeground'] = "red"

self.button.bind("<Enter>", self.turn_red)
```

Notice how the widget field of the event is being accessed in the `turn_red()` callback. This field contains the widget that caught the X event. The following table lists the other event fields you can access, and how they are denoted in Tk, which can be useful when referring to the Tk man pages.

<table>
<thead>
<tr>
<th>Tk</th>
<th>Tkinter Event Field</th>
<th>Tk</th>
<th>Tkinter Event Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>%f</td>
<td>focus</td>
<td>%A</td>
<td>char</td>
</tr>
<tr>
<td>%h</td>
<td>height</td>
<td>%E</td>
<td>send_event</td>
</tr>
<tr>
<td>%k</td>
<td>keycode</td>
<td>%K</td>
<td>keysym</td>
</tr>
<tr>
<td>%s</td>
<td>state</td>
<td>%N</td>
<td>keysym_num</td>
</tr>
<tr>
<td>%t</td>
<td>time</td>
<td>%T</td>
<td>type</td>
</tr>
<tr>

<td>width</td>
<td>%W</td>
<td>widget</td>
</tr>
<tr>
<td>%x</td>
<td>x</td>
<td>%X</td>
<td>x_root</td>
</tr>
<tr>
<td>%y</td>
<td>y</td>
<td>%Y</td>
<td>y_root</td>
</tr>
</tbody>
</table>

### 25.1.6.8. The index Parameter

A number of widgets require “index” parameters to be passed. These are used to point at a specific place in a Text widget, or to particular characters in an Entry widget, or to particular menu items in a Menu widget.

Entry widget indexes (index, view index, etc.)
Entry widgets have options that refer to character positions in the text being displayed. You can use these `tkinter` functions to access these special points in text widgets:

**Text widget indexes**

The index notation for Text widgets is very rich and is best described in the Tk man pages.

**Menu indexes** (menu.invoke(), menu.entryconfig(), etc.)

Some options and methods for menus manipulate specific menu entries. Anytime a menu index is needed for an option or a parameter, you may pass in:

- an integer which refers to the numeric position of the entry in the widget, counted from the top, starting with 0;
- the string "active", which refers to the menu position that is currently under the cursor;
- the string "last" which refers to the last menu item;
- An integer preceded by `@`, as in `@6`, where the integer is interpreted as a y pixel coordinate in the menu’s coordinate system;
- the string "none", which indicates no menu entry at all, most often used with menu.activate() to deactivate all entries, and finally,
- a text string that is pattern matched against the label of the menu entry, as scanned from the top of the menu to the bottom. Note that this index type is considered after all the others, which means that matches for menu items labelled `last`, `active`, or `none` may be interpreted as the above literals, instead.

### 25.1.6.9. Images

Bitmap/ Pixelmap images can be created through the subclasses of
tkinter.Image:

- BitmapImage can be used for X11 bitmap data.
- PhotoImage can be used for GIF and PPM/PGM color bitmaps.

Either type of image is created through either the `file` or the `data` option (other options are available as well).

The image object can then be used wherever an `image` option is supported by some widget (e.g. labels, buttons, menus). In these cases, Tk will not keep a reference to the image. When the last Python reference to the image object is deleted, the image data is deleted as well, and Tk will display an empty box wherever the image was used.
25.1.7. File Handlers

Tk allows you to register and unregister a callback function which will be called from the Tk mainloop when I/O is possible on a file descriptor. Only one handler may be registered per file descriptor. Example code:

```python
import tkinter
widget = tkinter.Tk()
mask = tkinter.READABLE | tkinter.WRITABLE
widget.tk.createfilehandler(file, mask, callback)
...
widget.tk.deletefilehandler(file)
```

This feature is not available on Windows.

Since you don’t know how many bytes are available for reading, you may not want to use the `BufferedIOBase` or `TextIOBase read()` or `readline()` methods, since these will insist on reading a predefined number of bytes. For sockets, the `recv()` or `recvfrom()` methods will work fine; for other files, use raw reads or `os.read(file.fileno(), maxbytecount)`.

**Widget.tk.createfilehandler**(file, mask, func)

Registers the file handler callback function `func`. The `file` argument may either be an object with a `fileno()` method (such as a file or socket object), or an integer file descriptor. The `mask` argument is an ORed combination of any of the three constants below. The callback is called as follows:

```python
callback(file, mask)
```
Widget.tk. **deletefilehandler**(file)

Unregisters a file handler.

`tkinter.READABLE`  
`tkinter.WRITABLE`  
`tkinter.EXCEPTION`

Constants used in the `mask` arguments.
25.2. tkinter.ttk — Tk themed widgets

Source code: Lib/tkinter/ttk.py

The tkinter.ttk module provides access to the Tk themed widget set, introduced in Tk 8.5. If Python has not been compiled against Tk 8.5, this module can still be accessed if Tile has been installed. The former method using Tk 8.5 provides additional benefits including anti-aliased font rendering under X11 and window transparency (requiring a composition window manager on X11).

The basic idea for tkinter.ttk is to separate, to the extent possible, the code implementing a widget's behavior from the code implementing its appearance.

Tk Widget Styling Support
A document introducing theming support for Tk
25.2.1. Using Ttk

To start using Ttk, import its module:

```python
from tkinter import ttk
```

To override the basic Tk widgets, the import should follow the Tk import:

```python
from tkinter import *
from tkinter.ttk import *
```

That code causes several `tkinter.ttk` widgets (Button, Checkbutton, Entry, Frame, Label, LabelFrame, Menubutton, PanedWindow, Radiobutton, Scale and Scrollbar) to automatically replace the Tk widgets.

This has the direct benefit of using the new widgets which gives a better look and feel across platforms; however, the replacement widgets are not completely compatible. The main difference is that widget options such as “fg”, “bg” and others related to widget styling are no longer present in Ttk widgets. Instead, use the `ttk.Style` class for improved styling effects.

See also:

**Converting existing applications to use Tile widgets**

A monograph (using Tcl terminology) about differences typically encountered when moving applications to use the new widgets.
25.2.2. Ttk Widgets

Ttk comes with 17 widgets, eleven of which already existed in tkinter: Button, Checkbutton, Entry, Frame, Label, LabelFrame, Menubutton, PanedWindow, Radiobutton, Scale and Scrollbar. The other six are new: Combobox, Notebook, Progressbar, Separator, Sizegrip and Treeview. And all them are subclasses of Widget.

Using the Ttk widgets gives the application an improved look and feel. As discussed above, there are differences in how the styling is coded.

Tk code:

```python
l1 = tkinter.Label(text="Test", fg="black", bg="white")
l2 = tkinter.Label(text="Test", fg="black", bg="white")
```

Ttk code:

```python
style = ttk.Style()
style.configure("BW.TLabel", foreground="black", background="white")
l1 = ttk.Label(text="Test", style="BW.TLabel")
l2 = ttk.Label(text="Test", style="BW.TLabel")
```

For more information about TtkStyling, see the Style class documentation.
25.2.3. Widget

ttk.Widget defines standard options and methods supported by Tk themed widgets and is not supposed to be directly instantiated.

25.2.3.1. Standard Options

All the ttk Widgets accept the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td>Specifies the window class. The class is used when querying the option database for the window’s other options, to determine the default bindtags for the window, and to select the widget’s default layout and style. This option is read-only, and may only be specified when the window is created.</td>
</tr>
<tr>
<td>cursor</td>
<td>Specifies the mouse cursor to be used for the widget. If set to the empty string (the default), the cursor is inherited for the parent widget.</td>
</tr>
<tr>
<td>takefocus</td>
<td>Determines whether the window accepts the focus during keyboard traversal. 0, 1 or an empty string is returned. If 0 is returned, it means that the window should be skipped entirely during keyboard traversal. If 1, it means that the window should receive the input focus as long as it is viewable. And an empty string means that the traversal scripts make the decision about whether or not to focus on the window.</td>
</tr>
<tr>
<td>style</td>
<td>May be used to specify a custom widget style.</td>
</tr>
</tbody>
</table>

25.2.3.2. Scrollable Widget Options
The following options are supported by widgets that are controlled by a scrollbar.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xscrollcommand</td>
<td>Used to communicate with horizontal scrollbars. When the view in the widget's window change, the widget will generate a Tcl command based on the scrollcommand. Usually this option consists of the method Scrollbar.set() of some scrollbar. This will cause the scrollbar to be updated whenever the view in the window changes.</td>
</tr>
<tr>
<td>yscrollcommand</td>
<td>Used to communicate with vertical scrollbars. For some more information, see above.</td>
</tr>
</tbody>
</table>

### 25.2.3.3. Label Options

The following options are supported by labels, buttons and other button-like widgets.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>Specifies a text string to be displayed inside the widget.</td>
</tr>
<tr>
<td>textvariable</td>
<td>Specifies a name whose value will be used in place of the text option resource.</td>
</tr>
<tr>
<td>underline</td>
<td>If set, specifies the index (0-based) of a character to underline in the text string. The underline</td>
</tr>
</tbody>
</table>
Character is used for mnemonic activation.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>image</code></td>
<td>Specifies an image to display. This is a list of 1 or more elements. The first element is the default image name. The rest of the list is a sequence of statespec/value pairs as defined by <code>Style.map()</code>, specifying different images to use when the widget is in a particular state or a combination of states. All images in the list should have the same size.</td>
</tr>
<tr>
<td><code>compound</code></td>
<td>Specifies how to display the image relative to the text, in the case both text and images options are present. Valid values are:</td>
</tr>
<tr>
<td></td>
<td>• text: display text only</td>
</tr>
<tr>
<td></td>
<td>• image: display image only</td>
</tr>
<tr>
<td></td>
<td>• top, bottom, left, right: display image above, below, left of, or right of the text, respectively.</td>
</tr>
<tr>
<td></td>
<td>• none: the default. display the image if present, otherwise the text.</td>
</tr>
<tr>
<td><code>width</code></td>
<td>If greater than zero, specifies how much space, in character widths, to allocate for the text label, if less than zero, specifies a minimum width. If zero or unspecified, the natural width of the text label is used.</td>
</tr>
</tbody>
</table>

### 25.2.3.4. Compatibility Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>state</code></td>
<td>May be set to “normal” or “disabled” to control the “disabled” state bit. This is a write-only option: setting it changes the widget state, but the <code>Widget.state()</code> method does not affect this option.</td>
</tr>
</tbody>
</table>
25.2.3.5. Widget States

The widget state is a bitmap of independent state flags.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>The mouse cursor is over the widget and pressing a mouse button will cause some action to occur</td>
</tr>
<tr>
<td>disabled</td>
<td>Widget is disabled under program control</td>
</tr>
<tr>
<td>focus</td>
<td>Widget has keyboard focus</td>
</tr>
<tr>
<td>pressed</td>
<td>Widget is being pressed</td>
</tr>
<tr>
<td>selected</td>
<td>“On”, “true”, or “current” for things like Checkbuttons and radiobuttons</td>
</tr>
<tr>
<td>background</td>
<td>Windows and Mac have a notion of an “active” or foreground window. The background state is set for widgets in a background window, and cleared for those in the foreground window</td>
</tr>
<tr>
<td>readonly</td>
<td>Widget should not allow user modification</td>
</tr>
<tr>
<td>alternate</td>
<td>A widget-specific alternate display format</td>
</tr>
<tr>
<td>invalid</td>
<td>The widget’s value is invalid</td>
</tr>
</tbody>
</table>

A state specification is a sequence of state names, optionally prefixed with an exclamation point indicating that the bit is off.

25.2.3.6. ttk.Widget

Besides the methods described below, the ttk.Widget supports the methods tkinter.Widget.cget() and tkinter.Widget.configure().
class tkinter.ttk.Widget

identify(x, y)

Returns the name of the element at position $x$ $y$, or the empty string if the point does not lie within any element.

$x$ and $y$ are pixel coordinates relative to the widget.

instate(statespec, callback=None, *args, **kw)

Test the widget's state. If a callback is not specified, returns True if the widget state matches statespec and False otherwise. If callback is specified then it is called with args if widget state matches statespec.

state(statespec=None)

Modify or inquire widget state. If statespec is specified, sets the widget state according to it and return a new statespec indicating which flags were changed. If statespec is not specified, returns the currently-enabled state flags.

statespec will usually be a list or a tuple.
25.2.4. Combobox

The `ttk.Combobox` widget combines a text field with a pop-down list of values. This widget is a subclass of `Entry`.

Besides the methods inherited from `Widget`: `Widget.cget()`, `Widget.configure()`, `Widget.identify()`, `Widget.instate()` and `Widget.state()`, and the following inherited from `Entry`: `Entry.bbox()`, `Entry.delete()`, `Entry.icursor()`, `Entry.index()`, `Entry.insert()`, `Entry.selection()`, `Entry.xview()`, it has some other methods, described at `ttk.Combobox`.

25.2.4.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exportselection</td>
<td>Boolean value. If set, the widget selection is linked to the Window Manager selection (which can be returned by invoking Misc.selection_get, for example).</td>
</tr>
<tr>
<td>justify</td>
<td>Specifies how the text is aligned within the widget. One of “left”, “center”, or “right”.</td>
</tr>
<tr>
<td>height</td>
<td>Specifies the height of the pop-down listbox, in rows.</td>
</tr>
<tr>
<td>postcommand</td>
<td>A script (possibly registered with Misc.register) that is called immediately before displaying the values. It may specify which values to display.</td>
</tr>
</tbody>
</table>
One of “normal”, “readonly”, or “disabled”. In the “readonly” state, the value may not be edited directly, and the user can only selection of the values from the dropdown list. In the “normal” state, the text field is directly editable. In the “disabled” state, no interaction is possible.

textvariable Specifies a name whose value is linked to the widget value. Whenever the value associated with that name changes, the widget value is updated, and vice versa. See tkinter.StringVar.

values Specifies the list of values to display in the drop-down listbox.

width Specifies an integer value indicating the desired width of the entry window, in average-size characters of the widget’s font.

25.2.4.2. Virtual events

The combobox widgets generates a <<ComboboxSelected>> virtual event when the user selects an element from the list of values.

25.2.4.3. ttk.Combobox

class tkinter.ttk.Combobox

    current(newindex=None)

    If newindex is specified, sets the combobox value to the element position newindex. Otherwise, returns the index of the current value or -1 if the current value is not in the values list.

    get()

    Returns the current value of the combobox.
**set**(value)

Sets the value of the combobox to *value*.
25.2.5. Notebook

Ttk Notebook widget manages a collection of windows and displays a single one at a time. Each child window is associated with a tab, which the user may select to change the currently-displayed window.

25.2.5.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>height</td>
<td>If present and greater than zero, specifies the desired height of the pane area (not including internal padding or tabs). Otherwise, the maximum height of all panes is used.</td>
</tr>
<tr>
<td>padding</td>
<td>Specifies the amount of extra space to add around the outside of the notebook. The padding is a list up to four length specifications left top right bottom. If fewer than four elements are specified, bottom defaults to top, right defaults to left, and top defaults to left.</td>
</tr>
<tr>
<td>width</td>
<td>If present and greater than zero, specified the desired width of the pane area (not including internal padding). Otherwise, the maximum width of all panes is used.</td>
</tr>
</tbody>
</table>

25.2.5.2. Tab Options

There are also specific options for tabs:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
state | Either “normal”, “disabled” or “hidden”. If “disabled”, then the tab is not selectable. If “hidden”, then the tab is not shown.

sticky | Specifies how the child window is positioned within the pane area. Value is a string containing zero or more of the characters “n”, “s”, “e” or “w”. Each letter refers to a side (north, south, east or west) that the child window will stick to, as per the grid() geometry manager.

padding | Specifies the amount of extra space to add between the notebook and this pane. Syntax is the same as for the option padding used by this widget.

text | Specifies a text to be displayed in the tab.

image | Specifies an image to display in the tab. See the option image described in Widget.

compound | Specifies how to display the image relative to the text, in the case both options text and image are present. See Label Options for legal values.

underline | Specifies the index (0-based) of a character to underline in the text string. The underlined character is used for mnemonic activation if Notebook.enable_traversal() is called.

25.2.5.3. Tab Identifiers

The tab_id present in several methods of ttk.Notebook may take any of the following forms:

- An integer between zero and the number of tabs
- The name of a child window
- A positional specification of the form “@x,y”, which identifies the tab
- The literal string “current”, which identifies the currently-selected tab
- The literal string “end”, which returns the number of tabs (only valid for `Notebook.index()`)

### 25.2.5.4. Virtual Events

This widget generates a `<NotebookTabChanged>` virtual event after a new tab is selected.

### 25.2.5.5. `ttk.Notebook`

```python
class tkinter.ttk.Notebook

- **add(child, **kw)**
  
  Adds a new tab to the notebook.

  If window is currently managed by the notebook but hidden, it is restored to its previous position.

  See Tab Options for the list of available options.

- **forget(tab_id)**

  Removes the tab specified by `tab_id`, unmaps and unmanages the associated window.

- **hide(tab_id)**

  Hides the tab specified by `tab_id`.

  The tab will not be displayed, but the associated window remains managed by the notebook and its configuration remembered. Hidden tabs may be restored with the `add()` command.
**identify**(*x*, *y*)

Returns the name of the tab element at position *x*, *y*, or the empty string if none.

**index**(*tab_id*)

Returns the numeric index of the tab specified by *tab_id*, or the total number of tabs if *tab_id* is the string “end”.

**insert**(*pos*, *child*, **kw*)

Inserts a pane at the specified position.

*pos* is either the string “end”, an integer index, or the name of a managed child. If *child* is already managed by the notebook, moves it to the specified position.

See [Tab Options](#) for the list of available options.

**select**(*tab_id=None*)

Selects the specified *tab_id*.

The associated child window will be displayed, and the previously-selected window (if different) is unmapped. If *tab_id* is omitted, returns the widget name of the currently selected pane.

**tab**(*tab_id*, *option=None*, **kw*)

Query or modify the options of the specific *tab_id*.

If *kw* is not given, returns a dictionary of the tab option values. If *option* is specified, returns the value of that *option*. Otherwise, sets the options to the corresponding values.

**tabs**()
Returns a list of windows managed by the notebook.

**enable_traversal()**

Enable keyboard traversal for a toplevel window containing this notebook.

This will extend the bindings for the toplevel window containing the notebook as follows:

- **Control-Tab**: selects the tab following the currently selected one.
- **Shift-Control-Tab**: selects the tab preceding the currently selected one.
- **Alt-K**: where $K$ is the mnemonic (underlined) character of any tab, will select that tab.

Multiple notebooks in a single toplevel may be enabled for traversal, including nested notebooks. However, notebook traversal only works properly if all panes have the notebook they are in as master.
25.2.6. Progressbar

The `ttk.Progressbar` widget shows the status of a long-running operation. It can operate in two modes: 1) the determinate mode which shows the amount completed relative to the total amount of work to be done and 2) the indeterminate mode which provides an animated display to let the user know that work is progressing.

25.2.6.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orient</td>
<td>One of “horizontal” or “vertical”. Specifies the orientation of the progress bar.</td>
</tr>
<tr>
<td>length</td>
<td>Specifies the length of the long axis of the progress bar (width if horizontal, height if vertical).</td>
</tr>
<tr>
<td>mode</td>
<td>One of “determinate” or “indeterminate”.</td>
</tr>
<tr>
<td>maximum</td>
<td>A number specifying the maximum value. Defaults to 100.</td>
</tr>
<tr>
<td>value</td>
<td>The current value of the progress bar. In “determinate” mode, this represents the amount of work completed. In “indeterminate” mode, it is interpreted as modulo <code>maximum</code>; that is, the progress bar completes one “cycle” when its value increases by <code>maximum</code>.</td>
</tr>
<tr>
<td>variable</td>
<td>A name which is linked to the option value. If specified, the value of the progress bar is automatically set to the value of this name whenever the latter is modified.</td>
</tr>
<tr>
<td></td>
<td>Read-only option. The widget periodically</td>
</tr>
</tbody>
</table>
phase | increments the value of this option whenever its value is greater than 0 and, in determinate mode, less than maximum. This option may be used by the current theme to provide additional animation effects.

25.2.6.2. ttk.Progressbar

class tkinter.ttk.**Progressbar**

**start**(interval=None)
Begin autoincrement mode: schedules a recurring timer event that calls **Progressbar.step()** every interval milliseconds. If omitted, interval defaults to 50 milliseconds.

**step**(amount=None)
Increments the progress bar’s value by amount.

amount defaults to 1.0 if omitted.

**stop()**
Stop autoincrement mode: cancels any recurring timer event initiated by **Progressbar.start()** for this progress bar.
25.2.7. Separator

The ttk.Separator widget displays a horizontal or vertical separator bar.

It has no other methods besides the ones inherited from ttk.Widget.

25.2.7.1. Options

This widget accepts the following specific option:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orient</td>
<td>One of “horizontal” or “vertical”. Specifies the orientation of the separator.</td>
</tr>
</tbody>
</table>
25.2.8. Sizegrip

The ttk.Sizegrip widget (also known as a grow box) allows the user to resize the containing toplevel window by pressing and dragging the grip.

This widget has neither specific options nor specific methods, besides the ones inherited from ttk.Widget.

25.2.8.1. Platform-specific notes

- On MacOS X, toplevel windows automatically include a built-in size grip by default. Adding a Sizegrip is harmless, since the built-in grip will just mask the widget.

25.2.8.2. Bugs

- If the containing toplevel’s position was specified relative to the right or bottom of the screen (e.g. ....), the Sizegrip widget will not resize the window.
- This widget supports only “southeast” resizing.
25.2.9. Treeview

The `ttk.Treeview` widget displays a hierarchical collection of items. Each item has a textual label, an optional image, and an optional list of data values. The data values are displayed in successive columns after the tree label.

The order in which data values are displayed may be controlled by setting the widget option `displaycolumns`. The tree widget can also display column headings. Columns may be accessed by number or symbolic names listed in the widget option columns. See Column Identifiers.

Each item is identified by a unique name. The widget will generate item IDs if they are not supplied by the caller. There is a distinguished root item, named `{}`. The root item itself is not displayed; its children appear at the top level of the hierarchy.

Each item also has a list of tags, which can be used to associate event bindings with individual items and control the appearance of the item.

The Treeview widget supports horizontal and vertical scrolling, according to the options described in Scrollable Widget Options and the methods `Treeview.xview()` and `Treeview.yview()`.

25.2.9.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns</td>
<td>A list of column identifiers, specifying the number of columns and their names.</td>
</tr>
<tr>
<td><strong>displaycolumns</strong></td>
<td>A list of column identifiers (either symbolic or integer indices) specifying which data columns are displayed and the order in which they appear, or the string “#all”.</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>height</strong></td>
<td>Specifies the number of rows which should be visible. Note: the requested width is determined from the sum of the column widths.</td>
</tr>
<tr>
<td><strong>padding</strong></td>
<td>Specifies the internal padding for the widget. The padding is a list of up to four length specifications.</td>
</tr>
<tr>
<td><strong>selectmode</strong></td>
<td>Controls how the built-in class bindings manage the selection. One of “extended”, “browse” or “none”. If set to “extended” (the default), multiple items may be selected. If “browse”, only a single item will be selected at a time. If “none”, the selection will not be changed. Note that the application code and tag bindings can set the selection however they wish, regardless of the value of this option.</td>
</tr>
<tr>
<td><strong>show</strong></td>
<td>A list containing zero or more of the following values, specifying which elements of the tree to display.</td>
</tr>
<tr>
<td></td>
<td>- tree: display tree labels in column #0.</td>
</tr>
<tr>
<td></td>
<td>- headings: display the heading row.</td>
</tr>
<tr>
<td></td>
<td>The default is “tree headings”, i.e., show all elements.</td>
</tr>
</tbody>
</table>
25.2.9.2. Item Options

The following item options may be specified for items in the insert and item widget commands.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>The textual label to display for the item.</td>
</tr>
<tr>
<td>image</td>
<td>A Tk Image, displayed to the left of the label.</td>
</tr>
<tr>
<td>values</td>
<td>The list of values associated with the item. Each item should have the same number of values as the widget option columns. If there are fewer values than columns, the remaining values are assumed empty. If there are more values than columns, the extra values are ignored.</td>
</tr>
<tr>
<td>open</td>
<td>True/False value indicating whether the item’s children should be displayed or hidden.</td>
</tr>
<tr>
<td>tags</td>
<td>A list of tags associated with this item.</td>
</tr>
</tbody>
</table>

25.2.9.3. Tag Options

The following options may be specified on tags:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreground</td>
<td>Specifies the text foreground color.</td>
</tr>
<tr>
<td>background</td>
<td>Specifies the cell or item background color.</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>font</td>
<td>Specifies the font to use when drawing text.</td>
</tr>
<tr>
<td>image</td>
<td>Specifies the item image, in case the item’s image option is empty.</td>
</tr>
</tbody>
</table>

### 25.2.9.4. Column Identifiers

Column identifiers take any of the following forms:

- A symbolic name from the list of columns option.
- An integer n, specifying the nth data column.
- A string of the form #n, where n is an integer, specifying the nth display column.

**Notes:**

- Item’s option values may be displayed in a different order than the order in which they are stored.
- Column #0 always refers to the tree column, even if show=”tree” is not specified.

A data column number is an index into an item’s option values list; a display column number is the column number in the tree where the values are displayed. Tree labels are displayed in column #0. If option displaycolumns is not set, then data column n is displayed in column #n+1. Again, **column #0 always refers to the tree column**.

### 25.2.9.5. Virtual Events

The Treeview widget generates the following virtual events.

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>&lt;&lt;TreeviewSelect&gt;&gt;</th>
<th>Generated whenever the selection changes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;&lt;TreeviewOpen&gt;&gt;</td>
<td>Generated just before setting the focus item to open=True.</td>
</tr>
<tr>
<td>&lt;&lt;TreeviewClose&gt;&gt;</td>
<td>Generated just after setting the focus item to open=False.</td>
</tr>
</tbody>
</table>

The `Treeview.focus()` and `Treeview.selection()` methods can be used to determine the affected item or items.

25.2.9.6. ttk.Treeview

```python
class tkinter.ttk.Treeview

bbox(item, column=None)
```

Returns the bounding box (relative to the treeview widget’s window) of the specified `item` in the form `(x, y, width, height)`.

If `column` is specified, returns the bounding box of that cell. If the `item` is not visible (i.e., if it is a descendant of a closed item or is scrolled offscreen), returns an empty string.

```python
get_children(item=None)
```

Returns the list of children belonging to `item`.

If `item` is not specified, returns root children.

```python
set_children(item, *newchildren)
```

Replaces `item`’s child with `newchildren`.

Children present in `item` that are not present in `newchildren` are detached from the tree. No items in `newchildren` may be an ancestor of `item`. Note that not specifying `newchildren` results in
detaching item's children.

**column**(*column*, **option=None, **kw*)

Query or modify the options for the specified column.

If **kw** is not given, returns a dict of the column option values. If **option** is specified then the value for that **option** is returned. Otherwise, sets the options to the corresponding values.

The valid options/values are:

- **id**
  Returns the column name. This is a read-only option.

- **anchor**: One of the standard Tk anchor values.
  Specifies how the text in this column should be aligned with respect to the cell.

- **minwidth**: width
  The minimum width of the column in pixels. The treeview widget will not make the column any smaller than specified by this option when the widget is resized or the user drags a column.

- **stretch**: True/False
  Specifies whether the column's width should be adjusted when the widget is resized.

- **width**: width
  The width of the column in pixels.

To configure the tree column, call this with column = “#0”

**delete**( *items*)

Delete all specified items and all their descendants.
The root item may not be deleted.

**detach(**items**)

Unlinks all of the specified items from the tree.

The items and all of their descendants are still present, and may be reinserted at another point in the tree, but will not be displayed.

The root item may not be detached.

**exists(**item**)

Returns True if the specified item is present in the tree.

**focus(**item=None**)

If item is specified, sets the focus item to item. Otherwise, returns the current focus item, or " if there is none.

**heading(**column, option=None, **kw**)

Query or modify the heading options for the specified column.

If kw is not given, returns a dict of the heading option values. If option is specified then the value for that option is returned. Otherwise, sets the options to the corresponding values.

The valid options/values are:

- text: text
  The text to display in the column heading.

- image: imageName
  Specifies an image to display to the right of the column heading.

- anchor: anchor
Specifies how the heading text should be aligned. One of the standard Tk anchor values.

- command: callback
  A callback to be invoked when the heading label is pressed.

To configure the tree column heading, call this with column = “#0”.

**identify**(component, x, y)

Returns a description of the specified component under the point given by x and y, or the empty string if no such component is present at that position.

**identify_row**(y)

Returns the item ID of the item at position y.

**identify_column**(x)

Returns the data column identifier of the cell at position x.

The tree column has ID #0.

**identify_region**(x, y)

Returns one of:

<table>
<thead>
<tr>
<th>region</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>heading</td>
<td>Tree heading area.</td>
</tr>
<tr>
<td>separator</td>
<td>Space between two columns headings.</td>
</tr>
<tr>
<td>tree</td>
<td>The tree area.</td>
</tr>
<tr>
<td>cell</td>
<td>A data cell.</td>
</tr>
</tbody>
</table>

Availability: Tk 8.6.
**identify_element**(x, y)

Returns the element at position x, y.

Availability: Tk 8.6.

**index**(item)

Returns the integer index of item within its parent’s list of children.

**insert**(parent, index, iid=None, **kw)

Creates a new item and returns the item identifier of the newly created item.

parent is the item ID of the parent item, or the empty string to create a new top-level item. index is an integer, or the value “end”, specifying where in the list of parent’s children to insert the new item. If index is less than or equal to zero, the new node is inserted at the beginning; if index is greater than or equal to the current number of children, it is inserted at the end. If iid is specified, it is used as the item identifier; iid must not already exist in the tree. Otherwise, a new unique identifier is generated.

See Item Options for the list of available points.

**item**(item, option=None, **kw)

Query or modify the options for the specified item.

If no options are given, a dict with options/values for the item is returned. If option is specified then the value for that option is returned. Otherwise, sets the options to the corresponding values as given by kw.
**move**(item, parent, index)

Moves item to position index in parent’s list of children.

It is illegal to move an item under one of its descendants. If index is less than or equal to zero, item is moved to the beginning; if greater than or equal to the number of children, it is moved to the end. If item was detached it is reattached.

**next**(item)

Returns the identifier of item’s next sibling, or "" if item is the last child of its parent.

**parent**(item)

Returns the ID of the parent of item, or "" if item is at the top level of the hierarchy.

**prev**(item)

Returns the identifier of item’s previous sibling, or "" if item is the first child of its parent.

**reattach**(item, parent, index)

An alias for Treeview.move().

**see**(item)

Ensure that item is visible.

Sets all of item’s ancestors open option to True, and scrolls the widget if necessary so that item is within the visible portion of the tree.

**selection**(selop=None, items=None)

If selop is not specified, returns selected items. Otherwise, it will act according to the following selection methods.
**selection_set**(*items*)

*items* becomes the new selection.

**selection_add**(*items*)

Add *items* to the selection.

**selection_remove**(*items*)

Remove *items* from the selection.

**selection_toggle**(*items*)

Toggle the selection state of each item in *items*.

**set**(*item, column=None, value=None*)

With one argument, returns a dictionary of column/value pairs for the specified *item*. With two arguments, returns the current value of the specified *column*. With three arguments, sets the value of given *column* in given *item* to the specified *value*.

**tag_bind**(*tagname, sequence=None, callback=None*)

Bind a callback for the given event sequence to the tag *tagname*. When an event is delivered to an item, the callbacks for each of the item’s tags option are called.

**tag_configure**(*tagname, option=None, **kw*)

Query or modify the options for the specified *tagname*.

If *kw* is not given, returns a dict of the option settings for *tagname*. If *option* is specified, returns the value for that *option* for the specified *tagname*. Otherwise, sets the options to the corresponding values for the given *tagname*.

**tag_has**(*tagname, item=None*)

If *item* is specified, returns 1 or 0 depending on whether the
specified item has the given tagname. Otherwise, returns a list of all items that have the specified tag.

Availability: Tk 8.6

**xview**(*args*)
Query or modify horizontal position of the treeview.

**yview**(*args*)
Query or modify vertical position of the treeview.
25.2.10. Ttk Styling

Each widget in ttk is assigned a style, which specifies the set of elements making up the widget and how they are arranged, along with dynamic and default settings for element options. By default the style name is the same as the widget's class name, but it may be overridden by the widget's style option. If you don't know the class name of a widget, use the method Misc.winfo_class() (somewidget.winfo_class()).

See also:

**Tcl'2004 conference presentation**

This document explains how the theme engine works

class ttk.Style

This class is used to manipulate the style database.

**configure(style, query_opt=None, **kw)**

Query or set the default value of the specified option(s) in style.

Each key in kw is an option and each value is a string identifying the value for that option.

For example, to change every default button to be a flat button with some padding and a different background color:

```python
from tkinter import ttk
import tkinter

root = tkinter.Tk()
```
```python
ttk.Style().configure("TButton", padding=6, relief='groove', background="#ccc")
btn = ttk.Button(text="Sample")
btn.pack()
root.mainloop()
```

**map(style, query_opt=None, **kw)**

Query or sets dynamic values of the specified option(s) in style.

Each key in kw is an option and each value should be a list or a tuple (usually) containing statespecs grouped in tuples, lists, or some other preference. A statespec is a compound of one or more states and then a value.

An example may make it more understandable:

```python
import tkinter
from tkinter import ttk

root = tkinter.Tk()

style = ttk.Style()
style.map("C.TButton",
    foreground=[('pressed', 'red'), ('active',)],
    background=[('pressed', '!disabled', 'black')]
)

colored_btn = ttk.Button(text="Test", style="C.

root.mainloop()
```

Note that the order of the (states, value) sequences for an
option does matter, if the order is changed to `[(active, blue), (pressed, red)]` in the foreground option, for example, the result would be a blue foreground when the widget were in active or pressed states.

**lookup(style, option, state=None, default=None)**

Returns the value specified for `option` in `style`.

If `state` is specified, it is expected to be a sequence of one or more states. If the `default` argument is set, it is used as a fallback value in case no specification for `option` is found.

To check what font a Button uses by default:

```python
from tkinter import ttk
print(ttk.Style().lookup("TButton", "font"))
```

**layout(style, layoutspec=None)**

Define the widget layout for given `style`. If `layoutspec` is omitted, return the layout specification for given style.

`layoutspec`, if specified, is expected to be a list or some other sequence type (excluding strings), where each item should be a tuple and the first item is the layout name and the second item should have the format described in Layouts.

To understand the format, see the following example (it is not intended to do anything useful):

```python
from tkinter import ttk
import tkinter

root = tkinter.Tk()
```
```python
style = ttk.Style()
style.layout("TMenubutton", [
    ("Menubutton.background", None),
    ("Menubutton.button", {"children":
        [("Menubutton.focus", {"children":
            [("Menubutton.padding", {"children":
                [("Menubutton.label", {"side": "
            })]
        })]
    })
]),
])

mbtn = ttk.Menubutton(text='Text')
mbtn.pack()
root.mainloop()
```

**element_create**(elementname, etype, *args, **kw)

Create a new element in the current theme, of the given etype which is expected to be either “image”, “from” or “vsapi”. The latter is only available in Tk 8.6a for Windows XP and Vista and is not described here.

If “image” is used, args should contain the default image name followed by statespec/value pairs (this is the imagespec), and kw may have the following options:

- border=padding
  padding is a list of up to four integers, specifying the left, top, right, and bottom borders, respectively.

- height=height
  Specifies a minimum height for the element. If less than zero, the base image's height is used as a default.
- padding=padding
  Specifies the element’s interior padding. Defaults to border’s value if not specified.

- sticky=spec
  Specifies how the image is placed within the final parcel. spec contains zero or more characters “n”, “s”, “w”, or “e”.

- width=width
  Specifies a minimum width for the element. If less than zero, the base image’s width is used as a default.

If “from” is used as the value of etype, element_create() will clone an existing element. args is expected to contain a themename, from which the element will be cloned, and optionally an element to clone from. If this element to clone from is not specified, an empty element will be used. kw is discarded.

**element_names()**
Returns the list of elements defined in the current theme.

**element_options(elementname)**
Returns the list of elementname’s options.

**theme_create(themename, parent=None, settings=None)**
Create a new theme.

It is an error if themename already exists. If parent is specified, the new theme will inherit styles, elements and layouts from the parent theme. If settings are present they are expected to have the same syntax used for theme_settings().
**theme_settings**(themename, settings)

Temporarily sets the current theme to *themename*, apply specified *settings* and then restore the previous theme.

Each key in *settings* is a style and each value may contain the keys ‘configure’, ‘map’, ‘layout’ and ‘element create’ and they are expected to have the same format as specified by the methods `Style.configure()`, `Style.map()`, `Style.layout()` and `Style.element_create()` respectively.

As an example, let's change the Combobox for the default theme a bit:

```python
from tkinter import ttk
import tkinter

root = tkinter.Tk()

style = ttk.Style()
style.theme_settings("default", {
    "TCombobox": {
        "configure": {"padding": 5},
        "map": {
            "background": ["active", "green2"],
            "!disabled": "green4",
            "fieldbackground": ["!disabled", "green3"],
            "foreground": ["focus", "OliveDrab1"],
            "!disabled": "OliveDrab1"
        }
    }
})

combo = ttk.Combobox().pack()
```
```
root.mainloop()
```

**theme_names()**

Returns a list of all known themes.

**theme_use(themename=None)**

If *themename* is not given, returns the theme in use. Otherwise, sets the current theme to *themename*, refreshes all widgets and emits a `<<ThemeChanged>>` event.

### 25.2.10.1. Layouts

A layout can be just `None`, if it takes no options, or a dict of options specifying how to arrange the element. The layout mechanism uses a simplified version of the pack geometry manager: given an initial cavity, each element is allocated a parcel. Valid options/values are:

- **side: whichside**
  
  Specifies which side of the cavity to place the element; one of top, right, bottom or left. If omitted, the element occupies the entire cavity.

- **sticky: nswe**
  
  Specifies where the element is placed inside its allocated parcel.

- **unit: 0 or 1**
  
  If set to 1, causes the element and all of its descendants to be treated as a single element for the purposes of `Widget.identify()` et al. It's used for things like scrollbar thumbs with grips.

- **children: [sublayout... ]**
Specifies a list of elements to place inside the element. Each element is a tuple (or other sequence type) where the first item is the layout name, and the other is a Layout.
25.3. tkinter.tix — Extension widgets for Tk

Source code: Lib/tkinter/tix.py

Deprecated since version 3.6: This Tk extension is unmaintained and should not be used in new code. Use tkinter.ttk instead.

The tkinter.tix (Tk Interface Extension) module provides an additional rich set of widgets. Although the standard Tk library has many useful widgets, they are far from complete. The tkinter.tix library provides most of the commonly needed widgets that are missing from standard Tk: HList, ComboBox, Control (a.k.a. SpinBox) and an assortment of scrollable widgets. tkinter.tix also includes many more widgets that are generally useful in a wide range of applications: NoteBook, FileEntry, PanedWindow, etc; there are more than 40 of them.

With all these new widgets, you can introduce new interaction techniques into applications, creating more useful and more intuitive user interfaces. You can design your application by choosing the most appropriate widgets to match the special needs of your application and users.

**Tix Programming Guide**
On-line version of the programmer’s reference material.

**Tix Development Applications**
Tix applications for development of Tix and Tkinter programs. Tide applications work under Tk or Tkinter, and include **TixInspect**, an inspector to remotely modify and debug Tix/Tk/Tkinter applications.
25.3.1. Using Tix

class tkinter.tix.Tk(screenName=None, baseName=None, className='Tix')

Toplevel widget of Tix which represents mostly the main window of an application. It has an associated Tcl interpreter.

Classes in the tkinter.tix module subclasses the classes in the tkinter. The former imports the latter, so to use tkinter.tix with Tkinter, all you need to do is to import one module. In general, you can just import tkinter.tix, and replace the toplevel call to tkinter.Tk with tix.Tk:

```python
from tkinter import tix
from tkinter.constants import *
root = tix.Tk()
```

To use tkinter.tix, you must have the Tix widgets installed, usually alongside your installation of the Tk widgets. To test your installation, try the following:

```python
from tkinter import tix
root = tix.Tk()
root.tk.eval('package require Tix')
```

If this fails, you have a Tk installation problem which must be resolved before proceeding. Use the environment variable TIX_LIBRARY to point to the installed Tix library directory, and make sure you have the dynamic object library (tix8183.dll or libtix8183.so) in the same directory that contains your Tk dynamic object library (tk8183.dll or libtk8183.so). The directory with the dynamic
object library should also have a file called `pkgIndex.tcl` (case sensitive), which contains the line:

```tcl
package ifneeded Tix 8.1 [list load "[file join $dir tix8183.dll]"
```
25.3.2. Tix Widgets

Tix introduces over 40 widget classes to the tkinter repertoire.

25.3.2.1. Basic Widgets

class tkinter.tix.Balloon
   A Balloon that pops up over a widget to provide help. When the user moves the cursor inside a widget to which a Balloon widget has been bound, a small pop-up window with a descriptive message will be shown on the screen.

class tkinter.tix.ButtonBox
   The ButtonBox widget creates a box of buttons, such as is commonly used for Ok Cancel.

class tkinter.tix.ComboBox
   The ComboBox widget is similar to the combo box control in MS Windows. The user can select a choice by either typing in the entry subwidget or selecting from the listbox subwidget.

class tkinter.tix.Control
   The Control widget is also known as the SpinBox widget. The user can adjust the value by pressing the two arrow buttons or by entering the value directly into the entry. The new value will be checked against the user-defined upper and lower limits.

class tkinter.tix.LabelEntry
   The LabelEntry widget packages an entry widget and a label into one mega widget. It can be used to simplify the creation of “entry-form” type of interface.
class tkinter.tix.LabelFrame

The LabelFrame widget packages a frame widget and a label into one mega widget. To create widgets inside a LabelFrame widget, one creates the new widgets relative to the frame subwidget and manage them inside the frame subwidget.

class tkinter.tix.Meter

The Meter widget can be used to show the progress of a background job which may take a long time to execute.

class tkinter.tix.OptionMenu

The OptionMenu creates a menu button of options.

class tkinter.tix.PopupMenu

The PopupMenu widget can be used as a replacement of the tk_popup command. The advantage of the Tix PopupMenu widget is it requires less application code to manipulate.

class tkinter.tix.Select

The Select widget is a container of button subwidgets. It can be used to provide radio-box or check-box style of selection options for the user.

class tkinter.tix.StdButtonBox

The StdButtonBox widget is a group of standard buttons for Motif-like dialog boxes.

25.3.2.2. File Selectors

class tkinter.tix.DirList

The DirList widget displays a list view of a directory, its previous directories and its sub-directories. The user can choose one of the
directories displayed in the list or change to another directory.

class tkinter.tix.DirTree

The DirTree widget displays a tree view of a directory, its previous directories and its sub-directories. The user can choose one of the directories displayed in the list or change to another directory.

class tkinter.tix.DirSelectDialog

The DirSelectDialog widget presents the directories in the file system in a dialog window. The user can use this dialog window to navigate through the file system to select the desired directory.

class tkinter.tix.DirSelectBox

The DirSelectBox is similar to the standard Motif(TM) directory-selection box. It is generally used for the user to choose a directory. DirSelectBox stores the directories mostly recently selected into a ComboBox widget so that they can be quickly selected again.

class tkinter.tix.ExFileSelectBox

The ExFileSelectBox widget is usually embedded in a tixExFileSelectDialog widget. It provides a convenient method for the user to select files. The style of the ExFileSelectBox widget is very similar to the standard file dialog on MS Windows 3.1.

class tkinter.tix.FileSelectBox

The FileSelectBox is similar to the standard Motif(TM) file-selection box. It is generally used for the user to choose a file. FileSelectBox stores the files mostly recently selected into a ComboBox widget so that they can be quickly selected again.

class tkinter.tix.FileEntry

The FileEntry widget can be used to input a filename. The user can type in the filename manually. Alternatively, the user can press the
button widget that sits next to the entry, which will bring up a file selection dialog.

### 25.3.2.3. Hierarchical ListBox

**class tkinter.tix.HList**

The HList widget can be used to display any data that have a hierarchical structure, for example, file system directory trees. The list entries are indented and connected by branch lines according to their places in the hierarchy.

**class tkinter.tix.CheckList**

The CheckList widget displays a list of items to be selected by the user. CheckList acts similarly to the Tk checkbutton or radiobutton widgets, except it is capable of handling many more items than checkbuttons or radiobuttons.

**class tkinter.tix.Tree**

The Tree widget can be used to display hierarchical data in a tree form. The user can adjust the view of the tree by opening or closing parts of the tree.

### 25.3.2.4. Tabular ListBox

**class tkinter.tix.TList**

The TList widget can be used to display data in a tabular format. The list entries of a TList widget are similar to the entries in the Tk listbox widget. The main differences are (1) the TList widget can display the list entries in a two dimensional format and (2) you can use graphical images as well as multiple colors and fonts for the list entries.
25.3.2.5. Manager Widgets

*class* tkinter.tix.*PanedWindow*

The *PanedWindow* widget allows the user to interactively manipulate the sizes of several panes. The panes can be arranged either vertically or horizontally. The user changes the sizes of the panes by dragging the resize handle between two panes.

*class* tkinter.tix.*ListNoteBook*

The *ListNoteBook* widget is very similar to the TixNoteBook widget: it can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages (windows). At one time only one of these pages can be shown. The user can navigate through these pages by choosing the name of the desired page in the hlist subwidget.

*class* tkinter.tix.*NoteBook*

The *NoteBook* widget can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages. At one time only one of these pages can be shown. The user can navigate through these pages by choosing the visual “tabs” at the top of the NoteBook widget.

25.3.2.6. Image Types

The *tkinter.tix* module adds:

- *pixmap* capabilities to all *tkinter.tix* and *tkinter* widgets to create color images from XPM files.
- *Compound* image types can be used to create images that consists of multiple horizontal lines; each line is composed of a series of items (texts, bitmaps, images or spaces) arranged from
left to right. For example, a compound image can be used to display a bitmap and a text string simultaneously in a Tk Button widget.

25.3.2.7. Miscellaneous Widgets

class tkinter.tix.InputOnly

The InputOnly widgets are to accept inputs from the user, which can be done with the bind command (Unix only).

25.3.2.8. Form Geometry Manager

In addition, tkinter.tix augments tkinter by providing:

class tkinter.tix.Form

The Form geometry manager based on attachment rules for all Tk widgets.
25.3.3. Tix Commands

class tkinter.tix.tixCommand

The tix commands provide access to miscellaneous elements of Tix's internal state and the Tix application context. Most of the information manipulated by these methods pertains to the application as a whole, or to a screen or display, rather than to a particular window.

To view the current settings, the common usage is:

```python
from tkinter import tix
root = tix.Tk()
print(root.tix_configure())
```

tixCommand.tix_configure(cnf=None, **kw)

Query or modify the configuration options of the Tix application context. If no option is specified, returns a dictionary all of the available options. If option is specified with no value, then the method returns a list describing the one named option (this list will be identical to the corresponding sublist of the value returned if no option is specified). If one or more option-value pairs are specified, then the method modifies the given option(s) to have the given value(s); in this case the method returns an empty string. Option may be any of the configuration options.

tixCommand.tix_cget(option)

Returns the current value of the configuration option given by option. Option may be any of the configuration options.

tixCommand.tix_getbitmap(name)

Locates a bitmap file of the name name.xpm or name in one of the
bitmap directories (see the `tix_addbitmapdir()` method). By using `tix_getbitmap()`, you can avoid hard coding the pathnames of the bitmap files in your application. When successful, it returns the complete pathname of the bitmap file, prefixed with the character `@`. The returned value can be used to configure the `bitmap` option of the Tk and Tix widgets.

**tixCommand.** `tix_addbitmapdir(directory)`

Tix maintains a list of directories under which the `tix_getimage()` and `tix_getbitmap()` methods will search for image files. The standard bitmap directory is `$TIX_LIBRARY/bitmaps`. The `tix_addbitmapdir()` method adds `directory` into this list. By using this method, the image files of an application can also be located using the `tix_getimage()` or `tix_getbitmap()` method.

**tixCommand.** `tix_filedialog([dlgclass])`

Returns the file selection dialog that may be shared among different calls from this application. This method will create a file selection dialog widget when it is called the first time. This dialog will be returned by all subsequent calls to `tix_filedialog()`. An optional `dlgclass` parameter can be passed as a string to specify what type of file selection dialog widget is desired. Possible options are `tix`, `FileSelectDialog` or `tixExFileSelectDialog`.

**tixCommand.** `tix_getimage(self, name)`

Locates an image file of the name `name.xpm`, `name.xbm` or `name.ppm` in one of the bitmap directories (see the `tix_addbitmapdir()` method above). If more than one file with the same name (but different extensions) exist, then the image type
is chosen according to the depth of the X display: xbm images are chosen on monochrome displays and color images are chosen on color displays. By using `tix_getimage()`, you can avoid hard coding the pathnames of the image files in your application. When successful, this method returns the name of the newly created image, which can be used to configure the `image` option of the Tk and Tix widgets.

```
tixCommand.tix_option_get(name)
```

Gets the options maintained by the Tix scheme mechanism.

```
tixCommand.tix_resetoptions(newScheme, newFontSet[, newScmPrio])
```

Resets the scheme and fontset of the Tix application to `newScheme` and `newFontSet`, respectively. This affects only those widgets created after this call. Therefore, it is best to call the `resetoptions` method before the creation of any widgets in a Tix application.

The optional parameter `newScmPrio` can be given to reset the priority level of the Tk options set by the Tix schemes.

Because of the way Tk handles the X option database, after Tix has been has imported and inited, it is not possible to reset the color schemes and font sets using the `tix_config()` method. Instead, the `tix_resetoptions()` method must be used.
25.4. `tkinter.scrolledtext` — Scrolled Text Widget

Source code: `Lib/tkinter/scrolledtext.py`

The `tkinter.scrolledtext` module provides a class of the same name which implements a basic text widget which has a vertical scrollbar configured to do the “right thing.” Using the `ScrolledText` class is a lot easier than setting up a text widget and scrollbar directly. The constructor is the same as that of the `tkinter.Text` class.

The text widget and scrollbar are packed together in a `Frame`, and the methods of the `Grid` and `Pack` geometry managers are acquired from the `Frame` object. This allows the `ScrolledText` widget to be used directly to achieve most normal geometry management behavior.

Should more specific control be necessary, the following attributes are available:

`ScrolledText.frame`

The frame which surrounds the text and scroll bar widgets.

`ScrolledText.vbar`

The scroll bar widget.
Created using Sphinx 1.6.3.
25.5. IDLE

**Source code:** Lib/idlelib/

IDLE is Python's Integrated Development and Learning Environment.

IDLE has the following features:

- coded in 100% pure Python, using the **tkinter** GUI toolkit
- cross-platform: works mostly the same on Windows, Unix, and Mac OS X
- Python shell window (interactive interpreter) with colorizing of code input, output, and error messages
- multi-window text editor with multiple undo, Python colorizing, smart indent, call tips, auto completion, and other features
- search within any window, replace within editor windows, and search through multiple files (grep)
- debugger with persistent breakpoints, stepping, and viewing of global and local namespaces
- configuration, browsers, and other dialogs
25.5.1. Menus

IDLE has two main window types, the Shell window and the Editor window. It is possible to have multiple editor windows simultaneously. Output windows, such as used for Edit / Find in Files, are a subtype of edit window. They currently have the same top menu as Editor windows but a different default title and context menu.

IDLE’s menus dynamically change based on which window is currently selected. Each menu documented below indicates which window type it is associated with.

25.5.1.1. File menu (Shell and Editor)

New File
    Create a new file editing window.

Open…
    Open an existing file with an Open dialog.

Recent Files
    Open a list of recent files. Click one to open it.

Open Module…
    Open an existing module (searches sys.path).

Class Browser
    Show functions, classes, and methods in the current Editor file in a tree structure. In the shell, open a module first.

Path Browser
    Show sys.path directories, modules, functions, classes and methods in a tree structure.

Save
    Save the current window to the associated file, if there is one.
Windows that have been changed since being opened or last saved have a * before and after the window title. If there is no associated file, do Save As instead.

Save As…
Save the current window with a Save As dialog. The file saved becomes the new associated file for the window.

Save Copy As…
Save the current window to different file without changing the associated file.

Print Window
Print the current window to the default printer.

Close
Close the current window (ask to save if unsaved).

Exit
Close all windows and quit IDLE (ask to save unsaved windows).

25.5.1.2. Edit menu (Shell and Editor)

Undo
Undo the last change to the current window. A maximum of 1000 changes may be undone.

Redo
Redo the last undone change to the current window.

Cut
Copy selection into the system-wide clipboard; then delete the selection.

Copy
Copy selection into the system-wide clipboard.

Paste
Insert contents of the system-wide clipboard into the current
The clipboard functions are also available in context menus.

Select All
Select the entire contents of the current window.

Find…
Open a search dialog with many options

Find Again
Repeat the last search, if there is one.

Find Selection
Search for the currently selected string, if there is one.

Find in Files…
Open a file search dialog. Put results in a new output window.

Replace…
Open a search-and-replace dialog.

Go to Line
Move cursor to the line number requested and make that line visible.

Show Completions
Open a scrollable list allowing selection of keywords and attributes. See Completions in the Tips sections below.

Expand Word
Expand a prefix you have typed to match a full word in the same window; repeat to get a different expansion.

Show call tip
After an unclosed parenthesis for a function, open a small window with function parameter hints.

Show surrounding parens
Highlight the surrounding parenthesis.
25.5.1.3. Format menu (Editor window only)

Indent Region
Shift selected lines right by the indent width (default 4 spaces).

Dedent Region
Shift selected lines left by the indent width (default 4 spaces).

Comment Out Region
Insert ## in front of selected lines.

Uncomment Region
Remove leading # or ## from selected lines.

Tabify Region
Turn leading stretches of spaces into tabs. (Note: We recommend using 4 space blocks to indent Python code.)

Untabify Region
Turn all tabs into the correct number of spaces.

Toggle Tabs
Open a dialog to switch between indenting with spaces and tabs.

New Indent Width
Open a dialog to change indent width. The accepted default by the Python community is 4 spaces.

Format Paragraph
Reformat the current blank-line-delimited paragraph in comment block or multiline string or selected line in a string. All lines in the paragraph will be formatted to less than N columns, where N defaults to 72.

Strip trailing whitespace
Remove trailing space and other whitespace characters after the last non-whitespace character of a line by applying str.rstrip to each line, including lines within multiline strings.
25.5.1.4. Run menu (Editor window only)

Python Shell
- Open or wake up the Python Shell window.

Check Module
- Check the syntax of the module currently open in the Editor window. If the module has not been saved IDLE will either prompt the user to save or autosave, as selected in the General tab of the Idle Settings dialog. If there is a syntax error, the approximate location is indicated in the Editor window.

Run Module
- Do Check Module (above). If no error, restart the shell to clean the environment, then execute the module. Output is displayed in the Shell window. Note that output requires use of `print` or `write`. When execution is complete, the Shell retains focus and displays a prompt. At this point, one may interactively explore the result of execution. This is similar to executing a file with `python -i file` at a command line.

25.5.1.5. Shell menu (Shell window only)

View Last Restart
- Scroll the shell window to the last Shell restart.

Restart Shell
- Restart the shell to clean the environment.

Interrupt Execution
- Stop a running program.

25.5.1.6. Debug menu (Shell window only)

Go to File/Line
Look on the current line, with the cursor, and the line above for a filename and line number. If found, open the file if not already open, and show the line. Use this to view source lines referenced in an exception traceback and lines found by Find in Files. Also available in the context menu of the Shell window and Output windows.

Debugger (toggle)
When activated, code entered in the Shell or run from an Editor will run under the debugger. In the Editor, breakpoints can be set with the context menu. This feature is still incomplete and somewhat experimental.

Stack Viewer
Show the stack traceback of the last exception in a tree widget, with access to locals and globals.

Auto-open Stack Viewer
Toggle automatically opening the stack viewer on an unhandled exception.

25.5.1.7. Options menu (Shell and Editor)

Configure IDLE
Open a configuration dialog and change preferences for the following: fonts, indentation, keybindings, text color themes, startup windows and size, additional help sources, and extensions (see below). On OS X, open the configuration dialog by selecting Preferences in the application menu. To use a new built-in color theme (IDLE Dark) with older IDLEs, save it as a new custom theme.

Non-default user settings are saved in a .idlerc directory in the user’s home directory. Problems caused by bad user configuration files are solved by editing or deleting one or more of the files in
Code Context (toggle)(Editor Window only)
    Open a pane at the top of the edit window which shows the block context of the code which has scrolled above the top of the window.

25.5.1.8. Window menu (Shell and Editor)

Zoom Height
    Toggles the window between normal size and maximum height. The initial size defaults to 40 lines by 80 chars unless changed on the General tab of the Configure IDLE dialog.

The rest of this menu lists the names of all open windows; select one to bring it to the foreground (deiconifying it if necessary).

25.5.1.9. Help menu (Shell and Editor)

About IDLE
    Display version, copyright, license, credits, and more.

IDLE Help
    Display a help file for IDLE detailing the menu options, basic editing and navigation, and other tips.

Python Docs
    Access local Python documentation, if installed, or start a web browser and open docs.python.org showing the latest Python documentation.

Turtle Demo
    Run the turtledemo module with example python code and turtle drawings.

Additional help sources may be added here with the Configure IDLE
dialog under the General tab.

25.5.1.10. Context Menus

Open a context menu by right-clicking in a window (Control-click on OS X). Context menus have the standard clipboard functions also on the Edit menu.

Cut
   Copy selection into the system-wide clipboard; then delete the selection.

Copy
   Copy selection into the system-wide clipboard.

Paste
   Insert contents of the system-wide clipboard into the current window.

Editor windows also have breakpoint functions. Lines with a breakpoint set are specially marked. Breakpoints only have an effect when running under the debugger. Breakpoints for a file are saved in the user’s .idlerc directory.

Set Breakpoint
   Set a breakpoint on the current line.

Clear Breakpoint
   Clear the breakpoint on that line.

Shell and Output windows have the following.

Go to file/line
   Same as in Debug menu.
25.5.2. Editing and navigation

In this section, ‘C’ refers to the Control key on Windows and Unix and the Command key on Mac OS X.

- **Backspace** deletes to the left; **Del** deletes to the right
- **C-Backspace** delete word left; **C-Del** delete word to the right
- Arrow keys and **Page Up/Page Down** to move around
- **C-LeftArrow** and **C-RightArrow** moves by words
- **Home/End** go to begin/end of line
- **C-Home/C-End** go to begin/end of file
- Some useful Emacs bindings are inherited from Tcl/Tk:
  - **C-a** beginning of line
  - **C-e** end of line
  - **C-k** kill line (but doesn’t put it in clipboard)
  - **C-l** center window around the insertion point
  - **C-b** go backward one character without deleting (usually you can also use the cursor key for this)
  - **C-f** go forward one character without deleting (usually you can also use the cursor key for this)
  - **C-p** go up one line (usually you can also use the cursor key for this)
  - **C-d** delete next character

Standard keybindings (like **C-c** to copy and **C-v** to paste) may work. Keybindings are selected in the Configure IDLE dialog.
25.5.2.1. Automatic indentation

After a block-opening statement, the next line is indented by 4 spaces (in the Python Shell window by one tab). After certain keywords (break, return etc.) the next line is dedented. In leading indentation, Backspace deletes up to 4 spaces if they are there. Tab inserts spaces (in the Python Shell window one tab), number depends on Indent width. Currently, tabs are restricted to four spaces due to Tcl/Tk limitations.

See also the indent/dedent region commands in the edit menu.

25.5.2.2. Completions

Completions are supplied for functions, classes, and attributes of classes, both built-in and user-defined. Completions are also provided for filenames.

The AutoCompleteWindow (ACW) will open after a predefined delay (default is two seconds) after a ‘.’ or (in a string) an os.sep is typed. If after one of those characters (plus zero or more other characters) a tab is typed the ACW will open immediately if a possible continuation is found.

If there is only one possible completion for the characters entered, a Tab will supply that completion without opening the ACW.

‘Show Completions’ will force open a completions window, by default the C-space will open a completions window. In an empty string, this will contain the files in the current directory. On a blank line, it will contain the built-in and user-defined functions and classes in the current namespaces, plus any modules imported. If some characters
have been entered, the ACW will attempt to be more specific.

If a string of characters is typed, the ACW selection will jump to the entry most closely matching those characters. Entering a tab will cause the longest non-ambiguous match to be entered in the Editor window or Shell. Two tab in a row will supply the current ACW selection, as will return or a double click. Cursor keys, Page Up/Down, mouse selection, and the scroll wheel all operate on the ACW.

“Hidden” attributes can be accessed by typing the beginning of hidden name after a ‘.’, e.g. ‘_’. This allows access to modules with __all__ set, or to class-private attributes.

Completions and the ‘Expand Word’ facility can save a lot of typing!

Completions are currently limited to those in the namespaces. Names in an Editor window which are not via __main__ and sys.modules will not be found. Run the module once with your imports to correct this situation. Note that IDLE itself places quite a few modules in sys.modules, so much can be found by default, e.g. the re module.

If you don’t like the ACW popping up unbidden, simply make the delay longer or disable the extension.

25.5.2.3. Calltips

A calltip is shown when one types ( after the name of an accessible function. A name expression may include dots and subscripts. A calltip remains until it is clicked, the cursor is moved out of the argument area, or ) is typed. When the cursor is in the argument part of a definition, the menu or shortcut display a calltip.

A calltip consists of the function signature and the first line of the
docstring. For builtins without an accessible signature, the calltip consists of all lines up the fifth line or the first blank line. These details may change.

The set of accessible functions depends on what modules have been imported into the user process, including those imported by Idle itself, and what definitions have been run, all since the last restart.

For example, restart the Shell and enter `itertools.count()`. A calltip appears because Idle imports itertools into the user process for its own use. (This could change.) Enter `turtle.write()` and nothing appears. Idle does not import turtle. The menu or shortcut do nothing either. Enter `import turtle` and then `turtle.write()` will work.

In an editor, import statements have no effect until one runs the file. One might want to run a file after writing the import statements at the top, or immediately run an existing file before editing.

25.5.2.4. Python Shell window

- **C-c** interrupts executing command

- **C-d** sends end-of-file; closes window if typed at a `>>>` prompt

- **Alt-/** (Expand word) is also useful to reduce typing

Command history

- **Alt-p** retrieves previous command matching what you have typed. On OS X use **C-p**.
- **Alt-n** retrieves next. On OS X use **C-n**.
- **Return** while on any previous command retrieves that command
25.5.2.5. Text colors

Idle defaults to black on white text, but colors text with special meanings. For the shell, these are shell output, shell error, user output, and user error. For Python code, at the shell prompt or in an editor, these are keywords, built-in class and function names, names following `class` and `def`, strings, and comments. For any text window, these are the cursor (when present), found text (when possible), and selected text.

Text coloring is done in the background, so uncolorized text is occasionally visible. To change the color scheme, use the Configure IDLE dialog Highlighting tab. The marking of debugger breakpoint lines in the editor and text in popups and dialogs is not user-configurable.
25.5.3. Startup and code execution

Upon startup with the `-s` option, IDLE will execute the file referenced by the environment variables IDLESTARTUP or PYTHONSTARTUP. IDLE first checks for IDLESTARTUP; if IDLESTARTUP is present the file referenced is run. If IDLESTARTUP is not present, IDLE checks for PYTHONSTARTUP. Files referenced by these environment variables are convenient places to store functions that are used frequently from the IDLE shell, or for executing import statements to import common modules.

In addition, Tk also loads a startup file if it is present. Note that the Tk file is loaded unconditionally. This additional file is `.Idle.py` and is looked for in the user’s home directory. Statements in this file will be executed in the Tk namespace, so this file is not useful for importing functions to be used from IDLE’s Python shell.

25.5.3.1. Command line usage

```
idle.py [-c command] [-d] [-e] [-h] [-i] [-r file] [arg ...]
```

- `-c command` run command in the shell window
- `-d` enable debugger and open shell window
- `-e` open editor window
- `-h` print help message with legal combinations
- `-i` open shell window
- `-r file` run file in shell window
- `-s` run `$IDLESTARTUP` or `$PYTHONSTARTUP` first
- `-t title` set title of shell window
- `-` run stdin in shell (`-` must be last option)
If there are arguments:

- If `-`, `-c`, or `-r` is used, all arguments are placed in `sys.argv[1:]` and `sys.argv[0]` is set to '', `-c`, or `-r`. No editor window is opened, even if that is the default set in the Options dialog.
- Otherwise, arguments are files opened for editing and `sys.argv` reflects the arguments passed to IDLE itself.

25.5.3.2. Startup failure

IDLE uses a socket to communicate between the IDLE GUI process and the user code execution process. A connection must be established whenever the Shell starts or restarts. (The latter is indicated by a divider line that says ‘RESTART’). If the user process fails to connect to the GUI process, it displays a Tk error box with a ‘cannot connect’ message that directs the user here. It then exits.

A common cause of failure is a user-written file with the same name as a standard library module, such as `random.py` and `tkinter.py`. When such a file is located in the same directory as a file that is about to be run, IDLE cannot import the stdlib file. The current fix is to rename the user file.

Though less common than in the past, an antivirus or firewall program may stop the connection. If the program cannot be taught to allow the connection, then it must be turned off for IDLE to work. It is safe to allow this internal connection because no data is visible on external ports. A similar problem is a network mis-configuration that blocks connections.

Python installation issues occasionally stop IDLE: multiple versions can clash, or a single installation might need admin access. If one
undo the clash, or cannot or does not want to run as admin, it might be easiest to completely remove Python and start over.

A zombie pythonw.exe process could be a problem. On Windows, use Task Manager to detect and stop one. Sometimes a restart initiated by a program crash or Keyboard Interrupt (control-C) may fail to connect. Dismissing the error box or Restart Shell on the Shell menu may fix a temporary problem.

When IDLE first starts, it attempts to read user configuration files in ~/.idlerc/ (~ is one's home directory). If there is a problem, an error message should be displayed. Leaving aside random disk glitches, this can be prevented by never editing the files by hand, using the configuration dialog, under Options, instead Options. Once it happens, the solution may be to delete one or more of the configuration files.

If IDLE quits with no message, and it was not started from a console, try starting from a console (python -m idlelib) and see if a message appears.

25.5.3.3. IDLE-console differences

With rare exceptions, the result of executing Python code with IDLE is intended to be the same as executing the same code in a console window. However, the different interface and operation occasionally affect visible results. For instance, sys.modules starts with more entries.

IDLE also replaces sys.stdin, sys.stdout, and sys.stderr with objects that get input from and send output to the Shell window. When Shell has the focus, it controls the keyboard and screen. This is normally transparent, but functions that directly access the keyboard
and screen will not work. If `sys` is reset with `importlib.reload(sys)`, IDLE’s changes are lost and things like `input`, `raw_input`, and `print` will not work correctly.

With IDLE’s Shell, one enters, edits, and recalls complete statements. Some consoles only work with a single physical line at a time. IDLE uses `exec` to run each statement. As a result, `['__builtins__']` is always defined for each statement.

25.5.3.4. Developing tkinter applications

IDLE is intentionally different from standard Python in order to facilitate development of tkinter programs. Enter `import tkinter as tk; root = tk.Tk()` in standard Python and nothing appears. Enter the same in IDLE and a tk window appears. In standard Python, one must also enter `root.update()` to see the window. IDLE does the equivalent in the background, about 20 times a second, which is about every 50 milliseconds. Next enter `b = tk.Button(root, text='button'); b.pack()`. Again, nothing visibly changes in standard Python until one enters `root.update()`.

Most tkinter programs run `root.mainloop()`, which usually does not return until the tk app is destroyed. If the program is run with `python -i` or from an IDLE editor, a `>>>` shell prompt does not appear until `mainloop()` returns, at which time there is nothing left to interact with.

When running a tkinter program from an IDLE editor, one can comment out the mainloop call. One then gets a shell prompt immediately and can interact with the live application. One just has to remember to re-enable the mainloop call when running in standard
Python.

25.5.3.5. Running without a subprocess

By default, IDLE executes user code in a separate subprocess via a socket, which uses the internal loopback interface. This connection is not externally visible and no data is sent to or received from the Internet. If firewall software complains anyway, you can ignore it.

If the attempt to make the socket connection fails, Idle will notify you. Such failures are sometimes transient, but if persistent, the problem may be either a firewall blocking the connection or misconfiguration of a particular system. Until the problem is fixed, one can run Idle with the -n command line switch.

If IDLE is started with the -n command line switch it will run in a single process and will not create the subprocess which runs the RPC Python execution server. This can be useful if Python cannot create the subprocess or the RPC socket interface on your platform. However, in this mode user code is not isolated from IDLE itself. Also, the environment is not restarted when Run/Run Module (F5) is selected. If your code has been modified, you must reload() the affected modules and re-import any specific items (e.g. from foo import baz) if the changes are to take effect. For these reasons, it is preferable to run IDLE with the default subprocess if at all possible.

*Deprecated since version 3.4.*
25.5.4. Help and preferences

25.5.4.1. Additional help sources

IDLE includes a help menu entry called “Python Docs” that will open the extensive sources of help, including tutorials, available at docs.python.org. Selected URLs can be added or removed from the help menu at any time using the Configure IDLE dialog. See the IDLE help option in the help menu of IDLE for more information.

25.5.4.2. Setting preferences

The font preferences, highlighting, keys, and general preferences can be changed via Configure IDLE on the Option menu. Keys can be user defined; IDLE ships with four built-in key sets. In addition, a user can create a custom key set in the Configure IDLE dialog under the keys tab.

25.5.4.3. Extensions

IDLE contains an extension facility. Preferences for extensions can be changed with the Extensions tab of the preferences dialog. See the beginning of config-extensions.def in the idlelib directory for further information. The only current default extension is zzdummy, an example also used for testing.
25.6. Other Graphical User Interface Packages

Major cross-platform (Windows, Mac OS X, Unix-like) GUI toolkits are available for Python:

See also:

**PyGObject**
PyGObject provides introspection bindings for C libraries using GObject. One of these libraries is the GTK+ 3 widget set. GTK+ comes with many more widgets than Tkinter provides. An online Python GTK+ 3 Tutorial is available.

**PyGTK**
PyGTK provides bindings for an older version of the library, GTK+ 2. It provides an object oriented interface that is slightly higher level than the C one. There are also bindings to GNOME. An online tutorial is available.

**PyQt**
PyQt is a sip-wrapped binding to the Qt toolkit. Qt is an extensive C++ GUI application development framework that is available for Unix, Windows and Mac OS X. sip is a tool for generating bindings for C++ libraries as Python classes, and is specifically designed for Python.

**PySide**
PySide is a newer binding to the Qt toolkit, provided by Nokia. Compared to PyQt, its licensing scheme is friendlier to non-open source applications.

**wxPython**
wxPython is a cross-platform GUI toolkit for Python that is built
around the popular **wxWidgets** (formerly wxWindows) C++ toolkit. It provides a native look and feel for applications on Windows, Mac OS X, and Unix systems by using each platform’s native widgets where ever possible, (GTK+ on Unix-like systems). In addition to an extensive set of widgets, wxPython provides classes for online documentation and context sensitive help, printing, HTML viewing, low-level device context drawing, drag and drop, system clipboard access, an XML-based resource format and more, including an ever growing library of user-contributed modules.

PyGTK, PyQt, and wxPython, all have a modern look and feel and more widgets than Tkinter. In addition, there are many other GUI toolkits for Python, both cross-platform, and platform-specific. See the **GUI Programming** page in the Python Wiki for a much more complete list, and also for links to documents where the different GUI toolkits are compared.
26. Development Tools

The modules described in this chapter help you write software. For example, the `pydoc` module takes a module and generates documentation based on the module's contents. The `doctest` and `unittest` modules contains frameworks for writing unit tests that automatically exercise code and verify that the expected output is produced. `2to3` can translate Python 2.x source code into valid Python 3.x code.

The list of modules described in this chapter is:

- **26.1. typing — Support for type hints**
  - 26.1.1. Type aliases
  - 26.1.2. NewType
  - 26.1.3. Callable
  - 26.1.4. Generics
  - 26.1.5. User-defined generic types
  - 26.1.6. The Any type
  - 26.1.7. Classes, functions, and decorators
- **26.2. pydoc — Documentation generator and online help system**
- **26.3. doctest — Test interactive Python examples**
  - 26.3.1. Simple Usage: Checking Examples in Docstrings
  - 26.3.2. Simple Usage: Checking Examples in a Text File
  - 26.3.3. How It Works
    - 26.3.3.1. Which Docstrings Are Examined?
    - 26.3.3.2. How are Docstring Examples Recognized?
    - 26.3.3.3. What’s the Execution Context?
    - 26.3.3.4. What About Exceptions?
    - 26.3.3.5. Option Flags
    - 26.3.3.6. Directives
    - 26.3.3.7. Warnings
• 26.3.4. Basic API
• 26.3.5. Unittest API
• 26.3.6. Advanced API
  ■ 26.3.6.1. DocTest Objects
  ■ 26.3.6.2. Example Objects
  ■ 26.3.6.3. DocTestFinder objects
  ■ 26.3.6.4. DocTestParser objects
  ■ 26.3.6.5. DocTestRunner objects
  ■ 26.3.6.6. OutputChecker objects

26.1. **typing** — Support for type hints

*New in version 3.5.*

**Source code:** Lib/typing.py

**Note:** The typing module has been included in the standard library on a **provisional basis**. New features might be added and API may change even between minor releases if deemed necessary by the core developers.

This module supports type hints as specified by **PEP 484** and **PEP 526**. The most fundamental support consists of the types **Any**, **Union**, **Tuple**, **Callable**, **TypeVar**, and **Generic**. For full specification please see **PEP 484**. For a simplified introduction to type hints see **PEP 483**.

The function below takes and returns a string and is annotated as follows:

```python
def greeting(name: str) -> str:
    return 'Hello ' + name
```

In the function `greeting`, the argument `name` is expected to be of type **str** and the return type **str**. Subtypes are accepted as arguments.
26.1.1. Type aliases

A type alias is defined by assigning the type to the alias. In this example, `Vector` and `List[float]` will be treated as interchangeable synonyms:

```python
from typing import List
Vector = List[float]

def scale(scalar: float, vector: Vector) -> Vector:
    return [scalar * num for num in vector]

# typechecks; a list of floats qualifies as a Vector
new_vector = scale(2.0, [1.0, -4.2, 5.4])
```

Type aliases are useful for simplifying complex type signatures. For example:

```python
from typing import Dict, Tuple, List

ConnectionOptions = Dict[str, str]
Address = Tuple[str, int]
Server = Tuple[Address, ConnectionOptions]

def broadcast_message(message: str, servers: List[Server])
    ...

# The static type checker will treat the previous type signature as being exactly equivalent to this one.

def broadcast_message(message: str,
    servers: List[Tuple[Tuple[str, int], Dict[str, str]]])
    ...
```
Note that `None` as a type hint is a special case and is replaced by `type(None)`.
26.1.2. NewType

Use the `NewType()` helper function to create distinct types:

```python
from typing import NewType

UserId = NewType('UserId', int)
some_id = UserId(52431)
```

The static type checker will treat the new type as if it were a subclass of the original type. This is useful in helping catch logical errors:

```python
def get_user_name(user_id: UserId) -> str:
    ...

# typechecks
user_a = get_user_name(UserId(42351))

# does not typecheck; an int is not a UserId
user_b = get_user_name(-1)
```

You may still perform all `int` operations on a variable of type `UserId`, but the result will always be of type `int`. This lets you pass in a `UserId` wherever an `int` might be expected, but will prevent you from accidentally creating a `UserId` in an invalid way:

```python
# 'output' is of type 'int', not 'UserId'
output = UserId(23143) + UserId(5431)
```

Note that these checks are enforced only by the static type checker. At runtime the statement `Derived = NewType('Derived', Base)` will make `Derived` a function that immediately returns whatever parameter you pass it. That means the expression
Derived(some_value) does not create a new class or introduce any overhead beyond that of a regular function call.

More precisely, the expression some_value is Derived(some_value) is always true at runtime.

This also means that it is not possible to create a subtype of Derived since it is an identity function at runtime, not an actual type. Similarly, it is not possible to create another NewType() based on a Derived type:

```python
from typing import NewType

UserId = NewType('UserId', int)

# Fails at runtime and does not typecheck
class AdminUserId(UserId): pass

# Also does not typecheck
ProUserId = NewType('ProUserId', UserId)
```

See PEP 484 for more details.

**Note:** Recall that the use of a type alias declares two types to be *equivalent* to one another. Doing Alias = Original will make the static type checker treat Alias as being *exactly equivalent* to Original in all cases. This is useful when you want to simplify complex type signatures.

In contrast, NewType declares one type to be a *subtype* of another. Doing Derived = NewType('Derived', Original) will make the static type checker treat Derived as a *subclass* of Original, which means a value of type Original cannot be used in places
where a value of type Derived is expected. This is useful when you want to prevent logic errors with minimal runtime cost.
26.1.3. Callable

Frameworks expecting callback functions of specific signatures might be type hinted using `Callable[[Arg1Type, Arg2Type], ReturnType]`.

For example:

```python
from typing import Callable

def feeder(get_next_item: Callable[[], str]) -> None:
    # Body

def async_query(on_success: Callable[[int], None],
                 on_error: Callable[[int, Exception],
                                   None],
    # Body
```

It is possible to declare the return type of a callable without specifying the call signature by substituting a literal ellipsis for the list of arguments in the type hint: `Callable[... , ReturnType]`. 
26.1.4. Generics

Since type information about objects kept in containers cannot be statically inferred in a generic way, abstract base classes have been extended to support subscription to denote expected types for container elements.

```python
from typing import Mapping, Sequence

def notify_by_email(employees: Sequence[Employee], overrides: Mapping[str, str]) ->
```

Generics can be parametrized by using a new factory available in typing called `TypeVar`.

```python
from typing import Sequence, TypeVar

T = TypeVar('T')  # Declare type variable

def first(l: Sequence[T]) -> T:  # Generic function
    return l[0]
```
26.1.5. User-defined generic types

A user-defined class can be defined as a generic class.

```python
from typing import TypeVar, Generic
from logging import Logger

T = TypeVar('T')

class LoggedVar(Generic[T]):
    def __init__(self, value: T, name: str, logger: Logger):
        self.name = name
        self.logger = logger
        self.value = value

    def set(self, new: T) -> None:
        self.log('Set ' + repr(self.value))
        self.value = new

    def get(self) -> T:
        self.log('Get ' + repr(self.value))
        return self.value

    def log(self, message: str) -> None:
        self.logger.info('%s: %s', self.name, message)
```

Generic[T] as a base class defines that the class LoggedVar takes a single type parameter T. This also makes T valid as a type within the class body.

The Generic base class uses a metaclass that defines __getitem__() so that LoggedVar[t] is valid as a type:

```python
from typing import Iterable
```
```python
def zero_all_vars(vars: Iterable[LoggedVar[int]]) -> None:
    for var in vars:
        var.set(0)
```

A generic type can have any number of type variables, and type variables may be constrained:

```python
from typing import TypeVar, Generic
...
T = TypeVar('T')
S = TypeVar('S', int, str)

class StrangePair(Generic[T, S]):
    ...
```

Each type variable argument to `Generic` must be distinct. This is thus invalid:

```python
from typing import TypeVar, Generic
...
T = TypeVar('T')

class Pair(Generic[T, T]):  # INVALID
    ...
```

You can use multiple inheritance with `Generic`:

```python
from typing import TypeVar, Generic, Sized
T = TypeVar('T')

class LinkedList(Sized, Generic[T]):
    ...
```
When inheriting from generic classes, some type variables could be fixed:

```python
from typing import TypeVar, Mapping

T = TypeVar('T')

class MyDict(Mapping[str, T]):
    ...
```

In this case `MyDict` has a single parameter, `T`.

Using a generic class without specifying type parameters assumes `Any` for each position. In the following example, `MyIterable` is not generic but implicitly inherits from `Iterable[Any]`:

```python
from typing import Iterable

class MyIterable(Iterable):  # Same as Iterable[Any]
    ...
```

User defined generic type aliases are also supported. Examples:

```python
from typing import TypeVar, Iterable, Tuple, Union

S = TypeVar('S')
Response = Union[Iterable[S], int]

# Return type here is same as Union[Iterable[str], int]

def response(query: str) -> Response[str]:
    ...

T = TypeVar('T', int, float, complex)
Vec = Iterable[Tuple[T, T]]
```
The metaclass used by `Generic` is a subclass of `abc.ABCMeta`. A generic class can be an ABC by including abstract methods or properties, and generic classes can also have ABCs as base classes without a metaclass conflict. Generic metaclasses are not supported. The outcome of parameterizing generics is cached, and most types in the typing module are hashable and comparable for equality.
26.1.6. The **Any** type

A special kind of type is **Any**. A static type checker will treat every type as being compatible with **Any** and **Any** as being compatible with every type.

This means that it is possible to perform any operation or method call on a value of type on **Any** and assign it to any variable:

```python
from typing import Any

a = None  # type: Any
a = []     # OK
a = 2      # OK

s = ''     # type: str
s = a      # OK

def foo(item: Any) -> int:
    # Typechecks; 'item' could be any type, and that type might have a 'bar' method
    item.bar()
    ...
```

Notice that no typechecking is performed when assigning a value of type **Any** to a more precise type. For example, the static type checker did not report an error when assigning `a` to `s` even though `s` was declared to be of type **str** and receives an **int** value at runtime!

Furthermore, all functions without a return type or parameter types will implicitly default to using **Any**:

```python
def legacy_parser(text):
```
This behavior allows `Any` to be used as an *escape hatch* when you need to mix dynamically and statically typed code.

Contrast the behavior of `Any` with the behavior of `object`. Similar to `Any`, every type is a subtype of `object`. However, unlike `Any`, the reverse is not true: `object` is *not* a subtype of every other type.

That means when the type of a value is `object`, a type checker will reject almost all operations on it, and assigning it to a variable (or using it as a return value) of a more specialized type is a type error. For example:

```python
def hash_a(item: object) -> int:
    # Fails; an object does not have a 'magic' method
    item.magic()

def hash_b(item: Any) -> int:
    # Typechecks
    item.magic()

# Typechecks, since ints and strs are subclasses of
hash_a(42)
hash_a("foo")
```
Use `object` to indicate that a value could be any type in a typesafe manner. Use `Any` to indicate that a value is dynamically typed.
26.1.7. Classes, functions, and decorators

The module defines the following classes, functions and decorators:

class typing. **TypeVar**

Type variable.

Usage:

```python
T = TypeVar('T')  # Can be anything
A = TypeVar('A', str, bytes)  # Must be str or by
```

Type variables exist primarily for the benefit of static type checkers. They serve as the parameters for generic types as well as for generic function definitions. See class Generic for more information on generic types.Generic functions work as follows:

```python
def repeat(x: T, n: int) -> Sequence[T]:
    """Return a list containing n references to x"
    return [x] * n

def longest(x: A, y: A) -> A:
    """Return the longest of two strings.""
    return x if len(x) >= len(y) else y
```

The latter example's signature is essentially the overloading of (str, str) -> str and (bytes, bytes) -> bytes. Also note that if the arguments are instances of some subclass of str, the return type is still plain str.

At runtime, **isinstance(x, T)** will raise **TypeError**. In general, **isinstance()** and **issubclass()** should not be used
with types.

Type variables may be marked covariant or contravariant by passing covariant=True or contravariant=True. See PEP 484 for more details. By default type variables are invariant. Alternatively, a type variable may specify an upper bound using bound=<type>. This means that an actual type substituted (explicitly or implicitly) for the type variable must be a subclass of the boundary type, see PEP 484.

class typing.Generic
Abstract base class for generic types.

A generic type is typically declared by inheriting from an instantiation of this class with one or more type variables. For example, a generic mapping type might be defined as:

class Mapping(Generic[KT, VT]):
    def __getitem__(self, key: KT) -> VT:
        ...
        # Etc.

This class can then be used as follows:

X = TypeVar('X')
Y = TypeVar('Y')

def lookup_name(mapping: Mapping[X, Y], key: X, def
try:
    return mapping[key]
except KeyError:
    return default

class typing.Type(Generic[CT_co])
A variable annotated with `C` may accept a value of type `C`. In contrast, a variable annotated with `Type[C]` may accept values that are classes themselves – specifically, it will accept the class `object` of `C`. For example:

```python
a = 3  # Has type 'int'
b = int  # Has type 'Type[int]'
c = type(a)  # Also has type 'Type[int]'
```

Note that `Type[C]` is covariant:

```python
class User: ...
class BasicUser(User): ...
class ProUser(User): ...
class TeamUser(User): ...

# Accepts User, BasicUser, ProUser, TeamUser, ...
def make_new_user(user_class: Type[User]) -> User
    # ...
    return user_class()
```

The fact that `Type[C]` is covariant implies that all subclasses of `C` should implement the same constructor signature and class method signatures as `C`. The type checker should flag violations of this, but should also allow constructor calls in subclasses that match the constructor calls in the indicated base class. How the type checker is required to handle this particular case may change in future revisions of PEP 484.

The only legal parameters for `Type` are classes, unions of classes, and `Any`. For example:

```python
def new_non_team_user(user_class: Type[Union[Base
```
Type[Any] is equivalent to Type which in turn is equivalent to type, which is the root of Python's metaclass hierarchy.

class typing.Iterable(Generic[T_co])
    A generic version of collections.abc.Iterable.

class typing.Iterator(Iterable[T_co])
    A generic version of collections.abc.Iterator.

class typing.Reversible(Iterable[T_co])
    A generic version of collections.abc.Reversible.

class typing.SupportsInt
    An ABC with one abstract method __int__.

class typing.SupportsFloat
    An ABC with one abstract method __float__.

class typing.SupportsComplex
    An ABC with one abstract method __complex__.

class typing.SupportsBytes
    An ABC with one abstract method __bytes__.

class typing.SupportsAbs
    An ABC with one abstract method __abs__ that is covariant in its return type.

class typing.SupportsRound
    An ABC with one abstract method __round__ that is covariant in its return type.
class typing.**Container**(Generic[T_co])  
A generic version of collections.abc.Container.

class typing.**Hashable**  
An alias to collections.abc.Hashable

class typing.**Sized**  
An alias to collections.abc.Sized

class typing.**Collection**(Sized, Iterable[T_co], Container[T_co])  
A generic version of collections.abc.Collection
  
  *New in version 3.6.*

class typing.**AbstractSet**(Sized, Collection[T_co])  
A generic version of collections.abc.Set.

class typing.**MutableSet**(AbstractSet[T])  
A generic version of collections.abc.MutableSet.

class typing.**Mapping**(Sized, Collection[KT], Generic[VT_co])  
A generic version of collections.abc.Mapping.

class typing.**MutableMapping**(Mapping[KT, VT])  
A generic version of collections.abc.MutableMapping.

class typing.**Sequence**(Reversible[T_co], Collection[T_co])  
A generic version of collections.abc.Sequence.

class typing.**MutableSequence**(Sequence[T])  
A generic version of collections.abc.MutableSequence.
class typing. **ByteString**(Sequence[int])

A generic version of collections.abc ByteString.

This type represents the types bytes, bytearray, and memoryview.

As a shorthand for this type, bytes can be used to annotate arguments of any of the types mentioned above.

class typing. **Deque**(deque, MutableSequence[T])

A generic version of collections.deque.

New in version 3.6.1.

class typing. **List**(list, MutableSequence[T])

Generic version of list. Useful for annotating return types. To annotate arguments it is preferred to use abstract collection types such as Mapping, Sequence, or AbstractSet.

This type may be used as follows:

```python
T = TypeVar('T', int, float)
def vec2(x: T, y: T) -> List[T]:
    return [x, y]
def keep_positives(vector: Sequence[T]) -> List[T]
    return [item for item in vector if item > 0]
```

class typing. **Set**(set, MutableSet[T])

A generic version of builtins.set.

class typing. **FrozenSet**(frozenset, AbstractSet[T_co])
A generic version of `builtins.frozenset`.

class typing. **MappingView** (Sized, Iterable[T_co])

A generic version of `collections.abc.MappingView`.

class typing. **KeysView** (MappingView[KT_co],
AbstractSet[KT_co])

A generic version of `collections.abc.KeysView`.

class typing. **ItemsView** (MappingView, Generic[KT_co, VT_co])

A generic version of `collections.abc.ItemsView`.

class typing. **ValuesView** (MappingView[VT_co])

A generic version of `collections.abc.ValuesView`.

class typing. **Awaitable** (Generic[T_co])

A generic version of `collections.abc.Awaitable`.

class typing. **Coroutine** (Awaitable[V_co], Generic[T_co
T_contra, V_co])

A generic version of `collections.abcCoroutine`. The variance and order of type variables correspond to those of `Generator`, for example:

```python
from typing import List, Coroutine
c = None  # type: Coroutine[List[str], str, int]
...
x = c.send('hi')  # type: List[str]
async def bar() -> None:
    x = await c  # type: int
```

class typing. **AsyncIterable** (Generic[T_co])

A generic version of `collections.abc.AsyncIterable`. 
class typing.AsyncIterator(AsyncIterable[T_co])
    A generic version of collections.abc.AsyncIterator.

class typing.ContextManager(Generic[T_co])
    A generic version of contextlib.AbstractContextManager.

    New in version 3.6.

class typing.Dict(dict, MutableMapping[KT, VT])
    A generic version of dict. The usage of this type is as follows:

    ```python
    def get_position_in_index(word_list: Dict[str, int]) -> int:
        return word_list[word]
    ```

class typing.DefaultDict(collections.defaultdict, 
                        MutableMapping[KT, VT])
    A generic version of collections.defaultdict.

class typing.Counter(collections.Counter, Dict[T, int])
    A generic version of collections.Counter.

    New in version 3.6.1.

class typing.ChainMap(collections.ChainMap, 
                       MutableMapping[KT, VT])
    A generic version of collections.ChainMap.

    New in version 3.6.1.

class typing.Generator(Iterator[T_co], Generic[T_co, T_contra, V_co])
    A generator can be annotated by the generic type
Generator[YieldType, SendType, ReturnType]. For example:

```python
def echo_round() -> Generator[int, float, str]:
    sent = yield 0
    while sent >= 0:
        sent = yield round(sent)
    return 'Done'
```

Note that unlike many other generics in the typing module, the SendType of `Generator` behaves contravariantly, not covariantly or invariantly.

If your generator will only yield values, set the SendType and ReturnType to None:

```python
def infinite_stream(start: int) -> Generator[int, None, None]:
    while True:
        yield start
        start += 1
```

Alternatively, annotate your generator as having a return type of either Iterable[YieldType] or Iterator[YieldType]:

```python
def infinite_stream(start: int) -> Iterator[int]:
    while True:
        yield start
        start += 1
```

```class typing.AsyncGenerator(AsyncIterator[T_co],
Generic[T_co, T_contra])
An async generator can be annotated by the generic type AsyncGenerator[YieldType, SendType]. For example:
```
async def echo_round() -> AsyncGenerator[int, float]:
sent = yield 0

while sent >= 0.0:
    rounded = await round(sent)
    sent = yield rounded

Unlike normal generators, async generators cannot return a value, so there is no ReturnType type parameter. As with Generator, the SendType behaves contravariantly.

If your generator will only yield values, set the SendType to None:

async def infinite_stream(start: int) -> AsyncGenerator:
    while True:
        yield start
        start = await increment(start)

Alternatively, annotate your generator as having a return type of either AsyncIterable[YieldType] or AsyncIterator[YieldType]:

async def infinite_stream(start: int) -> AsyncIterator:
    while True:
        yield start
        start = await increment(start)

New in version 3.5.4.

class typing.Text

Text is an alias for str. It is provided to supply a forward compatible path for Python 2 code: in Python 2, Text is an alias for unicode.
Use `Text` to indicate that a value must contain a unicode string in a manner that is compatible with both Python 2 and Python 3:

```python
def add_unicode_checkmark(text: Text) -> Text:
    return text + u' \u2713'
```

**class typing.io**

Wrapper namespace for I/O stream types.

This defines the generic type `IO[AnyStr]` and aliases `TextIO` and `BinaryIO` for respectively `IO[str]` and `IO[bytes]`. These represent the types of I/O streams such as returned by `open()`.

These types are also accessible directly as `typing.IO`, `typing.TextIO`, and `typing.BinaryIO`.

**class typing.re**

Wrapper namespace for regular expression matching types.

This defines the type aliases `Pattern` and `Match` which correspond to the return types from `re.compile()` and `re.match()`. These types (and the corresponding functions) are generic in `AnyStr` and can be made specific by writing `Pattern[str]`, `Pattern[bytes]`, `Match[str]`, or `Match[bytes]`.

These types are also accessible directly as `typing.Pattern` and `typing.Match`.

**class typing.NamedTuple**

Typed version of namedtuple.

Usage:
class Employee(NamedTuple):
    name: str
    id: int

This is equivalent to:

Employee = collections.namedtuple('Employee', ['n

To give a field a default value, you can assign to it in the class body:

class Employee(NamedTuple):
    name: str
    id: int = 3

employee = Employee('Guido')
assert employee.id == 3

Fields with a default value must come after any fields without a default.

The resulting class has two extra attributes: _field_types, giving a dict mapping field names to types, and _field_defaults, a dict mapping field names to default values. (The field names are in the _fields attribute, which is part of the namedtuple API.)

NamedTuple subclasses can also have docstrings and methods:

class Employee(NamedTuple):
    """Represents an employee."""
    name: str
    id: int = 3
```python
def __repr__(self) -> str:
    return f'<Employee {self.name}, id={self.id}>
```

Backward-compatible usage:

```python
Employee = NamedTuple('Employee', [('name', str)],
```

*Changed in version 3.6:* Added support for **PEP 526** variable annotation syntax.

*Changed in version 3.6.1:* Added support for default values, methods, and docstrings.

**typing.** `NewType(typ)`

A helper function to indicate a distinct types to a typechecker, see `NewType`. At runtime it returns a function that returns its argument.

Usage:

```python
UserId = NewType('UserId', int)
first_user = UserId(1)
```

**typing.** `cast(typ, val)`

Cast a value to a type.

This returns the value unchanged. To the type checker this signals that the return value has the designated type, but at runtime we intentionally don’t check anything (we want this to be as fast as possible).

**typing.** `get_type_hints(obj[, globals[, locals]])`

Return a dictionary containing type hints for a function, method, module or class object.
This is often the same as `obj.__annotations__`. In addition, forward references encoded as string literals are handled by evaluating them in `globals` and `locals` namespaces. If necessary, `Optional[t]` is added for function and method annotations if a default value equal to `None` is set. For a class `C`, return a dictionary constructed by merging all the `__annotations__` along `C.__mro__` in reverse order.

@typing.overload
The `@overload` decorator allows describing functions and methods that support multiple different combinations of argument types. A series of `@overload`-decorated definitions must be followed by exactly one non-`@overload`-decorated definition (for the same function/method). The `@overload`-decorated definitions are for the benefit of the type checker only, since they will be overwritten by the non-`@overload`-decorated definition, while the latter is used at runtime but should be ignored by a type checker. At runtime, calling a `@overload`-decorated function directly will raise `NotImplementedError`. An example of overload that gives a more precise type than can be expressed using a union or a type variable:

```python
@overload
def process(response: None) -> None:
    ...
@overload
def process(response: int) -> Tuple[int, str]:
    ...
@overload
def process(response: bytes) -> str:
    ...
def process(response):
    <actual implementation>
```
See PEP 484 for details and comparison with other typing semantics.

@typing.no_type_check(arg)
Decorator to indicate that annotations are not type hints.

The argument must be a class or function; if it is a class, it applies recursively to all methods defined in that class (but not to methods defined in its superclasses or subclasses).

This mutates the function(s) in place.

@typing.no_type_check_decorator(decorator)
Decorator to give another decorator the no_type_check() effect.

This wraps the decorator with something that wraps the decorated function in no_type_check().

typing.Any
Special type indicating an unconstrained type.

- Every type is compatible with Any.
- Any is compatible with every type.

typing.Union
Union type; Union[X, Y] means either X or Y.

To define a union, use e.g. Union[int, str]. Details:

- The arguments must be types and there must be at least one.
- Unions of unions are flattened, e.g.:

  Union[Union[int, str], float] == Union[int, str]
Unions of a single argument vanish, e.g.:

```python
Union[int] == int  # The constructor actually returns int
```

Redundant arguments are skipped, e.g.:

```python
Union[int, str, int] == Union[int, str]
```

When comparing unions, the argument order is ignored, e.g.:

```python
Union[int, str] == Union[str, int]
```

When a class and its subclass are present, the latter is skipped, e.g.:

```python
Union[int, object] == object
```

You cannot subclass or instantiate a union.

You cannot write `Union[X][Y]`.

You can use `Optional[X]` as a shorthand for `Union[X, None]`.

**typing.Optional**

Optional type.

`Optional[X]` is equivalent to `Union[X, None]`.

Note that this is not the same concept as an optional argument, which is one that has a default. An optional argument with a default needn't use the `Optional` qualifier on its type annotation.
(although it is inferred if the default is None). A mandatory argument may still have an Optional type if an explicit value of None is allowed.

typing. **Tuple**

Tuple type; `Tuple[X, Y]` is the type of a tuple of two items with the first item of type `X` and the second of type `Y`.

Example: `Tuple[T1, T2]` is a tuple of two elements corresponding to type variables `T1` and `T2`. `Tuple[int, float, str]` is a tuple of an int, a float and a string.

To specify a variable-length tuple of homogeneous type, use literal ellipsis, e.g. `Tuple[int, ...]`. A plain `Tuple` is equivalent to `Tuple[Any, ...]`, and in turn to `tuple`.

**typing. Callable**

 Callable type; `Callable[[int], str]` is a function of (int) -> str.

The subscription syntax must always be used with exactly two values: the argument list and the return type. The argument list must be a list of types or an ellipsis; the return type must be a single type.

There is no syntax to indicate optional or keyword arguments; such function types are rarely used as callback types. `Callable[... , ReturnType]` (literal ellipsis) can be used to type hint a callable taking any number of arguments and returning `ReturnType`. A plain `Callable` is equivalent to `Callable[... , Any]`, and in turn to `collections.abc.Callable`. 
typing.ClassVar

Special type construct to mark class variables.

As introduced in PEP 526, a variable annotation wrapped in `ClassVar` indicates that a given attribute is intended to be used as a class variable and should not be set on instances of that class.

Usage:

```python
class Starship:
    stats: ClassVar[Dict[str, int]] = {}  # class variable
    damage: int = 10  # instance variable
```

`ClassVar` accepts only types and cannot be further subscribed.

`ClassVar` is not a class itself, and should not be used with `isinstance()` or `issubclass()`. `ClassVar` does not change Python runtime behavior, but it can be used by third-party type checkers. For example, a type checker might flag the following code as an error:

```python
enterprise_d = Starship(3000)
enterprise_d.stats = {}  # Error, setting class variable on instance
Starship.stats = {}  # This is OK
```

New in version 3.5.3.

typing.AnyStr

`AnyStr` is a type variable defined as `AnyStr = TypeVar('AnyStr', str, bytes)`.

It is meant to be used for functions that may accept any kind of string without allowing different kinds of strings to mix. For
example:

```python
def concat(a: AnyStr, b: AnyStr) -> AnyStr:
    return a + b
```

```
concat(u"foo", u"bar")    # Ok, output has type 'unicode'
concat(b"foo", b"bar")   # Ok, output has type 'bytes'
concat(u"foo", b"bar")   # Error, cannot mix unicode and bytes
```

typing. **TYPE_CHECKING**

A special constant that is assumed to be True by 3rd party static type checkers. It is False at runtime. Usage:

```python
if TYPE_CHECKING:
    import expensive_mod

def fun(arg: 'expensive_mod.SomeType') -> None:
    local_var: expensive_mod.AnotherType = other_
```

Note that the first type annotation must be enclosed in quotes, making it a “forward reference”, to hide the `expensive_mod` reference from the interpreter runtime. Type annotations for local variables are not evaluated, so the second annotation does not need to be enclosed in quotes.
26.2. **pydoc** — Documentation generator and online help system

**Source code:** Lib/pydoc.py

The **pydoc** module automatically generates documentation from Python modules. The documentation can be presented as pages of text on the console, served to a Web browser, or saved to HTML files.

For modules, classes, functions and methods, the displayed documentation is derived from the docstring (i.e. the `__doc__` attribute) of the object, and recursively of its documentable members. If there is no docstring, **pydoc** tries to obtain a description from the block of comment lines just above the definition of the class, function or method in the source file, or at the top of the module (see `inspect.getcomments()`).

The built-in function **help()** invokes the online help system in the interactive interpreter, which uses **pydoc** to generate its documentation as text on the console. The same text documentation can also be viewed from outside the Python interpreter by running **pydoc** as a script at the operating system’s command prompt. For example, running

```
pydoc sys
```

at a shell prompt will display documentation on the **sys** module, in a style similar to the manual pages shown by the Unix **man** command. The argument to **pydoc** can be the name of a function, module, or
package, or a dotted reference to a class, method, or function within a module or module in a package. If the argument to `pydoc` looks like a path (that is, it contains the path separator for your operating system, such as a slash in Unix), and refers to an existing Python source file, then documentation is produced for that file.

**Note:** In order to find objects and their documentation, `pydoc` imports the module(s) to be documented. Therefore, any code on module level will be executed on that occasion. Use an `if __name__ == '__main__':` guard to only execute code when a file is invoked as a script and not just imported.

When printing output to the console, `pydoc` attempts to paginate the output for easier reading. If the PAGER environment variable is set, `pydoc` will use its value as a pagination program.

Specifying a `-w` flag before the argument will cause HTML documentation to be written out to a file in the current directory, instead of displaying text on the console.

Specifying a `-k` flag before the argument will search the synopsis lines of all available modules for the keyword given as the argument, again in a manner similar to the Unix `man` command. The synopsis line of a module is the first line of its documentation string.

You can also use `pydoc` to start an HTTP server on the local machine that will serve documentation to visiting Web browsers. `pydoc -p 1234` will start a HTTP server on port 1234, allowing you to browse the documentation at `http://localhost:1234/` in your preferred Web browser. Specifying `0` as the port number will select an arbitrary unused port.
pydoc -b will start the server and additionally open a web browser to a module index page. Each served page has a navigation bar at the top where you can Get help on an individual item, Search all modules with a keyword in their synopsis line, and go to the Module index, Topics and Keywords pages.

When pydoc generates documentation, it uses the current environment and path to locate modules. Thus, invoking pydoc spam documents precisely the version of the module you would get if you started the Python interpreter and typed import spam.

Module docs for core modules are assumed to reside in https://docs.python.org/X.Y/library/ where X and Y are the major and minor version numbers of the Python interpreter. This can be overridden by setting the PYTHONDONTCS environment variable to a different URL or to a local directory containing the Library Reference Manual pages.

*Changed in version 3.2:* Added the -b option.

*Changed in version 3.3:* The -g command line option was removed.

*Changed in version 3.4:* pydoc now uses inspect.signature() rather than inspect.getfullargspec() to extract signature information from callables.
26.3. doctest — Test interactive Python examples

Source code: Lib/doctest.py

The doctest module searches for pieces of text that look like interactive Python sessions, and then executes those sessions to verify that they work exactly as shown. There are several common ways to use doctest:

- To check that a module’s docstrings are up-to-date by verifying that all interactive examples still work as documented.
- To perform regression testing by verifying that interactive examples from a test file or a test object work as expected.
- To write tutorial documentation for a package, liberally illustrated with input-output examples. Depending on whether the examples or the expository text are emphasized, this has the flavor of “literate testing” or “executable documentation”.

Here’s a complete but small example module:

```python
"""
This is the "example" module.

The example module supplies one function, factorial().

>>> factorial(5)
120
"""

def factorial(n):
    """Return the factorial of n, an exact integer >
```
>>> [factorial(n) for n in range(6)]
[1, 1, 2, 6, 24, 120]

>>> factorial(30)
265252859812191058636308480000000

>>> factorial(-1)
Traceback (most recent call last):
...
ValueError: n must be >= 0

Factorials of floats are OK, but the float must

>>> factorial(30.1)
Traceback (most recent call last):
...
ValueError: n must be exact integer

>>> factorial(30.0)
265252859812191058636308480000000

It must also not be ridiculously large:

>>> factorial(1e100)
Traceback (most recent call last):
...
OverflowError: n too large

import math

if not n >= 0:
    raise ValueError("n must be >= 0")

if math.floor(n) != n:
    raise ValueError("n must be exact integer")

if n+1 == n:  # catch a value like 1e300
    raise OverflowError("n too large")

result = 1
factor = 2

while factor <= n:
    result *= factor
    factor += 1
If you run `example.py` directly from the command line, `doctest` works its magic:

```
$ python example.py
$
```

There's no output! That's normal, and it means all the examples worked. Pass `-v` to the script, and `doctest` prints a detailed log of what it's trying, and prints a summary at the end:

```
$ python example.py -v
Trying:
  factorial(5)
Expecting:
   120
ok
Trying:
  [factorial(n) for n in range(6)]
Expecting:
   [1, 1, 2, 6, 24, 120]
ok
```

And so on, eventually ending with:

```
Trying:
  factorial(1e100)
Expecting:
  Traceback (most recent call last):
```
...  

OverflowError: n too large
ok
2 items passed all tests:
   1 tests in __main__
   8 tests in __main__.factorial
9 tests in 2 items.
9 passed and 0 failed.
Test passed.
$

That's all you need to know to start making productive use of doctest! Jump in. The following sections provide full details. Note that there are many examples of doctests in the standard Python test suite and libraries. Especially useful examples can be found in the standard test file Lib/test/test_doctest.py.
26.3.1. Simple Usage: Checking Examples in Docstrings

The simplest way to start using doctest (but not necessarily the way you'll continue to do it) is to end each module M with:

```python
if __name__ == "__main__":
    import doctest
    doctest.testmod()
```

doctest then examines docstrings in module M.

Running the module as a script causes the examples in the docstrings to get executed and verified:

```bash
python M.py
```

This won't display anything unless an example fails, in which case the failing example(s) and the cause(s) of the failure(s) are printed to stdout, and the final line of output is ***Test Failed*** N failures., where N is the number of examples that failed.

Run it with the -v switch instead:

```bash
python M.py -v
```

and a detailed report of all examples tried is printed to standard output, along with assorted summaries at the end.

You can force verbose mode by passing `verbose=True` to `testmod()`, or prohibit it by passing `verbose=False`. In either of those cases, `sys.argv` is not examined by `testmod()` (so passing
There is also a command line shortcut for running `testmod()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the module name(s) on the command line:

```
python -m doctest -v example.py
```

This will import `example.py` as a standalone module and run `testmod()` on it. Note that this may not work correctly if the file is part of a package and imports other submodules from that package.

For more information on `testmod()`, see section Basic API.
26.3.2. Simple Usage: Checking Examples in a Text File

Another simple application of doctest is testing interactive examples in a text file. This can be done with the `testfile()` function:

```python
import doctest
doctest.testfile("example.txt")
```

That short script executes and verifies any interactive Python examples contained in the file `example.txt`. The file content is treated as if it were a single giant docstring; the file doesn’t need to contain a Python program! For example, perhaps `example.txt` contains this:

The ``example`` module
======================

Using ``factorial``
----------------

This is an example text file in reStructuredText for ``factorial`` from the ``example`` module:

```text
>>> from example import factorial
```

Now use it:

```text
>>> factorial(6)
120
```

Running `doctest.testfile("example.txt")` then finds the
error in this documentation:

```
File "./example.txt", line 14, in example.txt
Failed example:
    factorial(6)
Expected:
    120
Got:
    720
```

As with `testmod()`, `testfile()` won’t display anything unless an example fails. If an example does fail, then the failing example(s) and the cause(s) of the failure(s) are printed to stdout, using the same format as `testmod()`.

By default, `testfile()` looks for files in the calling module's directory. See section Basic API for a description of the optional arguments that can be used to tell it to look for files in other locations.

Like `testmod()`, `testfile()`'s verbosity can be set with the `-v` command-line switch or with the optional keyword argument `verbose`.

There is also a command line shortcut for running `testfile()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the file name(s) on the command line:

```
python -m doctest -v example.txt
```

Because the file name does not end with `.py`, `doctest` infers that it must be run with `testfile()`, not `testmod()`.

For more information on `testfile()`, see section Basic API.
26.3.3. How It Works

This section examines in detail how doctest works: which docstrings it looks at, how it finds interactive examples, what execution context it uses, how it handles exceptions, and how option flags can be used to control its behavior. This is the information that you need to know to write doctest examples; for information about actually running doctest on these examples, see the following sections.

26.3.3.1. Which Docstrings Are Examined?

The module docstring, and all function, class and method docstrings are searched. Objects imported into the module are not searched.

In addition, if M.__test__ exists and “is true”, it must be a dict, and each entry maps a (string) name to a function object, class object, or string. Function and class object docstrings found from M.__test__ are searched, and strings are treated as if they were docstrings. In output, a key K in M.__test__ appears with name

\[<\text{name of M}.\_\text{test}.\_\text{K}\]

Any classes found are recursively searched similarly, to test docstrings in their contained methods and nested classes.

**CPython implementation detail:** Prior to version 3.4, extension modules written in C were not fully searched by doctest.

26.3.3.2. How are Docstring Examples Recognized?

In most cases a copy-and-paste of an interactive console session
works fine, but doctest isn’t trying to do an exact emulation of any specific Python shell.

```python
>>> # comments are ignored
>>> x = 12
>>> x
12
>>> if x == 13:
...    print("yes")
... else:
...    print("no")
...    print("NO")
...    print("NO!!")
no
NO
NO!!
```

Any expected output must immediately follow the final '```' or '```' line containing the code, and the expected output (if any) extends to the next '```' or all-whitespace line.

The fine print:

- Expected output cannot contain an all-whitespace line, since such a line is taken to signal the end of expected output. If expected output does contain a blank line, put `<BLANKLINE>` in your doctest example each place a blank line is expected.

- All hard tab characters are expanded to spaces, using 8-column tab stops. Tabs in output generated by the tested code are not modified. Because any hard tabs in the sample output are expanded, this means that if the code output includes hard tabs, the only way the doctest can pass is if the
NORMALIZE_WHITESPACE option or directive is in effect. Alternatively, the test can be rewritten to capture the output and compare it to an expected value as part of the test. This handling of tabs in the source was arrived at through trial and error, and has proven to be the least error prone way of handling them. It is possible to use a different algorithm for handling tabs by writing a custom DocTestParser class.

- Output to stdout is captured, but not output to stderr (exception tracebacks are captured via a different means).

- If you continue a line via backslashing in an interactive session, or for any other reason use a backslash, you should use a raw docstring, which will preserve your backslashes exactly as you type them:

```python
>>> def f(x):
...     r'''Backslashes in a raw docstring: m\n'''
>>> print(f.__doc__)
Backslashes in a raw docstring: m\n```

Otherwise, the backslash will be interpreted as part of the string. For example, the `\n` above would be interpreted as a newline character. Alternatively, you can double each backslash in the doctest version (and not use a raw string):

```python
>>> def f(x):
...     '''Backslashes in a raw docstring: m\n'''
>>> print(f.__doc__)
Backslashes in a raw docstring: m\n```

- The starting column doesn’t matter:
and as many leading whitespace characters are stripped from the expected output as appeared in the initial '>>> ' line that started the example.

26.3.3.3. What’s the Execution Context?

By default, each time doctest finds a docstring to test, it uses a shallow copy of M’s globals, so that running tests doesn’t change the module’s real globals, and so that one test in M can’t leave behind crumbs that accidentally allow another test to work. This means examples can freely use any names defined at top-level in M, and names defined earlier in the docstring being run. Examples cannot see names defined in other docstrings.

You can force use of your own dict as the execution context by passing globs=your_dict to testmod() or testfile() instead.

26.3.3.4. What About Exceptions?

No problem, provided that the traceback is the only output produced by the example: just paste in the traceback. [1] Since tracebacks contain details that are likely to change rapidly (for example, exact file paths and line numbers), this is one case where doctest works hard to be flexible in what it accepts.

Simple example:
That doctest succeeds if `ValueError` is raised, with the `list.remove(x): x not in list` detail as shown.

The expected output for an exception must start with a traceback header, which may be either of the following two lines, indented the same as the first line of the example:

```
Traceback (most recent call last):
Traceback (innermost last):
```

The traceback header is followed by an optional traceback stack, whose contents are ignored by doctest. The traceback stack is typically omitted, or copied verbatim from an interactive session.

The traceback stack is followed by the most interesting part: the line(s) containing the exception type and detail. This is usually the last line of a traceback, but can extend across multiple lines if the exception has a multi-line detail:

```
>>> raise ValueError('multi\n line\ndetail')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: multi
 line
detail
```

The last three lines (starting with `ValueError`) are compared against the exception’s type and detail, and the rest are ignored.
Best practice is to omit the traceback stack, unless it adds significant documentation value to the example. So the last example is probably better as:

```python
>>> raise ValueError('multi
 line\ndetail')
Traceback (most recent call last):
...  
ValueError: multi
 line
detail
```

Note that tracebacks are treated very specially. In particular, in the rewritten example, the use of `...` is independent of doctest's **ELLIPSIS** option. The ellipsis in that example could be left out, or could just as well be three (or three hundred) commas or digits, or an indented transcript of a Monty Python skit.

Some details you should read once, but won't need to remember:

- Doctest can't guess whether your expected output came from an exception traceback or from ordinary printing. So, e.g., an example that expects `ValueError: 42 is prime` will pass whether `ValueError` is actually raised or if the example merely prints that traceback text. In practice, ordinary output rarely begins with a traceback header line, so this doesn't create real problems.

- Each line of the traceback stack (if present) must be indented further than the first line of the example, or start with a non-alphabetic character. The first line following the traceback header indented the same and starting with an alphanumeric is taken to be the start of the exception detail. Of course this does the right thing for genuine tracebacks.
- When the `IGNORE_EXCEPTION_DETAIL` doctest option is specified, everything following the leftmost colon and any module information in the exception name is ignored.

- The interactive shell omits the traceback header line for some `SyntaxError` exceptions. But doctest uses the traceback header line to distinguish exceptions from non-exceptions. So in the rare case where you need to test a `SyntaxError` that omits the traceback header, you will need to manually add the traceback header line to your test example.

- For some `SyntaxError` exceptions, Python displays the character position of the syntax error, using a `^` marker:

```
>>> 1 1
    File "<stdin>", line 1
    1 1
   ^
SyntaxError: invalid syntax
```

Since the lines showing the position of the error come before the exception type and detail, they are not checked by doctest. For example, the following test would pass, even though it puts the `^` marker in the wrong location:

```
>>> 1 1
    File "<stdin>", line 1
    1 1
   ^
SyntaxError: invalid syntax
```

26.3.3.5. Option Flags
A number of option flags control various aspects of doctest’s behavior. Symbolic names for the flags are supplied as module constants, which can be bitwise ORed together and passed to various functions. The names can also be used in doctest directives, and may be passed to the doctest command line interface via the -o option.

New in version 3.4: The -o command line option.

The first group of options define test semantics, controlling aspects of how doctest decides whether actual output matches an example’s expected output:

**doctest.DO NOT ACCEPT TRUE FOR 1**

By default, if an expected output block contains just 1, an actual output block containing just 1 or just True is considered to be a match, and similarly for 0 versus False. When **DO NOT ACCEPT TRUE FOR 1** is specified, neither substitution is allowed. The default behavior caters to that Python changed the return type of many functions from integer to boolean; doctests expecting “little integer” output still work in these cases. This option will probably go away, but not for several years.

**doctest.DO NOT ACCEPT BLANKLINE**

By default, if an expected output block contains a line containing only the string <BLANKLINE>, then that line will match a blank line in the actual output. Because a genuinely blank line delimits the expected output, this is the only way to communicate that a blank line is expected. When **DO NOT ACCEPT BLANKLINE** is specified, this substitution is not allowed.

**doctest.NORMALIZE_WHITESPACE**

When specified, all sequences of whitespace (blanks and...
newlines) are treated as equal. Any sequence of whitespace within the expected output will match any sequence of whitespace within the actual output. By default, whitespace must match exactly. **NORMALIZE_WHITESPACE** is especially useful when a line of expected output is very long, and you want to wrap it across multiple lines in your source.

**doctest.ELLIPSIS**

When specified, an ellipsis marker (…) in the expected output can match any substring in the actual output. This includes substrings that span line boundaries, and empty substrings, so it’s best to keep usage of this simple. Complicated uses can lead to the same kinds of “oops, it matched too much!” surprises that .* is prone to in regular expressions.

**doctest.IGNORE_EXCEPTION_DETAIL**

When specified, an example that expects an exception passes if an exception of the expected type is raised, even if the exception detail does not match. For example, an example expecting `ValueError: 42` will pass if the actual exception raised is `ValueError: 3*14`, but will fail, e.g., if `TypeError` is raised.

It will also ignore the module name used in Python 3 doctest reports. Hence both of these variations will work with the flag specified, regardless of whether the test is run under Python 2.7 or Python 3.2 (or later versions):

```
>>> raise CustomError('message')
Traceback (most recent call last):
  CustomError: message

>>> raise CustomError('message')
Traceback (most recent call last):
```
my_module.CustomButton: message

Note that **ELLIPSIS** can also be used to ignore the details of the exception message, but such a test may still fail based on whether or not the module details are printed as part of the exception name. Using **IGNORE_EXCEPTION_DETAIL** and the details from Python 2.3 is also the only clear way to write a doctest that doesn’t care about the exception detail yet continues to pass under Python 2.3 or earlier (those releases do not support **doctest directives** and ignore them as irrelevant comments). For example:

```python
>>> (1, 2)[3] = 'moo'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: object doesn't support item assignment
```

passes under Python 2.3 and later Python versions with the flag specified, even though the detail changed in Python 2.4 to say “does not” instead of “doesn’t”.

*Changed in version 3.2:* **IGNORE_EXCEPTION_DETAIL** now also ignores any information relating to the module containing the exception under test.

**doctest SKIP**

When specified, do not run the example at all. This can be useful in contexts where doctest examples serve as both documentation and test cases, and an example should be included for documentation purposes, but should not be checked. E.g., the example’s output might be random; or the example might depend on resources which would be unavailable to the test driver.

The SKIP flag can also be used for temporarily “commenting out”
examples.

doctest.COMPARISON_FLAGS
A bitmask or’ing together all the comparison flags above.

The second group of options controls how test failures are reported:

doctest.REPORT_UDIFF
When specified, failures that involve multi-line expected and actual outputs are displayed using a unified diff.

doctest.REPORT_CDIFF
When specified, failures that involve multi-line expected and actual outputs will be displayed using a context diff.

doctest.REPORT_NDIFF
When specified, differences are computed by `difflib.Differ`, using the same algorithm as the popular `ndiff.py` utility. This is the only method that marks differences within lines as well as across lines. For example, if a line of expected output contains digit 1 where actual output contains letter l, a line is inserted with a caret marking the mismatching column positions.

doctest.REPORT_ONLY_FIRST_FAILURE
When specified, display the first failing example in each doctest, but suppress output for all remaining examples. This will prevent doctest from reporting correct examples that break because of earlier failures; but it might also hide incorrect examples that fail independently of the first failure. When `REPORT_ONLY_FIRST_FAILURE` is specified, the remaining examples are still run, and still count towards the total number of failures reported; only the output is suppressed.
doctest.**FAIL_FAST**

When specified, exit after the first failing example and don’t attempt to run the remaining examples. Thus, the number of failures reported will be at most 1. This flag may be useful during debugging, since examples after the first failure won’t even produce debugging output.

The doctest command line accepts the option `-f` as a shorthand for `-o FAIL_FAST`.

*New in version 3.4.*

doctest.**REPORTING_FLAGS**

A bitmask or’ing together all the reporting flags above.

There is also a way to register new option flag names, though this isn’t useful unless you intend to extend doctest internals via subclassing:

**doctest.**`register_optionflag(name)`

Create a new option flag with a given name, and return the new flag's integer value. `register_optionflag()` can be used when subclassing `OutputChecker` or `DocTestRunner` to create new options that are supported by your subclasses. `register_optionflag()` should always be called using the following idiom:

```
MY_FLAG = register_optionflag('MY_FLAG')
```

**26.3.3.6. Directives**

Doctest directives may be used to modify the option flags for an individual example. Doctest directives are special Python comments
following an example's source code:

```plaintext
directive ::= "#" "doctest:" directive
directive_options ::= directive_option ("," directive_option)*
directive_option ::= on_or_off directive_option_name
on_or_off ::= "+" | "-
directive_option_name ::= "DONT_ACCEPT_BLANKLINE"
```

Whitespace is not allowed between the + or - and the directive option name. The directive option name can be any of the option flag names explained above.

An example's doctest directives modify doctest's behavior for that single example. Use + to enable the named behavior, or - to disable it.

For example, this test passes:

```python
>>> print(list(range(20))) # doctest: +NORMALIZE_WHITESPACE
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19]
```

Without the directive it would fail, both because the actual output doesn't have two blanks before the single-digit list elements, and because the actual output is on a single line. This test also passes, and also requires a directive to do so:

```python
>>> print(list(range(20))) # doctest: +ELLIPSIS
[0, 1, ..., 18, 19]
```

Multiple directives can be used on a single physical line, separated by commas:
If multiple directive comments are used for a single example, then they are combined:

```
>>> print(list(range(20)))  # doctest: +ELLIPSIS, +NORMALIZE_WHITESPACE
[0, 1, ..., 18, 19]
```

As the previous example shows, you can add `...` lines to your example containing only directives. This can be useful when an example is too long for a directive to comfortably fit on the same line:

```
>>> print(list(range(5)) + list(range(10, 20)) + list(...  # doctest: +ELLIPSIS
              [0, ..., 4, 10, ..., 19, 30, ..., 39]
```

Note that since all options are disabled by default, and directives apply only to the example they appear in, enabling options (via `+` in a directive) is usually the only meaningful choice. However, option flags can also be passed to functions that run doctests, establishing different defaults. In such cases, disabling an option via `-` in a directive can be useful.

### 26.3.3.7. Warnings

`doctest` is serious about requiring exact matches in expected output. If even a single character doesn’t match, the test fails. This will probably surprise you a few times, as you learn exactly what Python does and doesn’t guarantee about output. For example, when printing
a dict, Python doesn’t guarantee that the key-value pairs will be printed in any particular order, so a test like

```python
>>> foo()
{'Hermione': 'hippogryph', 'Harry': 'broomstick'}
```

is vulnerable! One workaround is to do

```python
>>> foo() == {'Hermione': 'hippogryph', 'Harry': 'broomstick'}
True
```

instead. Another is to do

```python
>>> d = sorted(foo().items())
>>> d
[('Harry', 'broomstick'), ('Hermione', 'hippogryph')]
```

There are others, but you get the idea.

Another bad idea is to print things that embed an object address, like

```python
>>> id(1.0)  # certain to fail some of the time
7948648
>>> class C: pass
>>> C()  # the default repr() for instances embeds
<__main__.C instance at 0x00AC18F0>
```

The **ELLIPSIS** directive gives a nice approach for the last example:

```python
>>> C() #doctest: +ELLIPSIS
<__main__.C instance at 0x...>
```

Floating-point numbers are also subject to small output variations
across platforms, because Python defers to the platform C library for float formatting, and C libraries vary widely in quality here.

```
>>> 1./7  # risky
0.14285714285714285
>>> print(1./7)  # safer
0.142857142857
>>> print(round(1./7, 6))  # much safer
0.142857
```

Numbers of the form \( I/2.**J \) are safe across all platforms, and I often contrive doctest examples to produce numbers of that form:

```
>>> 3./4  # utterly safe
0.75
```

Simple fractions are also easier for people to understand, and that makes for better documentation.
26.3.4. Basic API

The functions `testmod()` and `testfile()` provide a simple interface to doctest that should be sufficient for most basic uses. For a less formal introduction to these two functions, see sections Simple Usage: Checking Examples in Docstrings and Simple Usage: Checking Examples in a Text File.

```
doctest.testfile(filename, module_relative=True, name=None, package=None, globs=None, verbose=None, report=True, optionflags=0, extraglobs=None, raise_on_error=False, parser=DocTestParser(), encoding=None)
```

All arguments except `filename` are optional, and should be specified in keyword form.

Test examples in the file named `filename`. Return `failure_count, test_count`.

Optional argument `module_relative` specifies how the filename should be interpreted:

- If `module_relative` is `True` (the default), then `filename` specifies an OS-independent module-relative path. By default, this path is relative to the calling module’s directory; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, `filename` should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If `module_relative` is `False`, then `filename` specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.
Optional argument *name* gives the name of the test; by default, or if None, `os.path.basename(filename)` is used.

Optional argument *package* is a Python package or the name of a Python package whose directory should be used as the base directory for a module-relative filename. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify *package* if *module_relative* is *False*.

Optional argument *globs* gives a dict to be used as the globals when executing examples. A new shallow copy of this dict is created for the doctest, so its examples start with a clean slate. By default, or if None, a new empty dict is used.

Optional argument *extraglobs* gives a dict merged into the globals used to execute examples. This works like `dict.update()`: if *globs* and *extraglobs* have a common key, the associated value in *extraglobs* appears in the combined dict. By default, or if None, no extra globals are used. This is an advanced feature that allows parameterization of doctests. For example, a doctest can be written for a base class, using a generic name for the class, then reused to test any number of subclasses by passing an *extraglobs* dict mapping the generic name to the subclass to be tested.

Optional argument *verbose* prints lots of stuff if true, and prints only failures if false; by default, or if None, it's true if and only if '-v' is in `sys.argv`.

Optional argument *report* prints a summary at the end when true, else prints nothing at the end. In verbose mode, the summary is detailed, else the summary is very brief (in fact, empty if all tests passed).
Optional argument *optionflags* (default value 0) takes the bitwise OR of option flags. See section Option Flags.

Optional argument *raise_on_error* defaults to false. If true, an exception is raised upon the first failure or unexpected exception in an example. This allows failures to be post-mortem debugged. Default behavior is to continue running examples.

Optional argument *parser* specifies a *DocTestParser* (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., *DocTestParser()*).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

```
doctest.testmod(m=None, name=None, globs=None, verbose=None, report=True, optionflags=0, extraglobs=None, raise_on_error=False, exclude_empty=False)
```

All arguments are optional, and all except for *m* should be specified in keyword form.

Test examples in docstrings in functions and classes reachable from module *m* (or module *__main__* if *m* is not supplied or is *None*), starting with *m.__doc__*.

Also test examples reachable from dict *m.__test__*, if it exists and is not *None*. *m.__test__* maps names (strings) to functions, classes and strings; function and class docstrings are searched for examples; strings are searched directly, as if they were docstrings.

Only docstrings attached to objects belonging to module *m* are searched.

Return *(failure_count, test_count)*.
Optional argument `name` gives the name of the module; by default, or if None, `m.__name__` is used.

Optional argument `exclude_empty` defaults to false. If true, objects for which no doctests are found are excluded from consideration. The default is a backward compatibility hack, so that code still using `doctest.master.summarize()` in conjunction with `testmod()` continues to get output for objects with no tests. The `exclude_empty` argument to the newer `DocTestFinder` constructor defaults to true.

Optional arguments `extraglobs`, `verbose`, `report`, `optionflags`, `raise_on_error`, and `globs` are the same as for function `testfile()` above, except that `globs` defaults to `m.__dict__`.

    doctest.run_docstring_examples(f, globs, verbose=False, name="NoName", compileflags=None, optionflags=0)

Test examples associated with object `f`; for example, `f` may be a string, a module, a function, or a class object.

A shallow copy of dictionary argument `globs` is used for the execution context.

Optional argument `name` is used in failure messages, and defaults to "NoName".

If optional argument `verbose` is true, output is generated even if there are no failures. By default, output is generated only in case of an example failure.

Optional argument `compileflags` gives the set of flags that should be used by the Python compiler when running the examples. By
default, or if None, flags are deduced corresponding to the set of future features found in "glob."

Optional argument optionflags works as for function testfile() above.
26.3.5. Unittest API

As your collection of doctest'ed modules grows, you'll want a way to run all their doctests systematically. `doctest` provides two functions that can be used to create `unittest` test suites from modules and text files containing doctests. To integrate with `unittest` test discovery, include a `load_tests()` function in your test module:

```python
import unittest
import doctest
import my_module_with_doctests

def load_tests(loader, tests, ignore):
    tests.addTests(doctest.DocTestSuite(my_module_with_doctests))
    return tests
```

There are two main functions for creating `unittest.TestSuite` instances from text files and modules with doctests:

- `doctest.DocFileSuite(*paths, module_relative=True, package=None, setUp=None, tearDown=None, globs=None, optionflags=0, parser=DocTestParser(), encoding=None)`

  Convert doctest tests from one or more text files to a `unittest.TestSuite`.

- The returned `unittest.TestSuite` is to be run by the unittest framework and runs the interactive examples in each file. If an example in any file fails, then the synthesized unit test fails, and a `failureException` exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

  Pass one or more paths (as strings) to text files to be examined.
Options may be provided as keyword arguments:

Optional argument *module_relative* specifies how the filenames in *paths* should be interpreted:

- If *module_relative* is `True` (the default), then each filename in *paths* specifies an OS-independent module-relative path. By default, this path is relative to the calling module's directory; but if the *package* argument is specified, then it is relative to that package. To ensure OS-independence, each filename should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If *module_relative* is `False`, then each filename in *paths* specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument *package* is a Python package or the name of a Python package whose directory should be used as the base directory for module-relative filenames in *paths*. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify *package* if *module_relative* is `False`.

Optional argument *setUp* specifies a set-up function for the test suite. This is called before running the tests in each file. The *setUp* function will be passed a `DocTest` object. The setUp function can access the test globals as the *globs* attribute of the test passed.

Optional argument *tearDown* specifies a tear-down function for the test suite. This is called after running the tests in each file. The *tearDown* function will be passed a `DocTest` object. The tearDown function can access the test globals as the *globs* attribute of the test passed.
Optional argument *globs* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globs* is a new empty dictionary.

Optional argument *optionflags* specifies the default doctest options for the tests, created by or-ing together individual option flags. See section **Option Flags**. See function `set_unittest_reportflags()` below for a better way to set reporting options.

Optional argument *parser* specifies a `DocTestParser` (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

The global `__file__` is added to the globals provided to doctests loaded from a text file using `DocFileSuite()`.

```python
doctest.DocTestSuite(module=None, globs=None, extraglobs=None, test_finder=None, setUp=None, tearDown=None, checker=None)
```

Convert doctest tests for a module to a `unittest.TestSuite`.

The returned `unittest.TestSuite` is to be run by the unittest framework and runs each doctest in the module. If any of the doctests fail, then the synthesized unit test fails, and a `failureException` exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Optional argument *module* provides the module to be tested. It can be a module object or a (possibly dotted) module name. If not
specified, the module calling this function is used.

Optional argument *globs* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globs* is a new empty dictionary.

Optional argument *extraglobs* specifies an extra set of global variables, which is merged into *globs*. By default, no extra globals are used.

Optional argument *test_finder* is the *DocTestFinder* object (or a drop-in replacement) that is used to extract doctests from the module.

Optional arguments *setUp*, *tearDown*, and *optionflags* are the same as for function *DocFileSuite()* above.

This function uses the same search technique as *testmod()*.

*Changed in version 3.5:* *DocTestSuite()* returns an empty *unittest.TestSuite* if *module* contains no docstrings instead of raising *ValueError*.

Under the covers, *DocTestSuite()* creates a *unittest.TestSuite* out of doctest.DocTestCase instances, and *DocTestCase* is a subclass of *unittest.TestCase*. *DocTestCase* isn't documented here (it's an internal detail), but studying its code can answer questions about the exact details of *unittest* integration.

Similarly, *DocFileSuite()* creates a *unittest.TestSuite* out of doctest.DocFileCase instances, and *DocFileCase* is a subclass of *DocTestCase*. 
So both ways of creating a `unittest.TestSuite` run instances of `DocTestCase`. This is important for a subtle reason: when you run `doctest` functions yourself, you can control the `doctest` options in use directly, by passing option flags to `doctest` functions. However, if you're writing a `unittest` framework, `unittest` ultimately controls when and how tests get run. The framework author typically wants to control `doctest` reporting options (perhaps, e.g., specified by command line options), but there's no way to pass options through `unittest` to `doctest` test runners.

For this reason, `doctest` also supports a notion of `doctest` reporting flags specific to `unittest` support, via this function:

```python
doctest.set_unittest_reportflags(flags)
```

Set the `doctest` reporting flags to use.

Argument `flags` takes the `bitwise OR` of option flags. See section `Option Flags`. Only “reporting flags” can be used.

This is a module-global setting, and affects all future doctests run by module `unittest`: the `runTest()` method of `DocTestCase` looks at the option flags specified for the test case when the `DocTestCase` instance was constructed. If no reporting flags were specified (which is the typical and expected case), `doctest`'s `unittest` reporting flags are `bitwise OR`ed into the option flags, and the option flags so augmented are passed to the `DocTestRunner` instance created to run the doctest. If any reporting flags were specified when the `DocTestCase` instance was constructed, `doctest`'s `unittest` reporting flags are ignored.

The value of the `unittest` reporting flags in effect before the
function was called is returned by the function.
26.3.6. Advanced API

The basic API is a simple wrapper that’s intended to make doctest easy to use. It is fairly flexible, and should meet most users’ needs; however, if you require more fine-grained control over testing, or wish to extend doctest’s capabilities, then you should use the advanced API.

The advanced API revolves around two container classes, which are used to store the interactive examples extracted from doctest cases:

- **Example**: A single Python statement, paired with its expected output.
- **DocTest**: A collection of Examples, typically extracted from a single docstring or text file.

Additional processing classes are defined to find, parse, and run, and check doctest examples:

- **DocTestFinder**: Finds all docstrings in a given module, and uses a DocTestParser to create a DocTest from every docstring that contains interactive examples.
- **DocTestParser**: Creates a DocTest object from a string (such as an object’s docstring).
- **DocTestRunner**: Executes the examples in a DocTest, and uses an OutputChecker to verify their output.
- **OutputChecker**: Compares the actual output from a doctest example with the expected output, and decides whether they match.

The relationships among these processing classes are summarized in the following diagram:
26.3.6.1. DocTest Objects

```python
class doctest.DocTest(examples, globs, name, filename, lineno, docstring)
```

A collection of doctest examples that should be run in a single namespace. The constructor arguments are used to initialize the attributes of the same names.

**DocTest** defines the following attributes. They are initialized by the constructor, and should not be modified directly.

**examples**

A list of `Example` objects encoding the individual interactive Python examples that should be run by this test.

**globs**

The namespace (aka globals) that the examples should be run in. This is a dictionary mapping names to values. Any changes to the namespace made by the examples (such as binding new variables) will be reflected in `globs` after the test is run.

**name**

A string name identifying the `DocTest`. Typically, this is the
name of the object or file that the test was extracted from.

**filename**
The name of the file that this `DocTest` was extracted from; or `None` if the filename is unknown, or if the `DocTest` was not extracted from a file.

**lineno**
The line number within `filename` where this `DocTest` begins, or `None` if the line number is unavailable. This line number is zero-based with respect to the beginning of the file.

**docstring**
The string that the test was extracted from, or `None` if the string is unavailable, or if the test was not extracted from a string.

### 26.3.6.2. Example Objects

```python
class doctest.Example(source, want, exc_msg=None, lineno=0, indent=0, options=None)
```

A single interactive example, consisting of a Python statement and its expected output. The constructor arguments are used to initialize the attributes of the same names.

`Example` defines the following attributes. They are initialized by the constructor, and should not be modified directly.

**source**
A string containing the example's source code. This source code consists of a single Python statement, and always ends with a newline; the constructor adds a newline when necessary.
want
The expected output from running the example's source code (either from stdout, or a traceback in case of exception). *want* ends with a newline unless no output is expected, in which case it's an empty string. The constructor adds a newline when necessary.

exc_msg
The exception message generated by the example, if the example is expected to generate an exception; or *None* if it is not expected to generate an exception. This exception message is compared against the return value of `traceback.format_exception_only()`. *exc_msg* ends with a newline unless it's *None*. The constructor adds a newline if needed.

lineno
The line number within the string containing this example where the example begins. This line number is zero-based with respect to the beginning of the containing string.

indent
The example's indentation in the containing string, i.e., the number of space characters that precede the example's first prompt.

options
A dictionary mapping from option flags to *True* or *False*, which is used to override default options for this example. Any option flags not contained in this dictionary are left at their default value (as specified by the *DocTestRunner*’s *optionflags*). By default, no options are set.
26.3.6.3. DocTestFinder objects

```
class doctest.DocTestFinder(verbose=False, parser=DocTestParser(), recurse=True, exclude_empty=True)
```

A processing class used to extract the DocTests that are relevant to a given object, from its docstring and the docstrings of its contained objects. DocTests can be extracted from modules, classes, functions, methods, staticmethods, classmethods, and properties.

The optional argument `verbose` can be used to display the objects searched by the finder. It defaults to `False` (no output).

The optional argument `parser` specifies the DocTestParser object (or a drop-in replacement) that is used to extract doctests from docstrings.

If the optional argument `recurse` is false, then `DocTestFinder.find()` will only examine the given object, and not any contained objects.

If the optional argument `exclude_empty` is false, then `DocTestFinder.find()` will include tests for objects with empty docstrings.

`DocTestFinder` defines the following method:

```
find(obj[, name][, module][, globs][, extraglobs])
```

Return a list of the DocTests that are defined by `obj`'s docstring, or by any of its contained objects' docstrings.

The optional argument `name` specifies the object's name; this
name will be used to construct names for the returned `DocTest`s. If `name` is not specified, then `obj.__name__` is used.

The optional parameter `module` is the module that contains the given object. If the module is not specified or is `None`, then the test finder will attempt to automatically determine the correct module. The object’s module is used:

- As a default namespace, if `globs` is not specified.
- To prevent the `DocTestFinder` from extracting DocTests from objects that are imported from other modules. (Contained objects with modules other than `module` are ignored.)
- To find the name of the file containing the object.
- To help find the line number of the object within its file.

If `module` is `False`, no attempt to find the module will be made. This is obscure, of use mostly in testing doctest itself: if `module` is `False`, or is `None` but cannot be found automatically, then all objects are considered to belong to the (non-existent) module, so all contained objects will (recursively) be searched for doctests.

The globals for each `DocTest` is formed by combining `globs` and `extraglobs` (bindings in `extraglobs` override bindings in `globs`). A new shallow copy of the globals dictionary is created for each `DocTest`. If `globs` is not specified, then it defaults to the module’s `__dict__`, if specified, or `{}` otherwise. If `extraglobs` is not specified, then it defaults to `{}`.

**26.3.6.4. DocTestParser objects**
class doctest.DoctestParser

A processing class used to extract interactive examples from a string, and use them to create a DocTest object.

DocTestParser defines the following methods:

get_doctest(string, globs, name, filename, lineno)

Extract all doctest examples from the given string, and collect them into a DocTest object.

globs, name, filename, and lineno are attributes for the new DocTest object. See the documentation for DocTest for more information.

get_examples(string, name='<string>')

Extract all doctest examples from the given string, and return them as a list of Example objects. Line numbers are 0-based. The optional argument name is a name identifying this string, and is only used for error messages.

parse(string, name='<string>')

Divide the given string into examples and intervening text, and return them as a list of alternating Examples and strings. Line numbers for the Examples are 0-based. The optional argument name is a name identifying this string, and is only used for error messages.

26.3.6.5. DocTestRunner objects

class doctest.DoctestRunner(checker=None, verbose=None, optionflags=0)

A processing class used to execute and verify the interactive
examples in a DocTest.

The comparison between expected outputs and actual outputs is done by an OutputChecker. This comparison may be customized with a number of option flags; see section Option Flags for more information. If the option flags are insufficient, then the comparison may also be customized by passing a subclass of OutputChecker to the constructor.

The test runner’s display output can be controlled in two ways. First, an output function can be passed to TestRunner.run(); this function will be called with strings that should be displayed. It defaults to sys.stdout.write. If capturing the output is not sufficient, then the display output can be also customized by subclassing DocTestRunner, and overriding the methods report_start(), report_success(), report_unexpected_exception(), and report_failure().

The optional keyword argument checker specifies the OutputChecker object (or drop-in replacement) that should be used to compare the expected outputs to the actual outputs of doctest examples.

The optional keyword argument verbose controls the DocTestRunner’s verbosity. If verbose is True, then information is printed about each example, as it is run. If verbose is False, then only failures are printed. If verbose is unspecified, or None, then verbose output is used iff the command-line switch -v is used.

The optional keyword argument optionflags can be used to control
how the test runner compares expected output to actual output, and how it displays failures. For more information, see section Option Flags.

**DocTestParser** defines the following methods:

**report_start**(out, test, example)

Report that the test runner is about to process the given example. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *test* is the test containing *example*. *out* is the output function that was passed to **DocTestRunner**.run().

**report_success**(out, test, example, got)

Report that the given example ran successfully. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to **DocTestRunner**.run().

**report_failure**(out, test, example, got)

Report that the given example failed. This method is provided to allow subclasses of **DocTestRunner** to customize their output; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. 
out is the output function that was passed to DocTestRunner.run().

report_unexpected_exception(out, test, example, exc_info)

Report that the given example raised an unexpected exception. This method is provided to allow subclasses of DocTestRunner to customize their output; it should not be called directly.

example is the example about to be processed. exc_info is a tuple containing information about the unexpected exception (as returned by sys.exc_info()). test is the test containing example. out is the output function that was passed to DocTestRunner.run().

run(test, compileflags=None, out=None, clear_globs=True)

Run the examples in test (a DocTest object), and display the results using the writer function out.

The examples are run in the namespace test.globs. If clear_globs is true (the default), then this namespace will be cleared after the test runs, to help with garbage collection. If you would like to examine the namespace after the test completes, then use clear_globs=False.

compileflags gives the set of flags that should be used by the Python compiler when running the examples. If not specified, then it will default to the set of future-import flags that apply to globals.

The output of each example is checked using the DocTestRunner’s output checker, and the results are
formatted by the DocTestRunner.report_*() methods.

**summarize**(verbose=None)

Print a summary of all the test cases that have been run by this DocTestRunner, and return a named tuple TestResults(failed, attempted).

The optional `verbose` argument controls how detailed the summary is. If the verbosity is not specified, then the DocTestRunner's verbosity is used.

### 26.3.6.6. OutputChecker objects

**class doctest.OutputChecker**

A class used to check the whether the actual output from a doctest example matches the expected output. OutputChecker defines two methods: `check_output()`, which compares a given pair of outputs, and returns true if they match; and `output_difference()`, which returns a string describing the differences between two outputs.

OutputChecker defines the following methods:

**check_output**(want, got, optionflags)

Return `True` iff the actual output from an example (`got`) matches the expected output (`want`). These strings are always considered to match if they are identical; but depending on what option flags the test runner is using, several non-exact match types are also possible. See section Option Flags for more information about option flags.

**output_difference**(example, got, optionflags)
Return a string describing the differences between the expected output for a given example (example) and the actual output (got). optionflags is the set of option flags used to compare want and got.
26.3.7. Debugging

Doctest provides several mechanisms for debugging doctest examples:

- Several functions convert doctests to executable Python programs, which can be run under the Python debugger, `pdb`.

- The `DebugRunner` class is a subclass of `DocTestRunner` that raises an exception for the first failing example, containing information about that example. This information can be used to perform post-mortem debugging on the example.

- The `unittest` cases generated by `DocTestSuite()` support the `debug()` method defined by `unittest.TestCase`.

- You can add a call to `pdb.set_trace()` in a doctest example, and you'll drop into the Python debugger when that line is executed. Then you can inspect current values of variables, and so on. For example, suppose `a.py` contains just this module docstring:

```python
""
>>> def f(x):
...     g(x*2)
>>> def g(x):
...     print(x+3)
...     import pdb; pdb.set_trace()
>>> f(3)
g
""
```

Then an interactive Python session may look like this:
Functions that convert doctests to Python code, and possibly run the synthesized code under the debugger:

`doctest.script_from_examples(s)`

Convert text with examples to a script.
Argument `s` is a string containing doctest examples. The string is converted to a Python script, where doctest examples in `s` are converted to regular code, and everything else is converted to Python comments. The generated script is returned as a string. For example,

```python
import doctest
print(doctest.script_from_examples(r"""
    Set x and y to 1 and 2.
    >>> x, y = 1, 2

    Print their sum:
    >>> print(x+y)
    3
"""))
```

displays:

```python
# Set x and y to 1 and 2.
x, y = 1, 2
#
# Print their sum:
print(x+y)
# Expected:
## 3
```

This function is used internally by other functions (see below), but can also be useful when you want to transform an interactive Python session into a Python script.

doctest.testsource(module, name)

Convert the doctest for an object to a script.

Argument `module` is a module object, or dotted name of a module, containing the object whose doctests are of interest. Argument
name is the name (within the module) of the object with the doctests of interest. The result is a string, containing the object's docstring converted to a Python script, as described for script_from_examples() above. For example, if module a.py contains a top-level function f(), then

```python
import a, doctest
print(doctest.testsource(a, "a.f"))
```

prints a script version of function f()’s docstring, with doctests converted to code, and the rest placed in comments.

doctest.debug(module, name, pm=False)

Debug the doctests for an object.

The module and name arguments are the same as for function testsource() above. The synthesized Python script for the named object’s docstring is written to a temporary file, and then that file is run under the control of the Python debugger, pdb.

A shallow copy of module.__dict__ is used for both local and global execution context.

Optional argument pm controls whether post-mortem debugging is used. If pm has a true value, the script file is run directly, and the debugger gets involved only if the script terminates via raising an unhandled exception. If it does, then post-mortem debugging is invoked, via pdb.post_mortem(), passing the traceback object from the unhandled exception. If pm is not specified, or is false, the script is run under the debugger from the start, via passing an appropriate exec() call to pdb.run().

doctest.debug_src(src, pm=False, globs=None)
Debug the doctests in a string.

This is like function `debug()` above, except that a string containing doctest examples is specified directly, via the `src` argument.

Optional argument `pm` has the same meaning as in function `debug()` above.

Optional argument `globals` gives a dictionary to use as both local and global execution context. If not specified, or `None`, an empty dictionary is used. If specified, a shallow copy of the dictionary is used.

The `DebugRunner` class, and the special exceptions it may raise, are of most interest to testing framework authors, and will only be sketched here. See the source code, and especially `DebugRunner`'s docstring (which is a doctest!) for more details:

```python
class doctest.DebugRunner(checker=None, verbose=None, optionflags=0)
```

A subclass of `DocTestRunner` that raises an exception as soon as a failure is encountered. If an unexpected exception occurs, an `UnexpectedException` exception is raised, containing the test, the example, and the original exception. If the output doesn't match, then a `DocTestFailure` exception is raised, containing the test, the example, and the actual output.

For information about the constructor parameters and methods, see the documentation for `DocTestRunner` in section `Advanced API`.

There are two exceptions that may be raised by `DebugRunner`
instances:

exception doctest.**DocTestFailure**(test, example, got)

An exception raised by **DocTestRunner** to signal that a doctest example’s actual output did not match its expected output. The constructor arguments are used to initialize the attributes of the same names.

**DocTestFailure** defines the following attributes:

**DocTestFailure**.test

The **DocTest** object that was being run when the example failed.

**DocTestFailure**.example

The **Example** that failed.

**DocTestFailure**.got

The example’s actual output.

exception doctest.**UnexpectedException**(test, example, exc_info)

An exception raised by **DocTestRunner** to signal that a doctest example raised an unexpected exception. The constructor arguments are used to initialize the attributes of the same names.

**UnexpectedException** defines the following attributes:

**UnexpectedException**.test

The **DocTest** object that was being run when the example failed.

**UnexpectedException**.example

The **Example** that failed.
UnexpectedException.**exc_info**

A tuple containing information about the unexpected exception, as returned by `sys.exc_info()`.
26.3.8. Soapbox

As mentioned in the introduction, doctest has grown to have three primary uses:

1. Checking examples in docstrings.
2. Regression testing.
3. Executable documentation / literate testing.

These uses have different requirements, and it is important to distinguish them. In particular, filling your docstrings with obscure test cases makes for bad documentation.

When writing a docstring, choose docstring examples with care. There's an art to this that needs to be learned—it may not be natural at first. Examples should add genuine value to the documentation. A good example can often be worth many words. If done with care, the examples will be invaluable for your users, and will pay back the time it takes to collect them many times over as the years go by and things change. I'm still amazed at how often one of my doctest examples stops working after a “harmless” change.

Doctest also makes an excellent tool for regression testing, especially if you don’t skimp on explanatory text. By interleaving prose and examples, it becomes much easier to keep track of what's actually being tested, and why. When a test fails, good prose can make it much easier to figure out what the problem is, and how it should be fixed. It's true that you could write extensive comments in code-based testing, but few programmers do. Many have found that using doctest approaches instead leads to much clearer tests. Perhaps this is simply because doctest makes writing prose a little easier than writing code, while writing comments in code is a little harder. I think it goes deeper
than just that: the natural attitude when writing a doctest-based test is that you want to explain the fine points of your software, and illustrate them with examples. This in turn naturally leads to test files that start with the simplest features, and logically progress to complications and edge cases. A coherent narrative is the result, instead of a collection of isolated functions that test isolated bits of functionality seemingly at random. It's a different attitude, and produces different results, blurring the distinction between testing and explaining.

Regression testing is best confined to dedicated objects or files. There are several options for organizing tests:

- Write text files containing test cases as interactive examples, and test the files using `testfile()` or `DocFileSuite()`. This is recommended, although is easiest to do for new projects, designed from the start to use doctest.
- Define functions named `_regrtest_topic` that consist of single docstrings, containing test cases for the named topics. These functions can be included in the same file as the module, or separated out into a separate test file.
- Define a `__test__` dictionary mapping from regression test topics to docstrings containing test cases.

When you have placed your tests in a module, the module can itself be the test runner. When a test fails, you can arrange for your test runner to re-run only the failing doctest while you debug the problem. Here is a minimal example of such a test runner:

```python
if __name__ == '__main__':
    import doctest
    flags = doctest.REPORT_NDIFF|doctest.FAIL_FAST
    if len(sys.argv) > 1:
        name = sys.argv[1]
        if name in globals():
```
obj = globals()[name]
else:
    obj = __test__/name
doctest.run_docstring_examples(obj, globals(),
optionflags=flags)
else:
    fail, total = doctest.testmod(optionflags=flags)
    print("{} failures out of {} tests".format(fail, total))

Footnotes

[1] Examples containing both expected output and an exception are not supported. Trying to guess where one ends and the other begins is too error-prone, and that also makes for a confusing test.
26.4. **unittest** — Unit testing framework

**Source code:** Lib/unittest/__init__.py

(If you are already familiar with the basic concepts of testing, you might want to skip to the list of assert methods.)

The **unittest** unit testing framework was originally inspired by JUnit and has a similar flavor as major unit testing frameworks in other languages. It supports test automation, sharing of setup and shutdown code for tests, aggregation of tests into collections, and independence of the tests from the reporting framework.

To achieve this, **unittest** supports some important concepts in an object-oriented way:

**test fixture**

A *test fixture* represents the preparation needed to perform one or more tests, and any associate cleanup actions. This may involve, for example, creating temporary or proxy databases, directories, or starting a server process.

**test case**

A *test case* is the individual unit of testing. It checks for a specific response to a particular set of inputs. **unittest** provides a base class, **TestCase**, which may be used to create new test cases.

**test suite**

A *test suite* is a collection of test cases, test suites, or both. It is used to aggregate tests that should be executed together.

**test runner**
A test runner is a component which orchestrates the execution of tests and provides the outcome to the user. The runner may use a graphical interface, a textual interface, or return a special value to indicate the results of executing the tests.

**Module** doctest
Another test-support module with a very different flavor.

**Simple Smalltalk Testing: With Patterns**
Kent Beck’s original paper on testing frameworks using the pattern shared by unittest.

**Nose and py.test**
Third-party unittest frameworks with a lighter-weight syntax for writing tests. For example, `assert func(10) == 42`.

**The Python Testing Tools Taxonomy**
An extensive list of Python testing tools including functional testing frameworks and mock object libraries.

**Testing in Python Mailing List**
A special-interest-group for discussion of testing, and testing tools, in Python.

The script `Tools/unittestgui/unittestgui.py` in the Python source distribution is a GUI tool for test discovery and execution. This is intended largely for ease of use for those new to unit testing. For production environments it is recommended that tests be driven by a continuous integration system such as Buildbot, Jenkins or Hudson.
26.4.1. Basic example

The `unittest` module provides a rich set of tools for constructing and running tests. This section demonstrates that a small subset of the tools suffice to meet the needs of most users.

Here is a short script to test three string methods:

```python
import unittest

class TestStringMethods(unittest.TestCase):
    def test_upper(self):
        self.assertEqual('foo'.upper(), 'FOO')

    def test_isupper(self):
        self.assertTrue('FOO'.isupper())
        self.assertFalse('Foo'.isupper())

    def test_split(self):
        s = 'hello world'
        self.assertEqual(s.split(), ['hello', 'world'])
        # check that s.split fails when the separator is not a string
        with self.assertRaises(TypeError):
            s.split(2)

if __name__ == '__main__':
    unittest.main()
```

A testcase is created by subclassing `unittest.TestCase`. The three individual tests are defined with methods whose names start with the letters `test`. This naming convention informs the test runner about which methods represent tests.
The crux of each test is a call to `assertEqual()` to check for an expected result; `assertTrue()` or `assertFalse()` to verify a condition; or `assertRaises()` to verify that a specific exception gets raised. These methods are used instead of the `assert` statement so the test runner can accumulate all test results and produce a report.

The `setUp()` and `tearDown()` methods allow you to define instructions that will be executed before and after each test method. They are covered in more detail in the section Organizing test code.

The final block shows a simple way to run the tests. `unittest.main()` provides a command-line interface to the test script. When run from the command line, the above script produces an output that looks like this:

```
...  
Ran 3 tests in 0.000s
OK
```

Passing the `-v` option to your test script will instruct `unittest.main()` to enable a higher level of verbosity, and produce the following output:

```
test_isupper (__main__.TestStringMethods) ... ok
test_split (__main__.TestStringMethods) ... ok
test_upper (__main__.TestStringMethods) ... ok

Ran 3 tests in 0.001s
OK
```

The above examples show the most commonly used `unittest` features which are sufficient to meet many everyday testing needs. The remainder of the documentation explores the full feature set from first principles.
26.4.2. Command-Line Interface

The unittest module can be used from the command line to run tests from modules, classes or even individual test methods:

```
python -m unittest test_module1 test_module2
python -m unittest test_module.TestCase
python -m unittest test_module.TestCase.test_method
```

You can pass in a list with any combination of module names, and fully qualified class or method names.

Test modules can be specified by file path as well:

```
python -m unittest tests/tests/test_something.py
```

This allows you to use the shell filename completion to specify the test module. The file specified must still be importable as a module. The path is converted to a module name by removing the ‘.py’ and converting path separators into ‘.’. If you want to execute a test file that isn’t importable as a module you should execute the file directly instead.

You can run tests with more detail (higher verbosity) by passing in the -v flag:

```
python -m unittest -v test_module
```

When executed without arguments Test Discovery is started:

```
python -m unittest
```
For a list of all the command-line options:

```
python -m unittest -h
```

*Changed in version 3.2:* In earlier versions it was only possible to run individual test methods and not modules or classes.

### 26.4.2.1. Command-line options

`unittest` supports these command-line options:

- `-b, --buffer`
  
  The standard output and standard error streams are buffered during the test run. Output during a passing test is discarded. Output is echoed normally on test fail or error and is added to the failure messages.

- `-c, --catch`
  
  Control-C during the test run waits for the current test to end and then reports all the results so far. A second Control-C raises the normal `KeyboardInterrupt` exception.

  See [Signal Handling](https://docs.python.org/3/library/traceback.html) for the functions that provide this functionality.

- `-f, --failfast`
  
  Stop the test run on the first error or failure.

- `--locals`
  
  Show local variables in tracebacks.

*New in version 3.2:* The command-line options `-b, -c` and `-f` were added.
New in version 3.5: The command-line option `--locals`.

The command line can also be used for test discovery, for running all of the tests in a project or just a subset.
26.4.3. Test Discovery

New in version 3.2.

Unittest supports simple test discovery. In order to be compatible with test discovery, all of the test files must be modules or packages (including namespace packages) importable from the top-level directory of the project (this means that their filenames must be valid identifiers).

Test discovery is implemented in TestLoader.discover(), but can also be used from the command line. The basic command-line usage is:

```bash
cd project_directory
python -m unittest discover
```

**Note:** As a shortcut, python -m unittest is the equivalent of python -m unittest discover. If you want to pass arguments to test discovery the discover sub-command must be used explicitly.

The discover sub-command has the following options:

- **-v, --verbose**
  Verbose output

- **-s, --start-directory directory**
  Directory to start discovery (. default)

- **-p, --pattern pattern**
  Pattern to match test files (test*.py default)
-t, --top-level-directory directory

Top level directory of project (defaults to start directory)

The -s, -p, and -t options can be passed in as positional arguments in that order. The following two command lines are equivalent:

```
python -m unittest discover -s project_directory -p
python -m unittest discover project_directory "*_test.py"
```

As well as being a path it is possible to pass a package name, for example `myproject.subpackage.test`, as the start directory. The package name you supply will then be imported and its location on the filesystem will be used as the start directory.

**Caution:** Test discovery loads tests by importing them. Once test discovery has found all the test files from the start directory you specify it turns the paths into package names to import. For example `foo/bar/baz.py` will be imported as `foo.bar.baz`.

If you have a package installed globally and attempt test discovery on a different copy of the package then the import *could* happen from the wrong place. If this happens test discovery will warn you and exit.

If you supply the start directory as a package name rather than a path to a directory then discover assumes that whichever location it imports from is the location you intended, so you will not get the warning.

Test modules and packages can customize test loading and discovery by through the **load_tests protocol**.

*Changed in version 3.4:* Test discovery supports **namespace**
packages.
26.4.4. Organizing test code

The basic building blocks of unit testing are test cases — single scenarios that must be set up and checked for correctness. In unittest, test cases are represented by unittest.TestCase instances. To make your own test cases you must write subclasses of TestCase or use FunctionTestCase.

The testing code of a TestCase instance should be entirely self contained, such that it can be run either in isolation or in arbitrary combination with any number of other test cases.

The simplest TestCase subclass will simply implement a test method (i.e. a method whose name starts with test) in order to perform specific testing code:

```python
import unittest
class DefaultWidgetSizeTestCase(unittest.TestCase):
    def test_default_widget_size(self):
        widget = Widget('The widget')
        self.assertEqual(widget.size(), (50, 50))
```

Note that in order to test something, we use one of the assert*() methods provided by the TestCase base class. If the test fails, an exception will be raised, and unittest will identify the test case as a failure. Any other exceptions will be treated as errors.

Tests can be numerous, and their set-up can be repetitive. Luckily, we can factor out set-up code by implementing a method called setUp(), which the testing framework will automatically call for every single test we run:
import unittest

class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def test_default_widget_size(self):
        self.assertEqual(self.widget.size(), (50, 50), 'incorrect default size')

    def test_widget_resize(self):
        self.widget.resize(100, 150)
        self.assertEqual(self.widget.size(), (100, 150), 'wrong size after resize')

Note: The order in which the various tests will be run is determined by sorting the test method names with respect to the built-in ordering for strings.

If the setUp() method raises an exception while the test is running, the framework will consider the test to have suffered an error, and the test method will not be executed.

Similarly, we can provide a tearDown() method that tidies up after the test method has been run:

import unittest

class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def tearDown(self):
        self.widget.dispose()
If `setUp()` succeeded, `tearDown()` will be run whether the test method succeeded or not.

Such a working environment for the testing code is called a *fixture*.

Test case instances are grouped together according to the features they test. `unittest` provides a mechanism for this: the *test suite*, represented by `unittest`'s `TestSuite` class. In most cases, calling `unittest.main()` will do the right thing and collect all the module’s test cases for you, and then execute them.

However, should you want to customize the building of your test suite, you can do it yourself:

```python
def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('test_default_size'))
    suite.addTest(WidgetTestCase('test_resize'))
    return suite
```

You can place the definitions of test cases and test suites in the same modules as the code they are to test (such as `widget.py`), but there are several advantages to placing the test code in a separate module, such as `test_widget.py`:

- The test module can be run standalone from the command line.
- The test code can more easily be separated from shipped code.
- There is less temptation to change test code to fit the code it tests without a good reason.
- Test code should be modified much less frequently than the code it tests.
- Tested code can be refactored more easily.
- Tests for modules written in C must be in separate modules
anyway, so why not be consistent?

- If the testing strategy changes, there is no need to change the source code.
26.4.5. Re-using old test code

Some users will find that they have existing test code that they would like to run from unittest, without converting every old test function to a TestCase subclass.

For this reason, unittest provides a FunctionTestCase class. This subclass of TestCase can be used to wrap an existing test function. Set-up and tear-down functions can also be provided.

Given the following test function:

```python
def testSomething():
    something = makeSomething()
    assert something.name is not None
    # ...
```

one can create an equivalent test case instance as follows, with optional set-up and tear-down methods:

```python
testcase = unittest.FunctionTestCase(testSomething,
    setUp=makeSomethingDB,
    tearDown=deleteSomethingDB)
```

**Note:** Even though FunctionTestCase can be used to quickly convert an existing test base over to a unittest-based system, this approach is not recommended. Taking the time to set up proper TestCase subclasses will make future test refactorings infinitely easier.

In some cases, the existing tests may have been written using the
doctest module. If so, doctest provides a DocTestSuite class that can automatically build unittest.TestSuite instances from the existing doctest-based tests.
26.4.6. Skipping tests and expected failures

*New in version 3.1.*

Unittest supports skipping individual test methods and even whole classes of tests. In addition, it supports marking a test as an “expected failure,” a test that is broken and will fail, but shouldn’t be counted as a failure on a TestResult.

Skipping a test is simply a matter of using the `skip()` decorator or one of its conditional variants.

Basic skipping looks like this:

```python
class MyTestCase(unittest.TestCase):
    @unittest.skip("demonstrating skipping")
    def test_nothing(self):
        self.fail("shouldn't happen")

    @unittest.skipIf(mylib.__version__ < (1, 3), "not supported in this library")
    def test_format(self):
        # Tests that work for only a certain version
        pass

    @unittest.skipUnless(sys.platform.startswith("wi"))
    def test_windows_support(self):
        # windows specific testing code
        pass
```

This is the output of running the example above in verbose mode:
Classes can be skipped just like methods:

```python
@unittest.skip("showing class skipping")
class MySkippedTestCase(unittest.TestCase):
    def test_not_run(self):
        pass
```

`TestCase.setUp()` can also skip the test. This is useful when a resource that needs to be set up is not available.

Expected failures use the `expectedFailure()` decorator.

```python
class ExpectedFailureTestCase(unittest.TestCase):
    @unittest.expectedFailure
    def test_fail(self):
        self.assertEqual(1, 0, "broken")
```

It's easy to roll your own skipping decorators by making a decorator that calls `skip()` on the test when it wants it to be skipped. This decorator skips the test unless the passed object has a certain attribute:

```python
def skipUnlessHasattr(obj, attr):
    if hasattr(obj, attr):
        return lambda func: func
```
The following decorators implement test skipping and expected failures:

@unittest.skip(reason)
   Unconditionally skip the decorated test. reason should describe why the test is being skipped.

@unittest.skipIf(condition, reason)
   Skip the decorated test if condition is true.

@unittest.skipUnless(condition, reason)
   Skip the decorated test unless condition is true.

@unittest.expectedFailure
   Mark the test as an expected failure. If the test fails when run, the test is not counted as a failure.

exception unittest.SkipTest(reason)
   This exception is raised to skip a test.

   Usually you can use TestCase.skipTest() or one of the skipping decorators instead of raising this directly.

Skipped tests will not have setUp() or tearDown() run around them. Skipped classes will not have setUpClass() or tearDownClass() run. Skipped modules will not have setUpModule() or tearDownModule() run.
26.4.7. Distinguishing test iterations using subtests

*New in version 3.4.*

When some of your tests differ only by a some very small differences, for instance some parameters, unittest allows you to distinguish them inside the body of a test method using the `subTest()` context manager.

For example, the following test:

```python
class NumbersTest(unittest.TestCase):
    def test_even(self):
        """Test that numbers between 0 and 5 are all even""
        for i in range(0, 6):
            with self.subTest(i=i):
                self.assertEqual(i % 2, 0)
```

will produce the following output:

```
FAIL: test_even (__main__.NumbersTest) (i=1)
Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0
```
FAIL: test_even (__main__.NumbersTest) (i=3)

-------------------
Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0

-------------------
FAIL: test_even (__main__.NumbersTest) (i=5)

-------------------
Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0

Without using a subtest, execution would stop after the first failure, and the error would be less easy to diagnose because the value of i wouldn’t be displayed:
26.4.8. Classes and functions

This section describes in depth the API of unittest.

26.4.8.1. Test cases

class unittest.TestCase(methodName='runTest')

Instances of the TestCase class represent the logical test units in the unittest universe. This class is intended to be used as a base class, with specific tests being implemented by concrete subclasses. This class implements the interface needed by the test runner to allow it to drive the tests, and methods that the test code can use to check for and report various kinds of failure.

Each instance of TestCase will run a single base method: the method named methodName. In most uses of TestCase, you will neither change the methodName nor reimplement the default runTest() method.

Changed in version 3.2: TestCase can be instantiated successfully without providing a methodName. This makes it easier to experiment with TestCase from the interactive interpreter.

TestCase instances provide three groups of methods: one group used to run the test, another used by the test implementation to check conditions and report failures, and some inquiry methods allowing information about the test itself to be gathered.

Methods in the first group (running the test) are:

setUp()
Method called to prepare the test fixture. This is called immediately before calling the test method; other than `AssertionError` or `SkipTest`, any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

**tearDown()**

Method called immediately after the test method has been called and the result recorded. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception, other than `AssertionError` or `SkipTest`, raised by this method will be considered an additional error rather than a test failure (thus increasing the total number of reported errors). This method will only be called if the `setUp()` succeeds, regardless of the outcome of the test method. The default implementation does nothing.

**setUpClass()**

A class method called before tests in an individual class run. `setUpClass` is called with the class as the only argument and must be decorated as a `classmethod()`:

```python
@classmethod
def setUpClass(cls):
    ...
```

See [Class and Module Fixtures](#) for more details.

*New in version 3.2.*

**tearDownClass()**

A class method called after tests in an individual class have run.
tearDownClass is called with the class as the only argument and must be decorated as a `classmethod()`:

```python
@classmethod
def tearDownClass(cls):
    ...
```

See [Class and Module Fixtures](#) for more details.

*New in version 3.2.*

**run**(result=None)
Run the test, collecting the result into the `TestResult` object passed as `result`. If `result` is omitted or `None`, a temporary result object is created (by calling the `defaultTestResult()` method) and used. The result object is returned to `run()`'s caller.

The same effect may be had by simply calling the `TestCase` instance.

*Changed in version 3.3:* Previous versions of `run` did not return the result. Neither did calling an instance.

**skipTest**(reason)
Calling this during a test method or `setUp()` skips the current test. See [Skipping tests and expected failures](#) for more information.

*New in version 3.1.*

**subTest**(msg=None, **params)
Return a context manager which executes the enclosed code
block as a subtest. *msg* and *params* are optional, arbitrary values which are displayed whenever a subtest fails, allowing you to identify them clearly.

A test case can contain any number of subtest declarations, and they can be arbitrarily nested.

See [Distinguishing test iterations using subtests](#) for more information.

*New in version 3.4.*

**debug()**

Run the test without collecting the result. This allows exceptions raised by the test to be propagated to the caller, and can be used to support running tests under a debugger.

The [TestCase](#) class provides several assert methods to check for and report failures. The following table lists the most commonly used methods (see the tables below for more assert methods):

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertEqual(a, b)</code></td>
<td><code>a == b</code></td>
<td></td>
</tr>
<tr>
<td><code>assertNotEqual(a, b)</code></td>
<td><code>a != b</code></td>
<td></td>
</tr>
<tr>
<td><code>assertTrue(x)</code></td>
<td><code>bool(x) is True</code></td>
<td></td>
</tr>
<tr>
<td><code>assertFalse(x)</code></td>
<td><code>bool(x) is False</code></td>
<td></td>
</tr>
<tr>
<td><code>assertIs(a, b)</code></td>
<td><code>a is b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertIsNot(a, b)</code></td>
<td><code>a is not b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertIsNone(x)</code></td>
<td><code>x is None</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertIsNotNone(x)</code></td>
<td><code>x is not None</code></td>
<td>3.1</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Version</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td><code>assertIn(a, b)</code></td>
<td>Test that ( a ) in ( b ).</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertNotIn(a, b)</code></td>
<td>Test that ( a ) not in ( b ).</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertIsInstance(a, b)</code></td>
<td>Test that ( a ) is an instance of ( b ).</td>
<td>3.2</td>
</tr>
<tr>
<td><code>assertNotIsInstance(a, b)</code></td>
<td>Test that ( a ) is not an instance of ( b ).</td>
<td>3.2</td>
</tr>
</tbody>
</table>

All the `assert` methods accept a `msg` argument that, if specified, is used as the error message on failure (see also `longMessage`).

Note that the `msg` keyword argument can be passed to `assertRaises()`, `assertRaisesRegex()`, `assertWarns()`, `assertWarnsRegex()` only when they are used as a context manager.

**assertEqual(first, second, msg=None)**

Test that `first` and `second` are equal. If the values do not compare equal, the test will fail.

In addition, if `first` and `second` are the exact same type and one of list, tuple, dict, set, frozenset or str or any type that a subclass registers with `addTypeEqualityFunc()` the type-specific equality function will be called in order to generate a more useful default error message (see also the list of type-specific methods).

*Changed in version 3.1:* Added the automatic calling of type-specific equality function.

*Changed in version 3.2:* `assertMultiLineEqual()` added as the default type equality function for comparing strings.
assertNotEqual\((first, second, msg=None)\)
Test that first and second are not equal. If the values do compare equal, the test will fail.

assertTrue\((expr, msg=None)\)
assertFalse\((expr, msg=None)\)
Test that expr is true (or false).

Note that this is equivalent to bool(expr) is True and not to expr is True (use assertIs(expr, True) for the latter). This method should also be avoided when more specific methods are available (e.g. assertEqual(a, b) instead of assertTrue(a == b)), because they provide a better error message in case of failure.

assertIs\((first, second, msg=None)\)
assertIsNot\((first, second, msg=None)\)
Test that first and second evaluate (or don’t evaluate) to the same object.

New in version 3.1.

assertIsNone\((expr, msg=None)\)
assertIsNotNone\((expr, msg=None)\)
Test that expr is (or is not) None.

New in version 3.1.

assertIn\((first, second, msg=None)\)
assertNotIn\((first, second, msg=None)\)
Test that first is (or is not) in second.

New in version 3.1.
**assertIsInstance**(obj, cls, msg=None)

**assertNotIsInstance**(obj, cls, msg=None)

Test that *obj* is (or is not) an instance of *cls* (which can be a class or a tuple of classes, as supported by **isinstance()**). To check for the exact type, use **assertIs(type(obj), cls)**.

*New in version 3.2.*

It is also possible to check the production of exceptions, warnings, and log messages using the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>assertRaises</strong>(exc, fun, *args, **kwds)</td>
<td>fun(*args, **kwds) raises exc</td>
<td></td>
</tr>
<tr>
<td><strong>assertRaisesRegex</strong>(exc, r, fun, *args, **kwds)</td>
<td>fun(*args, **kwds) raises exc and the message matches regex r</td>
<td>3.1</td>
</tr>
<tr>
<td><strong>assertWarns</strong>(warn, fun, *args, **kwds)</td>
<td>fun(*args, **kwds) raises warn</td>
<td>3.2</td>
</tr>
<tr>
<td><strong>assertWarnsRegex</strong>(warn, r, fun, *args, **kwds)</td>
<td>fun(*args, **kwds) raises warn and the message matches regex r</td>
<td>3.2</td>
</tr>
<tr>
<td><strong>assertLogs</strong>(logger, level)</td>
<td>The with block logs on logger with minimum level</td>
<td>3.4</td>
</tr>
</tbody>
</table>

**assertRaises**(exception, callable, *args, **kwds)

Test that an exception is raised when *callable* is called with any
positional or keyword arguments that are also passed to assertRaises(). The test passes if exception is raised, is an error if another exception is raised, or fails if no exception is raised. To catch any of a group of exceptions, a tuple containing the exception classes may be passed as exception.

If only the exception and possibly the msg arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```python
with self.assertRaises(SomeException):
    do_something()
```

When used as a context manager, assertRaises() accepts the additional keyword argument msg.

The context manager will store the caught exception object in its exception attribute. This can be useful if the intention is to perform additional checks on the exception raised:

```python
with self.assertRaises(SomeException) as cm:
    do_something()

the_exception = cm.exception
self.assertEqual(the_exception.error_code, 3)
```

*Changed in version 3.1:* Added the ability to use assertRaises() as a context manager.

*Changed in version 3.2:* Added the exception attribute.

*Changed in version 3.3:* Added the msg keyword argument when used as a context manager.
assertRaisesRegex(exception, regex, callable, *args, **kwds)

assertRaisesRegex(exception, regex, msg=None)

Like `assertRaises()` but also tests that `regex` matches on the string representation of the raised exception. `regex` may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`. Examples:

```python
self.assertRaisesRegex(ValueError, "invalid literal for.*XYZ'
int, 'XYZ')
```

or:

```python
with self.assertRaisesRegex(ValueError, 'literal'
int('XYZ')
```

*New in version 3.1:* under the name `assertRaisesRegexp`.

*Changed in version 3.2:* Renamed to `assertRaisesRegex()`.

*Changed in version 3.3:* Added the `msg` keyword argument when used as a context manager.

assertWarns(warning, callable, *args, **kwds)

assertWarns(warning, msg=None)

Test that a warning is triggered when `callable` is called with any positional or keyword arguments that are also passed to `assertWarns()`. The test passes if `warning` is triggered and fails if it isn't. Any exception is an error. To catch any of a group of warnings, a tuple containing the warning classes may be passed as `warnings`. 
If only the *warning* and possibly the *msg* arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```python
with self.assertWarns(SomeWarning):
    do_something()
```

When used as a context manager, *assertWarns()* accepts the additional keyword argument *msg*.

The context manager will store the caught warning object in its *warning* attribute, and the source line which triggered the warnings in the *filename* and *lineno* attributes. This can be useful if the intention is to perform additional checks on the warning caught:

```python
with self.assertWarns(SomeWarning) as cm:
    do_something()
    self.assertIn('myfile.py', cm.filename)
    self.assertEqual(320, cm.lineno)
```

This method works regardless of the warning filters in place when it is called.

*New in version 3.2.*

*Changed in version 3.3:* Added the *msg* keyword argument when used as a context manager.

*assertWarnsRegex*(warning, regex, callable, *args, **kwds)

*assertWarnsRegex*(warning, regex, msg=None)

Like *assertWarns()* but also tests that *regex* matches on the message of the triggered warning. *regex* may be a regular
expression object or a string containing a regular expression suitable for use by `re.search()`. Example:

```python
self.assertWarnsRegex(DeprecationWarning, 
    r'legacy_function\(\) is legacy_function, 'XYZ')
```

or:

```python
with self.assertWarnsRegex(RuntimeWarning, 'unsafe frobnicating') as w:
    frobnicate('/etc/passwd')
```

*New in version 3.2.*

*Changed in version 3.3:* Added the `msg` keyword argument when used as a context manager.

### assertLogs

#### Signature

```python
assertLogs(logger=None, level=None)
```

#### Description

A context manager to test that at least one message is logged on the `logger` or one of its children, with at least the given `level`.

If given, `logger` should be a `logging.Logger` object or a `str` giving the name of a logger. The default is the root logger, which will catch all messages.

If given, `level` should be either a numeric logging level or its string equivalent (for example either "ERROR" or `logging.ERROR`). The default is `logging.INFO`.

The test passes if at least one message emitted inside the `with` block matches the `logger` and `level` conditions, otherwise it fails.
The object returned by the context manager is a recording helper which keeps tracks of the matching log messages. It has two attributes:

**records**
- A list of `logging.LogRecord` objects of the matching log messages.

**output**
- A list of `str` objects with the formatted output of matching messages.

Example:

```python
with self.assertLogs('foo', level='INFO') as cm:
    logging.getLogger('foo').info('first message')
    logging.getLogger('foo.bar').error('second message')
self.assertEqual(cm.output, ['INFO:foo:first message', 'ERROR:foo.bar:second message'])
```

*New in version 3.4.*

There are also other methods used to perform more specific checks, such as:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertAlmostEqual(a, b)</code></td>
<td><code>round(a-b, 7) == 0</code></td>
<td></td>
</tr>
<tr>
<td><code>assertNotAlmostEqual(a, b)</code></td>
<td><code>round(a-b, 7) != 0</code></td>
<td></td>
</tr>
<tr>
<td><code>assertGreater(a, b)</code></td>
<td><code>a &gt; b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertGreaterEqual(a, b)</code></td>
<td><code>a &gt;= b</code></td>
<td>3.1</td>
</tr>
</tbody>
</table>
### b)

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertLess(a, b)</code></td>
<td>$a &lt; b$</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertLessEqual(a, b)</code></td>
<td>$a \leq b$</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertRegex(s, r)</code></td>
<td><code>r.search(s)</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertNotRegex(s, r)</code></td>
<td><code>not r.search(s)</code></td>
<td>3.2</td>
</tr>
<tr>
<td><code>assertCountEqual(a, b)</code></td>
<td>$a$ and $b$ have the same elements in the same number, regardless of their order</td>
<td>3.2</td>
</tr>
</tbody>
</table>

### assertAlmostEqual

`assertAlmostEqual(first, second, places=7, msg=None, delta=None)`

Test that `first` and `second` are approximately (or not approximately) equal by computing the difference, rounding to the given number of decimal `places` (default 7), and comparing to zero. Note that these methods round the values to the given number of decimal places (i.e. like the `round()` function) and not significant digits.

If `delta` is supplied instead of `places` then the difference between `first` and `second` must be less or equal to (or greater than) `delta`.

Supplying both `delta` and `places` raises a `TypeError`.

**Changed in version 3.2:** `assertAlmostEqual()` automatically considers almost equal objects that compare equal. `assertNotAlmostEqual()` automatically fails if the objects compare equal. Added the `delta` keyword argument.
**assertGreater**(*first, second, msg=None*)

**assertGreaterEqual**(*first, second, msg=None*)

**assertLess**(*first, second, msg=None*)

**assertLessEqual**(*first, second, msg=None*)

Test that *first* is respectively >, >=, < or <= than *second* depending on the method name. If not, the test will fail:

```python
>>> self.assertGreaterEqual(3, 4)
AssertionError: "3" unexpectedly not greater than or equal to "4"
```

*New in version 3.1.*

**assertRegex**(*text, regex, msg=None*)

**assertNotRegex**(*text, regex, msg=None*)

Test that a *regex* search matches (or does not match) *text*. In case of failure, the error message will include the pattern and the *text* (or the pattern and the part of *text* that unexpectedly matched). *regex* may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`.

*New in version 3.1:* under the name `assertRegexpMatches`.

*Changed in version 3.2:* The method `assertRegexpMatches()` has been renamed to `assertRegex()`.

*New in version 3.2:* `assertNotRegex()`.

*New in version 3.5:* The name `assertNotRegexpMatches` is a deprecated alias for `assertNotRegex()`.
**assertCountEqual**(first, second, msg=None)

Test that sequence first contains the same elements as second, regardless of their order. When they don’t, an error message listing the differences between the sequences will be generated.

Duplicate elements are *not* ignored when comparing first and second. It verifies whether each element has the same count in both sequences. Equivalent to:

```python
assertEqual(Counter(list(first)),
            Counter(list(second)))
```
but works with sequences of unhashable objects as well.

*New in version 3.2.*

The **assertEqual()** method dispatches the equality check for objects of the same type to different type-specific methods. These methods are already implemented for most of the built-in types, but it’s also possible to register new methods using **addTypeEqualityFunc()**:

**addTypeEqualityFunc**(typeobj, function)

Registers a type-specific method called by **assertEqual()** to check if two objects of exactly the same typeobj (not subclasses) compare equal. function must take two positional arguments and a third msg=None keyword argument just as **assertEqual()** does. It must raise **self.failureException(msg)** when inequality between the first two parameters is detected – possibly providing useful information and explaining the inequalities in details in the error message.
New in version 3.1.

The list of type-specific methods automatically used by `assertEquals()` are summarized in the following table. Note that it's usually not necessary to invoke these methods directly.

<table>
<thead>
<tr>
<th>Method</th>
<th>Used to compare</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertMultiLineEqual(a, b)</code></td>
<td>strings</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertSequenceEqual(a, b)</code></td>
<td>sequences</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertListEqual(a, b)</code></td>
<td>lists</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertTupleEqual(a, b)</code></td>
<td>tuples</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertSetEqual(a, b)</code></td>
<td>sets or frozensets</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertDictEqual(a, b)</code></td>
<td>dicts</td>
<td>3.1</td>
</tr>
</tbody>
</table>

**assertMultiLineEqual** *(first, second, msg=None)*

Test that the multiline string `first` is equal to the string `second`. When not equal a diff of the two strings highlighting the differences will be included in the error message. This method is used by default when comparing strings with `assertEquals()`.

New in version 3.1.

**assertSequenceEqual** *(first, second, msg=None, seq_type=None)*

Tests that two sequences are equal. If a `seq_type` is supplied, both `first` and `second` must be instances of `seq_type` or a failure will be raised. If the sequences are different an error message is constructed that shows the difference between the two.
This method is not called directly by `assertEqual()`, but it's used to implement `assertListEqual()` and `assertTupleEqual()`.

*New in version 3.1.*

**assertListEqual**(first, second, msg=None)

**assertTupleEqual**(first, second, msg=None)

Tests that two lists or tuples are equal. If not, an error message is constructed that shows only the differences between the two. An error is also raised if either of the parameters are of the wrong type. These methods are used by default when comparing lists or tuples with `assertEqual()`.

*New in version 3.1.*

**assertSetEqual**(first, second, msg=None)

Tests that two sets are equal. If not, an error message is constructed that lists the differences between the sets. This method is used by default when comparing sets or frozensets with `assertEqual()`.

Fails if either of `first` or `second` does not have a `set.difference()` method.

*New in version 3.1.*

**assertDictEqual**(first, second, msg=None)

Tests that two dictionaries are equal. If not, an error message is constructed that shows the differences in the dictionaries. This method will be used by default to compare dictionaries in calls to `assertEqual()`.
Finally the `TestCase` provides the following methods and attributes:

**fail** *(msg=None)*

Signals a test failure unconditionally, with `msg` or `None` for the error message.

**failureException**

This class attribute gives the exception raised by the test method. If a test framework needs to use a specialized exception, possibly to carry additional information, it must subclass this exception in order to “play fair” with the framework. The initial value of this attribute is `AssertionError`.

**longMessage**

This class attribute determines what happens when a custom failure message is passed as the `msg` argument to an `assertXYY` call that fails. `True` is the default value. In this case, the custom message is appended to the end of the standard failure message. When set to `False`, the custom message replaces the standard message.

The class setting can be overridden in individual test methods by assigning an instance attribute, `self.longMessage`, to `True` or `False` before calling the assert methods.

The class setting gets reset before each test call.

*New in version 3.1.*
maxDiff

This attribute controls the maximum length of diffs output by assert methods that report diffs on failure. It defaults to 80*8 characters. Assert methods affected by this attribute are assertSequenceEqual() (including all the sequence comparison methods that delegate to it), assertDictEqual() and assertMultiLineEqual().

Setting maxDiff to None means that there is no maximum length of diffs.

New in version 3.2.

Testing frameworks can use the following methods to collect information on the test:

countTestCases()

Return the number of tests represented by this test object. For TestCase instances, this will always be 1.

defaultTestResult()

Return an instance of the test result class that should be used for this test case class (if no other result instance is provided to the run() method).

For TestCase instances, this will always be an instance of TestResult; subclasses of TestCase should override this as necessary.

id()

Return a string identifying the specific test case. This is usually the full name of the test method, including the module and class name.
**shortDescription()**

Returns a description of the test, or None if no description has been provided. The default implementation of this method returns the first line of the test method's docstring, if available, or None.

*Changed in version 3.1:* In 3.1 this was changed to add the test name to the short description even in the presence of a docstring. This caused compatibility issues with unittest extensions and adding the test name was moved to the `TextTestResult` in Python 3.2.

**addCleanup(function, *args, **kwargs)**

Add a function to be called after `tearDown()` to cleanup resources used during the test. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into `addCleanup()` when they are added.

If `setUp()` fails, meaning that `tearDown()` is not called, then any cleanup functions added will still be called.

*New in version 3.1.*

**doCleanups()**

This method is called unconditionally after `tearDown()`, or after `setUp()` if `setUp()` raises an exception.

It is responsible for calling all the cleanup functions added by `addCleanup()`. If you need cleanup functions to be called prior to `tearDown()` then you can call `doCleanups()` yourself.
doCleanups() pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

*New in version 3.1.*

```python
class unittest.FunctionTestCase(testFunc, setUp=None, tearDown=None, description=None)
```

This class implements the portion of the `TestCase` interface which allows the test runner to drive the test, but does not provide the methods which test code can use to check and report errors. This is used to create test cases using legacy test code, allowing it to be integrated into a `unittest`-based test framework.

### 26.4.8.1.1. Deprecated aliases

For historical reasons, some of the `TestCase` methods had one or more aliases that are now deprecated. The following table lists the correct names along with their deprecated aliases:

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Deprecated alias</th>
<th>Deprecation</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertEqual()</code></td>
<td><code>failUnlessEqual</code></td>
<td>assertEq</td>
</tr>
<tr>
<td><code>assertNotEqual()</code></td>
<td><code>failIfEqual</code></td>
<td>assertNotEq</td>
</tr>
<tr>
<td><code>assertTrue()</code></td>
<td><code>failUnless</code></td>
<td>assert_</td>
</tr>
<tr>
<td><code>assertFalse()</code></td>
<td><code>failIf</code></td>
<td></td>
</tr>
<tr>
<td><code>assertRaises()</code></td>
<td><code>failUnlessRaises</code></td>
<td></td>
</tr>
<tr>
<td><code>assertAlmostEqual()</code></td>
<td><code>failUnlessAlmostEqual</code></td>
<td>assertAlm</td>
</tr>
<tr>
<td><code>assertNotAlmostEqual()</code></td>
<td><code>failIfAlmostEqual</code></td>
<td>assertNotAlm</td>
</tr>
<tr>
<td><code>assertRegex()</code></td>
<td><code>assertRegexpMatches</code></td>
<td></td>
</tr>
<tr>
<td><code>assertNotRegex()</code></td>
<td><code>assertNotRegexpMatches</code></td>
<td></td>
</tr>
</tbody>
</table>
assertRaisesRegex()

*Deprecated since version 3.1:* the fail* aliases listed in the second column.

*Deprecated since version 3.2:* the assert* aliases listed in the third column.

*Deprecated since version 3.2:* `assertRegexpMatches` and `assertRaisesRegexp` have been renamed to `assertRegex()` and `assertRaisesRegex()`.

*Deprecated since version 3.5:* the `assertNotRegexpMatches` name in favor of `assertNotRegex()`.

### 26.4.8.2. Grouping tests

```python
class unittest.TestSuite(tests=())
```

This class represents an aggregation of individual test cases and test suites. The class presents the interface needed by the test runner to allow it to be run as any other test case. Running a `TestSuite` instance is the same as iterating over the suite, running each test individually.

If `tests` is given, it must be an iterable of individual test cases or other test suites that will be used to build the suite initially. Additional methods are provided to add test cases and suites to the collection later on.

`TestSuite` objects behave much like `TestCase` objects, except they do not actually implement a test. Instead, they are used to aggregate tests into groups of tests that should be run together.
Some additional methods are available to add tests to TestSuite instances:

addTest\([test]\)

Add a TestCase or TestSuite to the suite.

addTests\([tests]\)

Add all the tests from an iterable of TestCase and TestSuite instances to this test suite.

This is equivalent to iterating over tests, calling addTest() for each element.

TestSuite shares the following methods with TestCase:

run\([result]\)

Run the tests associated with this suite, collecting the result into the test result object passed as result. Note that unlike TestCase.run(), TestSuite.run() requires the result object to be passed in.

debug()

Run the tests associated with this suite without collecting the result. This allows exceptions raised by the test to be propagated to the caller and can be used to support running tests under a debugger.

countTestCases()

Return the number of tests represented by this test object, including all individual tests and sub-suites.

___iter___()

Tests grouped by a TestSuite are always accessed by
iteration. Subclasses can lazily provide tests by overriding `__iter__()`. Note that this method may be called several times on a single suite (for example when counting tests or comparing for equality) so the tests returned by repeated iterations before `TestSuite.run()` must be the same for each call iteration. After `TestSuite.run()`, callers should not rely on the tests returned by this method unless the caller uses a subclass that overrides `TestSuite._removeTestAtIndex()` to preserve test references.

*Changed in version 3.2:* In earlier versions the `TestSuite` accessed tests directly rather than through iteration, so overriding `__iter__()` wasn’t sufficient for providing tests.

*Changed in version 3.4:* In earlier versions the `TestSuite` held references to each `TestCase` after `TestSuite.run()`. Subclasses can restore that behavior by overriding `TestSuite._removeTestAtIndex()`.

In the typical usage of a `TestSuite` object, the `run()` method is invoked by a TestRunner rather than by the end-user test harness.

### 26.4.8.3. Loading and running tests

*class unittest.TestLoader*

The `TestLoader` class is used to create test suites from classes and modules. Normally, there is no need to create an instance of this class; the `unittest` module provides an instance that can be shared as `unittest.defaultTestLoader`. Using a subclass or
instance, however, allows customization of some configurable properties.

**TestLoader** objects have the following attributes:

**errors**
A list of the non-fatal errors encountered while loading tests. Not reset by the loader at any point. Fatal errors are signalled by the relevant a method raising an exception to the caller. Non-fatal errors are also indicated by a synthetic test that will raise the original error when run.

*New in version 3.5.*

**TestLoader** objects have the following methods:

**loadTestsFromTestCase**(testCaseClass)
Return a suite of all test cases contained in the **TestCase**-derived testCaseClass.

A test case instance is created for each method named by **getTestCaseNames**(). By default these are the method names beginning with test. If **getTestCaseNames**() returns no methods, but the **runTest**() method is implemented, a single test case is created for that method instead.

**loadTestsFromModule**(module, pattern=None)
Return a suite of all test cases contained in the given module. This method searches **module** for classes derived from **TestCase** and creates an instance of the class for each test method defined for the class.

**Note:** While using a hierarchy of **TestCase**-derived classes
can be convenient in sharing fixtures and helper functions, defining test methods on base classes that are not intended to be instantiated directly does not play well with this method. Doing so, however, can be useful when the fixtures are different and defined in subclasses.

If a module provides a `load_tests` function it will be called to load the tests. This allows modules to customize test loading. This is the `load_tests` protocol. The `pattern` argument is passed as the third argument to `load_tests`.

*Changed in version 3.2:* Support for `load_tests` added.

*Changed in version 3.5:* The undocumented and unofficial `use_load_tests` default argument is deprecated and ignored, although it is still accepted for backward compatibility. The method also now accepts a keyword-only argument `pattern` which is passed to `load_tests` as the third argument.

`loadTestsFromName(name, module=None)`

Return a suite of all test cases given a string specifier.

The specifier `name` is a “dotted name” that may resolve either to a module, a test case class, a test method within a test case class, a `TestSuite` instance, or a callable object which returns a `TestCase` or `TestSuite` instance. These checks are applied in the order listed here; that is, a method on a possible test case class will be picked up as “a test method within a test case class”, rather than “a callable object”.

For example, if you have a module `SampleTests` containing a `TestCase`-derived class `SampleTestCase` with three test methods (`test_one()`, `test_two()`, and `test_three()`),
the specifier 'SampleTests.SampleTestCase' would cause this method to return a suite which will run all three test methods. Using the specifier 'SampleTests.SampleTestCase.test_two' would cause it to return a test suite which will run only the test_two() test method. The specifier can refer to modules and packages which have not been imported; they will be imported as a side-effect.

The method optionally resolves name relative to the given module.

*Changed in version 3.5:* If an ImportError or AttributeError occurs while traversing name then a synthetic test that raises that error when run will be returned. These errors are included in the errors accumulated by self.errors.

**loadTestsFromNames**(names, module=None)

Similar to loadTestsFromName(), but takes a sequence of names rather than a single name. The return value is a test suite which supports all the tests defined for each name.

**getTestCaseNames**(testCaseClass)

Return a sorted sequence of method names found within testCaseClass; this should be a subclass of TestCase.

**discover**(start_dir, pattern='test*.py', top_level_dir=None)

Find all the test modules by recursing into subdirectories from the specified start directory, and return a TestSuite object containing them. Only test files that match pattern will be loaded. (Using shell style pattern matching.) Only module
names that are importable (i.e. are valid Python identifiers) will be loaded.

All test modules must be importable from the top level of the project. If the start directory is not the top level directory then the top level directory must be specified separately.

If importing a module fails, for example due to a syntax error, then this will be recorded as a single error and discovery will continue. If the import failure is due to `SkipTest` being raised, it will be recorded as a skip instead of an error.

If a package (a directory containing a file named `__init__.py`) is found, the package will be checked for a `load_tests` function. If this exists then it will be called `package.load_tests(loader, tests, pattern)`. Test discovery takes care to ensure that a package is only checked for tests once during an invocation, even if the `load_tests` function itself calls `loader.discover`.

If `load_tests` exists then discovery does not recurse into the package, `load_tests` is responsible for loading all tests in the package.

The pattern is deliberately not stored as a loader attribute so that packages can continue discovery themselves. `top_level_dir` is stored so `load_tests` does not need to pass this argument in to `loader.discover()`.

`start_dir` can be a dotted module name as well as a directory.

*New in version 3.2.*
Changed in version 3.4: Modules that raise `SkipTest` on import are recorded as skips, not errors. Discovery works for namespace packages. Paths are sorted before being imported so that execution order is the same even if the underlying file system’s ordering is not dependent on file name.

Changed in version 3.5: Found packages are now checked for `load_tests` regardless of whether their path matches `pattern`, because it is impossible for a package name to match the default pattern.

The following attributes of a `TestLoader` can be configured either by subclassing or assignment on an instance:

**testMethodPrefix**
String giving the prefix of method names which will be interpreted as test methods. The default value is `'test'`.

This affects `getTestCaseNames()` and all the `loadTestsFrom*()` methods.

**sortTestMethodsUsing**
Function to be used to compare method names when sorting them in `getTestCaseNames()` and all the `loadTestsFrom*()` methods.

**suiteClass**
Callable object that constructs a test suite from a list of tests. No methods on the resulting object are needed. The default value is the `TestSuite` class.

This affects all the `loadTestsFrom*()` methods.
**class unittest.TestResult**

This class is used to compile information about which tests have succeeded and which have failed.

A `TestResult` object stores the results of a set of tests. The `TestCase` and `TestSuite` classes ensure that results are properly recorded; test authors do not need to worry about recording the outcome of tests.

Testing frameworks built on top of `unittest` may want access to the `TestResult` object generated by running a set of tests for reporting purposes; a `TestResult` instance is returned by the `TestRunner.run()` method for this purpose.

`TestResult` instances have the following attributes that will be of interest when inspecting the results of running a set of tests:

**errors**

A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents a test which raised an unexpected exception.

**failures**

A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents a test where a failure was explicitly signalled using the `TestCase.assert*()` methods.

**skipped**

A list containing 2-tuples of `TestCase` instances and strings holding the reason for skipping the test.

*New in version 3.1.*
expectedFailures
A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents an expected failure of the test case.

unexpectedSuccesses
A list containing `TestCase` instances that were marked as expected failures, but succeeded.

shouldStop
Set to `True` when the execution of tests should stop by `stop()`.

testsRun
The total number of tests run so far.

buffer
If set to true, `sys.stdout` and `sys.stderr` will be buffered in between `startTest()` and `stopTest()` being called. Collected output will only be echoed onto the real `sys.stdout` and `sys.stderr` if the test fails or errors. Any output is also attached to the failure / error message.

New in version 3.2.

failfast
If set to true `stop()` will be called on the first failure or error, halting the test run.

New in version 3.2.

tb_locals
If set to true then local variables will be shown in tracebacks.
New in version 3.5.

**wasSuccessful()**

Return **True** if all tests run so far have passed, otherwise returns **False**.

*Changed in version 3.4:* Returns **False** if there were any unexpectedSuccesses from tests marked with the `expectedFailure()` decorator.

**stop()**

This method can be called to signal that the set of tests being run should be aborted by setting the `shouldStop` attribute to **True**. TestRunner objects should respect this flag and return without running any additional tests.

For example, this feature is used by the **TextTestRunner** class to stop the test framework when the user signals an interrupt from the keyboard. Interactive tools which provide TestRunner implementations can use this in a similar manner.

The following methods of the **TestResult** class are used to maintain the internal data structures, and may be extended in subclasses to support additional reporting requirements. This is particularly useful in building tools which support interactive reporting while tests are being run.

**startTest(test)**

Called when the test case `test` is about to be run.

**stopTest(test)**

Called after the test case `test` has been executed, regardless of
the outcome.

**startTestRun()**
Called once before any tests are executed.

*New in version 3.1.*

**stopTestRun()**
Called once after all tests are executed.

*New in version 3.1.*

**addError(test, err)**
Called when the test case *test* raises an unexpected exception. *err* is a tuple of the form returned by `sys.exc_info()`:

```
(type, value, traceback)
```

The default implementation appends a tuple `(test, formatted_err)` to the instance's `errors` attribute, where `formatted_err` is a formatted traceback derived from *err*.

**addFailure(test, err)**
Called when the test case *test* signals a failure. *err* is a tuple of the form returned by `sys.exc_info()`:

```
(type, value, traceback)
```

The default implementation appends a tuple `(test, formatted_err)` to the instance’s `failures` attribute, where `formatted_err` is a formatted traceback derived from *err*.

**addSuccess(test)**
Called when the test case *test* succeeds.
The default implementation does nothing.

**addSkip**(test, *reason*)
Called when the test case test is skipped. *reason* is the reason the test gave for skipping.

The default implementation appends a tuple *(test, reason)* to the instance’s skipped attribute.

**addExpectedFailure**(test, *err*)
Called when the test case test fails, but was marked with the expectedFailure() decorator.

The default implementation appends a tuple *(test, formatted_err)* to the instance’s expectedFailures attribute, where *formatted_err* is a formatted traceback derived from *err*.

**addUnexpectedSuccess**(test)
Called when the test case test was marked with the expectedFailure() decorator, but succeeded.

The default implementation appends the test to the instance’s unexpectedSuccesses attribute.

**addSubTest**(test, subtest, *outcome*)
Called when a subtest finishes. test is the test case corresponding to the test method. subtest is a custom TestCase instance describing the subtest.

If *outcome* is None, the subtest succeeded. Otherwise, it failed with an exception where *outcome* is a tuple of the form returned by sys.exc_info(): (type, value, traceback).
The default implementation does nothing when the outcome is a success, and records subtest failures as normal failures.

New in version 3.4.

class unittest.TextTestResult(stream, descriptions, verbosity)
A concrete implementation of TestResult used by the TextTestRunner.

New in version 3.2: This class was previously named _TextTestResult. The old name still exists as an alias but is deprecated.

unittest.defaultTestLoader
Instance of the TestLoader class intended to be shared. If no customization of the TestLoader is needed, this instance can be used instead of repeatedly creating new instances.

class unittest.TextTestRunner(stream=None, descriptions=True, verbosity=1, failfast=False, buffer=False, resultclass=None, warnings=None, *, tb_locals=False)
A basic test runner implementation that outputs results to a stream. If stream is None, the default, sys.stderr is used as the output stream. This class has a few configurable parameters, but is essentially very simple. Graphical applications which run test suites should provide alternate implementations. Such implementations should accept **kwargs as the interface to construct runners changes when features are added to unittest.

By default this runner shows DeprecationWarning, PendingDeprecationWarning, ResourceWarning and ImportWarning even if they are ignored by default. Deprecation
warnings caused by deprecated unittest methods are also special-cased and, when the warning filters are 'default' or 'always', they will appear only once per-module, in order to avoid too many warning messages. This behavior can be overridden using Python's -Wd or -Wa options (see Warning control) and leaving warnings to None.

*Changed in version 3.2:* Added the warnings argument.

*Changed in version 3.2:* The default stream is set to sys.stderr at instantiation time rather than import time.

*Changed in version 3.5:* Added the tb_locals parameter.

_**_makeResult()_

This method returns the instance of TestResult used by run(). It is not intended to be called directly, but can be overridden in subclasses to provide a custom TestResult.

_**_makeResult()_** instantiates the class or callable passed in the TextTestRunner constructor as the resultclass argument. It defaults to TextTestResult if no resultclass is provided. The result class is instantiated with the following arguments:

```
stream, descriptions, verbosity
```

**run(test)**

This method is the main public interface to the TextTestRunner. This method takes a TestSuite or TestCase instance. A TestResult is created by calling _**_makeResult()_** and the test(s) are run and the results printed to stdout.
A command-line program that loads a set of tests from `module` and runs them; this is primarily for making test modules conveniently executable. The simplest use for this function is to include the following line at the end of a test script:

```python
if __name__ == '__main__':
    unittest.main()
```

You can run tests with more detailed information by passing in the `verbosity` argument:

```python
if __name__ == '__main__':
    unittest.main(verbosity=2)
```

The `defaultTest` argument is either the name of a single test or an iterable of test names to run if no test names are specified via `argv`. If not specified or `None` and no test names are provided via `argv`, all tests found in `module` are run.

The `argv` argument can be a list of options passed to the program, with the first element being the program name. If not specified or `None`, the values of `sys.argv` are used.

The `testRunner` argument can either be a test runner class or an already created instance of it. By default, it calls `sys.exit()` with an exit code indicating success or failure of the tests run.

The `testLoader` argument has to be a `TestLoader` instance, and defaults to `defaultTestLoader`.

```python
unittest.main(module='__main__', defaultTest=None, argv=None, testRunner=None, testLoader=unittest.defaultTestLoader, exit=True, verbosity=1, failfast=None, catchbreak=None, buffer=None, warnings=None)
```
main supports being used from the interactive interpreter by passing in the argument exit=False. This displays the result on standard output without calling sys.exit():

```python
>>> from unittest import main
>>> main(module='test_module', exit=False)
```

The failfast, catchbreak and buffer parameters have the same effect as the same-name command-line options.

The warnings argument specifies the warning filter that should be used while running the tests. If it's not specified, it will remain None if a -W option is passed to python (see Warning control), otherwise it will be set to 'default'.

Calling main actually returns an instance of the TestProgram class. This stores the result of the tests run as the result attribute.

*Changed in version 3.1:* The exit parameter was added.

*Changed in version 3.2:* The verbosity, failfast, catchbreak, buffer and warnings parameters were added.

*Changed in version 3.4:* The defaultTest parameter was changed to also accept an iterable of test names.

26.4.8.3.1. load_tests Protocol

*New in version 3.2.*

Modules or packages can customize how tests are loaded from them during normal test runs or test discovery by implementing a function
called load_tests.

If a test module defines load_tests it will be called by TestLoader.loadTestsFromModule() with the following arguments:

```python
load_tests(loader, standard_tests, pattern)
```

where pattern is passed straight through from loadTestsFromModule. It defaults to None.

It should return a TestSuite.

loader is the instance of TestLoader doing the loading. standard_tests are the tests that would be loaded by default from the module. It is common for test modules to only want to add or remove tests from the standard set of tests. The third argument is used when loading packages as part of test discovery.

A typical load_tests function that loads tests from a specific set of TestCase classes may look like:

```python
test_cases = (TestCase1, TestCase2, TestCase3)
def load_tests(loader, tests, pattern):
    suite = TestSuite()
    for test_class in test_cases:
        tests = loader.loadTestsFromTestCase(test_class)
        suite.addTests(tests)
    return suite
```

If discovery is started in a directory containing a package, either from the command line or by calling TestLoader.discover(), then the
package __init__.py will be checked for load_tests. If that function does not exist, discovery will recurse into the package as though it were just another directory. Otherwise, discovery of the package's tests will be left up to load_tests which is called with the following arguments:

```python
load_tests(loader, standard_tests, pattern)
```

This should return a `TestSuite` representing all the tests from the package. (`standard_tests` will only contain tests collected from `__init__.py`.)

Because the pattern is passed into load_tests the package is free to continue (and potentially modify) test discovery. A ‘do nothing’ `load_tests` function for a test package would look like:

```python
def load_tests(loader, standard_tests, pattern):
    # top level directory cached on loader instance
    this_dir = os.path.dirname(__file__)
    package_tests = loader.discover(start_dir=this_dir)
    standard_tests.addTests(package_tests)
    return standard_tests
```

*Changed in version 3.5:* Discovery no longer checks package names for matching pattern due to the impossibility of package names matching the default pattern.
26.4.9. Class and Module Fixtures

Class and module level fixtures are implemented in TestSuite. When the test suite encounters a test from a new class then tearDownClass() from the previous class (if there is one) is called, followed by setUpClass() from the new class.

Similarly if a test is from a different module from the previous test then tearDownModule from the previous module is run, followed by setUpModule from the new module.

After all the tests have run the final tearDownClass and tearDownModule are run.

Note that shared fixtures do not play well with [potential] features like test parallelization and they break test isolation. They should be used with care.

The default ordering of tests created by the unittest test loaders is to group all tests from the same modules and classes together. This will lead to setUpClass / setUpModule (etc) being called exactly once per class and module. If you randomize the order, so that tests from different modules and classes are adjacent to each other, then these shared fixture functions may be called multiple times in a single test run.

Shared fixtures are not intended to work with suites with non-standard ordering. A BaseTestSuite still exists for frameworks that don’t want to support shared fixtures.

If there are any exceptions raised during one of the shared fixture functions the test is reported as an error. Because there is no
corresponding test instance an \_ErrorHolder object (that has the same interface as a \_TesteCase) is created to represent the error. If you are just using the standard unittest test runner then this detail doesn’t matter, but if you are a framework author it may be relevant.

26.4.9.1. setUpClass and tearDownClass

These must be implemented as class methods:

```python
import unittest

class Test(unittest.TestCase):
    @classmethod
    def setUpClass(cls):
        cls._connection = createExpensiveConnectionObject

    @classmethod
    def tearDownClass(cls):
        cls._connection.destroy()
```

If you want the setUpClass and tearDownClass on base classes called then you must call up to them yourself. The implementations in TestCase are empty.

If an exception is raised during a setUpClass then the tests in the class are not run and the tearDownClass is not run. Skipped classes will not have setUpClass or tearDownClass run. If the exception is a SkipTest exception then the class will be reported as having been skipped instead of as an error.

26.4.9.2. setUpModule and tearDownModule
These should be implemented as functions:

```python
def setUpModule():
    createConnection()

def tearDownModule():
    closeConnection()
```

If an exception is raised in a `setUpModule` then none of the tests in the module will be run and the `tearDownModule` will not be run. If the exception is a `SkipTest` exception then the module will be reported as having been skipped instead of as an error.
26.4.10. Signal Handling

*New in version 3.2.*

The `-c/--catch` command-line option to unittest, along with the `catchbreak` parameter to `unittest.main()`, provide more friendly handling of control-C during a test run. With catch break behavior enabled control-C will allow the currently running test to complete, and the test run will then end and report all the results so far. A second control-c will raise a `KeyboardInterrupt` in the usual way.

The control-c handling signal handler attempts to remain compatible with code or tests that install their own `signal.SIGINT` handler. If the `unittest` handler is called but *isn’t* the installed `signal.SIGINT` handler, i.e. it has been replaced by the system under test and delegated to, then it calls the default handler. This will normally be the expected behavior by code that replaces an installed handler and delegates to it. For individual tests that need `unittest` control-c handling disabled the `removeHandler()` decorator can be used.

There are a few utility functions for framework authors to enable control-c handling functionality within test frameworks.

*unittest.* **installHandler()**
  - Install the control-c handler. When a `signal.SIGINT` is received (usually in response to the user pressing control-c) all registered results have `stop()` called.

*unittest.* **registerResult(result)**
Register a `TestResult` object for control-c handling. Registering a result stores a weak reference to it, so it doesn't prevent the result from being garbage collected.

Registering a `TestResult` object has no side-effects if control-c handling is not enabled, so test frameworks can unconditionally register all results they create independently of whether or not handling is enabled.

```python
unittest.removeResult(result)
```

Remove a registered result. Once a result has been removed then `stop()` will no longer be called on that result object in response to a control-c.

```python
unittest.removeHandler(function=None)
```

When called without arguments this function removes the control-c handler if it has been installed. This function can also be used as a test decorator to temporarily remove the handler whilst the test is being executed:

```python
@unittest.removeHandler
def test_signal_handling(self):
    ...
```
26.5. `unittest.mock` — mock object library

*New in version 3.3.*

**Source code:** Lib/unittest/mock.py

`unittest.mock` is a library for testing in Python. It allows you to replace parts of your system under test with mock objects and make assertions about how they have been used.

`unittest.mock` provides a core `Mock` class removing the need to create a host of stubs throughout your test suite. After performing an action, you can make assertions about which methods / attributes were used and arguments they were called with. You can also specify return values and set needed attributes in the normal way.

Additionally, mock provides a `patch()` decorator that handles patching module and class level attributes within the scope of a test, along with `sentinel` for creating unique objects. See the [quick guide](#) for some examples of how to use `Mock`, `MagicMock` and `patch()`.

Mock is very easy to use and is designed for use with `unittest`. Mock is based on the ‘action -> assertion’ pattern instead of ‘record -> replay’ used by many mocking frameworks.

There is a backport of `unittest.mock` for earlier versions of Python, available as `mock` on PyPI.
26.5.1. Quick Guide

Mock and MagicMock objects create all attributes and methods as you access them and store details of how they have been used. You can configure them, to specify return values or limit what attributes are available, and then make assertions about how they have been used:

```python
>>> from unittest.mock import MagicMock
>>> thing = ProductionClass()
>>> thing.method = MagicMock(return_value=3)
>>> thing.method(3, 4, 5, key='value')
3
>>> thing.method.assert_called_with(3, 4, 5, key='value')
```

side_effect allows you to perform side effects, including raising an exception when a mock is called:

```python
>>> mock = Mock(side_effect=KeyError('foo'))
>>> mock()
Traceback (most recent call last):
... KeyError: 'foo'
```

```python
>>> values = {'a': 1, 'b': 2, 'c': 3}
>>> def side_effect(arg):
...     return values[arg]
...
>>> mock.side_effect = side_effect
>>> mock('a'), mock('b'), mock('c')
(1, 2, 3)
>>> mock.side_effect = [5, 4, 3, 2, 1]
>>> mock(), mock(), mock()
(5, 4, 3)
```
Mock has many other ways you can configure it and control its behaviour. For example the `spec` argument configures the mock to take its specification from another object. Attempting to access attributes or methods on the mock that don’t exist on the spec will fail with an `AttributeError`.

The `patch()` decorator / context manager makes it easy to mock classes or objects in a module under test. The object you specify will be replaced with a mock (or other object) during the test and restored when the test ends:

```python
>>> from unittest.mock import patch
global
... @patch('module.ClassName2')
... @patch('module.ClassName1')
... def test(MockClass1, MockClass2):
...     module.ClassName1()
...     module.ClassName2()
...     assert MockClass1 is module.ClassName1
...     assert MockClass2 is module.ClassName2
...     assert MockClass1.called
...     assert MockClass2.called
... >>> test()
```

**Note**: When you nest patch decorators the mocks are passed in to the decorated function in the same order they applied (the normal python order that decorators are applied). This means from the bottom up, so in the example above the mock for `module.ClassName1` is passed in first.

With `patch()` it matters that you patch objects in the namespace where they are looked up. This is normally straightforward, but for a quick guide read where to patch.
As well as a decorator `patch()` can be used as a context manager in a `with` statement:

```python
>>> with patch.object(ProductionClass, 'method', return_value=...  
...     thing = ProductionClass()
...     thing.method(1, 2, 3)
...  
>>> mock_method.assert_called_once_with(1, 2, 3)
```

There is also `patch.dict()` for setting values in a dictionary just during a scope and restoring the dictionary to its original state when the test ends:

```python
>>> foo = {'key': 'value'}
>>> original = foo.copy()
>>> with patch.dict(foo, {'newkey': 'newvalue'}, clear=True)
...     assert foo == {'newkey': 'newvalue'}
...
>>> assert foo == original
```

Mock supports the mocking of Python magic methods. The easiest way of using magic methods is with the `Mock` class. It allows you to do things like:

```python
>>> mock = MagicMock()
>>> mock.__str__.return_value = 'foobaz'
>>> str(mock)
'foobaz'
>>> mock.__str__.assert_called_with()
```

Mock allows you to assign functions (or other Mock instances) to magic methods and they will be called appropriately. The `MagicMock` class is just a Mock variant that has all of the magic methods pre-
created for you (well, all the useful ones anyway).

The following is an example of using magic methods with the ordinary Mock class:

```python
>>> mock = Mock()
>>> mock.__str__ = Mock(return_value='wheeeeee')
>>> str(mock)
'wheeeeee'
```

For ensuring that the mock objects in your tests have the same api as the objects they are replacing, you can use auto-speccing. Auto-speccing can be done through the autospec argument to patch, or the create_autospec() function. Auto-speccing creates mock objects that have the same attributes and methods as the objects they are replacing, and any functions and methods (including constructors) have the same call signature as the real object.

This ensures that your mocks will fail in the same way as your production code if they are used incorrectly:

```python
>>> from unittest.mock import create_autospec
>>> def function(a, b, c):
...     pass
...
>>> mock_function = create_autospec(function, return_value='fishy')
>>> mock_function(1, 2, 3)
'fishy'
>>> mock_function.assert_called_once_with(1, 2, 3)
>>> mock_function('wrong arguments')
Traceback (most recent call last):
  ...TypeError: <lambda>() takes exactly 3 arguments (1 given)
```
`create_autospec()` can also be used on classes, where it copies the signature of the `__init__` method, and on callable objects where it copies the signature of the `__call__` method.
26.5.2. The Mock Class

Mock is a flexible mock object intended to replace the use of stubs and test doubles throughout your code.Mocks are callable and create attributes as new mocks when you access them [1]. Accessing the same attribute will always return the same mock. Mocks record how you use them, allowing you to make assertions about what your code has done to them.

MagicMock is a subclass of Mock with all the magic methods pre-created and ready to use. There are also non-callable variants, useful when you are mocking out objects that aren’t callable: NonCallableMock and NonCallable MagicMock

The patch() decorators makes it easy to temporarily replace classes in a particular module with a Mock object. By default patch() will create a MagicMock for you. You can specify an alternative class of Mock using the new_callable argument to patch().

class unittest.mock.Mock(spec=None, side_effect=None, return_value=DEFAULT, wraps=None, name=None, spec_set=None, unsafe=False, **kwargs)

Create a new Mock object. Mock takes several optional arguments that specify the behaviour of the Mock object:

- spec: This can be either a list of strings or an existing object (a class or instance) that acts as the specification for the mock object. If you pass in an object then a list of strings is formed by calling dir on the object (excluding unsupported magic attributes and methods). Accessing any attribute not in this list will raise an AttributeError.
If `spec` is an object (rather than a list of strings) then `__class__` returns the class of the spec object. This allows mocks to pass `isinstance()` tests.

- **spec_set**: A stricter variant of `spec`. If used, attempting to set or get an attribute on the mock that isn't on the object passed as `spec_set` will raise an `AttributeError`.

- **side_effect**: A function to be called whenever the Mock is called. See the side_effect attribute. Useful for raising exceptions or dynamically changing return values. The function is called with the same arguments as the mock, and unless it returns `DEFAULT`, the return value of this function is used as the return value.

  Alternatively `side_effect` can be an exception class or instance. In this case the exception will be raised when the mock is called.

  If `side_effect` is an iterable then each call to the mock will return the next value from the iterable.

  A side_effect can be cleared by setting it to `None`.

- **return_value**: The value returned when the mock is called. By default this is a new Mock (created on first access). See the return_value attribute.

- **unsafe**: By default if any attribute starts with `assert` or `assert` will raise an `AttributeError`. Passing `unsafe=True` will allow access to these attributes.

  New in version 3.5.
• **wraps**: Item for the mock object to wrap. If *wraps* is not None then calling the Mock will pass the call through to the wrapped object (returning the real result). Attribute access on the mock will return a Mock object that wraps the corresponding attribute of the wrapped object (so attempting to access an attribute that doesn’t exist will raise an *AttributeError*).

If the mock has an explicit *return_value* set then calls are not passed to the wrapped object and the *return_value* is returned instead.

• **name**: If the mock has a name then it will be used in the repr of the mock. This can be useful for debugging. The name is propagated to child mocks.

Mocks can also be called with arbitrary keyword arguments. These will be used to set attributes on the mock after it is created. See the `configure_mock()` method for details.

**assert_called(**args**, **kwargs)**

Assert that the mock was called at least once.

```python
>>> mock = Mock()
>>> mock.method()  
<Mock name='mock.method()' id='...'>
>>> mock.method().assert_called()
```

*New in version 3.6.*

**assert_called_once(**args**, **kwargs)**

Assert that the mock was called exactly once.

```python
>>> mock = Mock()
>>> mock.method()
```
assert_called_once_with(*args, **kwargs)

This method is a convenient way of asserting that calls are made in a particular way:

```python
>>> mock = Mock()
>>> mock.method(1, 2, 3, test='wow')
<Mock name='mock.method()' id='...'>
>>> mock.method.assert_called_once_with(1, 2, 3, test='wow')
```

assert_called_once_with(*args, **kwargs)

Assert that the mock was called exactly once and that that call was with the specified arguments.

```python
>>> mock = Mock(return_value=None)
>>> mock('foo', bar='baz')
>>> mock.assert_called_once_with('foo', bar='baz')
>>> mock('other', bar='values')
>>> mock.assert_called_once_with('other', bar='values')
Traceback (most recent call last):
  ...  
AssertionError: Expected 'mock' to be called once.
assert_any_call(*args, **kwargs)

assert the mock has been called with the specified arguments.

The assert passes if the mock has ever been called, unlike assert_called_with() and assert_called_once_with() that only pass if the call is the most recent one, and in the case of assert_called_once_with() it must also be the only call.

```python
>>> mock = Mock(return_value=None)
>>> mock(1, 2, arg='thing')
>>> mock('some', 'thing', 'else')
>>> mock.assert_any_call(1, 2, arg='thing')
```

assert_has_calls(calls, any_order=False)

assert the mock has been called with the specified calls. The mock_calls list is checked for the calls.

If any_order is false (the default) then the calls must be sequential. There can be extra calls before or after the specified calls.

If any_order is true then the calls can be in any order, but they must all appear in mock_calls.

```python
>>> mock = Mock(return_value=None)
>>> mock(1)
>>> mock(2)
>>> mock(3)
>>> mock(4)
>>> calls = [call(2), call(3)]
>>> mock.assert_has_calls(calls)
>>> calls = [call(4), call(2), call(3)]
>>> mock.assert_has_calls(calls, any_order=True)
```
assert_not_called()

Assert the mock was never called.

```python
>>> m = Mock()
>>> m.hello.assert_not_called()
>>> obj = m.hello()
>>> m.hello.assert_not_called()
Traceback (most recent call last):
  ...AssertionError: Expected 'hello' to not have been called.
```

*New in version 3.5.*

reset_mock(*, return_value=False, side_effect=False)

The reset_mock method resets all the call attributes on a mock object:

```python
>>> mock = Mock(return_value=None)
>>> mock('hello')
>>> mock.called
True
>>> mock.reset_mock()
>>> mock.called
False
```

*Changed in version 3.6:* Added two keyword only argument to the reset_mock function.

This can be useful where you want to make a series of assertions that reuse the same object. Note that reset_mock() doesn’t clear the return value, side_effect or any child attributes you have set using normal assignment by default. In case you want to reset return_value or
side_effect, then pass the corresponding parameter as True. Child mocks and the return value mock (if any) are reset as well.

**Note:** return_value, and side_effect are keyword only argument.

**mock_add_spec***(spec, spec_set=False)***

Add a spec to a mock. spec can either be an object or a list of strings. Only attributes on the spec can be fetched as attributes from the mock.

If spec_set is true then only attributes on the spec can be set.

**attach_mock***(mock, attribute)***

Attach a mock as an attribute of this one, replacing its name and parent. Calls to the attached mock will be recorded in the method_calls and mock_calls attributes of this one.

**configure_mock***(**kwargs)***

Set attributes on the mock through keyword arguments.

Attributes plus return values and side effects can be set on child mocks using standard dot notation and unpacking a dictionary in the method call:

```python
>>> mock = Mock()
>>> attrs = {'method.return_value': 3, 'other.side_effect': True}
>>> mock.configure_mock(**attrs)
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
```
The same thing can be achieved in the constructor call to mocks:

```python
>>> attrs = {'method.return_value': 3, 'other.side_effect': None}
>>> mock = Mock(some_attribute='eggs', **attrs)
>>> mock.some_attribute
'eggs'
>>> mock.method()
3
>>> mock(other())
Traceback (most recent call last):
  ...  
KeyError
```

`configure_mock()` exists to make it easier to do configuration after the mock has been created.

```python
@classmethod
def configure_mock(cls, **kw):
    pass
```

__dir__()

Mock objects limit the results of `dir(some_mock)` to useful results. For mocks with a spec this includes all the permitted attributes for the mock.

See `FILTER_DIR` for what this filtering does, and how to switch it off.

__get_child_mock__(**kw)

Create the child mocks for attributes and return value. By default child mocks will be the same type as the parent. Subclasses of Mock may want to override this to customize the way child mocks are made.
For non-callable mocks the callable variant will be used (rather than any custom subclass).

**called**

A boolean representing whether or not the mock object has been called:

```python
>>> mock = Mock(return_value=None)
>>> mock.called
False
>>> mock()
>>> mock.called
True
```

**call_count**

An integer telling you how many times the mock object has been called:

```python
>>> mock = Mock(return_value=None)
>>> mock.call_count
0
>>> mock()
>>> mock()
>>> mock.call_count
2
```

**return_value**

Set this to configure the value returned by calling the mock:

```python
>>> mock = Mock()
>>> mock.return_value = 'fish'
>>> mock()
'fish'
```

The default return value is a mock object and you can configure
it in the normal way:

```python
>>> mock = Mock()
>>> mock.return_value.attribute = sentinel.Attribute
>>> mock.return_value()
<Mock name='mock()()' id='...'>
>>> mock.return_value.assert_called_with()
```

`return_value` can also be set in the constructor:

```python
>>> mock = Mock(return_value=3)
>>> mock.return_value
3
>>> mock()
3
```

**side_effect**

This can either be a function to be called when the mock is called, an iterable or an exception (class or instance) to be raised.

If you pass in a function it will be called with same arguments as the mock and unless the function returns the `DEFAULT` singleton the call to the mock will then return whatever the function returns. If the function returns `DEFAULT` then the mock will return its normal value (from the `return_value`).

If you pass in an iterable, it is used to retrieve an iterator which must yield a value on every call. This value can either be an exception instance to be raised, or a value to be returned from the call to the mock (`DEFAULT` handling is identical to the function case).
An example of a mock that raises an exception (to test exception handling of an API):

```python
>>> mock = Mock()
>>> mock.side_effect = Exception('Boom!')
>>> mock()
Traceback (most recent call last):
  ...
Exception: Boom!
```

Using `side_effect` to return a sequence of values:

```python
>>> mock = Mock()
>>> mock.side_effect = [3, 2, 1]
>>> mock(), mock(), mock()
(3, 2, 1)
```

Using a callable:

```python
>>> mock = Mock(return_value=3)
>>> def side_effect(*args, **kwargs):
...     return DEFAULT
...
>>> mock.side_effect = side_effect
>>> mock()
3
```

`side_effect` can be set in the constructor. Here's an example that adds one to the value the mock is called with and returns it:

```python
>>> side_effect = lambda value: value + 1
>>> mock = Mock(side_effect=side_effect)
>>> mock(3)
4
```
>>> mock(-8)
-7

Setting `side_effect` to `None` clears it:

```python
>>> m = Mock(side_effect=KeyError, return_value=None)
>>> m()
Traceback (most recent call last):
  ... KeyError
>>> m.side_effect = None
>>> m()
3
```

**call_args**

This is either `None` (if the mock hasn't been called), or the arguments that the mock was last called with. This will be in the form of a tuple: the first member is any ordered arguments the mock was called with (or an empty tuple) and the second member is any keyword arguments (or an empty dictionary).

```python
>>> mock = Mock(return_value=None)
>>> print(mock.call_args)
None
>>> mock()
>>> mock.call_args
call()
>>> mock.call_args == ()
True
>>> mock(3, 4)
>>> mock.call_args
call(3, 4)
>>> mock.call_args == ((3, 4),)
True
>>> mock(3, 4, 5, key='fish', next='w00t!')
```
mock.call_args
call(3, 4, 5, key='fish', next='w00t!')

`call_args`, along with members of the lists `call_args_list`, `method_calls` and `mock_calls` are `call` objects. These are tuples, so they can be unpacked to get at the individual arguments and make more complex assertions. See `calls as tuples`.

**call_args_list**
This is a list of all the calls made to the mock object in sequence (so the length of the list is the number of times it has been called). Before any calls have been made it is an empty list. The `call` object can be used for conveniently constructing lists of calls to compare with `call_args_list`.

```python
>>> mock = Mock(return_value=None)
>>> mock()
>>> mock(3, 4)
>>> mock(key='fish', next='w00t!')
>>> mock.call_args_list
[call(), call(3, 4), call(key='fish', next='w00t!')]
>>> expected = [(), ((3, 4),), ({'key': 'fish'},
>>> mock.call_args_list == expected
True
```

Members of `call_args_list` are `call` objects. These can be unpacked as tuples to get at the individual arguments. See `calls as tuples`.

**method_calls**
As well as tracking calls to themselves, mocks also track calls to methods and attributes, and their methods and attributes:
>>> mock = Mock()
>>> mock.method()
<Mock name='mock.method()' id='...'>
>>> mock.property.method.attribute()
<Mock name='mock.property.method.attribute()' id='...'>
>>> mock.method_calls
[call.method(), call.property.method.attribute()]

Members of `method_calls` are `call` objects. These can be unpacked as tuples to get at the individual arguments. See `calls as tuples`.

**mock_calls**

`mock_calls` records *all* calls to the mock object, its methods, magic methods *and* return value mocks.

```python
>>> mock = MagicMock()
>>> result = mock(1, 2, 3)
>>> mock.first(a=3)
<MagicMock name='mock.first()' id='...'>
>>> mock.second()
<MagicMock name='mock.second()' id='...'>
>>> int(mock)
1
>>> result(1)
<MagicMock name='mock()' id='...'>
>>> expected = [call(1, 2, 3), call.first(a=3), ...
call.__int__(), call()(1)]
>>> mock.mock_calls == expected
True
```

Members of `mock_calls` are `call` objects. These can be unpacked as tuples to get at the individual arguments. See `calls as tuples`.
__class__

Normally the __class__ attribute of an object will return its type. For a mock object with a spec, __class__ returns the spec class instead. This allows mock objects to pass isinstance() tests for the object they are replacing / masquerading as:

```python
>>> mock = Mock(spec=3)
>>> isinstance(mock, int)
True
```

__class__ is assignable to, this allows a mock to pass an isinstance() check without forcing you to use a spec:

```python
>>> mock = Mock()
>>> mock.__class__ = dict
>>> isinstance(mock, dict)
True
```

class unittest.mock.**NonCallableMock**(spec=None, wraps=None, name=None, spec_set=None, **kwargs)

A non-callable version of **Mock**. The constructor parameters have the same meaning of **Mock**, with the exception of return_value and side_effect which have no meaning on a non-callable mock.

Mock objects that use a class or an instance as a spec or spec_set are able to pass isinstance() tests:

```python
>>> mock = Mock(spec=SomeClass)
>>> isinstance(mock, SomeClass)
True
>>> mock = Mock(spec_set=SomeClass())
```
isinstance(mock, SomeClass)
True

The **Mock** classes have support for mocking magic methods. See [magic methods](#) for the full details.

The mock classes and the `patch()` decorators all take arbitrary keyword arguments for configuration. For the `patch()` decorators the keywords are passed to the constructor of the mock being created. The keyword arguments are for configuring attributes of the mock:

```python
>>> m = MagicMock(attribute=3, other='fish')
>>> m.attribute
3
>>> m.other
'fish'
```

The return value and side effect of child mocks can be set in the same way, using dotted notation. As you can't use dotted names directly in a call you have to create a dictionary and unpack it using `**`:

```python
>>> attrs = {'method.return_value': 3, 'other.side_effect': lambda: 'eggs'}
>>> mock = Mock(some_attribute='eggs', **attrs)
>>> mock.some_attribute
'eggs'
>>> mock.method()
3
>>> mock.other()
Traceback (most recent call last):
  ...
  ...
  ...
  ... ValueError: ... rule...others'
```

A callable mock which was created with a `spec` (or a `spec_set`) will introspect the specification object's signature when matching calls to
the mock. Therefore, it can match the actual call’s arguments regardless of whether they were passed positionally or by name:

```python
>>> def f(a, b, c): pass
... >>> mock = Mock(spec=f)
>>> mock(1, 2, c=3)
<Mock name='mock()' id='140161580456576'>
>>> mock.assert_called_with(1, 2, 3)
>>> mock.assert_called_with(a=1, b=2, c=3)
```

This applies to `assert_called_with()`, `assert_called_once_with()`, `assert_has_calls()` and `assert_any_call()`. When Autospeccing, it will also apply to method calls on the mock object.

*Changed in version 3.4:* Added signature introspection on specced and autospecced mock objects.

```python
class unittest.mock.PropertyMock(*args, **kwargs)

A mock intended to be used as a property, or other descriptor, on a class. `PropertyMock` provides `__get__() `and `__set__() `methods so you can specify a return value when it is fetched.

Fetching a `PropertyMock` instance from an object calls the mock, with no args. Setting it calls the mock with the value being set.
```

```python
>>> class Foo:
...     @property
...     def foo(self):
...         return 'something'
...     @foo.setter
...     def foo(self, value):
...         pass
```
...  
```python
with patch('__main__.Foo.foo', new_callable=MagicMock):
    mock_foo = MagicMock()
    mock_foo.return_value = 'mockity-mock'
    this_foo = Foo()
    print(this_foo.foo)
    this_foo.foo = 6

mockity-mock
>>> mock_foo.mock_calls
[call(), call(6)]
```

Because of the way mock attributes are stored you can't directly attach a `PropertyMock` to a mock object. Instead you can attach it to the mock type object:

```python
>>> m = MagicMock()
>>> p = PropertyMock(return_value=3)
>>> type(m).foo = p
>>> m.foo
3
>>> p.assert_called_once_with()
```

### 26.5.2.1. Calling

Mock objects are callable. The call will return the value set as the `return_value` attribute. The default return value is a new Mock object; it is created the first time the return value is accessed (either explicitly or by calling the Mock) - but it is stored and the same one returned each time.

Calls made to the object will be recorded in the attributes like `call_args` and `call_args_list`. 
If `side_effect` is set then it will be called after the call has been recorded, so if `side_effect` raises an exception the call is still recorded.

The simplest way to make a mock raise an exception when called is to make `side_effect` an exception class or instance:

```python
>>> m = MagicMock(side_effect=IndexError)
>>> m(1, 2, 3)
Traceback (most recent call last):
 ...
IndexError
>>> m.mock_calls
[call(1, 2, 3)]
>>> m.side_effect = KeyError('Bang!')
>>> m('two', 'three', 'four')
Traceback (most recent call last):
 ...
KeyError: 'Bang!'
>>> m.mock_calls
[call(1, 2, 3), call('two', 'three', 'four')]
```

If `side_effect` is a function then whatever that function returns is what calls to the mock return. The `side_effect` function is called with the same arguments as the mock. This allows you to vary the return value of the call dynamically, based on the input:

```python
>>> def side_effect(value):
...     return value + 1
...
>>> m = MagicMock(side_effect=side_effect)
>>> m(1)
2
>>> m(2)
3
```
If you want the mock to still return the default return value (a new mock), or any set return value, then there are two ways of doing this. Either return mock.return_value from inside side_effect, or return DEFAULT:

```python
>>> m = MagicMock()
>>> def side_effect(*args, **kwargs):
...     return m.return_value
...
>>> m.side_effect = side_effect
>>> m.return_value = 3
>>> m()
3
>>> def side_effect(*args, **kwargs):
...     return DEFAULT
...
>>> m.side_effect = side_effect
>>> m()
3
```

To remove a side_effect, and return to the default behaviour, set the side_effect to None:

```python
>>> m = MagicMock(return_value=6)
>>> def side_effect(*args, **kwargs):
...     return 3
...
>>> m.side_effect = side_effect
>>> m()
3
>>> m.side_effect = None
>>> m()
```
The `side_effect` can also be any iterable object. Repeated calls to the mock will return values from the iterable (until the iterable is exhausted and a `StopIteration` is raised):

```python
>>> m = MagicMock(side_effect=[1, 2, 3])
>>> m()
1
2
3
>>> m()  # Traceback (most recent call last):
    ...
    StopIteration
```

If any members of the iterable are exceptions they will be raised instead of returned:

```python
>>> iterable = (33, ValueError, 66)
>>> m = MagicMock(side_effect=iterable)
>>> m()
33
>>> m()  # Traceback (most recent call last):
    ...
    ValueError
>>> m()
66
```

### 26.5.2.2. Deleting Attributes

Mock objects create attributes on demand. This allows them to
pretend to be objects of any type.

You may want a mock object to return False to a `hasattr()` call, or raise an `AttributeError` when an attribute is fetched. You can do this by providing an object as a spec for a mock, but that isn’t always convenient.

You “block” attributes by deleting them. Once deleted, accessing an attribute will raise an `AttributeError`.

```python
>>> mock = MagicMock()
>>> hasattr(mock, 'm')
True
>>> del mock.m
>>> hasattr(mock, 'm')
False
>>> del mock.f
>>> mock.f
Traceback (most recent call last):
  ... AttributeError: f
```

26.5.2.3. Mock names and the name attribute

Since “name” is an argument to the `Mock` constructor, if you want your mock object to have a “name” attribute you can’t just pass it in at creation time. There are two alternatives. One option is to use `configure_mock()`:

```python
>>> mock = MagicMock()
>>> mock.configure_mock(name='my_name')
>>> mock.name
'my_name'
```
A simpler option is to simply set the “name” attribute after mock creation:

```python
>>> mock = MagicMock()
>>> mock.name = "foo"
```

### 26.5.2.4. Attaching Mocks as Attributes

When you attach a mock as an attribute of another mock (or as the return value) it becomes a “child” of that mock. Calls to the child are recorded in the `method_calls` and `mock_calls` attributes of the parent. This is useful for configuring child mocks and then attaching them to the parent, or for attaching mocks to a parent that records all calls to the children and allows you to make assertions about the order of calls between mocks:

```python
>>> parent = MagicMock()
>>> child1 = MagicMock(return_value=None)
>>> child2 = MagicMock(return_value=None)
>>> parent.child1 = child1
>>> parent.child2 = child2
>>> child1(1)
>>> child2(2)
>>> parent.mock_calls
[call.child1(1), call.child2(2)]
```

The exception to this is if the mock has a name. This allows you to prevent the “parenting” if for some reason you don’t want it to happen.

```python
>>> mock = MagicMock()
>>> not_a_child = MagicMock(name='not-a-child')
>>> mock.attribute = not_a_child
>>> mock.attribute()
<MagicMock name='not-a-child()' id='...'>
```
Mocks created for you by `patch()` are automatically given names. To attach mocks that have names to a parent you use the `attach_mock()` method:

```python
>>> thing1 = object()
>>> thing2 = object()
>>> parent = MagicMock()
>>> with patch('__main__.thing1', return_value=None)
...     with patch('__main__.thing2', return_value=None)
...         parent.attach_mock(child1, 'child1')
...         parent.attach_mock(child2, 'child2')
...         child1('one')
...         child2('two')
... >>> parent.mock_calls
[call.child1('one'), call.child2('two')]
```

The only exceptions are magic methods and attributes (those that have leading and trailing double underscores). Mock doesn't create these but instead raises an `AttributeError`. This is because the interpreter will often implicitly request these methods, and gets very confused to get a new Mock object when it expects a magic method. If you need magic method support see [magic methods](#).

[^1]: [1]
26.5.3. The patchers

The patch decorators are used for patching objects only within the scope of the function they decorate. They automatically handle the unpatching for you, even if exceptions are raised. All of these functions can also be used in with statements or as class decorators.

26.5.3.1. patch

**Note:** patch() is straightforward to use. The key is to do the patching in the right namespace. See the section where to patch.

unittest.mock.patch(target, new=DEFAULT, spec=None, create=False, spec_set=None, autospec=None, new_callable=None, **kwargs)

patch() acts as a function decorator, class decorator or a context manager. Inside the body of the function or with statement, the target is patched with a new object. When the function/with statement exits the patch is undone.

If new is omitted, then the target is replaced with a MagicMock. If patch() is used as a decorator and new is omitted, the created mock is passed in as an extra argument to the decorated function. If patch() is used as a context manager the created mock is returned by the context manager.

target should be a string in the form 'package.module.ClassName'. The target is imported and the specified object replaced with the new object, so the target must be importable from the environment you are calling patch() from. The target is imported when the decorated function is executed,
not at decoration time.

The \textit{spec} and \textit{spec\_set} keyword arguments are passed to the \texttt{MagicMock} if \texttt{patch} is creating one for you.

In addition you can pass \texttt{spec=True} or \texttt{spec\_set=True}, which causes \texttt{patch} to pass in the object being mocked as the \texttt{spec/spec\_set} object.

\texttt{new\_callable} allows you to specify a different class, or callable object, that will be called to create the \texttt{new} object. By default \texttt{MagicMock} is used.

A more powerful form of \texttt{spec} is \texttt{autospec}. If you set \texttt{autospec=True} then the mock will be created with a \texttt{spec} from the object being replaced. All attributes of the mock will also have the \texttt{spec} of the corresponding attribute of the object being replaced. Methods and functions being mocked will have their arguments checked and will raise a \texttt{TypeError} if they are called with the wrong signature. For mocks replacing a class, their return value (the ‘instance’) will have the same \texttt{spec} as the class. See the \texttt{create\_autospec()} function and \texttt{Autospeccing}.

Instead of \texttt{autospec=True} you can pass \texttt{autospec=some\_object} to use an arbitrary object as the \texttt{spec} instead of the one being replaced.

By default \texttt{patch()} will fail to replace attributes that don’t exist. If you pass in \texttt{create=True}, and the attribute doesn’t exist, \texttt{patch} will create the attribute for you when the patched function is called, and delete it again afterwards. This is useful for writing tests against attributes that your production code creates at runtime. It is off by default because it can be dangerous. With it switched on you
can write passing tests against APIs that don’t actually exist!

**Note:**

*Changed in version 3.5:* If you are patching builtins in a module then you don’t need to pass `create=True`, it will be added by default.

Patch can be used as a `TestCase` class decorator. It works by decorating each test method in the class. This reduces the boilerplate code when your test methods share a common patchings set. `patch()` finds tests by looking for method names that start with `patch.TEST_PREFIX`. By default this is `'test'`, which matches the way `unittest` finds tests. You can specify an alternative prefix by setting `patch.TEST_PREFIX`.

Patch can be used as a context manager, with the `with` statement. Here the patching applies to the indented block after the `with` statement. If you use “as” then the patched object will be bound to the name after the “as”; very useful if `patch()` is creating a mock object for you.

`patch()` takes arbitrary keyword arguments. These will be passed to the `Mock` (or `new_callable`) on construction.

`patch.dict(...)`, `patch.multiple(...)`, and `patch.object(...)` are available for alternate use-cases.

`patch()` as function decorator, creating the mock for you and passing it into the decorated function:

```python
>>> @patch('__main__.SomeClass')
... def function(normal_argument, mock_class):
...     print(mock_class is SomeClass)
```
Patching a class replaces the class with a `MagicMock instance`. If the class is instantiated in the code under test then it will be the `return_value` of the mock that will be used.

If the class is instantiated multiple times you could use `side_effect` to return a new mock each time. Alternatively you can set the `return_value` to be anything you want.

To configure return values on methods of `instances` on the patched class you must do this on the `return_value`. For example:

```python
>>> class Class:
...     def method(self):
...         pass
...
>>> with patch('__main__.Class') as MockClass:
...     instance = MockClass.return_value
...     instance.method.return_value = 'foo'
...     assert Class() is instance
...     assert Class().method() == 'foo'
```

If you use `spec` or `spec_set` and `patch()` is replacing a `class`, then the return value of the created mock will have the same spec.

```python
>>> Original = Class
>>> patcher = patch('__main__.Class', spec=True)
>>> MockClass = patcher.start()
>>> instance = MockClass()
>>> assert isinstance(instance, Original)
>>> patcher.stop()
```
The `new_callable` argument is useful where you want to use an alternative class to the default `Mock` for the created mock. For example, if you wanted a `NonCallableMock` to be used:

```python
>>> thing = object()
>>> with patch('__main__.thing', new_callable=NonCallableMock) as mock_thing:
...    assert thing is mock_thing
...    thing()
...
Traceback (most recent call last):
...
TypeError: 'NonCallableMock' object is not callable
```

Another use case might be to replace an object with an `io.StringIO` instance:

```python
>>> from io import StringIO
>>> def foo():
...    print('Something')
...
>>> @patch('sys.stdout', new_callable=StringIO)
... def test(mock_stdout):
...    foo()
...    assert mock_stdout.getvalue() == 'Something

>>> test()
```

When `patch()` is creating a mock for you, it is common that the first thing you need to do is to configure the mock. Some of that configuration can be done in the call to `patch`. Any arbitrary keywords you pass into the call will be used to set attributes on the created mock:
As well as attributes on the created mock attributes, like the `return_value` and `side_effect`, of child mocks can also be configured. These aren't syntactically valid to pass in directly as keyword arguments, but a dictionary with these as keys can still be expanded into a `patch()` call using `**`:

```python
>>> config = {'method.return_value': 3, 'other.side_effect': None}
>>> patcher = patch('__main__.thing', **config)
>>> mock_thing = patcher.start()
>>> mock_thing.method()
3
>>> mock_thing.other()
Traceback (most recent call last):
  ... KeyError
```

26.5.3.2. patch.object

`patch.object(target, attribute, new=DEFAULT, spec=None, create=False, spec_set=None, autospec=None, new_callable=None, **kwargs)`

patch the named member (`attribute`) on an object (`target`) with a mock object.

`patch.object()` can be used as a decorator, class decorator or
a context manager. Arguments new, spec, create, spec_set, autospec and new_callable have the same meaning as for patch(). Like patch(), patch.object() takes arbitrary keyword arguments for configuring the mock object it creates.

When used as a class decorator patch.object() honours patch.TEST_PREFIX for choosing which methods to wrap.

You can either call patch.object() with three arguments or two arguments. The three argument form takes the object to be patched, the attribute name and the object to replace the attribute with.

When calling with the two argument form you omit the replacement object, and a mock is created for you and passed in as an extra argument to the decorated function:

```python
>>> @patch.object(SomeClass, 'class_method')
...    def test(mock_method):
...        SomeClass.class_method(3)
...        mock_method.assert_called_with(3)
...
>>> test()
```

spec, create and the other arguments to patch.object() have the same meaning as they do for patch().

### 26.5.3.3. patch.dict

Patch a dictionary, or dictionary like object, and restore the dictionary to its original state after the test.

in_dict can be a dictionary or a mapping like container. If it is a
mapping then it must at least support getting, setting and deleting items plus iterating over keys.

_in_dict_ can also be a string specifying the name of the dictionary, which will then be fetched by importing it.

(values can be a dictionary of values to set in the dictionary. _values_ can also be an iterable of (key, value) pairs.

If _clear_ is true then the dictionary will be cleared before the new values are set.

_patch.dict()_ can also be called with arbitrary keyword arguments to set values in the dictionary.

_patch.dict()_ can be used as a context manager, decorator or class decorator. When used as a class decorator _patch.dict()_ honours _patch.TEST_PREFIX_ for choosing which methods to wrap.

_patch.dict()_ can be used to add members to a dictionary, or simply let a test change a dictionary, and ensure the dictionary is restored when the test ends.

```python
>>> foo = {}
>>> with patch.dict(foo, {'newkey': 'newvalue'}):
...   assert foo == {'newkey': 'newvalue'}
...   ...
>>> assert foo == {}
```

```python
>>> import os
>>> with patch.dict('os.environ', {'newkey': 'newvalue'}):
...   print(os.environ['newkey'])
...   ...
```
newvalue

```python
>>> assert 'newkey' not in os.environ
```

Keywords can be used in the `patch.dict()` call to set values in the dictionary:

```python
>>> mymodule = MagicMock()
>>> mymodule.function.return_value = 'fish'
>>> with patch.dict('sys.modules', mymodule=mymodule):
...    import mymodule
...    mymodule.function('some', 'args')
...    'fish'
```

`patch.dict()` can be used with dictionary like objects that aren't actually dictionaries. At the very minimum they must support item getting, setting, deleting and either iteration or membership test. This corresponds to the magic methods `__getitem__()`, `__setitem__()`, `__delitem__()` and either `__iter__()` or `__contains__()`.

```python
>>> class Container:
...    def __init__(self):
...        self.values = {}
...    def __getitem__(self, name):
...        return self.values[name]
...    def __setitem__(self, name, value):
...        self.values[name] = value
...    def __delitem__(self, name):
...        del self.values[name]
...    def __iter__(self):
...        return iter(self.values)
...    thing = Container()
```
>>> thing['one'] = 1
>>> with patch.dict(thing, one=2, two=3):
...     assert thing['one'] == 2
...     assert thing['two'] == 3
...
>>> assert thing['one'] == 1
>>> assert list(thing) == ['one']

26.5.3.4. patch.multiple

patch.multiple(target, spec=None, create=False, spec_set=None, autospec=None, new_callable=None, **kwargs)

Perform multiple patches in a single call. It takes the object to be patched (either as an object or a string to fetch the object by importing) and keyword arguments for the patches:

```
with patch.multiple(settings, FIRST_PATCH='one', ...
```

Use DEFAULT as the value if you want patch.multiple() to create mocks for you. In this case the created mocks are passed into a decorated function by keyword, and a dictionary is returned when patch.multiple() is used as a context manager.

patch.multiple() can be used as a decorator, class decorator or a context manager. The arguments spec, spec_set, create, autospec and new_callable have the same meaning as for patch(). These arguments will be applied to all patches done by patch.multiple().

When used as a class decorator patch.multiple() honours patch.TEST_PREFIX for choosing which methods to wrap.
If you want `patch.multiple()` to create mocks for you, then you can use `DEFAULT` as the value. If you use `patch.multiple()` as a decorator then the created mocks are passed into the decorated function by keyword.

```python
>>> thing = object()
>>> other = object()

>>> @patch.multiple('__main__', thing=DEFAULT, other=
... def test_function(thing, other):
...   assert isinstance(thing, MagicMock)
...   assert isinstance(other, MagicMock)
... >>> test_function()
```

`patch.multiple()` can be nested with other `patch` decorators, but put arguments passed by keyword after any of the standard arguments created by `patch()`:

```python
>>> @patch('sys.exit')
... @patch.multiple('__main__', thing=DEFAULT, other=
... def test_function(mock_exit, other, thing):
...   assert 'other' in repr(other)
...   assert 'thing' in repr(thing)
...   assert 'exit' in repr(mock_exit)
... >>> test_function()
```

If `patch.multiple()` is used as a context manager, the value returned by the context manager is a dictionary where created mocks are keyed by name:

```python
>>> with patch.multiple('__.main__', thing=DEFAULT, o
```
...    assert 'other' in repr(values['other'])
...    assert 'thing' in repr(values['thing'])
...    assert values['thing'] is thing
...    assert values['other'] is other

26.5.3.5. patch methods: start and stop

All the patchers have start() and stop() methods. These make it simpler to do patching in setUp methods or where you want to do multiple patches without nesting decorators or with statements.

To use them call patch(), patch.object() or patch.dict() as normal and keep a reference to the returned patcher object. You can then call start() to put the patch in place and stop() to undo it.

If you are using patch() to create a mock for you then it will be returned by the call to patcher.start.

```python
>>> patcher = patch('package.module.ClassName')
>>> from package import module
>>> original = module.ClassName
>>> new_mock = patcher.start()
>>> assert module.ClassName is not original
>>> assert module.ClassName is new_mock
>>> patcher.stop()
>>> assert module.ClassName is original
>>> assert module.ClassName is not new_mock
```

A typical use case for this might be for doing multiple patches in the setUp method of a TestCase:

```python
>>> class MyTest(TestCase):
```
Caution: If you use this technique you must ensure that the patching is “undone” by calling stop. This can be fiddlier than you might think, because if an exception is raised in the setUp then tearDown is not called. unittest.TestCase.addCleanup() makes this easier:

As an added bonus you no longer need to keep a reference to the patcher object.
It is also possible to stop all patches which have been started by using `patch.stopall()`.

`patch.stopall()`  
Stop all active patches. Only stops patches started with `start`.

### 26.5.3.6. patch builtins

You can patch any builtins within a module. The following example patches builtin `ord()`:

```python
>>> @patch('__main__.ord')
... def test(mock_ord):
...     mock_ord.return_value = 101
...     print(ord('c'))
...
>>> test()
101
```

### 26.5.3.7. TEST_PREFIX

All of the patchers can be used as class decorators. When used in this way they wrap every test method on the class. The patchers recognise methods that start with `'test'` as being test methods. This is the same way that the `unittest.TestLoader` finds test methods by default.

It is possible that you want to use a different prefix for your tests. You can inform the patchers of the different prefix by setting `patch.TEST_PREFIX`:
>>> patch.TEST_PREFIX = 'foo'
>>> value = 3
>>> @patch('__main__.value', 'not three')
... class Thing:
...     def foo_one(self):
...         print(value)
...     def foo_two(self):
...         print(value)
...>>>
>>> Thing().foo_one()
not three
>>> Thing().foo_two()
not three
>>> value
3

### 26.5.3.8. Nesting Patch Decorators

If you want to perform multiple patches then you can simply stack up the decorators.

You can stack up multiple patch decorators using this pattern:

```python
>>> @patch.object(SomeClass, 'class_method')
... @patch.object(SomeClass, 'static_method')
... def test(mock1, mock2):
...     assert SomeClass.static_method is mock1
...     assert SomeClass.class_method is mock2
...     SomeClass.static_method('foo')
...     SomeClass.class_method('bar')
...     return mock1, mock2
...>>>
mock1, mock2 = test()
```
Note that the decorators are applied from the bottom upwards. This is the standard way that Python applies decorators. The order of the created mocks passed into your test function matches this order.

26.5.3.9. Where to patch

`patch()` works by (temporarily) changing the object that a `name` points to with another one. There can be many names pointing to any individual object, so for patching to work you must ensure that you patch the name used by the system under test.

The basic principle is that you patch where an object is `looked up`, which is not necessarily the same place as where it is defined. A couple of examples will help to clarify this.

Imagine we have a project that we want to test with the following structure:

```plaintext
a.py
   -> Defines SomeClass

b.py
   -> from a import SomeClass
   -> some_function instantiates SomeClass
```

Now we want to test `some_function` but we want to mock out `SomeClass` using `patch()`. The problem is that when we import module `b`, which we will have to do then it imports `SomeClass` from module `a`. If we use `patch()` to mock out `a.SomeClass` then it will have no effect on our test; module `b` already has a reference to the
real SomeClass and it looks like our patching had no effect.

The key is to patch out SomeClass where it is used (or where it is looked up). In this case some_function will actually look up SomeClass in module b, where we have imported it. The patching should look like:

```python
@patch ('b SomeClass')
```

However, consider the alternative scenario where instead of from a import SomeClass module b does import a and some_function uses a SomeClass. Both of these import forms are common. In this case the class we want to patch is being looked up in the module and so we have to patch a SomeClass instead:

```python
@patch ('a SomeClass')
```

**26.5.3.10. Patching Descriptors and Proxy Objects**

Both patch and patch.object correctly patch and restore descriptors: class methods, static methods and properties. You should patch these on the class rather than an instance. They also work with some objects that proxy attribute access, like the django settings object.
26.5.4. MagicMock and magic method support

26.5.4.1. Mocking Magic Methods

Mock supports mocking the Python protocol methods, also known as “magic methods”. This allows mock objects to replace containers or other objects that implement Python protocols.

Because magic methods are looked up differently from normal methods [2], this support has been specially implemented. This means that only specific magic methods are supported. The supported list includes almost all of them. If there are any missing that you need please let us know.

You mock magic methods by setting the method you are interested in to a function or a mock instance. If you are using a function then it must take self as the first argument [3].

```python
>>> def __str__(self):
    ...    return 'fooble'
    ...
>>> mock = Mock()
>>> mock.__str__ = __str__
>>> str(mock)
'fooble'
```

```python
>>> mock = Mock()
>>> mock.__str__ = Mock()
>>> mock.__str__.return_value = 'fooble'
>>> str(mock)
'fooble'
```
One use case for this is for mocking objects used as context managers in a `with` statement:

```python
>>> mock = Mock()
>>> mock.__enter__ = Mock(return_value='foo')
>>> mock.__exit__ = Mock(return_value=False)
>>> with mock as m:
    ...
    assert m == 'foo'
    ...
>>> mock.__enter__.assert_called_with()
>>> mock.__exit__.assert_called_with(None, None, None)
```

Calls to magic methods do not appear in `method_calls`, but they are recorded in `mock_calls`.

**Note:** If you use the `spec` keyword argument to create a mock then attempting to set a magic method that isn’t in the spec will raise an `AttributeError`.

The full list of supported magic methods is:

- `__hash__`, `__sizeof__`, `__repr__` and `__str__`
- `__dir__`, `__format__` and `__subclasses__`
- `__floor__`, `__trunc__` and `__ceil__`
- Comparisons: `__lt__`, `__gt__`, `__le__`, `__ge__`, `__eq__` and `__ne__`
- Container methods: `__getitem__`, `__setitem__`, `__delitem__`, `__contains__`, `__len__`, `__iter__`,
__reversed__ and __missing__

- Context manager: __enter__ and __exit__
- Unary numeric methods: __neg__, __pos__ and __invert__
- The numeric methods (including right hand and in-place variants): __add__, __sub__, __mul__, __matmul__, __div__, __truediv__, __floordiv__, __mod__, __divmod__, __lshift__, __rshift__, __and__, __xor__, __or__, and __pow__
- Numeric conversion methods: __complex__, __int__, __float__ and __index__
- Descriptor methods: __get__, __set__ and __delete__
- Pickling: __reduce__, __reduce_ex__, __getinitargs__, __getnewargs__, __getstate__ and __setstate__

The following methods exist but are not supported as they are either in use by mock, can't be set dynamically, or can cause problems:

- __getattr__, __setattr__, __init__ and __new__
- __prepare__, __instancecheck__, __subclasscheck__, __del__

26.5.4.2. Magic Mock

There are two MagicMock variants: MagicMock and NonCallableMagicMock.

```python
class unittest.mock.MagicMock(*args, **kw)
```

MagicMock is a subclass of Mock with default implementations of most of the magic methods. You can use MagicMock without having to configure the magic methods yourself.

The constructor parameters have the same meaning as for Mock.
If you use the `spec` or `spec_set` arguments then only magic methods that exist in the spec will be created.

```python
class unittest.mock.NonCallableMagicMock(*args, **kw)
A non-callable version of MagicMock.
```

The constructor parameters have the same meaning as for `MagicMock`, with the exception of `return_value` and `side_effect` which have no meaning on a non-callable mock.

The magic methods are setup with `MagicMock` objects, so you can configure them and use them in the usual way:

```python
>>> mock = MagicMock()
>>> mock[3] = 'fish'
>>> mock.__setitem__.assert_called_with(3, 'fish')
>>> mock.__getitem__.return_value = 'result'
>>> mock[2]
'result'
```

By default many of the protocol methods are required to return objects of a specific type. These methods are preconfigured with a default return value, so that they can be used without you having to do anything if you aren’t interested in the return value. You can still set the return value manually if you want to change the default.

Methods and their defaults:

- `__lt__`: NotImplemented
- `__gt__`: NotImplemented
- `__le__`: NotImplemented
- `__ge__`: NotImplemented
- `__int__`: 1
- `__contains__`: False
For example:

```python
>>> mock = MagicMock()
>>> int(mock)
1
>>> len(mock)
0
>>> list(mock)
[]
>>> object() in mock
False
```

The two equality methods, `__eq__()` and `__ne__()`, are special. They do the default equality comparison on identity, using the `side_effect` attribute, unless you change their return value to return something else:

```python
>>> MagicMock() == 3
False
>>> MagicMock() != 3
True
>>> mock = MagicMock()
>>> mock.__eq__.return_value = True
```
The return value of `MagicMock.__iter__()` can be any iterable object and isn't required to be an iterator:

```python
generate code
```

If the return value *is* an iterator, then iterating over it once will consume it and subsequent iterations will result in an empty list:

```python
generate code
```

`MagicMock` has all of the supported magic methods configured except for some of the obscure and obsolete ones. You can still set these up if you want.

Magic methods that are supported but not setup by default in `MagicMock` are:

- `__subclasses__`
- `__dir__`
- `__format__`
- `__get__`, `__set__` and `__delete__`
- `__reversed__` and `__missing__`
• `__reduce__`, `__reduce_ex__`, `__getinitargs__`, `__getnewargs__`, `__getstate__` and `__setstate__`
• `__getformat__` and `__setformat__`

Magic methods *should* be looked up on the class rather than the instance. Different versions of Python are inconsistent about applying this rule. The supported protocol methods should work with all supported versions of Python.

The function is basically hooked up to the class, but each `Mock` instance is kept isolated from the others.
26.5.5. Helpers

26.5.5.1. sentinel

unittest.mock.sentinel

The `sentinel` object provides a convenient way of providing unique objects for your tests.

Attributes are created on demand when you access them by name. Accessing the same attribute will always return the same object. The objects returned have a sensible repr so that test failure messages are readable.

The `sentinel` attributes don’t preserve their identity when they are copied or pickled.

Sometimes when testing you need to test that a specific object is passed as an argument to another method, or returned. It can be common to create named sentinel objects to test this. `sentinel` provides a convenient way of creating and testing the identity of objects like this.

In this example we monkey patch `method` to return `sentinel.some_object`:

```python
g>>> real = ProductionClass()
g>>> real.method = Mock(name="method")
g>>> real.method.return_value = sentinel.some_object
g>>> result = real.method()

g>>> assert result is sentinel.some_object

g>>> sentinel.some_object
```
26.5.5.2. DEFAULT

unittest.mock.DEFAULT

The DEFAULT object is a pre-created sentinel (actually sentinel.DEFAULT). It can be used by side_effect functions to indicate that the normal return value should be used.

26.5.5.3. call

unittest.mock.call(*args, **kwargs)

call() is a helper object for making simpler assertions, for comparing with call_args, call_args_list, mock_calls and method_calls. call() can also be used with assert_has_calls().

```python
>>> m = MagicMock(return_value=None)
>>> m(1, 2, a='foo', b='bar')
>>> m()
>>> m.call_args_list == [call(1, 2, a='foo', b='bar')]
True
```

call.call_list()

For a call object that represents multiple calls, call_list() returns a list of all the intermediate calls as well as the final call.

call_list is particularly useful for making assertions on “chained calls”. A chained call is multiple calls on a single line of code. This results in multiple entries in mock_calls on a mock. Manually constructing the sequence of calls can be tedious.

call_list() can construct the sequence of calls from the same
chained call:

```python
>>> m = MagicMock()
>>> m(1).method(arg='foo').other('bar')(2.0)
<MockMock name='mock().method().other()()' id='...'  
>>> kall = call(1).method(arg='foo').other('bar')(2.0)
>>> kall.call_list()
[call(1),
 call().method(arg='foo'),
 call().method().other('bar'),
 call().method().other()(2.0)]
>>> m.mock_calls == kall.call_list()
True
```

A `call` object is either a tuple of (positional args, keyword args) or (name, positional args, keyword args) depending on how it was constructed. When you construct them yourself this isn’t particularly interesting, but the `call` objects that are in the `Mock.call_args`, `Mock.call_args_list` and `Mock.mock_calls` attributes can be introspected to get at the individual arguments they contain.

The `call` objects in `Mock.call_args` and `Mock.call_args_list` are two-tuples of (positional args, keyword args) whereas the `call` objects in `Mock.mock_calls`, along with ones you construct yourself, are three-tuples of (name, positional args, keyword args).

You can use their “tupleness” to pull out the individual arguments for more complex introspection and assertions. The positional arguments are a tuple (an empty tuple if there are no positional arguments) and the keyword arguments are a dictionary:

```python
>>> m = MagicMock(return_value=None)
```
>>> m(1, 2, 3, arg='one', arg2='two')
>>> kall = m.call_args
>>> args, kwargs = kall
>>> args
(1, 2, 3)
>>> kwargs
{'arg2': 'two', 'arg': 'one'}
>>> args is kall[0]
True
>>> kwargs is kall[1]
True

>>> m = MagicMock()
>>> m.foo(4, 5, 6, arg='two', arg2='three')
<Mock name='mock.foo()' id='...'>
>>> kall = m.mock_calls[0]
>>> name, args, kwargs = kall
>>> name
'foo'
>>> args
(4, 5, 6)
>>> kwargs
{'arg2': 'three', 'arg': 'two'}
>>> name is m.mock_calls[0][0]
True

26.5.5.4. create_autospec

unittest.mock.create_autospec(spec, spec_set=False, instance=False, **kwargs)

Create a mock object using another object as a spec. Attributes on the mock will use the corresponding attribute on the spec object as their spec.

Functions or methods being mocked will have their arguments
checked to ensure that they are called with the correct signature.

If `spec_set` is `True` then attempting to set attributes that don't exist on the spec object will raise an `AttributeError`.

If a class is used as a spec then the return value of the mock (the instance of the class) will have the same spec. You can use a class as the spec for an instance object by passing `instance=True`. The returned mock will only be callable if instances of the mock are callable.

`create_autospec()` also takes arbitrary keyword arguments that are passed to the constructor of the created mock.

See `Autospeccing` for examples of how to use auto-speccing with `create_autospec()` and the `autospec` argument to `patch()`.

### 26.5.5.5. ANY

`unittest.mock.ANY`

Sometimes you may need to make assertions about some of the arguments in a call to mock, but either not care about some of the arguments or want to pull them individually out of `call_args` and make more complex assertions on them.

To ignore certain arguments you can pass in objects that compare equal to `everything`. Calls to `assert_called_with()` and `assert_called_once_with()` will then succeed no matter what was passed in.

```python
>>> mock = Mock(return_value=None)
>>> mock('foo', bar=obj())
```
ANY can also be used in comparisons with call lists like mock_calls:

```python
>>> m = MagicMock(return_value=None)
>>> m(1)
>>> m(1, 2)
>>> m(object())
>>> m.mock_calls == [call(1), call(1, 2), ANY]
True
```

### 26.5.5.6. FILTER_DIR

`unittest.mock.FILTER_DIR`

`FILTER_DIR` is a module level variable that controls the way mock objects respond to `dir()` (only for Python 2.6 or more recent). The default is `True`, which uses the filtering described below, to only show useful members. If you dislike this filtering, or need to switch it off for diagnostic purposes, then set `mock.FILTER_DIR = False`.

With filtering on, `dir(some_mock)` shows only useful attributes and will include any dynamically created attributes that wouldn’t normally be shown. If the mock was created with a `spec` (or `autospec` of course) then all the attributes from the original are shown, even if they haven’t been accessed yet:

```python
>>> dir(Mock())
['assert_any_call',
 'assert_called_once_with',
 'assert_called_with',
 'assert_has_calls',
 'attach_mock',
...
```
Many of the not-very-useful (private to `Mock` rather than the thing being mocked) underscore and double underscore prefixed attributes have been filtered from the result of calling `dir()` on a `Mock`. If you dislike this behaviour you can switch it off by setting the module level switch `FILTER_DIR`:

```python
>>> from unittest import mock
>>> mock.FILTER_DIR = False
>>> dir(mock.Mock())
[['_NonCallableMock__get_return_value',
  '_NonCallableMock__get_side_effect',
  '_NonCallableMock__return_value_doc',
  '_NonCallableMock__set_return_value',
  '_NonCallableMock__set_side_effect',
  '__call__',
  '__class__',
  ...
```

Alternatively you can just use `vars(my_mock)` (instance members) and `dir(type(my_mock))` (type members) to bypass the filtering irrespective of `mock.FILTER_DIR`.

### 26.5.5.7. mock_open

`unittest.mock.mock_open(mock=None, read_data=None)`
A helper function to create a mock to replace the use of `open()`. It works for `open()` called directly or used as a context manager.

The `mock` argument is the mock object to configure. If `None` (the default) then a `MagicMock` will be created for you, with the API limited to methods or attributes available on standard file handles.

`read_data` is a string for the `read()`, `readline()`, and `readlines()` methods of the file handle to return. Calls to those methods will take data from `read_data` until it is depleted. The mock of these methods is pretty simplistic: every time the `mock` is called, the `read_data` is rewound to the start. If you need more control over the data that you are feeding to the tested code you will need to customize this mock for yourself. When that is insufficient, one of the in-memory filesystem packages on PyPI can offer a realistic filesystem for testing.

*Changed in version 3.4:* Added `readline()` and `readlines()` support. The mock of `read()` changed to consume `read_data` rather than returning it on each call.

*Changed in version 3.5:* `read_data` is now reset on each call to the `mock`.

Using `open()` as a context manager is a great way to ensure your file handles are closed properly and is becoming common:

```python
with open('/some/path', 'w') as f:
    f.write('something')
```
The issue is that even if you mock out the call to `open()` it is the returned object that is used as a context manager (and has `__enter__() and `__exit__()` called).

Mocking context managers with a MagicMock is common enough and fiddly enough that a helper function is useful.

```python
>>> m = mock_open()
>>> with patch('__main__.open', m):
...     with open('foo', 'w') as h:
...         h.write('some stuff')
...
>>> m.mock_calls
[call('foo', 'w'),
 call().__enter__(),
 call().write('some stuff'),
 call().__exit__(None, None, None)]
>>> m.assert_called_once_with('foo', 'w')
>>> handle = m()
>>> handle.write.assert_called_once_with('some stuff')
```

And for reading files:

```python
>>> with patch('__main__.open', mock_open(read_data='bibble')) as h:
...     result = h.read()
...
>>> m.assert_called_once_with('foo')
>>> assert result == 'bibble'
```

### 26.5.5.8. Autospeccing

Autospeccing is based on the existing spec feature of mock. It limits
the api of mocks to the api of an original object (the spec), but it is recursive (implemented lazily) so that attributes of mocks only have the same api as the attributes of the spec. In addition mocked functions / methods have the same call signature as the original so they raise a TypeError if they are called incorrectly.

Before I explain how auto-speccing works, here's why it is needed.

Mock is a very powerful and flexible object, but it suffers from two flaws when used to mock out objects from a system under test. One of these flaws is specific to the Mock api and the other is a more general problem with using mock objects.

First the problem specific to Mock. Mock has two assert methods that are extremely handy: assert_called_with() and assert_called_once_with().

```python
>>> mock = Mock(name='Thing', return_value=None)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(1, 2, 3)
Traceback (most recent call last):
  ...  
AssertionError: Expected 'mock' to be called once. Called 2 times.
```

Because mocks auto-create attributes on demand, and allow you to call them with arbitrary arguments, if you misspell one of these assert methods then your assertion is gone:

```python
>>> mock = Mock(name='Thing', return_value=None)
>>> mock(1, 2, 3)
>>> mock.assert_called_once_with(4, 5, 6)
```
Your tests can pass silently and incorrectly because of the typo.

The second issue is more general to mocking. If you refactor some of your code, rename members and so on, any tests for code that is still using the old api but uses mocks instead of the real objects will still pass. This means your tests can all pass even though your code is broken.

Note that this is another reason why you need integration tests as well as unit tests. Testing everything in isolation is all fine and dandy, but if you don’t test how your units are “wired together” there is still lots of room for bugs that tests might have caught.

mock already provides a feature to help with this, called speccing. If you use a class or instance as the spec for a mock then you can only access attributes on the mock that exist on the real class:

```python
>>> from urllib import request
>>> mock = Mock(spec=request.Request)
>>> mock.assret_called_with
Traceback (most recent call last):
  ...
AttributeError: Mock object has no attribute 'assret
```

The spec only applies to the mock itself, so we still have the same issue with any methods on the mock:

```python
>>> mock.has_data()
<Mock object at 0x...>
>>> mock.has_data.assret_called_with()
```

Auto-speccing solves this problem. You can either pass autospec=True to `patch()` / `patch.object()` or use the
create_autospec() function to create a mock with a spec. If you use the autospec=True argument to patch() then the object that is being replaced will be used as the spec object. Because the speccing is done “lazily” (the spec is created as attributes on the mock are accessed) you can use it with very complex or deeply nested objects (like modules that import modules that import modules) without a big performance hit.

Here’s an example of it in use:

```python
>>> from urllib import request
>>> patcher = patch('__main__.request', autospec=True)
>>> mock_request = patcher.start()
>>> request is mock_request
True
>>> mock_request.Request
<MagicMock name='request.Request' spec='Request' id='...'>
```

You can see that request.Request has a spec. request.Request takes two arguments in the constructor (one of which is self). Here’s what happens if we try to call it incorrectly:

```python
>>> req = request.Request()
Traceback (most recent call last):
  ...
TypeError: <lambda>() takes at least 2 arguments (1 given)
```

The spec also applies to instantiated classes (i.e. the return value of specced mocks):

```python
>>> req = request.Request('foo')
>>> req
<NonCallableMagicMock name='request.Request()' spec='Request' id='...'>
```
Request objects are not callable, so the return value of instantiating our mocked out request.Request is a non-callable mock. With the spec in place any typos in our asserts will raise the correct error:

```python
>>> req.add_header('spam', 'eggs')
<MagicMock name='request.Request().add_header()' id='...'>
>>> req.add_header.assert_called_with
Traceback (most recent call last):
  ... 
AttributeError: Mock object has no attribute 'assret_called_with'
>>> req.add_header.assert_called_with('spam', 'eggs'
```

In many cases you will just be able to add `autospec=True` to your existing `patch()` calls and then be protected against bugs due to typos and api changes.

As well as using `autospec` through `patch()` there is a `create_autospec()` for creating autospecced mocks directly:

```python
>>> from urllib import request
>>> mock_request = create_autospec(request)
>>> mock_request.Request('foo', 'bar')
<NonCallableMagicMock name='mock.Request()' spec='Request'
```

This isn't without caveats and limitations however, which is why it is not the default behaviour. In order to know what attributes are available on the spec object, autospec has to introspect (access attributes) the spec. As you traverse attributes on the mock a corresponding traversal of the original object is happening under the hood. If any of your specced objects have properties or descriptors that can trigger code execution then you may not be able to use
autospec. On the other hand it is much better to design your objects so that introspection is safe [4].

A more serious problem is that it is common for instance attributes to be created in the `__init__()` method and not to exist on the class at all. `autospec` can't know about any dynamically created attributes and restricts the api to visible attributes.

```python
>>> class Something:
...   def __init__(self):
...     self.a = 33
...
>>> with patch('__main__.Something', autospec=True):
...   thing = Something()
...   thing.a
...
Traceback (most recent call last):
...
AttributeError: Mock object has no attribute 'a'
```

There are a few different ways of resolving this problem. The easiest, but not necessarily the least annoying, way is to simply set the required attributes on the mock after creation. Just because `autospec` doesn't allow you to fetch attributes that don't exist on the spec it doesn't prevent you setting them:

```python
>>> with patch('__main__.Something', autospec=True):
...   thing =Something()
...   thing.a = 33
...
```

There is a more aggressive version of both `spec` and `autospec` that `does` prevent you setting non-existent attributes. This is useful if you
want to ensure your code only sets valid attributes too, but obviously it prevents this particular scenario:

```python
>>> with patch('__main__.Something', autospec=True,
   ...         thing = Something()
   ...         thing.a = 33
   ...
Traceback (most recent call last):
   ...
AttributeError: Mock object has no attribute 'a'
```

Probably the best way of solving the problem is to add class attributes as default values for instance members initialised in `__init__()`. Note that if you are only setting default attributes in `__init__()` then providing them via class attributes (shared between instances of course) is faster too. e.g.

```python
class Something:
   a = 33
```

This brings up another issue. It is relatively common to provide a default value of `None` for members that will later be an object of a different type. `None` would be useless as a spec because it wouldn't let you access *any* attributes or methods on it. As `None` is *never* going to be useful as a spec, and probably indicates a member that will normally of some other type, autospec doesn't use a spec for members that are set to `None`. These will just be ordinary mocks (well - MagicMocks):

```python
>>> class Something:
   ...     member = None
   ...  
>>> mock = create_autospec(Something)
```
If modifying your production classes to add defaults isn’t to your liking then there are more options. One of these is simply to use an instance as the spec rather than the class. The other is to create a subclass of the production class and add the defaults to the subclass without affecting the production class. Both of these require you to use an alternative object as the spec. Thankfully `patch()` supports this - you can simply pass the alternative object as the `autospec` argument:

```python
>>> class Something:
...     def __init__(self):
...         self.a = 33
...
>>> class SomethingForTest(Something):
...     a = 33
...
>>> p = patch('__main__.Something', autospec=SomethingForTest)
>>> mock = p.start()
>>> mock.a
<NonCallableMagicMock name='Something.a' spec='int'>
```

This only applies to classes or already instantiated objects. Calling a mocked class to create a mock instance does not create a real instance. It is only attribute lookups - along with calls to `dir()` - that are done.

[4]
26.6. `unittest.mock` — getting started

*New in version 3.3.*
26.6.1. Using Mock

26.6.1.1. Mock Patching Methods

Common uses for Mock objects include:

- Patching methods
- Recording method calls on objects

You might want to replace a method on an object to check that it is called with the correct arguments by another part of the system:

```python
>>> real = SomeClass()
>>> real.method = MagicMock(name='method')
>>> real.method(3, 4, 5, key='value')
<MagicMock name='method()' id='...'>
```

Once our mock has been used (real.method in this example) it has methods and attributes that allow you to make assertions about how it has been used.

**Note:** In most of these examples the Mock and MagicMock classes are interchangeable. As the MagicMock is the more capable class it makes a sensible one to use by default.

Once the mock has been called its called attribute is set to True. More importantly we can use the assert_called_with() or assert_called_once_with() method to check that it was called with the correct arguments.

This example tests that calling ProductionClass().method results in a call to the something method:
26.6.1.2. Mock for Method Calls on an Object

In the last example we patched a method directly on an object to check that it was called correctly. Another common use case is to pass an object into a method (or some part of the system under test) and then check that it is used in the correct way.

The simple `ProductionClass` below has a `closer` method. If it is called with an object then it calls `close` on it.

```python
>>> class ProductionClass:
...     def closer(self, something):
...         something.close()
...
>>> real = ProductionClass()
>>> mock = Mock()
>>> real.closer(mock)
>>> mock.close.assert_called_with()
```

So to test it we need to pass in an object with a `close` method and check that it was called correctly.
We don’t have to do any work to provide the ‘close’ method on our mock. Accessing close creates it. So, if ‘close’ hasn't already been called then accessing it in the test will create it, but `assert_called_with()` will raise a failure exception.

26.6.1.3. Mocking Classes

A common use case is to mock out classes instantiated by your code under test. When you patch a class, then that class is replaced with a mock. Instances are created by calling the class. This means you access the “mock instance” by looking at the return value of the mocked class.

In the example below we have a function `some_function` that instantiates `Foo` and calls a method on it. The call to `patch()` replaces the class `Foo` with a mock. The `Foo` instance is the result of calling the mock, so it is configured by modifying the mock `return_value`.

```python
>>> def some_function():
...     instance = module.Foo()
...     return instance.method()
...
>>> with patch('module.Foo') as mock:
...     instance = mock.return_value
...     instance.method.return_value = 'the result'
...     result = some_function()
...     assert result == 'the result'
```

26.6.1.4. Naming your mocks

It can be useful to give your mocks a name. The name is shown in the
repr of the mock and can be helpful when the mock appears in test failure messages. The name is also propagated to attributes or methods of the mock:

```python
>>> mock = MagicMock(name='foo')
>>> mock
<MagicMock name='foo' id='...'>
>>> mock.method
<MagicMock name='foo.method' id='...'>
```

### 26.6.1.5. Tracking all Calls

Often you want to track more than a single call to a method. The **mock_calls** attribute records all calls to child attributes of the mock - and also to their children.

```python
>>> mock = MagicMock()  
>>> mock.method()  
<MagicMock name='mock.method()' id='...'>  
>>> mock.attribute.method(10, x=53)  
<MagicMock name='mock.attribute.method()' id='...'>  
>>> mock.mock_calls  
[call.method(), call.attribute.method(10, x=53)]
```

If you make an assertion about **mock_calls** and any unexpected methods have been called, then the assertion will fail. This is useful because as well as asserting that the calls you expected have been made, you are also checking that they were made in the right order and with no additional calls:

You use the **call** object to construct lists for comparing with **mock_calls**:
26.6.1.6. Setting Return Values and Attributes

Setting the return values on a mock object is trivially easy:

```python
>>> mock = Mock()
>>> mock.return_value = 3
>>> mock()
3
```

Of course you can do the same for methods on the mock:

```python
>>> mock = Mock()
>>> mock.method.return_value = 3
>>> mock.method()
3
```

The return value can also be set in the constructor:

```python
>>> mock = Mock(return_value=3)
>>> mock()
3
```

If you need an attribute setting on your mock, just do it:

```python
>>> mock = Mock()
>>> mock.x = 3
>>> mock.x
3
```

Sometimes you want to mock up a more complex situation, like for
example `mock.connection.cursor().execute("SELECT 1")`

If we wanted this call to return a list, then we have to configure the result of the nested call.

We can use `call` to construct the set of calls in a “chained call” like this for easy assertion afterwards:

```python
>>> mock = Mock()
>>> cursor = mock.connection.cursor().return_value
>>> cursor.execute.return_value = ['foo']
>>> mock.connection.cursor().execute("SELECT 1")
['foo']
>>> expected = call.connection.cursor().execute("SELECT 1")
>>> mock.mock_calls
[call.connection.cursor(), call.connection.cursor().execute("SELECT 1")]
>>> mock.mock_calls == expected
True
```

It is the call to `.call_list()` that turns our call object into a list of calls representing the chained calls.

### 26.6.1.7. Raising exceptions with mocks

A useful attribute is `side_effect`. If you set this to an exception class or instance then the exception will be raised when the mock is called.

```python
>>> mock = Mock(side_effect=Exception('Boom!'))
>>> mock()
Traceback (most recent call last):
  ...
Exception: Boom!
```
26.6.1.8. Side effect functions and iterables

side_effect can also be set to a function or an iterable. The use case for side_effect as an iterable is where your mock is going to be called several times, and you want each call to return a different value. When you set side_effect to an iterable every call to the mock returns the next value from the iterable:

```python
>>> mock = MagicMock(side_effect=[4, 5, 6])
>>> mock()
4
>>> mock()
5
>>> mock()
6
```

For more advanced use cases, like dynamically varying the return values depending on what the mock is called with, side_effect can be a function. The function will be called with the same arguments as the mock. Whatever the function returns is what the call returns:

```python
>>> vals = {(1, 2): 1, (2, 3): 2}
>>> def side_effect(*args):
...     return vals[args]
...
>>> mock = MagicMock(side_effect=side_effect)
>>> mock(1, 2)
1
>>> mock(2, 3)
2
```

26.6.1.9. Creating a Mock from an Existing Object
One problem with over use of mocking is that it couples your tests to the implementation of your mocks rather than your real code. Suppose you have a class that implements `some_method`. In a test for another class, you provide a mock of this object that also provides `some_method`. If later you refactor the first class, so that it no longer has `some_method` - then your tests will continue to pass even though your code is now broken!

Mock allows you to provide an object as a specification for the mock, using the `spec` keyword argument. Accessing methods / attributes on the mock that don't exist on your specification object will immediately raise an attribute error. If you change the implementation of your specification, then tests that use that class will start failing immediately without you having to instantiate the class in those tests.

```python
>>> mock = Mock(spec=SomeClass)
>>> mock.old_method()
Traceback (most recent call last):
 ... AttributeError: object has no attribute 'old_method'
```

Using a specification also enables a smarter matching of calls made to the mock, regardless of whether some parameters were passed as positional or named arguments:

```python
>>> def f(a, b, c): pass
 ... >>> mock = Mock(spec=f)
 ... >>> mock(1, 2, 3)
 <Mock name='mock()' id='140161580456576'>
 ... >>> mock.assert_called_with(a=1, b=2, c=3)
```

If you want this smarter matching to also work with method calls on the
mock, you can use auto-speccing.

If you want a stronger form of specification that prevents the setting of arbitrary attributes as well as the getting of them then you can use spec_set instead of spec.
26.6.2. Patch Decorators

**Note:** With `patch()` it matters that you patch objects in the namespace where they are looked up. This is normally straightforward, but for a quick guide read *where to patch.*

A common need in tests is to patch a class attribute or a module attribute, for example patching a builtin or patching a class in a module to test that it is instantiated. Modules and classes are effectively global, so patching on them has to be undone after the test or the patch will persist into other tests and cause hard to diagnose problems.

Mock provides three convenient decorators for this: `patch()`, `patch.object()` and `patch.dict()`. `patch` takes a single string, of the form `package.module.Class.attribute` to specify the attribute you are patching. It also optionally takes a value that you want the attribute (or class or whatever) to be replaced with. ‘patch.object’ takes an object and the name of the attribute you would like patched, plus optionally the value to patch it with.

**patch.object:**

```python
>>> original = SomeClass.attribute
>>> @patch.object(SomeClass, 'attribute', sentinel.attribute)
...   def test():
...       assert SomeClass.attribute == sentinel.attribute
...     test()
>>> assert SomeClass.attribute == original
```

```python
>>> @patch('package.module.attribute', sentinel.attribute)
```

```python
... def test():
...     from package.module import attribute
...     assert attribute is sentinel.attribute
...
>>> test()
```

If you are patching a module (including `builtins`) then use `patch()` instead of `patch.object()`:

```python
>>> mock = MagicMock(return_value=sentinel.file_handle)
>>> with patch('builtins.open', mock):
...     handle = open('filename', 'r')
...
>>> mock.assert_called_with('filename', 'r')
>>> assert handle == sentinel.file_handle, "incorrect file handle returned"
```

The module name can be `dotted`, in the form `package.module` if needed:

```python
>>> @patch('package.module.ClassName.attribute', sentinel)
... def test():
...     from package.module import ClassName
...     assert ClassName.attribute == sentinel.attribute
...
>>> test()
```

A nice pattern is to actually decorate test methods themselves:

```python
>>> class MyTest(unittest.TestCase):
...     @patch.object(SomeClass, 'attribute', sentinel)
...     def test_something(self):
...         self.assertEqual(SomeClass.attribute, sentinel)
...```
If you want to patch with a Mock, you can use `patch()` with only one argument (or `patch.object()` with two arguments). The mock will be created for you and passed into the test function / method:

```python
>>> original = SomeClass.attribute
>>> MyTest('test_something').test_something()
>>> assert SomeClass.attribute == original
```

You can stack up multiple patch decorators using this pattern:

```python
>>> class MyTest(unittest.TestCase):
...     @patch.object(SomeClass, 'static_method')
...     def test_something(self, mock_method):
...         SomeClass.static_method()
...         mock_method.assert_called_with()
...     ...
>>> MyTest('test_something').test_something()
```

When you nest patch decorators the mocks are passed in to the decorated function in the same order they applied (the normal `python` order that decorators are applied). This means from the bottom up, so in the example above the mock for `test_module.ClassName2` is passed in first.
There is also `patch.dict()` for setting values in a dictionary just during a scope and restoring the dictionary to its original state when the test ends:

```python
group = {'key': 'value'}
original = group.copy()
with patch.dict(group, {'newkey': 'newvalue'}, clear=True):
    ...
    assert group == {'newkey': 'newvalue'}
    ...
assert group == original
```

`patch`, `patch.object` and `patch.dict` can all be used as context managers.

Where you use `patch()` to create a mock for you, you can get a reference to the mock using the “as” form of the with statement:

```python
class ProductionClass:
    ...
    def method(self):
        pass
    ...
with patch.object(ProductionClass, 'method') as mock_method:
    ...
    mock_method.return_value = None
    ...
    real = ProductionClass()
    ...
    real.method(1, 2, 3)
    ...
mock_method.assert_called_with(1, 2, 3)
```

As an alternative `patch`, `patch.object` and `patch.dict` can be used as class decorators. When used in this way it is the same as applying the decorator individually to every method whose name starts with “test”.

26.6.3. Further Examples

Here are some more examples for some slightly more advanced scenarios.

26.6.3.1. Mocking chained calls

Mocking chained calls is actually straightforward with mock once you understand the `return_value` attribute. When a mock is called for the first time, or you fetch its `return_value` before it has been called, a new `Mock` is created.

This means that you can see how the object returned from a call to a mocked object has been used by interrogating the `return_value` mock:

```python
>>> mock = Mock()
>>> mock().foo(a=2, b=3)
<Mock name='mock().foo()' id='...'>
>>> mock.return_value.foo.assert_called_with(a=2, b=3)
```

From here it is a simple step to configure and then make assertions about chained calls. Of course another alternative is writing your code in a more testable way in the first place...

So, suppose we have some code that looks a little bit like this:

```python
>>> class Something:
...     ...     def __init__(self):
...         ...         self.backend = BackendProvider()
...     ...     def method(self):
...         ...         response = self.backend.get_endpoint('fc
```
Assuming that BackendProvider is already well tested, how do we test method()? Specifically, we want to test that the code section # more code uses the response object in the correct way.

As this chain of calls is made from an instance attribute we can monkey patch the backend attribute on a Something instance. In this particular case we are only interested in the return value from the final call to start_call so we don’t have much configuration to do. Let’s assume the object it returns is ‘file-like’, so we’ll ensure that our response object uses the builtin open() as its spec.

To do this we create a mock instance as our mock backend and create a mock response object for it. To set the response as the return value for that final start_call we could do this:

```python
mock_backend.get_endpoint.return_value.create_call.return_value.start_call.return_value
```

We can do that in a slightly nicer way using the configure_mock() method to directly set the return value for us:

```python
>>> something = Something()
>>> mock_response = Mock(spec=open)
>>> mock_backend = Mock()
>>> config = {'get_endpoint.return_value.create_call.return_value.start_call.return_value'
>>> mock_backend.configure_mock(**config)
```

With these we monkey patch the “mock backend” in place and can make the real call:

```python
>>> something.backend = mock_backend
```
Using `mock_calls` we can check the chained call with a single assert. A chained call is several calls in one line of code, so there will be several entries in `mock_calls`. We can use `call.call_list()` to create this list of calls for us:

```python
>>> chained = call.get_endpoint('foobar').create_call
>>> call_list = chained.call_list()
>>> assert mock_backend.mock_calls == call_list
```

### 26.6.3.2. Partial mocking

In some tests I wanted to mock out a call to `datetime.date.today()` to return a known date, but I didn’t want to prevent the code under test from creating new date objects. Unfortunately `datetime.date` is written in C, and so I couldn’t just monkey-patch out the static `date.today()` method.

I found a simple way of doing this that involved effectively wrapping the date class with a mock, but passing through calls to the constructor to the real class (and returning real instances).

The `patch` decorator is used here to mock out the `date` class in the module under test. The `side_effect` attribute on the mock date class is then set to a lambda function that returns a real date. When the mock date class is called a real date will be constructed and returned by `side_effect`.

```python
>>> from datetime import date
>>> with patch('mymodule.date') as mock_date:
...     mock_date.today.return_value = date(2010, 10
```
Note that we don’t patch `datetime.date` globally, we patch `date` in the module that uses it. See where to patch.

When `date.today()` is called a known date is returned, but calls to the `date(...)` constructor still return normal dates. Without this you can find yourself having to calculate an expected result using exactly the same algorithm as the code under test, which is a classic testing anti-pattern.

Calls to the date constructor are recorded in the `mock_date` attributes (`call_count` and friends) which may also be useful for your tests.

An alternative way of dealing with mocking dates, or other built-in classes, is discussed in this blog entry.

26.6.3.3. Mocking a Generator Method

A Python generator is a function or method that uses the `yield` statement to return a series of values when iterated over [1].

A generator method / function is called to return the generator object. It is the generator object that is then iterated over. The protocol method for iteration is `__iter__()`, so we can mock this using a `MagicMock`.

Here’s an example class with an “iter” method implemented as a generator:
How would we mock this class, and in particular its “iter” method?

To configure the values returned from the iteration (implicit in the call to \texttt{list}), we need to configure the object returned by the call to \texttt{foo.iter()}. 

```python
>>> mock_foo = MagicMock()
>>> mock_foo.iter.return_value = iter([1, 2, 3])
>>> list(mock_foo.iter())
[1, 2, 3]
```

There are also generator expressions and more advanced uses of generators, but we aren’t concerned about them here. A very good introduction to generators and how powerful they are is: Generator Tricks for Systems Programmers.

26.6.3.4. Applying the same patch to every test method

If you want several patches in place for multiple test methods the obvious way is to apply the patch decorators to every method. This can feel like unnecessary repetition. For Python 2.6 or more recent you can use \texttt{patch()} (in all its various forms) as a class decorator. This applies the patches to all test methods on the class. A test
method is identified by methods whose names start with test:

```python
>>> @patch('mymodule.SomeClass')
...     class MyTest(TestCase):
...         ...
...             def test_one(self, MockSomeClass):
...                 self.assertNotEqual(mymodule.SomeClass, MockSomeClass)
...             ...
...             def test_two(self, MockSomeClass):
...                 self.assertNotEqual(mymodule.SomeClass, MockSomeClass)
...             ...
...             def not_a_test(self):
...                 return 'something'
...             ...
>>> MyTest('test_one').test_one()
>>> MyTest('test_two').test_two()
>>> MyTest('test_two').not_a_test()
'something'
```

An alternative way of managing patches is to use the `patch methods: start and stop`. These allow you to move the patching into your `setUp` and `tearDown` methods.

```python
>>> class MyTest(TestCase):
...     ...
...         def setUp(self):
...             self.patcher = patch('mymodule.foo')
...             self.mock_foo = self.patcher.start()
...             ...
...         def test_foo(self):
...             self.assertNotEqual(mymodule.foo, self.mock_foo)
...             ...
...         def tearDown(self):
...             self.patcher.stop()
...             ...
>>> MyTest('test_foo').run()
```
If you use this technique you must ensure that the patching is “undone” by calling `stop`. This can be fiddlier than you might think, because if an exception is raised in the setUp then tearDown is not called. `unittest.TestCase.addCleanup()` makes this easier:

```python
>>> class MyTest(TestCase):
...     def setUp(self):
...         patcher = patch('mymodule.foo')
...         self.addCleanup(patcher.stop)
...         self.mock_foo = patcher.start()
...
...     def test_foo(self):
...         self.assertIs(mymodule.foo, self.mock_foo)
...
>>> MyTest('test_foo').run()
```

### 26.6.3.5. Mocking Unbound Methods

Whilst writing tests today I needed to patch an *unbound method* (patching the method on the class rather than on the instance). I needed self to be passed in as the first argument because I want to make asserts about which objects were calling this particular method. The issue is that you can’t patch with a mock for this, because if you replace an unbound method with a mock it doesn’t become a bound method when fetched from the instance, and so it doesn’t get self passed in. The workaround is to patch the unbound method with a real function instead. The `patch()` decorator makes it so simple to patch out methods with a mock that having to create a real function becomes a nuisance.

If you pass `autospec=True` to patch then it does the patching with a
real function object. This function object has the same signature as the one it is replacing, but delegates to a mock under the hood. You still get your mock auto-created in exactly the same way as before. What it means though, is that if you use it to patch out an unbound method on a class the mocked function will be turned into a bound method if it is fetched from an instance. It will have self passed in as the first argument, which is exactly what I wanted:

```python
>>> class Foo:
...     def foo(self):
...         pass
...
>>> with patch.object(Foo, 'foo', autospec=True) as mock_foo:
...     mock_foo.return_value = 'foo'
...     foo = Foo()
...     foo.foo()
...
'foo'
>>> mock_foo.assert_called_once_with('foo')
```

If we don’t use autospec=True then the unbound method is patched out with a Mock instance instead, and isn’t called with self.

26.6.3.6. Checking multiple calls with mock

mock has a nice API for making assertions about how your mock objects are used.

```python
>>> mock = Mock()
>>> mock.foo_bar.return_value = None
>>> mock.foo_bar('baz', spam='eggs')
>>> mock.foo_bar.assert_called_with('baz', spam='eggs')
```
If your mock is only being called once you can use the assert_called_once_with() method that also asserts that the call_count is one.

```python
>>> mock.foo_bar.assert_called_once_with('baz', spam)
>>> mock.foo_bar()
>>> mock.foo_bar.assert_called_once_with('baz', spam)
Traceback (most recent call last):
  ...  
AssertionError: Expected to be called once. Called 2
```

Both assert_called_with and assert_called_once_with make assertions about the most recent call. If your mock is going to be called several times, and you want to make assertions about all those calls you can use call_args_list:

```python
>>> mock = Mock(return_value=None)
>>> mock(1, 2, 3)
>>> mock(4, 5, 6)
>>> mock()
>>> mock.call_args_list
[call(1, 2, 3), call(4, 5, 6), call()]
```

The call helper makes it easy to make assertions about these calls. You can build up a list of expected calls and compare it to call_args_list. This looks remarkably similar to the repr of the call_args_list:

```python
>>> expected = [call(1, 2, 3), call(4, 5, 6), call()]
>>> mock.call_args_list == expected
True
```
26.6.3.7. Coping with mutable arguments

Another situation is rare, but can bite you, is when your mock is called with mutable arguments. `call_args` and `call_args_list` store references to the arguments. If the arguments are mutated by the code under test then you can no longer make assertions about what the values were when the mock was called.

Here’s some example code that shows the problem. Imagine the following functions defined in ‘mymodule’:

```python
def frob(val):
    pass

def grob(val):
    "First frob and then clear val"
    frob(val)
    val.clear()
```

When we try to test that `grob` calls `frob` with the correct argument look what happens:

```python
>>> with patch('mymodule.frob') as mock_frob:
...     val = {6}
...     mymodule.grob(val)
...     val.set()

>>> mock_frob.assert_called_with({6})
Traceback (most recent call last):
  ...  
AssertionError: Expected: (({6},), {})  
Called with: ((set(),), {})```
One possibility would be for mock to copy the arguments you pass in. This could then cause problems if you do assertions that rely on object identity for equality.

Here's one solution that uses the side_effect functionality. If you provide a side_effect function for a mock then side_effect will be called with the same args as the mock. This gives us an opportunity to copy the arguments and store them for later assertions. In this example I'm using another mock to store the arguments so that I can use the mock methods for doing the assertion. Again a helper function sets this up for me.

```python
>>> from copy import deepcopy
>>> from unittest.mock import Mock, patch, DEFAULT
>>> def copy_call_args(mock):
...     new_mock = Mock()
...     def side_effect(*args, **kwargs):
...         args = deepcopy(args)
...         kwargs = deepcopy(kwargs)
...         new_mock(*args, **kwargs)
...         return DEFAULT
...     mock.side_effect = side_effect
...     return new_mock
...
>>> with patch('mymodule.frob') as mock_frob:
...     new_mock = copy_call_args(mock_frob)
...     val = {6}
...     mymodule.grob(val)
...
>>> new_mock.assert_called_with({6})
>>> new_mock.call_args
{6}
```

copy_call_args is called with the mock that will be called. It returns a new mock that we do the assertion on. The side_effect function
makes a copy of the args and calls our new_mock with the copy.

**Note:** If your mock is only going to be used once there is an easier way of checking arguments at the point they are called. You can simply do the checking inside a side_effect function.

```python
>>> def side_effect(arg):
...    assert arg == {6}
...
>>> mock = Mock(side_effect=side_effect)
>>> mock({6})
>>> mock(set())
Traceback (most recent call last):
  ...
AssertionError
```

An alternative approach is to create a subclass of Mock or MagicMock that copies (using copy.deepcopy()) the arguments. Here's an example implementation:

```python
>>> from copy import deepcopy
>>> class CopyingMock(MagicMock):
...    def __call__(self, *args, **kwargs):
...        args = deepcopy(args)
...        kwargs = deepcopy(kwargs)
...        return super(CopyingMock, self).__call__
...
>>> c = CopyingMock(return_value=None)
>>> arg = set()
>>> c(arg)
>>> arg.add(1)
>>> c.assert_called_with(set())
>>> c.assert_called_with(arg)
Traceback (most recent call last):
  ...
AssertionError: Expected call: mock({1})
Actual call: mock(set())

>>> c.foo
<CopyingMock name='mock.foo' id='...'>

When you subclass Mock or MagicMock all dynamically created attributes, and the return_value will use your subclass automatically. That means all children of a CopyingMock will also have the type CopyingMock.

26.6.3.8. Nesting Patches

Using patch as a context manager is nice, but if you do multiple patches you can end up with nested with statements indenting further and further to the right:

```python
>>> class MyTest(TestCase):
...    ...
...    def test_foo(self):
...        with patch('mymodule.Foo') as mock_foo:
...            with patch('mymodule.Bar') as mock_bar:
...                with patch('mymodule.Spam') as mock_spam:
...                    assert mymodule.Foo is mock_foo
...                    assert mymodule.Bar is mock_bar
...                    assert mymodule.Spam is mock_spam
...        original = mymodule.Foo
>>> MyTest('test_foo').test_foo()
>>> assert mymodule.Foo is original
```

With unittest cleanup functions and the patch methods: start and stop we can achieve the same effect without the nested indentation. A simple helper method, create_patch, puts the patch in place and...
returns the created mock for us:

```python
>>> class MyTest(TestCase):
    ...
    ...
    def create_patch(self, name):
        patcher = patch(name)
        thing = patcher.start()
        self.addCleanup(patcher.stop)
        return thing
    ...
    ...
    def test_foo(self):
        mock_foo = self.create_patch('mymodule.Foo')
        mock_bar = self.create_patch('mymodule.Bar')
        mock_spam = self.create_patch('mymodule.Spam')
        ...
        assert mymodule.Foo is mock_foo
        assert mymodule.Bar is mock_bar
        assert mymodule.Spam is mock_spam
    ...
>>> original = mymodule.Foo
>>> MyTest('test_foo').run()
>>> assert mymodule.Foo is original
```

26.6.3.9. Mocking a dictionary with MagicMock

You may want to mock a dictionary, or other container object, recording all access to it whilst having it still behave like a dictionary.

We can do this with `MagicMock`, which will behave like a dictionary, and using `side_effect` to delegate dictionary access to a real underlying dictionary that is under our control.

When the `__getitem__()` and `__setitem__()` methods of our `MagicMock` are called (normal dictionary access) then `side_effect`
is called with the key (and in the case of \_\_setitem\_\_ the value too). We can also control what is returned.

After the MagicMock has been used we can use attributes like call_args_list to assert about how the dictionary was used:

```python
>>> my_dict = \{'a': 1, 'b': 2, 'c': 3\}
>>> def getitem(name):
...     return my_dict[name]
...
>>> def setitem(name, val):
...     my_dict[name] = val
...
>>> mock = MagicMock()
>>> mock.__getitem__.side_effect = getitem
>>> mock.__setitem__.side_effect = setitem
```

**Note:** An alternative to using MagicMock is to use Mock and only provide the magic methods you specifically want:

```python
>>> mock = Mock()
>>> mock.__getitem__ = Mock(side_effect=getitem)
>>> mock.__setitem__ = Mock(side_effect=setitem)
```

A third option is to use MagicMock but passing in dict as the spec (or spec_set) argument so that the MagicMock created only has dictionary magic methods available:

```python
>>> mock = MagicMock(spec_set=dict)
>>> mock.__getitem__.side_effect = getitem
>>> mock.__setitem__.side_effect = setitem
```

With these side effect functions in place, the mock will behave like a
normal dictionary but recording the access. It even raises a `KeyError` if you try to access a key that doesn’t exist.

```python
>>> mock['a']
1
>>> mock['c']
3
>>> mock['d']
Traceback (most recent call last):
...
KeyError: 'd'
>>> mock['b'] = 'fish'
>>> mock['d'] = 'eggs'
>>> mock['b']
'fish'
>>> mock['d']
'eggs'
```

After it has been used you can make assertions about the access using the normal mock methods and attributes:

```python
>>> mock.__getitem__.call_args_list
[call('a'), call('c'), call('d'), call('b'), call('d')]
>>> mock.__setitem__.call_args_list
[call('b', 'fish'), call('d', 'eggs')]
>>> my_dict
{'a': 1, 'c': 3, 'b': 'fish', 'd': 'eggs'}
```

26.6.3.10. Mock subclasses and their attributes

There are various reasons why you might want to subclass `Mock`. One reason might be to add helper methods. Here’s a silly example:

```python
>>> class MyMock(MagicMock):
```
```python
... def has Been called(self):
...
    return self.called
...
>>> mymock = MyMock(return_value=None)
>>> mymock
<MyMock id='...'>
>>> mymock.has been called()
False
>>> mymock()
>>> mymock.has been called()
True
```

The standard behaviour for Mock instances is that attributes and the return value mocks are of the same type as the mock they are accessed on. This ensures that Mock attributes are Mocks and MagicMock attributes are MagicMocks [2]. So if you're subclassing to add helper methods then they'll also be available on the attributes and return value mock of instances of your subclass.

```python
>>> mymock.foo
<MyMock name='mock.foo' id='...'>
>>> mymock.foo.has been called()
False
>>> mymock.foo()
<MyMock name='mock.foo()' id='...'>
>>> mymock.foo.has been called()
True
```

Sometimes this is inconvenient. For example, one user is subclassing mock to created a Twisted adaptor. Having this applied to attributes too actually causes errors.

Mock (in all its flavours) uses a method called _get_child_mock to create these “sub-mocks” for attributes and return values. You can prevent your subclass being used for attributes by overriding this
method. The signature is that it takes arbitrary keyword arguments (**kwargs) which are then passed onto the mock constructor:

```python
>>> class Subclass(MagicMock):
...     def _get_child_mock(self, **kwargs):
...         return MagicMock(**kwargs)
...
>>> mymock = Subclass()
>>> mymock.foo
<MagicMock name='mock.foo' id='...'>
>>> assert isinstance(mymock, Subclass)
>>> assert not isinstance(mymock.foo, Subclass)
>>> assert not isinstance(mymock(), Subclass)
```

An exception to this rule are the non-callable mocks. Attributes use the callable variant because otherwise non-callable mocks couldn’t have callable methods.

### 26.6.3.11. Mocking imports with patch.dict

One situation where mocking can be hard is where you have a local import inside a function. These are harder to mock because they aren’t using an object from the module namespace that we can patch out.

Generally local imports are to be avoided. They are sometimes done to prevent circular dependencies, for which there is usually a much better way to solve the problem (refactor the code) or to prevent “up front costs” by delaying the import. This can also be solved in better ways than an unconditional local import (store the module as a class or module attribute and only do the import on first use).

That aside there is a way to use `mock` to affect the results of an import. Importing fetches an `object` from the `sys.modules` dictionary. Note that it fetches an `object`, which need not be a module. Importing a
module for the first time results in a module object being put in
sys.modules, so usually when you import something you get a module
back. This need not be the case however.

This means you can use patch.dict() to temporarily put a mock in
place in sys.modules. Any imports whilst this patch is active will
fetch the mock. When the patch is complete (the decorated function
exits, the with statement body is complete or patcher.stop() is
called) then whatever was there previously will be restored safely.

Here's an example that mocks out the 'fooble' module.

```python
>>> mock = Mock()
>>> with patch.dict('sys.modules', {'fooble': mock})
...     import fooble
...     fooble.blob()
...
<Mock name='mock.blob()' id='...'>
>>> assert 'fooble' not in sys.modules
>>> mock.blob.assert_called_once_with()
```

As you can see the import fooble succeeds, but on exit there is no
'fooble' left in sys.modules.

This also works for the from module import name form:

```python
>>> mock = Mock()
>>> with patch.dict('sys.modules', {'fooble': mock})
...     from fooble import blob
...     blob.blip()
...
<Mock name='mock.blob.blip()' id='...'>
>>> mock.blob.blip.assert_called_once_with()
```
With slightly more work you can also mock package imports:

```python
>>> mock = Mock()
>>> modules = {'package': mock, 'package.module': mock}
>>> with patch.dict('sys.modules', modules):
...     from package.module import fooble
...     fooble()
...
<Mock name='mock.module.fooble()' id='...'>
>>> mock.module.fooble.assert_called_once_with()
```

### 26.6.3.12. Tracking order of calls and less verbose call assertions

The `Mock` class allows you to track the order of method calls on your mock objects through the `method_calls` attribute. This doesn’t allow you to track the order of calls between separate mock objects, however we can use `mock_calls` to achieve the same effect.

Because mocks track calls to child mocks in `mock_calls`, and accessing an arbitrary attribute of a mock creates a child mock, we can create our separate mocks from a parent one. Calls to those child mock will then all be recorded, in order, in the `mock_calls` of the parent:

```python
>>> manager = Mock()
>>> mock_foo = manager.foo
>>> mock_bar = manager.bar

>>> mock_foo.something()
<Mock name='mock.foo.something()' id='...'>
>>> mock_bar.other.thing()
<Mock name='mock.bar.other.thing()' id='...'>
```
We can then assert about the calls, including the order, by comparing with the `mock_calls` attribute on the manager mock:

```python
>>> expected_calls = [call.foo.something(), call.bar.other.thing()]
>>> manager.mock_calls == expected_calls
True
```

If `patch` is creating, and putting in place, your mocks then you can attach them to a manager mock using the `attach_mock()` method. After attaching calls will be recorded in `mock_calls` of the manager.

```python
>>> manager = MagicMock()
>>> with patch('mymodule.Class1') as MockClass1:
...     with patch('mymodule.Class2') as MockClass2:
...         manager.attach_mock(MockClass1, 'MockClass1')
...         manager.attach_mock(MockClass2, 'MockClass2')
...         MockClass1().foo()
...         MockClass2().bar()
...
<MagicMock name='mock.MockClass1().foo()' id='...'>
<MagicMock name='mock.MockClass2().bar()' id='...'>
>>> manager.mock_calls
[call.MockClass1(),
 call.MockClass1().foo(),
 call.MockClass2(),
 call.MockClass2().bar()]
```

If many calls have been made, but you’re only interested in a particular sequence of them then an alternative is to use the
assert_has_calls() method. This takes a list of calls (constructed with the call object). If that sequence of calls are in mock_calls then the assert succeeds.

```python
>>> m = MagicMock()
>>> m().foo().bar().baz()
<MagicMock name='mock().foo().bar().baz()' id='...'>
>>> m().one().two().three()
<MagicMock name='mock().one().two().three()' id='...'>
>>> calls = call.one().two().three().call_list()
>>> m.assert_has_calls(calls)
```

Even though the chained call `m().one().two().three()` aren't the only calls that have been made to the mock, the assert still succeeds.

Sometimes a mock may have several calls made to it, and you are only interested in asserting about some of those calls. You may not even care about the order. In this case you can pass any_order=True to assert_has_calls:

```python
>>> m = MagicMock()
>>> m(1), m.two(2, 3), m.seven(7), m.fifty('50')
(...)
>>> calls = [call.fifty('50'), call(1), call.seven(7)]
>>> m.assert_has_calls(calls, any_order=True)
```

### 26.6.3.13. More complex argument matching

Using the same basic concept as ANY we can implement matchers to do more complex assertions on objects used as arguments to mocks.

Suppose we expect some object to be passed to a mock that by
default compares equal based on object identity (which is the Python
default for user defined classes). To use `assert_called_with()`
we would need to pass in the exact same object. If we are only
interested in some of the attributes of this object then we can create a
matcher that will check these attributes for us.

You can see in this example how a ‘standard’ call to
`assert_called_with` isn’t sufficient:

```python
>>> class Foo:
    ...    def __init__(self, a, b):
    ...        self.a, self.b = a, b
    ...

>>> mock = Mock(return_value=None)
>>> mock(Foo(1, 2))
>>> mock.assert_called_with(Foo(1, 2))
Traceback (most recent call last):
  ...  AssertionError: Expected: call(<__main__.Foo object at 0x...>)
Actual call: call(<__main__.Foo object at 0x...>)
```

A comparison function for our Foo class might look something like
this:

```python
>>> def compare(self, other):
    ...    if not type(self) == type(other):
    ...        return False
    ...
    if self.a != other.a:
    ...        return False
    ...
    if self.b != other.b:
    ...        return False
    ...
    return True
    ...
```
And a matcher object that can use comparison functions like this for its equality operation would look something like this:

```python
>>> class Matcher:
...     def __init__(self, compare, some_obj):
...         self.compare = compare
...         self.some_obj = some_obj
...     def __eq__(self, other):
...         return self.compare(self.some_obj, other)
...```

Putting all this together:

```python
>>> match_foo = Matcher(compare, Foo(1, 2))
>>> mock.assert_called_with(match_foo)
```

The Matcher is instantiated with our compare function and the Foo object we want to compare against. In `assert_called_with` the Matcher equality method will be called, which compares the object the mock was called with against the one we created our matcher with. If they match then `assert_called_with` passes, and if they don’t an `AssertionError` is raised:

```python
>>> match_wrong = Matcher(compare, Foo(3, 4))
>>> mock.assert_called_with(match_wrong)
Traceback (most recent call last):
  ...
AssertionError: Expected: ((<Matcher object at 0x...>,), {})
Called with: ((<Foo object at 0x...>,), {})
```

With a bit of tweaking you could have the comparison function raise the `AssertionError` directly and provide a more useful failure message.
As of version 1.5, the Python testing library **PyHamcrest** provides similar functionality, that may be useful here, in the form of its equality matcher (*hamcrest.library.integration.match_equality*).
26.7. 2to3 - Automated Python 2 to 3 code translation

2to3 is a Python program that reads Python 2.x source code and applies a series of fixers to transform it into valid Python 3.x code. The standard library contains a rich set of fixers that will handle almost all code. 2to3 supporting library lib2to3 is, however, a flexible and generic library, so it is possible to write your own fixers for 2to3. lib2to3 could also be adapted to custom applications in which Python code needs to be edited automatically.
26.7.1. Using 2to3

2to3 will usually be installed with the Python interpreter as a script. It is also located in the `Tools/scripts` directory of the Python root.

2to3’s basic arguments are a list of files or directories to transform. The directories are recursively traversed for Python sources.

Here is a sample Python 2.x source file, `example.py`:

```python
def greet(name):
    print "Hello, {0}".format(name)
print "What's your name?"
name = raw_input()
greet(name)
```

It can be converted to Python 3.x code via 2to3 on the command line:

```
$ 2to3 example.py
```

A diff against the original source file is printed. 2to3 can also write the needed modifications right back to the source file. (A backup of the original file is made unless -n is also given.) Writing the changes back is enabled with the `-w` flag:

```
$ 2to3 -w example.py
```

After transformation, `example.py` looks like this:

```python
def greet(name):
    print("Hello, {0}".format(name))
print("What's your name?")
name = input()
```
greet(name)

Comments and exact indentation are preserved throughout the translation process.

By default, 2to3 runs a set of predefined fixers. The -l flag lists all available fixers. An explicit set of fixers to run can be given with -f. Likewise the -x explicitly disables a fixer. The following example runs only the imports and has_key fixers:

```
$ 2to3 -f imports -f has_key example.py
```

This command runs every fixer except the apply fixer:

```
$ 2to3 -x apply example.py
```

Some fixers are explicit, meaning they aren't run by default and must be listed on the command line to be run. Here, in addition to the default fixers, the idioms fixer is run:

```
$ 2to3 -f all -f idioms example.py
```

Notice how passing all enables all default fixers.

Sometimes 2to3 will find a place in your source code that needs to be changed, but 2to3 cannot fix automatically. In this case, 2to3 will print a warning beneath the diff for a file. You should address the warning in order to have compliant 3.x code.

2to3 can also refactor doctests. To enable this mode, use the -d flag. Note that only doctests will be refactored. This also doesn't require the module to be valid Python. For example, doctest like examples in a reST document could also be refactored with this option.
The -v option enables output of more information on the translation process.

Since some print statements can be parsed as function calls or statements, 2to3 cannot always read files containing the print function. When 2to3 detects the presence of the `from __future__ import print_function` compiler directive, it modifies its internal grammar to interpret `print()` as a function. This change can also be enabled manually with the -p flag. Use -p to run fixers on code that already has had its print statements converted.

The -o or --output-dir option allows specification of an alternate directory for processed output files to be written to. The -n flag is required when using this as backup files do not make sense when not overwriting the input files.

*New in version 3.2.3:* The -o option was added.

The -W or --write-unchanged-files flag tells 2to3 to always write output files even if no changes were required to the file. This is most useful with -o so that an entire Python source tree is copied with translation from one directory to another. This option implies the -w flag as it would not make sense otherwise.

*New in version 3.2.3:* The -W flag was added.

The --add-suffix option specifies a string to append to all output filenames. The -n flag is required when specifying this as backups are not necessary when writing to different filenames. Example:

```bash
$ 2to3 -n -W --add-suffix=3 example.py
```

Will cause a converted file named example.py3 to be written.
New in version 3.2.3: The --add-suffix option was added.

To translate an entire project from one directory tree to another use:

```bash
$ 2to3 --output-dir=python3-version/mycode -W -n python2-version/mycode
```
26.7.2. Fixers

Each step of transforming code is encapsulated in a fixer. The command `2to3 -l` lists them. As documented above, each can be turned on and off individually. They are described here in more detail.

**apply**

Removes usage of `apply()`. For example `apply(function, *args, **kwargs)` is converted to `function(*args, **kwargs)`.

**asserts**

Replaces deprecated `unittest` method names with the correct ones.

<table>
<thead>
<tr>
<th>From</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>failUnlessEqual(a, b)</code></td>
<td><code>assertEqual(a, b)</code></td>
</tr>
<tr>
<td><code>assertEquals(a, b)</code></td>
<td><code>assertEqual(a, b)</code></td>
</tr>
<tr>
<td><code>failIfEqual(a, b)</code></td>
<td><code>assertNotEqual(a, b)</code></td>
</tr>
<tr>
<td><code>assertNotEquals(a, b)</code></td>
<td><code>assertNotEqual(a, b)</code></td>
</tr>
<tr>
<td><code>failUnless(a)</code></td>
<td><code>assertTrue(a)</code></td>
</tr>
<tr>
<td><code>assert_(a)</code></td>
<td><code>assertTrue(a)</code></td>
</tr>
<tr>
<td><code>failIf(a)</code></td>
<td><code>assertFalse(a)</code></td>

<tr>
<td>failIfAlmostEqual(a, b)</td>
<td>assertNotAlmostEqual(a, b)</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>assertNotAlmostEquals(a, b)</td>
<td>assertNotAlmostEqual(a, b)</td>
</tr>
</tbody>
</table>

**basestring**

Converts basestring to str.

**buffer**

Converts buffer to memoryview. This fixer is optional because the memoryview API is similar but not exactly the same as that of buffer.

**dict**

Fixes dictionary iteration methods. dict.iteritems() is converted to dict.items(), dict.iterkeys() to dict.keys(), and dict.itervalues() to dict.values(). Similarly, dict.viewitems(), dict.viewkeys() and dict.viewvalues() are converted respectively to dict.items(), dict.keys() and dict.values(). It also wraps existing usages of dict.items(), dict.keys() and dict.values() in a call to list.

**except**

Converts except X, T to except X as T.

**exec**

Converts the exec statement to the exec() function.

**execfile**

Removes usage of execfile(). The argument to execfile() is wrapped in calls to open(), compile(), and exec().
exitfunc
Changes assignment of sys.exitfunc to use of the atexit module.

filter
Wraps filter() usage in a list call.

funcattrs
Fixes function attributes that have been renamed. For example, my_function.func_closure is converted to my_function.__closure__.

future
Removes from __future__ import new_feature statements.

getcwd
Renames os.getcwd() to os.getcwd().

has_key
Changes dict.has_key(key) to key in dict.

idioms
This optional fixer performs several transformations that make Python code more idiomatic. Type comparisons like type(x) is SomeClass and type(x) == SomeClass are converted to isinstance(x, SomeClass). while 1 becomes while True. This fixer also tries to make use of sorted() in appropriate places. For example, this block

```python
L = list(some_iterable)
L.sort()
```
is changed to

```python
L = sorted(some_iterable)
```

**import**

Detects sibling imports and converts them to relative imports.

**imports**

Handles module renames in the standard library.

**imports2**

Handles other modules renames in the standard library. It is separate from the `imports` fixer only because of technical limitations.

**input**

Converts `input(prompt)` to `eval(input(prompt))`.

**intern**

Converts `intern()` to `sys.intern()`.

**isinstance**

Fixes duplicate types in the second argument of `isinstance()`. For example, `isinstance(x, (int, int))` is converted to `isinstance(x, (int))`.

**itertools_imports**

Removes imports of `itertools.ifilter()`, `itertools.izip()`, and `itertools.imap()`. Imports of `itertools.ifilterfalse()` are also changed to `itertools.filterfalse()`.

**itertools**
Changes usage of `itertools.ifilter()`, `itertools.izip()`, and `itertools.imap()` to their built-in equivalents. `itertools.ifilterfalse()` is changed to `itertools.filterfalse()`.

**long**
Renames `long` to `int`.

**map**
Wraps `map()` in a `list` call. It also changes `map(None, x)` to `list(x)`. Using `from future_builtins import map` disables this fixer.

**metaclass**
Converts the old metaclass syntax (`__metaclass__ = Meta` in the class body) to the new (`class X(metaclass=Meta)`).

**methodattrs**
Fixes old method attribute names. For example, `meth.im_func` is converted to `meth.__func__`.

**ne**
Converts the old not-equal syntax, `<>`, to `!=`.

**next**
Converts the use of iterator's `next()` methods to the `next()` function. It also renames `next()` methods to `__next__()`.

**nonzero**
Renames `__nonzero__()` to `__bool__()`.

**numliterals**
Converts octal literals into the new syntax.

**operator**

Converts calls to various functions in the `operator` module to other, but equivalent, function calls. When needed, the appropriate `import` statements are added, e.g. `import collections`. The following mapping are made:

<table>
<thead>
<tr>
<th>From</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>operator.isCallable(obj)</code></td>
<td><code>hasattr(obj, '__call__')</code></td>
</tr>
<tr>
<td><code>operator.sequenceIncludes(obj)</code></td>
<td><code>operator.contains</code></td>
</tr>
<tr>
<td><code>operator.isSequenceType(obj)</code></td>
<td><code>isinstance(obj, collections.Sequence)</code></td>
</tr>
<tr>
<td><code>operator.isMappingType(obj)</code></td>
<td><code>isinstance(obj, collections.Mapping)</code></td>
</tr>
<tr>
<td><code>operator.isNumberType(obj)</code></td>
<td><code>isinstance(obj, numbers.Number)</code></td>
</tr>
<tr>
<td><code>operator.repeat(obj, n)</code></td>
<td><code>operator.mul(obj,)</code></td>
</tr>
<tr>
<td><code>operator.irepeat(obj, n)</code></td>
<td><code>operator.imul(obj)</code></td>
</tr>
</tbody>
</table>

**paren**

Add extra parenthesis where they are required in list comprehensions. For example, `[x for x in 1, 2]` becomes `[x for x in (1, 2)]`.

**print**

Converts the `print` statement to the `print()` function.

**raise**

Converts `raise E, V` to `raise E(V)`, and `raise E, V, T` to
raise E(V).with_traceback(T). If E is a tuple, the translation will be incorrect because substituting tuples for exceptions has been removed in 3.0.

**raw_input**

Converts raw_input() to input().

**reduce**

Handles the move of reduce() to functools.reduce().

**reload**

Converts reload() to imp.reload().

**renames**

Changes sys.maxint to sys.maxsize.

**repr**

Replaces backtick repr with the repr() function.

**set_literal**

Replaces use of the set constructor with set literals. This fixer is optional.

**standarderror**

Renames StandardError to Exception.

**sys_exc**

Changes the deprecated sys.exc_value, sys.exc_type, sys.exc_traceback to use sys.exc_info().

**throw**

Fixes the API change in generator's throw() method.
**tuple_params**
Removes implicit tuple parameter unpacking. This fixer inserts temporary variables.

**types**
Fixes code broken from the removal of some members in the types module.

**unicode**
Renames unicode to str.

**urllib**
Handles the rename of urllib and urllib2 to the urllib package.

**ws_comma**
Removes excess whitespace from comma separated items. This fixer is optional.

**xrange**
Renames xrange() to range() and wraps existing range() calls with list.

**xreadlines**
Changes for x in file.xreadlines() to for x in file.

**zip**
Wraps zip() usage in a list call. This is disabled when from future_builtins import zip appears.
26.7.3. **lib2to3** - 2to3's library

**Source code:** Lib/lib2to3/

**Note:** The **lib2to3** API should be considered unstable and may change drastically in the future.
26.8. **test** — Regression tests package for Python

**Note:** The **test** package is meant for internal use by Python only. It is documented for the benefit of the core developers of Python. Any use of this package outside of Python’s standard library is discouraged as code mentioned here can change or be removed without notice between releases of Python.

The **test** package contains all regression tests for Python as well as the modules **test.support** and **test.regrtest**. **test.support** is used to enhance your tests while **test.regrtest** drives the testing suite.

Each module in the **test** package whose name starts with **test_** is a testing suite for a specific module or feature. All new tests should be written using the **unittest** or **doctest** module. Some older tests are written using a “traditional” testing style that compares output printed to **sys.stdout**; this style of test is considered deprecated.

**See also:**

**Module unittest**
Writing PyUnit regression tests.

**Module doctest**
Tests embedded in documentation strings.
26.8.1. Writing Unit Tests for the test package

It is preferred that tests that use the unittest module follow a few guidelines. One is to name the test module by starting it with test_ and end it with the name of the module being tested. The test methods in the test module should start with test_ and end with a description of what the method is testing. This is needed so that the methods are recognized by the test driver as test methods. Also, no documentation string for the method should be included. A comment (such as # Tests function returns only True or False) should be used to provide documentation for test methods. This is done because documentation strings get printed out if they exist and thus what test is being run is not stated.

A basic boilerplate is often used:

```python
import unittest
from test import support

class MyTestCase1(unittest.TestCase):
    # Only use setUp() and tearDown() if necessary

    def setUp(self):
        ... code to execute in preparation for tests

    def tearDown(self):
        ... code to execute to clean up after tests

    def test_feature_one(self):
        # Test feature one.
        ... testing code ...
```
This code pattern allows the testing suite to be run by test.regrtest, on its own as a script that supports the unittest CLI, or via the python -m unittest CLI.

The goal for regression testing is to try to break code. This leads to a few guidelines to be followed:

- The testing suite should exercise all classes, functions, and constants. This includes not just the external API that is to be presented to the outside world but also “private” code.

- Whitebox testing (examining the code being tested when the tests are being written) is preferred. Blackbox testing (testing only the published user interface) is not complete enough to make sure all boundary and edge cases are tested.

- Make sure all possible values are tested including invalid ones. This makes sure that not only all valid values are acceptable but also that improper values are handled correctly.
• Exhaust as many code paths as possible. Test where branching occurs and thus tailor input to make sure as many different paths through the code are taken.

• Add an explicit test for any bugs discovered for the tested code. This will make sure that the error does not crop up again if the code is changed in the future.

• Make sure to clean up after your tests (such as close and remove all temporary files).

• If a test is dependent on a specific condition of the operating system then verify the condition already exists before attempting the test.

• Import as few modules as possible and do it as soon as possible. This minimizes external dependencies of tests and also minimizes possible anomalous behavior from side-effects of importing a module.

• Try to maximize code reuse. On occasion, tests will vary by something as small as what type of input is used. Minimize code duplication by subclassing a basic test class with a class that specifies the input:

```python
class TestFuncAcceptsSequencesMixin:
    func = mySuperWhammyFunction

    def test_func(self):
        self.func(self.arg)

class AcceptLists(TestFuncAcceptsSequencesMixin, arg = [1, 2, 3])
```
When using this pattern, remember that all classes that inherit from `unittest.TestCase` are run as tests. The Mixin class in the example above does not have any data and so can't be run by itself, thus it does not inherit from `unittest.TestCase`.

See also:

**Test Driven Development**

A book by Kent Beck on writing tests before code.
26.8.2. Running tests using the command-line interface

The `test` package can be run as a script to drive Python’s regression test suite, thanks to the `-m` option: `python -m test`. Under the hood, it uses `test.regrtest`; the call `python -m test.regrtest` used in previous Python versions still works. Running the script by itself automatically starts running all regression tests in the `test` package. It does this by finding all modules in the package whose name starts with `test_`, importing them, and executing the function `test_main()` if present or loading the tests via `unittest.TestLoader.loadTestsFromModule` if `test_main` does not exist. The names of tests to execute may also be passed to the script. Specifying a single regression test (`python -m test test_spam`) will minimize output and only print whether the test passed or failed.

Running `test` directly allows what resources are available for tests to use to be set. You do this by using the `-u` command-line option. Specifying `all` as the value for the `-u` option enables all possible resources: `python -m test -uall`. If all but one resource is desired (a more common case), a comma-separated list of resources that are not desired may be listed after `all`. The command `python -m test -uall,-audio,-largefile` will run `test` with all resources except the `audio` and `largefile` resources. For a list of all resources and more command-line options, run `python -m test -h`.

Some other ways to execute the regression tests depend on what platform the tests are being executed on. On Unix, you can run `make test` at the top-level directory where Python was built. On Windows, executing `rt.bat` from your `PCBuild` directory will run all regression
tests.
26.9. test.support — Utilities for the Python test suite

The test.support module provides support for Python’s regression test suite.

Note: test.support is not a public module. It is documented here to help Python developers write tests. The API of this module is subject to change without backwards compatibility concerns between releases.

This module defines the following exceptions:

exception test.support.TestFailed
    Exception to be raised when a test fails. This is deprecated in favor of unittest-based tests and unittest.TestCase's assertion methods.

exception test.support.ResourceDenied
    Subclass of unittest.SkipTest. Raised when a resource (such as a network connection) is not available. Raised by the requires() function.

The test.support module defines the following constants:

test.support.verbose
    True when verbose output is enabled. Should be checked when more detailed information is desired about a running test. verbose is set by test.regrtest.
test.support.is_jython
   True if the running interpreter is Jython.

test.support.TESTFN
   Set to a name that is safe to use as the name of a temporary file. Any temporary file that is created should be closed and unlinked (removed).

The test.support module defines the following functions:

test.support.forget(module_name)
   Remove the module named module_name from sys.modules and delete any byte-compiled files of the module.

test.support.is_resource_enabled(resource)
   Return True if resource is enabled and available. The list of available resources is only set when test.regrtest is executing the tests.

test.support.requires(resource, msg=None)
   Raise ResourceDenied if resource is not available. msg is the argument to ResourceDenied if it is raised. Always returns True if called by a function whose __name__ is '__main__'. Used when tests are executed by test.regrtest.

test.support.findfile(filename, subdir=None)
   Return the path to the file named filename. If no match is found filename is returned. This does not equal a failure since it could be the path to the file.

   Setting subdir indicates a relative path to use to find the file rather than looking directly in the path directories.
test.support.run_unittest(*classes)

Execute unittest.TestCase subclasses passed to the function. The function scans the classes for methods starting with the prefix test_ and executes the tests individually.

It is also legal to pass strings as parameters; these should be keys in sys.modules. Each associated module will be scanned by unittest.TestLoader.loadTestsFromModule(). This is usually seen in the following test_main() function:

```python
def test_main():
    support.run_unittest(__name__)
```

This will run all tests defined in the named module.

test.support.run_doctest(module, verbosity=None)

Run doctest.testmod() on the given module. Return (failure_count, test_count).

If verbosity is None, doctest.testmod() is run with verbosity set to verbose. Otherwise, it is run with verbosity set to None.

test.support.check_warnings(*filters, quiet=True)

A convenience wrapper for warnings.catch_warnings() that makes it easier to test that a warning was correctly raised. It is approximately equivalent to calling warnings.catch_warnings(record=True) with warnings.simplefilter() set to always and with the option to automatically validate the results that are recorded.

check_warnings accepts 2-tuples of the form ("message regexp", WarningCategory) as positional arguments. If one
or more filters are provided, or if the optional keyword argument quiet is False, it checks to make sure the warnings are as expected: each specified filter must match at least one of the warnings raised by the enclosed code or the test fails, and if any warnings are raised that do not match any of the specified filters the test fails. To disable the first of these checks, set quiet to True.

If no arguments are specified, it defaults to:

```python
check_warnings(("", Warning), quiet=True)
```

In this case all warnings are caught and no errors are raised.

On entry to the context manager, a WarningRecorder instance is returned. The underlying warnings list from `catch_warnings()` is available via the recorder object's `warnings` attribute. As a convenience, the attributes of the object representing the most recent warning can also be accessed directly through the recorder object (see example below). If no warning has been raised, then any of the attributes that would otherwise be expected on an object representing a warning will return None.

The recorder object also has a `reset()` method, which clears the warnings list.

The context manager is designed to be used like this:

```python
with check_warnings(("assertion is always true", "", UserWarning)):  
    exec('assert(False, "Hey!")')  
    warnings.warn(UserWarning("Hide me!"))
```

In this case if either warning was not raised, or some other warning
was raised, check_warnings() would raise an error.

When a test needs to look more deeply into the warnings, rather than just checking whether or not they occurred, code like this can be used:

```python
with check_warnings(quiet=True) as w:
    warnings.warn("foo")
    assert str(w.args[0]) == "foo"
    warnings.warn("bar")
    assert str(w.args[0]) == "bar"
    assert str(w.warnings[0].args[0]) == "foo"
    assert str(w.warnings[1].args[0]) == "bar"
    w.reset()
    assert len(w.warnings) == 0
```

Here all warnings will be caught, and the test code tests the captured warnings directly.

*Changed in version 3.2:* New optional arguments filters and quiet.

test.support.captured_stdin()
test.support.captured_stdout()
test.support.captured_stderr()

A context managers that temporarily replaces the named stream with `io.StringIO` object.

Example use with output streams:

```python
with captured_stdout() as stdout, captured_stderr() as stderr:
    print("hello")
    print("error", file=sys.stderr)
    assert stdout.getvalue() == "hello\n"
    assert stderr.getvalue() == "error\n"
```
Example use with input stream:

```python
with captured_stdin() as stdin:
    stdin.write('hello
')
    stdin.seek(0)
# call test code that consumes from sys.stdin
captured = input()
self.assertEqual(captured, 'hello')
```

test.support.temp_dir(path=None, quiet=False)
A context manager that creates a temporary directory at `path` and yields the directory.

If `path` is `None`, the temporary directory is created using `tempfile.mkdtemp()`. If `quiet` is `False`, the context manager raises an exception on error. Otherwise, if `path` is specified and cannot be created, only a warning is issued.

test.support.change_cwd(path, quiet=False)
A context manager that temporarily changes the current working directory to `path` and yields the directory.

If `quiet` is `False`, the context manager raises an exception on error. Otherwise, it issues only a warning and keeps the current working directory the same.

test.support.temp_cwd(name='tempcwd', quiet=False)
A context manager that temporarily creates a new directory and changes the current working directory (CWD).

The context manager creates a temporary directory in the current directory with name `name` before temporarily changing the current working directory. If `name` is `None`, the temporary directory is
created using `tempfile.mkdtemp()`.

If `quiet` is `False` and it is not possible to create or change the CWD, an error is raised. Otherwise, only a warning is raised and the original CWD is used.

test.support.temp_umask(umask)

A context manager that temporarily sets the process umask.

test.support.can_symlink()

Return `True` if the OS supports symbolic links, `False` otherwise.

@test.support.skip_unless_symlink

A decorator for running tests that require support for symbolic links.

@test.support.anticipate_failure(condition)

A decorator to conditionally mark tests with `unittest.expectedFailure()`. Any use of this decorator should have an associated comment identifying the relevant tracker issue.

@test.support.run_with_locale(catstr, *locales)

A decorator for running a function in a different locale, correctly resetting it after it has finished. `catstr` is the locale category as a string (for example "LC_ALL"). The `locales` passed will be tried sequentially, and the first valid locale will be used.

test.support.make_bad_fd()

Create an invalid file descriptor by opening and closing a temporary file, and returning its descriptor.

test.support.import_module(name, deprecated=False)

This function imports and returns the named module. Unlike a
normal import, this function raises `unittest.SkipTest` if the module cannot be imported.

Module and package deprecation messages are suppressed during this import if `deprecated` is True.

*New in version 3.1.*

```
import_fresh_module(name, fresh=(), blocked=(), deprecated=False)
```

This function imports and returns a fresh copy of the named Python module by removing the named module from `sys.modules` before doing the import. Note that unlike `reload()`, the original module is not affected by this operation.

`fresh` is an iterable of additional module names that are also removed from the `sys.modules` cache before doing the import.

`blocked` is an iterable of module names that are replaced with `None` in the module cache during the import to ensure that attempts to import them raise `ImportError`.

The named module and any modules named in the `fresh` and `blocked` parameters are saved before starting the import and then reinserted into `sys.modules` when the fresh import is complete.

Module and package deprecation messages are suppressed during this import if `deprecated` is True.

This function will raise `ImportError` if the named module cannot be imported.

Example use:
# Get copies of the warnings module for testing without affecting the version being used by the rest of the test suite. One copy uses the C implementation, the other is forced to use the pure Python fallback implementation

```python
py_warnings = import_fresh_module('warnings', blocked=True)
c_warnings = import_fresh_module('warnings', fresh=True)
```

*New in version 3.1.*

test.support.bind_port(sock, host=HOST)

Bind the socket to a free port and return the port number. Relies on ephemeral ports in order to ensure we are using an unbound port. This is important as many tests may be running simultaneously, especially in a buildbot environment. This method raises an exception if the `sock.family` is `AF_INET` and `sock.type` is `SOCK_STREAM`, and the socket has `SO_REUSEADDR` or `SO_REUSEPORT` set on it. Tests should never set these socket options for TCP/IP sockets. The only case for setting these options is testing multicasting via multiple UDP sockets.

Additionally, if the `SO_EXCLUSIVEADDRUSE` socket option is available (i.e. on Windows), it will be set on the socket. This will prevent anyone else from binding to our host/port for the duration of the test.

test.support.find_unused_port(family=socket.AF_INET, socktype=socket.SOCK_STREAM)

Returns an unused port that should be suitable for binding. This is achieved by creating a temporary socket with the same family and type as the `sock` parameter (default is `AF_INET`, `SOCK_STREAM`), and binding it to the specified host address (defaults to `0.0.0.0`) with the port set to 0, eliciting an unused ephemeral port from the
OS. The temporary socket is then closed and deleted, and the ephemeral port is returned.

Either this method or `bind_port()` should be used for any tests where a server socket needs to be bound to a particular port for the duration of the test. Which one to use depends on whether the calling code is creating a python socket, or if an unused port needs to be provided in a constructor or passed to an external program (i.e. the `-accept` argument to openssl's `s_server` mode). Always prefer `bind_port()` over `find_unused_port()` where possible. Using a hard coded port is discouraged since it can make multiple instances of the test impossible to run simultaneously, which is a problem for buildbots.

test.support.load_package_tests(pkg_dir, loader, standard_tests, pattern)

Generic implementation of the unittest `load_tests` protocol for use in test packages. `pkg_dir` is the root directory of the package; `loader, standard_tests, and pattern` are the arguments expected by `load_tests`. In simple cases, the test package's `__init__.py` can be the following:

```python
import os
from test.support import load_package_tests

def load_tests(*args):
    return load_package_tests(os.path.dirname(__file__))
```

test.support.detect_api_mismatch(ref_api, other_api, *, ignore=())

Returns the set of attributes, functions or methods of `ref_api` not found on `other_api`, except for a defined list of items to be ignored
in this check specified in `ignore`.

By default this skips private attributes beginning with ‘_’ but includes all magic methods, i.e. those starting and ending in ‘__’.

*New in version 3.5.*

def check__all__(test_case, module, name_of_module=None, extra=(), blacklist=())

Assert that the `__all__` variable of `module` contains all public names.

The module's public names (its API) are detected automatically based on whether they match the public name convention and were defined in `module`.

The `name_of_module` argument can specify (as a string or tuple thereof) what module(s) an API could be defined in in order to be detected as a public API. One case for this is when `module` imports part of its public API from other modules, possibly a C backend (like `csv` and its `_csv`).

The `extra` argument can be a set of names that wouldn't otherwise be automatically detected as “public”, like objects without a proper `__module__` attribute. If provided, it will be added to the automatically detected ones.

The `blacklist` argument can be a set of names that must not be treated as part of the public API even though their names indicate otherwise.

Example use:

```python
import bar
```
import foo
import unittest
from test import support

class MiscTestCase(unittest.TestCase):
    def test__all__(self):
        support.check__all__(self, foo)

class OtherTestCase(unittest.TestCase):
    def test__all__(self):
        extra = {'BAR_CONST', 'FOO_CONST'}
        blacklist = {'baz'} # Undocumented name.
        # bar imports part of its API from _bar.
        support.check__all__(self, bar, ('bar', '',
            extra=extra, blacklist

New in version 3.6.

The test.support module defines the following classes:

class test.support.TransientResource(exc, **kwargs)

Instances are a context manager that raises ResourceDenied if the specified exception type is raised. Any keyword arguments are treated as attribute/value pairs to be compared against any exception raised within the with statement. Only if all pairs match properly against attributes on the exception is ResourceDenied raised.

class test.support.EnvironmentVarGuard

Class used to temporarily set or unset environment variables. Instances can be used as a context manager and have a complete dictionary interface for querying/modifying the underlying os.environ. After exit from the context manager all changes to environment variables done through this instance will be rolled
Changed in version 3.1: Added dictionary interface.

EnvironmentVarGuard.set(envvar, value)
Temporarily set the environment variable envvar to the value of value.

EnvironmentVarGuard.unset(envvar)
Temporarily unset the environment variable envvar.

class test.support.SuppressCrashReport
A context manager used to try to prevent crash dialog popups on tests that are expected to crash a subprocess.

On Windows, it disables Windows Error Reporting dialogs using SetErrorMode.

On UNIX, resource.setrlimit() is used to set resource.RLIMIT_CORE's soft limit to 0 to prevent coredump file creation.

On both platforms, the old value is restored by __exit__().

class test.support.WarningsRecorder
Class used to record warnings for unit tests. See documentation of check_warnings() above for more details.
27. Debugging and Profiling

These libraries help you with Python development: the debugger enables you to step through code, analyze stack frames and set breakpoints etc., and the profilers run code and give you a detailed breakdown of execution times, allowing you to identify bottlenecks in your programs.

- **27.1. bdb — Debugger framework**
- **27.2. faulthandler — Dump the Python traceback**

27.1. **bdb — Debugger framework**

**Source code:** Lib/bdb.py

The `bdb` module handles basic debugger functions, like setting breakpoints or managing execution via the debugger.

The following exception is defined:

```python
exception bdb. BdbQuit

Exception raised by the Bdb class for quitting the debugger.
```

The `bdb` module also defines two classes:

```python
class bdb. Breakpoint(self, file, line, temporary=0, cond=None, funcname=None)
```

This class implements temporary breakpoints, ignore counts, disabling and (re-)enabling, and conditionals.

Breakpoints are indexed by number through a list called `bpbynumber` and by `(file, line)` pairs through `bplist`. The former points to a single instance of class `Breakpoint`. The latter points to a list of such instances since there may be more than one breakpoint per line.

When creating a breakpoint, its associated filename should be in canonical form. If a `funcname` is defined, a breakpoint hit will be counted when the first line of that function is executed. A conditional breakpoint always counts a hit.

`Breakpoint` instances have the following methods:
deleteMe()
Delete the breakpoint from the list associated to a file/line. If it is the last breakpoint in that position, it also deletes the entry for the file/line.

enable()
Mark the breakpoint as enabled.

disable()
Mark the breakpoint as disabled.

bpformat()
Return a string with all the information about the breakpoint, nicely formatted:

- The breakpoint number.
- If it is temporary or not.
- Its file,line position.
- The condition that causes a break.
- If it must be ignored the next N times.
- The breakpoint hit count.

New in version 3.2.

bpprint(out=None)
Print the output of bpformat() to the file out, or if it is None, to standard output.

class bdb.Bdb(skip=None)
The Bdb class acts as a generic Python debugger base class.

This class takes care of the details of the trace facility; a derived class should implement user interaction. The standard debugger class (pdb.Pdb) is an example.
The *skip* argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.

*New in version 3.1:* The *skip* argument.

The following methods of *Bdb* normally don’t need to be overridden.

**canonic**(*filename*)

Auxiliary method for getting a filename in a canonical form, that is, as a case-normalized (on case-insensitive filesystems) absolute path, stripped of surrounding angle brackets.

**reset()**

Set the botframe, stopframe, returnframe and quitting attributes with values ready to start debugging.

**trace_dispatch**(*frame, event, arg*)

This function is installed as the trace function of debugged frames. Its return value is the new trace function (in most cases, that is, itself).

The default implementation decides how to dispatch a frame, depending on the type of event (passed as a string) that is about to be executed. *event* can be one of the following:

- "line": A new line of code is going to be executed.
- "call": A function is about to be called, or another code block entered.
- "return": A function or other code block is about to
return.

- "exception": An exception has occurred.
- "c_call": A C function is about to be called.
- "c_return": A C function has returned.
- "c_exception": A C function has raised an exception.

For the Python events, specialized functions (see below) are called. For the C events, no action is taken.

The `arg` parameter depends on the previous event.

See the documentation for `sys.settrace()` for more information on the trace function. For more information on code and frame objects, refer to The standard type hierarchy.

**dispatch_line(frame)**

If the debugger should stop on the current line, invoke the `user_line()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_line()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_call(frame, arg)**

If the debugger should stop on this function call, invoke the `user_call()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_call()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_return(frame, arg)**

If the debugger should stop on this function return, invoke the
user_return() method (which should be overridden in subclasses). Raise a BdbQuit exception if the Bdb.quitting flag is set (which can be set from user_return()). Return a reference to the trace_dispatch() method for further tracing in that scope.

dispatch_exception(frame, arg)
If the debugger should stop at this exception, invokes the user_exception() method (which should be overridden in subclasses). Raise a BdbQuit exception if the Bdb.quitting flag is set (which can be set from user_exception()). Return a reference to the trace_dispatch() method for further tracing in that scope.

Normally derived classes don’t override the following methods, but they may if they want to redefine the definition of stopping and breakpoints.

stop_here(frame)
This method checks if the frame is somewhere below botframe in the call stack. botframe is the frame in which debugging started.

break_here(frame)
This method checks if there is a breakpoint in the filename and line belonging to frame or, at least, in the current function. If the breakpoint is a temporary one, this method deletes it.

break_anywhere(frame)
This method checks if there is a breakpoint in the filename of the current frame.
Derived classes should override these methods to gain control over debugger operation.

**user_call(frame, argument_list)**
This method is called from `dispatch_call()` when there is the possibility that a break might be necessary anywhere inside the called function.

**user_line(frame)**
This method is called from `dispatch_line()` when either `stop_here()` or `break_here()` yields `True`.

**user_return(frame, return_value)**
This method is called from `dispatch_return()` when `stop_here()` yields `True`.

**user_exception(frame, exc_info)**
This method is called from `dispatch_exception()` when `stop_here()` yields `True`.

**do_clear(arg)**
Handle how a breakpoint must be removed when it is a temporary one.

This method must be implemented by derived classes.

Derived classes and clients can call the following methods to affect the stepping state.

**set_step()**
Stop after one line of code.

**set_next(frame)**
Stop on the next line in or below the given frame.

**set_return**(frame)
Stop when returning from the given frame.

**set_until**(frame)
Stop when the line with the line no greater than the current one is reached or when returning from current frame.

**set_trace**(frame)
Start debugging from frame. If frame is not specified, debugging starts from caller's frame.

**set_continue**()
Stop only at breakpoints or when finished. If there are no breakpoints, set the system trace function to None.

**set_quit**()
Set the quitting attribute to True. This raises BdbQuit in the next call to one of the dispatch_*() methods.

Derived classes and clients can call the following methods to manipulate breakpoints. These methods return a string containing an error message if something went wrong, or None if all is well.

**set_break**(filename, lineno, temporary=0, cond, funcname)
Set a new breakpoint. If the lineno line doesn't exist for the filename passed as argument, return an error message. The filename should be in canonical form, as described in the canonic() method.

**clear_break**(filename, lineno)
Delete the breakpoints in `filename` and `lineno`. If none were set, an error message is returned.

**clear_bpbynumber**(*arg*)
Delete the breakpoint which has the index `arg` in the Breakpoint.bpbynumber. If `arg` is not numeric or out of range, return an error message.

**clear_all_file_breaks**(filename)
Delete all breakpoints in `filename`. If none were set, an error message is returned.

**clear_all_breaks**()
Delete all existing breakpoints.

**get_bpbynumber**(*arg*)
Return a breakpoint specified by the given number. If `arg` is a string, it will be converted to a number. If `arg` is a non-numeric string, if the given breakpoint never existed or has been deleted, a `ValueError` is raised.

*New in version 3.2.*

**get_break**(filename, lineno)
Check if there is a breakpoint for `lineno` of `filename`.

**get_breaks**(filename, lineno)
Return all breakpoints for `lineno` in `filename`, or an empty list if none are set.

**get_file_breaks**(filename)
Return all breakpoints in `filename`, or an empty list if none are set.
**get_all_breaks()**
Return all breakpoints that are set.

Derived classes and clients can call the following methods to get a data structure representing a stack trace.

**get_stack(f, t)**
Get a list of records for a frame and all higher (calling) and lower frames, and the size of the higher part.

**format_stack_entry(frame_lineno, lprefix=':')**
Return a string with information about a stack entry, identified by a (frame, lineno) tuple:

- The canonical form of the filename which contains the frame.
- The function name, or "<lambda>".
- The input arguments.
- The return value.
- The line of code (if it exists).

The following two methods can be called by clients to use a debugger to debug a statement, given as a string.

**run(cmd, globals=None, locals=None)**
Debug a statement executed via the exec() function. globals defaults to __main__.__dict__, locals defaults to globals.

**runeval(expr, globals=None, locals=None)**
Debug an expression executed via the eval() function. globals and locals have the same meaning as in run().

**runctx(cmd, globals, locals)**
For backwards compatibility. Calls the `run()` method.

**runcall** *(func, *args, **kwds)*

Debug a single function call, and return its result.

Finally, the module defines the following functions:

**bdb. checkfuncname** *(b, frame)*

Check whether we should break here, depending on the way the breakpoint `b` was set.

If it was set via line number, it checks if `b.line` is the same as the one in the frame also passed as argument. If the breakpoint was set via function name, we have to check we are in the right frame (the right function) and if we are in its first executable line.

**bdb. effective** *(file, line, frame)*

Determine if there is an effective (active) breakpoint at this line of code. Return a tuple of the breakpoint and a boolean that indicates if it is ok to delete a temporary breakpoint. Return `(None, None)` if there is no matching breakpoint.

**bdb. set_trace()**

Start debugging with a `Bdb` instance from caller’s frame.
27.2. `faulthandler` — Dump the Python traceback

New in version 3.3.

This module contains functions to dump Python tracebacks explicitly, on a fault, after a timeout, or on a user signal. Call `faulthandler.enable()` to install fault handlers for the SIGSEGV, SIGFPE, SIGABRT, SIGBUS, and SIGILL signals. You can also enable them at startup by setting the `PYTHONFAULTHANDLER` environment variable or by using the `-X faulthandler` command line option.

The fault handler is compatible with system fault handlers like Apport or the Windows fault handler. The module uses an alternative stack for signal handlers if the `sigaltstack()` function is available. This allows it to dump the traceback even on a stack overflow.

The fault handler is called on catastrophic cases and therefore can only use signal-safe functions (e.g. it cannot allocate memory on the heap). Because of this limitation traceback dumping is minimal compared to normal Python tracebacks:

- Only ASCII is supported. The `backslashreplace` error handler is used on encoding.
- Each string is limited to 500 characters.
- Only the filename, the function name and the line number are displayed. (no source code)
- It is limited to 100 frames and 100 threads.
- The order is reversed: the most recent call is shown first.
By default, the Python traceback is written to `sys.stderr`. To see
tracebacks, applications must be run in the terminal. A log file can
alternatively be passed to `faulthandler.enable()`.

The module is implemented in C, so tracebacks can be dumped on a
crash or when Python is deadlocked.
27.2.1. Dumping the traceback

faulthandler.dump_traceback(file=sys.stderr, all_threads=True)

Dump the tracebacks of all threads into file. If all_threads is False, dump only the current thread.

Changed in version 3.5: Added support for passing file descriptor to this function.
27.2.2. Fault handler state

`faulthandler.enable(file=sys.stderr, all_threads=True)`

Enable the fault handler: install handlers for the SIGSEGV, SIGFPE, SIGABRT, SIGBUS and SIGILL signals to dump the Python traceback. If `all_threads` is `True`, produce tracebacks for every running thread. Otherwise, dump only the current thread.

The `file` must be kept open until the fault handler is disabled: see issue with file descriptors.

*Changed in version 3.5:* Added support for passing file descriptor to this function.

*Changed in version 3.6:* On Windows, a handler for Windows exception is also installed.

`faulthandler.disable()`

Disable the fault handler: uninstall the signal handlers installed by `enable()`.

`faulthandler.is_enabled()`

Check if the fault handler is enabled.
27.2.3. Dumping the tracebacks after a timeout

```python
faulthandler.dump_traceback_later(timeout,
repeat=False, file=sys.stderr, exit=False)
```

Dump the tracebacks of all threads, after a timeout of `timeout` seconds, or every `timeout` seconds if `repeat` is True. If `exit` is True, call `_exit()` with status=1 after dumping the tracebacks. (Note `_exit()` exits the process immediately, which means it doesn't do any cleanup like flushing file buffers.) If the function is called twice, the new call replaces previous parameters and resets the timeout. The timer has a sub-second resolution.

The `file` must be kept open until the traceback is dumped or `cancel_dump_traceback_later()` is called: see issue with file descriptors.

This function is implemented using a watchdog thread and therefore is not available if Python is compiled with threads disabled.

*Changed in version 3.5:* Added support for passing file descriptor to this function.

```python
faulthandler.cancel_dump_traceback_later()
```

Cancel the last call to `dump_traceback_later()`. 

27.2.4. Dumping the traceback on a user signal

```python
faulthandler.register(signum, file=sys.stderr, all_threads=True, chain=False)
```

Register a user signal: install a handler for the `signum` signal to dump the traceback of all threads, or of the current thread if `all_threads` is `False`, into `file`. Call the previous handler if `chain` is `True`.

The `file` must be kept open until the signal is unregistered by `unregister()`; see issue with file descriptors.

Not available on Windows.

*Changed in version 3.5:* Added support for passing file descriptor to this function.

```python
faulthandler.unregister(signum)
```

Unregister a user signal: uninstall the handler of the `signum` signal installed by `register()`. Return `True` if the signal was registered, `False` otherwise.

Not available on Windows.
27.2.5. Issue with file descriptors

`enable()`, `dump_traceback_later()` and `register()` keep the file descriptor of their `file` argument. If the file is closed and its file descriptor is reused by a new file, or if `os.dup2()` is used to replace the file descriptor, the traceback will be written into a different file. Call these functions again each time that the file is replaced.
27.2.6. Example

Example of a segmentation fault on Linux with and without enabling the fault handler:

```
$ python3 -c "import ctypes; ctypes.string_at(0)"
Segmentation fault

$ python3 -q -X faulthandler
>>> import ctypes
>>> ctypes.string_at(0)
Fatal Python error: Segmentation fault
```

Current thread 0x00007fb899f39700 (most recent call first)
  File "/home/python/cpython/Lib/ctypes/__init__.py"
  File "<stdin>", line 1 in <module>
Segmentation fault
27.3. **pdb — The Python Debugger**

**Source code:** Lib/pdb.py

The module *pdb* defines an interactive source code debugger for Python programs. It supports setting (conditional) breakpoints and single stepping at the source line level, inspection of stack frames, source code listing, and evaluation of arbitrary Python code in the context of any stack frame. It also supports post-mortem debugging and can be called under program control.

The debugger is extensible – it is actually defined as the class *Pdb*. This is currently undocumented but easily understood by reading the source. The extension interface uses the modules *bdb* and *cmd*.

The debugger’s prompt is (Pdb). Typical usage to run a program under control of the debugger is:

```python
>>> import pdb
>>> import mymodule
>>> pdb.run('mymodule.test()')
> <string>(0)?()
(Pdb) continue
> <string>(1)?()
(Pdb) continue
NameError: 'spam'
> <string>(1)?()
(Pdb)
```

*Changed in version 3.3:* Tab-completion via the *readline* module is
available for commands and command arguments, e.g. the current
global and local names are offered as arguments of the p command.

pdb.py can also be invoked as a script to debug other scripts. For example:

```python
python3 -m pdb myscript.py
```

When invoked as a script, pdb will automatically enter post-mortem
debugging if the program being debugged exits abnormally. After post-
mortem debugging (or after normal exit of the program), pdb will
restart the program. Automatic restarting preserves pdb’s state (such
as breakpoints) and in most cases is more useful than quitting the
debugger upon program’s exit.

*New in version 3.2:* `pdb.py` now accepts a `-c` option that executes
commands as if given in a `.pdbrc` file, see `Debugger Commands`.

The typical usage to break into the debugger from a running program
is to insert

```python
import pdb; pdb.set_trace()
```

at the location you want to break into the debugger. You can then step
through the code following this statement, and continue running
without the debugger using the `continue` command.

The typical usage to inspect a crashed program is:

```python
>>> import pdb
>>> import mymodule
>>> mymodule.test()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
```
File "./mymodule.py", line 4, in test
test2()
File "./mymodule.py", line 3, in test2
    print(spam)
NameError: spam
>>> pdb.pm()
> ./mymodule.py(3)test2()
-> print(spam)
(Pdb)

The module defines the following functions; each enters the debugger in a slightly different way:

**pdb. run**(statement, globals=None, locals=None)

Execute the *statement* (given as a string or a code object) under debugger control. The debugger prompt appears before any code is executed; you can set breakpoints and type *continue*, or you can step through the statement using *step* or *next* (all these commands are explained below). The optional *globals* and *locals* arguments specify the environment in which the code is executed; by default the dictionary of the module *__main__* is used. (See the explanation of the built-in *exec()* or *eval()* functions.)

**pdb. runeval**(expression, globals=None, locals=None)

Evaluate the *expression* (given as a string or a code object) under debugger control. When *runeval()* returns, it returns the value of the expression. Otherwise this function is similar to *run()*.

**pdb. runcall**(function, *args, **kwds)

Call the *function* (a function or method object, not a string) with the given arguments. When *runcall()* returns, it returns whatever the function call returned. The debugger prompt appears as soon as the function is entered.
**pdb.set_trace()**

Enter the debugger at the calling stack frame. This is useful to hard-code a breakpoint at a given point in a program, even if the code is not otherwise being debugged (e.g. when an assertion fails).

**pdb.post_mortem(traceback=None)**

Enter post-mortem debugging of the given traceback object. If no traceback is given, it uses the one of the exception that is currently being handled (an exception must be being handled if the default is to be used).

**pdb.pm()**

Enter post-mortem debugging of the traceback found in `sys.last_traceback`.

The `run*` functions and `set_trace()` are aliases for instantiating the `Pdb` class and calling the method of the same name. If you want to access further features, you have to do this yourself:

```python
class pdb.Pdb(completekey='tab', stdin=None, stdout=None, skip=None, nosigint=False, readrc=True):
    Pdb is the debugger class.

    The completekey, stdin and stdout arguments are passed to the underlying `cmd.Cmd` class; see the description there.

    The skip argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. [1]

    By default, Pdb sets a handler for the SIGINT signal (which is sent when the user presses Ctrl-C on the console) when you give a
```
continue command. This allows you to break into the debugger again by pressing Ctrl-C. If you want Pdb not to touch the SIGINT handler, set nosigint to true.

The readrc argument defaults to true and controls whether Pdb will load .pdbrc files from the filesystem.

Example call to enable tracing with skip:

```python
import pdb; pdb.Pdb(skip=['django.*']).set_trace()
```

*New in version 3.1:* The skip argument.

*New in version 3.2:* The nosigint argument. Previously, a SIGINT handler was never set by Pdb.

*Changed in version 3.6:* The readrc argument.

```python
run(statement, globals=None, locals=None)
runeval(expression, globals=None, locals=None)
runcall(function, *args, **kwds)
set_trace()
```

See the documentation for the functions explained above.
27.3.1. Debugger Commands

The commands recognized by the debugger are listed below. Most commands can be abbreviated to one or two letters as indicated; e.g. h(e1p) means that either h or help can be used to enter the help command (but not he or he1, nor H or Help or HELP). Arguments to commands must be separated by whitespace (spaces or tabs). Optional arguments are enclosed in square brackets ([ ]) in the command syntax; the square brackets must not be typed. Alternatives in the command syntax are separated by a vertical bar (|).

Entering a blank line repeats the last command entered. Exception: if the last command was a list command, the next 11 lines are listed.

Commands that the debugger doesn’t recognize are assumed to be Python statements and are executed in the context of the program being debugged. Python statements can also be prefixed with an exclamation point (!). This is a powerful way to inspect the program being debugged; it is even possible to change a variable or call a function. When an exception occurs in such a statement, the exception name is printed but the debugger’s state is not changed.

The debugger supports aliases. Aliases can have parameters which allows one a certain level of adaptability to the context under examination.

Multiple commands may be entered on a single line, separated by ;;. (A single ; is not used as it is the separator for multiple commands in a line that is passed to the Python parser.) No intelligence is applied to separating the commands; the input is split at the first ;; pair, even if it is in the middle of a quoted string.
If a file `.pdbrc` exists in the user’s home directory or in the current directory, it is read in and executed as if it had been typed at the debugger prompt. This is particularly useful for aliases. If both files exist, the one in the home directory is read first and aliases defined there can be overridden by the local file.

*Changed in version 3.2:* `.pdbrc` can now contain commands that continue debugging, such as `continue` or `next`. Previously, these commands had no effect.

```
help [command]
```

Without argument, print the list of available commands. With a `command` as argument, print help about that command. `help pdb` displays the full documentation (the docstring of the `pdb` module). Since the `command` argument must be an identifier, `help exec` must be entered to get help on the `!` command.

```
where
```

Print a stack trace, with the most recent frame at the bottom. An arrow indicates the current frame, which determines the context of most commands.

```
down [count]
```

Move the current frame `count` (default one) levels down in the stack trace (to a newer frame).

```
up [count]
```

Move the current frame `count` (default one) levels up in the stack trace (to an older frame).

```
break ([([filename:]lineno | function) [, condition]])
```

With a `lineno` argument, set a break there in the current file. With a
function argument, set a break at the first executable statement within that function. The line number may be prefixed with a filename and a colon, to specify a breakpoint in another file (probably one that hasn't been loaded yet). The file is searched on \texttt{sys.path}. Note that each breakpoint is assigned a number to which all the other breakpoint commands refer.

If a second argument is present, it is an expression which must evaluate to true before the breakpoint is honored.

Without argument, list all breaks, including for each breakpoint, the number of times that breakpoint has been hit, the current ignore count, and the associated condition if any.

\texttt{tbreak }[(([filename:]lineno | function) [, condition])]]

Temporary breakpoint, which is removed automatically when it is first hit. The arguments are the same as for \texttt{break}.

\texttt{clear} [filename:lineno | bpnumber [bpnumber ...]]

With a \texttt{filename:lineno} argument, clear all the breakpoints at this line. With a space separated list of breakpoint numbers, clear those breakpoints. Without argument, clear all breaks (but first ask confirmation).

\texttt{disable} [bpnumber [bpnumber ...]]

Disable the breakpoints given as a space separated list of breakpoint numbers. Disabling a breakpoint means it cannot cause the program to stop execution, but unlike clearing a breakpoint, it remains in the list of breakpoints and can be (re-)enabled.

\texttt{enable} [bpnumber [bpnumber ...]]
Enable the breakpoints specified.

**ignore**  bpnumber  [count]
Set the ignore count for the given breakpoint number. If count is omitted, the ignore count is set to 0. A breakpoint becomes active when the ignore count is zero. When non-zero, the count is decremented each time the breakpoint is reached and the breakpoint is not disabled and any associated condition evaluates to true.

**condition**  bpnumber  [condition]
Set a new condition for the breakpoint, an expression which must evaluate to true before the breakpoint is honored. If condition is absent, any existing condition is removed; i.e., the breakpoint is made unconditional.

**commands**  [bpnumber]
Specify a list of commands for breakpoint number *bpnumber*. The commands themselves appear on the following lines. Type a line containing just **end** to terminate the commands. An example:

```
(Pdb) commands 1
(com) p some_variable
(com) end
(Pdb)
```

To remove all commands from a breakpoint, type commands and follow it immediately with end; that is, give no commands.

With no *bpnumber* argument, commands refers to the last breakpoint set.

You can use breakpoint commands to start your program up again.
Simply use the continue command, or step, or any other command that resumes execution.

Specifying any command resuming execution (currently continue, step, next, return, jump, quit and their abbreviations) terminates the command list (as if that command was immediately followed by end). This is because any time you resume execution (even with a simple next or step), you may encounter another breakpoint—which could have its own command list, leading to ambiguities about which list to execute.

If you use the ‘silent’ command in the command list, the usual message about stopping at a breakpoint is not printed. This may be desirable for breakpoints that are to print a specific message and then continue. If none of the other commands print anything, you see no sign that the breakpoint was reached.

**s(tep)**
Execute the current line, stop at the first possible occasion (either in a function that is called or on the next line in the current function).

**n(ext)**
Continue execution until the next line in the current function is reached or it returns. (The difference between next and step is that step stops inside a called function, while next executes called functions at (nearly) full speed, only stopping at the next line in the current function.)

**unt(il)** [lineno]
Without argument, continue execution until the line with a number greater than the current one is reached.
With a line number, continue execution until a line with a number greater or equal to that is reached. In both cases, also stop when the current frame returns.

*Changed in version 3.2:* Allow giving an explicit line number.

**r(eturn)**
Continue execution until the current function returns.

**c(ont(inue))**
Continue execution, only stop when a breakpoint is encountered.

**j(ump) lineno**
Set the next line that will be executed. Only available in the bottom-most frame. This lets you jump back and execute code again, or jump forward to skip code that you don’t want to run.

It should be noted that not all jumps are allowed – for instance it is not possible to jump into the middle of a `for` loop or out of a `finally` clause.

**l(ist) [first[, last]]**
List source code for the current file. Without arguments, list 11 lines around the current line or continue the previous listing. With `first` as argument, list 11 lines around the current line. With one argument, list 11 lines around at that line. With two arguments, list the given range; if the second argument is less than the first, it is interpreted as a count.

The current line in the current frame is indicated by `->`. If an exception is being debugged, the line where the exception was originally raised or propagated is indicated by `>>`, if it differs from the current line.
New in version 3.2: The >> marker.

ll | longlist
List all source code for the current function or frame. Interesting lines are marked as for list.

New in version 3.2.

a(rgs)
Print the argument list of the current function.

p expression
Evaluate the expression in the current context and print its value.

Note: print() can also be used, but is not a debugger command — this executes the Python print() function.

pp expression
Like the p command, except the value of the expression is pretty-printed using the pprint module.

what Isabel expression
Print the type of the expression.

source expression
Try to get source code for the given object and display it.

New in version 3.2.

display [expression]
Display the value of the expression if it changed, each time execution stops in the current frame.
Without expression, list all display expressions for the current frame.

New in version 3.2.

**undisplay** [expression]
Do not display the expression any more in the current frame. Without expression, clear all display expressions for the current frame.

New in version 3.2.

**interact**
Start an interactive interpreter (using the code module) whose global namespace contains all the (global and local) names found in the current scope.

New in version 3.2.

**alias** [name [command]]
Create an alias called *name* that executes *command*. The command must *not* be enclosed in quotes. Replaceable parameters can be indicated by `%1`, `%2`, and so on, while `%*` is replaced by all the parameters. If no command is given, the current alias for *name* is shown. If no arguments are given, all aliases are listed.

Aliases may be nested and can contain anything that can be legally typed at the pdb prompt. Note that internal pdb commands can be overridden by aliases. Such a command is then hidden until the alias is removed. Aliasing is recursively applied to the first word of the command line; all other words in the line are left alone.

As an example, here are two useful aliases (especially when
placed in the .pdbrc file):

```python
# Print instance variables (usage "pi classInst")
alias pi for k in %1.__dict__.keys(): print("%1.");
# Print instance variables in self
alias ps pi self
```

**unalias** name

Delete the specified alias.

**! statement**

Execute the (one-line) *statement* in the context of the current stack frame. The exclamation point can be omitted unless the first word of the statement resembles a debugger command. To set a global variable, you can prefix the assignment command with a **global** statement on the same line, e.g.:

(Pdb) **global** list_options; list_options = ['-l']
(Pdb)

**run** [args ...]

**restart** [args ...]

Restart the debugged Python program. If an argument is supplied, it is split with **shlex** and the result is used as the new **sys.argv**. History, breakpoints, actions and debugger options are preserved. **restart** is an alias for **run**.

**q**(uit)

Quit from the debugger. The program being executed is aborted.

**Footnotes**
Whether a frame is considered to originate in a certain module is determined by the `__name__` in the frame globals.
27.4. The Python Profilers

Source code: Lib/profile.py and Lib/pstats.py
27.4.1. Introduction to the profilers

cProfile and profile provide deterministic profiling of Python programs. A profile is a set of statistics that describes how often and for how long various parts of the program executed. These statistics can be formatted into reports via the pstats module.

The Python standard library provides two different implementations of the same profiling interface:

1. cProfile is recommended for most users; it's a C extension with reasonable overhead that makes it suitable for profiling long-running programs. Based on lsprof, contributed by Brett Rosen and Ted Czotter.
2. profile, a pure Python module whose interface is imitated by cProfile, but which adds significant overhead to profiled programs. If you're trying to extend the profiler in some way, the task might be easier with this module. Originally designed and written by Jim Roskind.

Note: The profiler modules are designed to provide an execution profile for a given program, not for benchmarking purposes (for that, there is timeit for reasonably accurate results). This particularly applies to benchmarking Python code against C code: the profilers introduce overhead for Python code, but not for C-level functions, and so the C code would seem faster than any Python one.
27.4.2. Instant User’s Manual

This section is provided for users that “don’t want to read the manual.” It provides a very brief overview, and allows a user to rapidly perform profiling on an existing application.

To profile a function that takes a single argument, you can do:

```python
import cProfile
import re

cProfile.run('re.compile("foo|bar")')
```

(Use `profile` instead of `cProfile` if the latter is not available on your system.)

The above action would run `re.compile()` and print profile results like the following:

```
197 function calls (192 primitive calls) in 0.

Ordered by: standard name

ncalls  tottime  percall  cumtime  percall filename:lineno
1      0.000    0.000    0.001    0.001 <string>:1
1      0.000    0.000    0.001    0.001 re.py:212
1      0.000    0.000    0.001    0.001 re.py:268
1      0.000    0.000    0.000    0.000 sre_compile
1      0.000    0.000    0.000    0.000 sre_compile
4      0.000    0.000    0.000    0.000 sre_compile
3/1    0.000    0.000    0.000    0.000 sre_compile
```

The first line indicates that 197 calls were monitored. Of those calls, 192 were `primitive`, meaning that the call was not induced via
recursion. The next line: Ordered by: standard name, indicates that the text string in the far right column was used to sort the output. The column headings include:

ncalls
for the number of calls.
tottime
for the total time spent in the given function (and excluding time made in calls to sub-functions)
percall
is the quotient of tottime divided by ncalls
cumtime
is the cumulative time spent in this and all subfunctions (from invocation till exit). This figure is accurate even for recursive functions.
percall
is the quotient of cumtime divided by primitive calls
filename:lineno(function)
provides the respective data of each function

When there are two numbers in the first column (for example 3/1), it means that the function recursed. The second value is the number of primitive calls and the former is the total number of calls. Note that when the function does not recurse, these two values are the same, and only the single figure is printed.

Instead of printing the output at the end of the profile run, you can save the results to a file by specifying a filename to the run() function:

```python
import cProfile
import re
```
cProfile.run('re.compile("foo|bar")', 'restats')

The `pstats.Stats` class reads profile results from a file and formats them in various ways.

The file `cProfile` can also be invoked as a script to profile another script. For example:

```python
python -m cProfile [-o output_file] [-s sort_order]
```

- `-o` writes the profile results to a file instead of to stdout
- `-s` specifies one of the `sort_stats()` sort values to sort the output by. This only applies when `-o` is not supplied.

The `pstats` module's `Stats` class has a variety of methods for manipulating and printing the data saved into a profile results file:

```python
import pstats
p = pstats.Stats('restats')
p.strip_dirs().sort_stats(-1).print_stats()
```

The `strip_dirs()` method removed the extraneous path from all the module names. The `sort_stats()` method sorted all the entries according to the standard module/line/name string that is printed. The `print_stats()` method printed out all the statistics. You might try the following sort calls:

```python
p.sort_stats('name')
p.print_stats()
```

The first call will actually sort the list by function name, and the second call will print out the statistics. The following are some interesting calls
to experiment with:

```python
p.sort_stats('cumulative').print_stats(10)
```

This sorts the profile by cumulative time in a function, and then only prints the ten most significant lines. If you want to understand what algorithms are taking time, the above line is what you would use.

If you were looking to see what functions were looping a lot, and taking a lot of time, you would do:

```python
p.sort_stats('time').print_stats(10)
```

to sort according to time spent within each function, and then print the statistics for the top ten functions.

You might also try:

```python
p.sort_stats('file').print_stats('__init__')
```

This will sort all the statistics by file name, and then print out statistics for only the class init methods (since they are spelled with `__init__` in them). As one final example, you could try:

```python
p.sort_stats('time', 'cumulative').print_stats(.5, 'init')
```

This line sorts statistics with a primary key of time, and a secondary key of cumulative time, and then prints out some of the statistics. To be specific, the list is first culled down to 50% (re: .5) of its original size, then only lines containing `init` are maintained, and that sub-sub-list is printed.

If you wondered what functions called the above functions, you could
now (p is still sorted according to the last criteria) do:

```python
p.print_callers(.5, 'init')
```

and you would get a list of callers for each of the listed functions.

If you want more functionality, you're going to have to read the manual, or guess what the following functions do:

```python
p.print_callees()
p.add('restats')
```

Invoked as a script, the `pstats` module is a statistics browser for reading and examining profile dumps. It has a simple line-oriented interface (implemented using `cmd`) and interactive help.
27.4.3. **profile** and **cProfile** Module Reference

Both the **profile** and **cProfile** modules provide the following functions:

**profile.run**(command, filename=None, sort=-1)

This function takes a single argument that can be passed to the **exec()** function, and an optional file name. In all cases this routine executes:

```python
exec(command, __main__.__dict__, __main__.__dict__)
```

and gathers profiling statistics from the execution. If no file name is present, then this function automatically creates a **Stats** instance and prints a simple profiling report. If the sort value is specified, it is passed to this **Stats** instance to control how the results are sorted.

**profile.runctx**(command, globals, locals, filename=None, sort=-1)

This function is similar to **run()**, with added arguments to supply the globals and locals dictionaries for the **command** string. This routine executes:

```python
exec(command, globals, locals)
```

and gathers profiling statistics as in the **run()** function above.

**class profile.Profile**(timer=None, timeunit=0.0, subcalls=True, builtins=True)
This class is normally only used if more precise control over profiling is needed than what the `cProfile.run()` function provides.

A custom timer can be supplied for measuring how long code takes to run via the `timer` argument. This must be a function that returns a single number representing the current time. If the number is an integer, the `timeunit` specifies a multiplier that specifies the duration of each unit of time. For example, if the timer returns times measured in thousands of seconds, the time unit would be `.001`.

Directly using the `Profile` class allows formatting profile results without writing the profile data to a file:

```python
import cProfile, pstats, io
pr = cProfile.Profile()
pr.enable()
# ... do something ...
pr.disable()
s = io.StringIO()
sortby = 'cumulative'
ps = pstats.Stats(pr, stream=s).sort_stats(sortby)
ps.print_stats()
print(s.getvalue())
```

**enable()**

Start collecting profiling data.

**disable()**

Stop collecting profiling data.

**create_stats()**

Stop collecting profiling data and record the results internally as
the current profile.

**print_stats**(*sort=-1*)
Create a **Stats** object based on the current profile and print the results to stdout.

**dump_stats**(*filename*)
Write the results of the current profile to *filename*.

**run**(*cmd*)
Profile the cmd via **exec()**.

**runctx**(*cmd, globals, locals*)
Profile the cmd via **exec()** with the specified global and local environment.

**runcall**(*func, *args, **kwargs*)
Profile **func(*args, **kwargs)**
27.4.4. The Stats Class

Analysis of the profiler data is done using the Stats class.

class pstats.Stats(*filenames or profile, stream=sys.stdout)

This class constructor creates an instance of a “statistics object” from a filename (or list of filenames) or from a Profile instance. Output will be printed to the stream specified by stream.

The file selected by the above constructor must have been created by the corresponding version of profile or cProfile. To be specific, there is no file compatibility guaranteed with future versions of this profiler, and there is no compatibility with files produced by other profilers. If several files are provided, all the statistics for identical functions will be coalesced, so that an overall view of several processes can be considered in a single report. If additional files need to be combined with data in an existing Stats object, the add() method can be used.

Instead of reading the profile data from a file, a cProfile.Profile or profile.Profile object can be used as the profile data source.

Stats objects have the following methods:

strip_dirs()

This method for the Stats class removes all leading path information from file names. It is very useful in reducing the size of the printout to fit within (close to) 80 columns. This method modifies the object, and the stripped information is lost. After performing a strip operation, the object is considered to have its
entries in a “random” order, as it was just after object initialization and loading. If \texttt{strip_dirs()} causes two function names to be indistinguishable (they are on the same line of the same filename, and have the same function name), then the statistics for these two entries are accumulated into a single entry.

\textbf{add\texttt{(*filenames)}}

This method of the \texttt{Stats} class accumulates additional profiling information into the current profiling object. Its arguments should refer to filenames created by the corresponding version of \texttt{profile.run()} or \texttt{cProfile.run()}. Statistics for identically named (re: file, line, name) functions are automatically accumulated into single function statistics.

\textbf{dump_stats\texttt{(*filename)}}

Save the data loaded into the \texttt{Stats} object to a file named \texttt{filename}. The file is created if it does not exist, and is overwritten if it already exists. This is equivalent to the method of the same name on the \texttt{profile.Profile} and \texttt{cProfile.Profile} classes.

\textbf{sort_stats\texttt{(*keys)}}

This method modifies the \texttt{Stats} object by sorting it according to the supplied criteria. The argument is typically a string identifying the basis of a sort (example: \texttt{'time'} or \texttt{'name'}).

When more than one key is provided, then additional keys are used as secondary criteria when there is equality in all keys selected before them. For example, \texttt{sort_stats('name', 'file')} will sort all the entries according to their function
name, and resolve all ties (identical function names) by sorting by file name.

Abbreviations can be used for any key names, as long as the abbreviation is unambiguous. The following are the keys currently defined:

<table>
<thead>
<tr>
<th>Valid Arg</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'calls'</td>
<td>call count</td>
</tr>
<tr>
<td>'cumulative'</td>
<td>cumulative time</td>
</tr>
<tr>
<td>'cumtime'</td>
<td>cumulative time</td>
</tr>
<tr>
<td>'file'</td>
<td>file name</td>
</tr>
<tr>
<td>'filename'</td>
<td>file name</td>
</tr>
<tr>
<td>'module'</td>
<td>file name</td>
</tr>
<tr>
<td>'ncalls'</td>
<td>call count</td>
</tr>
<tr>
<td>'pcalls'</td>
<td>primitive call count</td>
</tr>
<tr>
<td>'line'</td>
<td>line number</td>
</tr>
<tr>
<td>'name'</td>
<td>function name</td>
</tr>
<tr>
<td>'nfl'</td>
<td>name/file/line</td>
</tr>
<tr>
<td>'stdname'</td>
<td>standard name</td>
</tr>
<tr>
<td>'time'</td>
<td>internal time</td>
</tr>
<tr>
<td>'tottime'</td>
<td>internal time</td>
</tr>
</tbody>
</table>

Note that all sorts on statistics are in descending order (placing most time consuming items first), where as name, file, and line number searches are in ascending order (alphabetical). The subtle distinction between 'nfl' and 'stdname' is that the standard name is a sort of the name as printed, which means
that the embedded line numbers get compared in an odd way. For example, lines 3, 20, and 40 would (if the file names were the same) appear in the string order 20, 3 and 40. In contrast, 'nfl' does a numeric compare of the line numbers. In fact, sort_stats('nfl') is the same as sort_stats('name', 'file', 'line').

For backward-compatibility reasons, the numeric arguments -1, 0, 1, and 2 are permitted. They are interpreted as 'stdname', 'calls', 'time', and 'cumulative' respectively. If this old style format (numeric) is used, only one sort key (the numeric key) will be used, and additional arguments will be silently ignored.

**reverse_order()**

This method for the **Stats** class reverses the ordering of the basic list within the object. Note that by default ascending vs descending order is properly selected based on the sort key of choice.

**print_stats(***restrictions)**

This method for the **Stats** class prints out a report as described in the `profile.run()` definition.

The order of the printing is based on the last `sort_stats()` operation done on the object (subject to caveats in `add()` and `strip_dirs()`).

The arguments provided (if any) can be used to limit the list down to the significant entries. Initially, the list is taken to be the complete set of profiled functions. Each restriction is either an integer (to select a count of lines), or a decimal fraction
between 0.0 and 1.0 inclusive (to select a percentage of lines), or a string that will interpreted as a regular expression (to pattern match the standard name that is printed). If several restrictions are provided, then they are applied sequentially. For example:

```
print_stats(.1, 'foo:')
```

would first limit the printing to first 10% of list, and then only print functions that were part of filename .*foo:. In contrast, the command:

```
print_stats('foo:', .1)
```

would limit the list to all functions having file names .*foo:, and then proceed to only print the first 10% of them.

**print_callers(*restrictions)**

This method for the Stats class prints a list of all functions that called each function in the profiled database. The ordering is identical to that provided by print_stats(), and the definition of the restricting argument is also identical. Each caller is reported on its own line. The format differs slightly depending on the profiler that produced the stats:

- With profile, a number is shown in parentheses after each caller to show how many times this specific call was made. For convenience, a second non-parenthesized number repeats the cumulative time spent in the function at the right.
- With cProfile, each caller is preceded by three numbers: the number of times this specific call was made, and the total and cumulative times spent in the current
function while it was invoked by this specific caller.

print_callees(*restrictions)

This method for the Stats class prints a list of all function that were called by the indicated function. Aside from this reversal of direction of calls (re: called vs was called by), the arguments and ordering are identical to the print_callers() method.
27.4.5. What Is Deterministic Profiling?

Deterministic profiling is meant to reflect the fact that all function call, function return, and exception events are monitored, and precise timings are made for the intervals between these events (during which time the user’s code is executing). In contrast, statistical profiling (which is not done by this module) randomly samples the effective instruction pointer, and deduces where time is being spent. The latter technique traditionally involves less overhead (as the code does not need to be instrumented), but provides only relative indications of where time is being spent.

In Python, since there is an interpreter active during execution, the presence of instrumented code is not required to do deterministic profiling. Python automatically provides a hook (optional callback) for each event. In addition, the interpreted nature of Python tends to add so much overhead to execution, that deterministic profiling tends to only add small processing overhead in typical applications. The result is that deterministic profiling is not that expensive, yet provides extensive run time statistics about the execution of a Python program.

Call count statistics can be used to identify bugs in code (surprising counts), and to identify possible inline-expansion points (high call counts). Internal time statistics can be used to identify “hot loops” that should be carefully optimized. Cumulative time statistics should be used to identify high level errors in the selection of algorithms. Note that the unusual handling of cumulative times in this profiler allows statistics for recursive implementations of algorithms to be directly compared to iterative implementations.
27.4.6. Limitations

One limitation has to do with accuracy of timing information. There is a fundamental problem with deterministic profilers involving accuracy. The most obvious restriction is that the underlying “clock” is only ticking at a rate (typically) of about .001 seconds. Hence no measurements will be more accurate than the underlying clock. If enough measurements are taken, then the “error” will tend to average out. Unfortunately, removing this first error induces a second source of error.

The second problem is that it “takes a while” from when an event is dispatched until the profiler’s call to get the time actually gets the state of the clock. Similarly, there is a certain lag when exiting the profiler event handler from the time that the clock’s value was obtained (and then squirreled away), until the user’s code is once again executing. As a result, functions that are called many times, or call many functions, will typically accumulate this error. The error that accumulates in this fashion is typically less than the accuracy of the clock (less than one clock tick), but it can accumulate and become very significant.

The problem is more important with profile than with the lower-overhead cProfile. For this reason, profile provides a means of calibrating itself for a given platform so that this error can be probabilistically (on the average) removed. After the profiler is calibrated, it will be more accurate (in a least square sense), but it will sometimes produce negative numbers (when call counts are exceptionally low, and the gods of probability work against you :-). ) Do not be alarmed by negative numbers in the profile. They should only appear if you have calibrated your profiler, and the results are actually
better than without calibration.
27.4.7. Calibration

The profiler of the `profile` module subtracts a constant from each event handling time to compensate for the overhead of calling the time function, and socking away the results. By default, the constant is 0. The following procedure can be used to obtain a better constant for a given platform (see Limitations).

```python
import profile
pr = profile.Profile()
for i in range(5):
    print(pr.calibrate(10000))
```

The method executes the number of Python calls given by the argument, directly and again under the profiler, measuring the time for both. It then computes the hidden overhead per profiler event, and returns that as a float. For example, on a 1.8Ghz Intel Core i5 running Mac OS X, and using Python’s `time.clock()` as the timer, the magical number is about 4.04e-6.

The object of this exercise is to get a fairly consistent result. If your computer is very fast, or your timer function has poor resolution, you might have to pass 100000, or even 1000000, to get consistent results.

When you have a consistent answer, there are three ways you can use it:

```python
import profile

# 1. Apply computed bias to all Profile instances created thereafter.
profile.Profile.bias = your_computed_bias
```
# 2. Apply computed bias to a specific Profile instance.
pr = profile.Profile()
pr.bias = your_computed_bias

# 3. Specify computed bias in instance constructor.
pr = profile.Profile(bias=your_computed_bias)

If you have a choice, you are better off choosing a smaller constant, and then your results will “less often” show up as negative in profile statistics.
27.4.8. Using a custom timer

If you want to change how current time is determined (for example, to force use of wall-clock time or elapsed process time), pass the timing function you want to the Profile class constructor:

```python
pr = profile.Profile(your_time_func)
```

The resulting profiler will then call `your_time_func`. Depending on whether you are using `profile.Profile` or `cProfile.Profile`, `your_time_func`'s return value will be interpreted differently:

**profile.Profile**

`your_time_func` should return a single number, or a list of numbers whose sum is the current time (like what `os.times()` returns). If the function returns a single time number, or the list of returned numbers has length 2, then you will get an especially fast version of the dispatch routine.

Be warned that you should calibrate the profiler class for the timer function that you choose (see Calibration). For most machines, a timer that returns a lone integer value will provide the best results in terms of low overhead during profiling. (`os.times()` is pretty bad, as it returns a tuple of floating point values). If you want to substitute a better timer in the cleanest fashion, derive a class and hardwire a replacement dispatch method that best handles your timer call, along with the appropriate calibration constant.

**cProfile.Profile**

`your_time_func` should return a single number. If it returns integers, you can also invoke the class constructor with a second argument specifying the real duration of one unit of time. For
example, if `your_integer_time_func` returns times measured in thousands of seconds, you would construct the `Profile` instance as follows:

```python
pr = cProfile.Profile(your_integer_time_func, 0.0)
```

As the `cProfile.Profile` class cannot be calibrated, custom timer functions should be used with care and should be as fast as possible. For the best results with a custom timer, it might be necessary to hard-code it in the C source of the internal `_lsprof` module.

Python 3.3 adds several new functions in `time` that can be used to make precise measurements of process or wall-clock time. For example, see `time.perf_counter()`.
27.5. **timeit** — Measure execution time of small code snippets

**Source code:** Lib/timeit.py

This module provides a simple way to time small bits of Python code. It has both a Command-Line Interface as well as a callable one. It avoids a number of common traps for measuring execution times. See also Tim Peters’ introduction to the “Algorithms” chapter in the *Python Cookbook*, published by O'Reilly.
27.5.1. Basic Examples

The following example shows how the Command-Line Interface can be used to compare three different expressions:

```
$ python3 -m timeit ""-".join(str(n) for n in range(10000))"
10000 loops, best of 3: 30.2 usec per loop
$ python3 -m timeit ""-".join([str(n) for n in range(10000)])"
10000 loops, best of 3: 27.5 usec per loop
$ python3 -m timeit ""-".join(map(str, range(100)))"
10000 loops, best of 3: 23.2 usec per loop
```

This can be achieved from the Python Interface with:

```
>>> import timeit
>>> timeit.timeit(""-".join(str(n) for n in range(10000))", 0.3018611848820001
>>> timeit.timeit(""-".join([str(n) for n in range(10000)])", 0.2727368790656328
>>> timeit.timeit(""-".join(map(str, range(100)))", 0.23702679807320237
```

Note however that timeit will automatically determine the number of repetitions only when the command-line interface is used. In the Examples section you can find more advanced examples.
27.5.2. Python Interface

The module defines three convenience functions and a public class:

```python
timeit.timeit(stmt='pass', setup='pass', timer=<default timer>, number=1000000, globals=None)
```

Create a Timer instance with the given statement, setup code and timer function and run its `timeit()` method with number executions. The optional `globals` argument specifies a namespace in which to execute the code.

*Changed in version 3.5:* The optional `globals` parameter was added.

```python
timeit.repeat(stmt='pass', setup='pass', timer=<default timer>, repeat=3, number=1000000, globals=None)
```

Create a Timer instance with the given statement, setup code and timer function and run its `repeat()` method with the given `repeat` count and `number` executions. The optional `globals` argument specifies a namespace in which to execute the code.

*Changed in version 3.5:* The optional `globals` parameter was added.

```python
timeit.default_timer()
```

The default timer, which is always `time.perf_counter()`.

*Changed in version 3.3:* `time.perf_counter()` is now the default timer.

```python
class timeit.Timer(stmt='pass', setup='pass', timer=<timer function>, globals=None)
```
Class for timing execution speed of small code snippets.

The constructor takes a statement to be timed, an additional statement used for setup, and a timer function. Both statements default to 'pass'; the timer function is platform-dependent (see the module doc string). \texttt{stmt} and \texttt{setup} may also contain multiple statements separated by ; or newlines, as long as they don't contain multi-line string literals. The statement will by default be executed within \texttt{timeit}'s namespace; this behavior can be controlled by passing a namespace to \texttt{globals}.

To measure the execution time of the first statement, use the \texttt{timeit()} method. The \texttt{repeat()} and \texttt{autorange()} methods are convenience methods to call \texttt{timeit()} multiple times.

The execution time of \texttt{setup} is excluded from the overall timed execution run.

The \texttt{stmt} and \texttt{setup} parameters can also take objects that are callable without arguments. This will embed calls to them in a timer function that will then be executed by \texttt{timeit()}. Note that the timing overhead is a little larger in this case because of the extra function calls.

\textit{Changed in version 3.5:} The optional \texttt{globals} parameter was added.

\texttt{timeit(number=1000000)}

Time \texttt{number} executions of the main statement. This executes the setup statement once, and then returns the time it takes to execute the main statement a number of times, measured in seconds as a float. The argument is the number of times through the loop, defaulting to one million. The main statement,
the setup statement and the timer function to be used are passed to the constructor.

**Note:** By default, `timeit()` temporarily turns off garbage collection during the timing. The advantage of this approach is that it makes independent timings more comparable. This disadvantage is that GC may be an important component of the performance of the function being measured. If so, GC can be re-enabled as the first statement in the `setup` string. For example:

```python
timeit.Timer('for i in range(10): oct(i)', 'gc.enable()')
```

**autorange(callback=None)**

Automatically determine how many times to call `timeit()`.

This is a convenience function that calls `timeit()` repeatedly so that the total time >= 0.2 second, returning the eventual (number of loops, time taken for that number of loops). It calls `timeit()` with `number` set to successive powers of ten (10, 100, 1000, ...) up to a maximum of one billion, until the time taken is at least 0.2 second, or the maximum is reached.

If `callback` is given and is not `None`, it will be called after each trial with two arguments: `callback(number, time_taken)`.

*New in version 3.6.*

**repeat**(repeat=3, number=1000000)

Call `timeit()` a few times.

This is a convenience function that calls the `timeit()`
repeatedly, returning a list of results. The first argument specifies how many times to call `timeit()`. The second argument specifies the `number` argument for `timeit()`.

**Note:** It’s tempting to calculate mean and standard deviation from the result vector and report these. However, this is not very useful. In a typical case, the lowest value gives a lower bound for how fast your machine can run the given code snippet; higher values in the result vector are typically not caused by variability in Python’s speed, but by other processes interfering with your timing accuracy. So the `min()` of the result is probably the only number you should be interested in. After that, you should look at the entire vector and apply common sense rather than statistics.

```python
print_exc(file=None)
```

Helper to print a traceback from the timed code.

Typical use:

```python
t = Timer(...)  # outside the try/except
try:
    t.timeit(...)  # or t.repeat(...)
except Exception:
    t.print_exc()
```

The advantage over the standard traceback is that source lines in the compiled template will be displayed. The optional `file` argument directs where the traceback is sent; it defaults to `sys.stderr`.
27.5.3. Command-Line Interface

When called as a program from the command line, the following form is used:

```python
python -m timeit [-n N] [-r N] [-u U] [-s S] [-t] [-]
```

Where the following options are understood:

- `-n N, --number=N`  
  how many times to execute 'statement'

- `-r N, --repeat=N`  
  how many times to repeat the timer (default 3)

- `-s S, --setup=S`  
  statement to be executed once initially (default `pass`)

- `-p, --process`  
  measure process time, not wallclock time, using `time.process_time()` instead of `time.perf_counter()`, which is the default

  *New in version 3.3.*

- `-t, --time`  
  use `time.time()` (deprecated)

- `-u, --unit=U`  
  specify a time unit for timer output; can select usec, msec, or sec
New in version 3.5.

- **c**, **--clock**
  use `time.clock()` (deprecated)

- **v**, **--verbose**
  print raw timing results; repeat for more digits precision

- **h**, **--help**
  print a short usage message and exit

A multi-line statement may be given by specifying each line as a separate statement argument; indented lines are possible by enclosing an argument in quotes and using leading spaces. Multiple `-s` options are treated similarly.

If `-n` is not given, a suitable number of loops is calculated by trying successive powers of 10 until the total time is at least 0.2 seconds.

default_timer() measurements can be affected by other programs running on the same machine, so the best thing to do when accurate timing is necessary is to repeat the timing a few times and use the best time. The `-r` option is good for this; the default of 3 repetitions is probably enough in most cases. You can use `time.process_time()` to measure CPU time.

**Note:** There is a certain baseline overhead associated with executing a pass statement. The code here doesn’t try to hide it, but you should be aware of it. The baseline overhead can be measured by invoking the program without arguments, and it might differ between Python versions.
27.5.4. Examples

It is possible to provide a setup statement that is executed only once at the beginning:

$ python -m timeit -s 'text = "sample string"; char'

10000000 loops, best of 3: 0.0877 usec per loop

$ python -m timeit -s 'text = "sample string"; char'

1000000 loops, best of 3: 0.342 usec per loop

```python
>>> import timeit

>>> timeit.timeit('char in text', setup='text = "sample string"; char')
0.41440500499993504

>>> timeit.timeit('text.find(char)', setup='text = "sample string"; char')
1.7246671520006203
```

The same can be done using the `Timer` class and its methods:

```python
>>> import timeit

>>> t = timeit.Timer('char in text', setup='text = "sample string"; char')

>>> t.timeit()
0.395516149999312

>>> t.repeat()
[0.40193588800002544, 0.3960157959998014, 0.39594301399984033]
```

The following examples show how to time expressions that contain multiple lines. Here we compare the cost of using `hasattr()` vs. `try/except` to test for missing and present object attributes:

$ python -m timeit 'try:' 'str.__bool__' 'except AttributeError'

10000000 loops, best of 3: 15.7 usec per loop

$ python -m timeit 'if hasattr(str, "__bool__")': pass
To give the `timeit` module access to functions you define, you can pass a `setup` parameter which contains an import statement:

```python
>>> import timeit
>>> # attribute is missing
>>> s = ""
... try:
...     str.__bool__
... except AttributeError:
...     pass
... ""
>>> timeit.timeit(stmt=s, number=100000)
0.9138244460009446
>>> s = "if hasattr(str, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.5829014980008651
>>> # attribute is present
>>> s = ""
... try:
...     int.__bool__
... except AttributeError:
...     pass
... ""
>>> timeit.timeit(stmt=s, number=100000)
0.04215312199994514
>>> s = "if hasattr(int, '__bool__'): pass"
>>> timeit.timeit(stmt=s, number=100000)
0.08588060699912603
```
```python
def test():
    """Stupid test function""
    L = [i for i in range(100)]

if __name__ == '__main__':
    import timeit
    print(timeit.timeit("test()", setup="from __main__ import test"))
```

Another option is to pass `globals()` to the `globals` parameter, which will cause the code to be executed within your current global namespace. This can be more convenient than individually specifying imports:

```python
def f(x):
    return x**2
def g(x):
    return x**4
def h(x):
    return x**8

import timeit
print(timeit.timeit('[func(42) for func in (f,g,h)]'))
```

Created using Sphinx 1.6.3.
27.6. **trace** — Trace or track Python statement execution

**Source code:** Lib/trace.py

The `trace` module allows you to trace program execution, generate annotated statement coverage listings, print caller/callee relationships and list functions executed during a program run. It can be used in another program or from the command line.

**See also:**

**Coverage.py**  
A popular third-party coverage tool that provides HTML output along with advanced features such as branch coverage.
27.6.1. Command-Line Usage

The `trace` module can be invoked from the command line. It can be as simple as

```
python -m trace --count -C . somefile.py ...
```

The above will execute `somefile.py` and generate annotated listings of all Python modules imported during the execution into the current directory.

```
--help
```

Display usage and exit.

```
--version
```

Display the version of the module and exit.

27.6.1.1. Main options

At least one of the following options must be specified when invoking `trace`. The `--listfuncs` option is mutually exclusive with the `--trace` and `--count` options. When `--listfuncs` is provided, neither `--count` nor `--trace` are accepted, and vice versa.

```
-c, --count
```

Produce a set of annotated listing files upon program completion that shows how many times each statement was executed. See also `--coverdir`, `--file` and `--no-report` below.

```
-t, --trace
```

Display lines as they are executed.
**-l, --listfuncs**
Display the functions executed by running the program.

**-r, --report**
Produce an annotated list from an earlier program run that used the **--count** and **--file** option. This does not execute any code.

**-T, --trackcalls**
Display the calling relationships exposed by running the program.

### 27.6.1.2. Modifiers

**-f, --file=**<file>
Name of a file to accumulate counts over several tracing runs. Should be used with the **--count** option.

**-C, --coverdir=**<dir>
Directory where the report files go. The coverage report for **package.module** is written to file **dir/package/module.cover**.

**-m, --missing**
When generating annotated listings, mark lines which were not executed with `>>>>>>`.

**-s, --summary**
When using **--count** or **--report**, write a brief summary to stdout for each file processed.

**-R, --no-report**
Do not generate annotated listings. This is useful if you intend to
make several runs with \texttt{--count}, and then produce a single set of annotated listings at the end.

\textbf{-g, --timing}
Prefix each line with the time since the program started. Only used while tracing.

27.6.1.3. Filters

These options may be repeated multiple times.

\textbf{--ignore-module} = \texttt{<mod>}
Ignore each of the given module names and its submodules (if it is a package). The argument can be a list of names separated by a comma.

\textbf{--ignore-dir} = \texttt{<dir>}
Ignore all modules and packages in the named directory and subdirectories. The argument can be a list of directories separated by \texttt{os.pathsep}.
27.6.2. Programmatic Interface

class trace.Trace(count=1, trace=1, countfuncs=0, countcallers=0, ignoremods=(), ignoredirs=(), infile=None, outfile=None, timing=False)

Create an object to trace execution of a single statement or expression. All parameters are optional. count enables counting of line numbers. trace enables line execution tracing. countfuncs enables listing of the functions called during the run. countcallers enables call relationship tracking. ignoremods is a list of modules or packages to ignore. ignoredirs is a list of directories whose modules or packages should be ignored. infile is the name of the file from which to read stored count information. outfile is the name of the file in which to write updated count information. timing enables a timestamp relative to when tracing was started to be displayed.

run(cmd)

Execute the command and gather statistics from the execution with the current tracing parameters. cmd must be a string or code object, suitable for passing into exec().

runctx(cmd, globals=None, locals=None)

Execute the command and gather statistics from the execution with the current tracing parameters, in the defined global and local environments. If not defined, globals and locals default to empty dictionaries.

runfunc(func, *args, **kwds)

Call func with the given arguments under control of the Trace object with the current tracing parameters.
