What's New in Python

What's New In Python 3.6

- Summary – Release highlights
- New Features
  - PEP 498: Formatted string literals
  - PEP 526: Syntax for variable annotations
  - PEP 515: Underscores in Numeric Literals
  - PEP 525: Asynchronous Generators
  - PEP 530: Asynchronous Comprehensions
  - PEP 487: Simpler customization of class creation
  - PEP 487: Descriptor Protocol Enhancements
  - PEP 519: Adding a file system path protocol
  - PEP 495: Local Time Disambiguation
  - PEP 529: Change Windows filesystem encoding to UTF-8
  - PEP 528: Change Windows console encoding to UTF-8
  - PEP 520: Preserving Class Attribute Definition Order
  - PEP 468: Preserving Keyword Argument Order
  - New dict implementation
  - PEP 523: Adding a frame evaluation API to CPython
  - PYTHONMALLOC environment variable
  - DTrace and SystemTap probing support

- Other Language Changes
- New Modules
  - secrets
- Improved Modules
  - array
  - ast
  - asyncio
- binascii
-cmath
-collections
-concurrent.futures
-contextlib
-datetime
-decimal
-distutils
-email
-encodings
-enum
-faulthandler
-fileinput
-hashlib
-http.client
-idlelib and IDLE
-importlib
-inspect
-json
-logging
-math
-multiprocessing
-os
-pathlib
-pdb
-pickle
-pickletools
-pydoc
-random

- urllib.request
- urllib.robotparser
- venv
- warnings
- winreg
- winsound
- xmlrpc.client
- zipfile
- zlib

- Optimizations
- Build and C API Changes
- Other Improvements
- Deprecated
  - New Keywords
  - Deprecated Python behavior
  - Deprecated Python modules, functions and methods
    - asynchat
- asyncore
- dbm
- distutils
- grp
- importlib
- os
- re
- ssl
- tkinter
- venv

- Deprecated functions and types of the C API
- Deprecated Build Options

- Removed
  - API and Feature Removals

- Porting to Python 3.6
  - Changes in ‘python’ Command Behavior
  - Changes in the Python API
  - Changes in the C API
  - CPython bytecode changes

- Notable changes in Python 3.6.2
  - New make `regen-all` build target
  - Removal of make `touch` build target

- What's New In Python 3.5
  - Summary – Release highlights
  - New Features
    - PEP 492 - Coroutines with async and await syntax
    - PEP 465 - A dedicated infix operator for matrix multiplication
    - PEP 448 - Additional Unpacking Generalizations
    - PEP 461 - percent formatting support for bytes and bytearray
    - PEP 484 - Type Hints
    - PEP 471 - os.scandir() function – a better and faster directory iterator
- PEP 475: Retry system calls failing with EINTR
- PEP 479: Change StopIteration handling inside generators
- PEP 485: A function for testing approximate equality
- PEP 486: Make the Python Launcher aware of virtual environments
- PEP 488: Elimination of PYO files
- PEP 489: Multi-phase extension module initialization

Other Language Changes

New Modules
- typing
- zipapp

Improved Modules
- argparse
- asyncio
- bz2
- cgi
- cmath
- code
- collections
- collections.abc
- compileall
- concurrent.futures
- configparser
- contextlib
- csv
- curses
- dbm
- difflib
- distutils
- doctest
- email
- enum
- faulthandler
- functools
- glob
- gzip
- heapq
- http
- http.client
- idlelib and IDLE
- imaplib
- imghdr
- importlib
- inspect
- io
- ipaddress
- json
- linecache
- locale
- logging
- lzma
- math
- multiprocessing
- operator
- os
- pathlib
- pickle
- poplib
- re
- readline
- selectors
- shutil
- signal
- smtpd
- smtplib
- sndhdr
- socket
- ssl
  - Memory BIO Support
  - Application-Layer Protocol Negotiation Support
  - Other Changes
- sqlite3
- subprocess
- sys
- sysconfig
- tarfile
- threading
- time
- timeit
- tkinter
- traceback
- types
- unicodedata
- unittest
- unittest.mock
- urllib
- wsgiref
- xmlrpc
- xml.sax
- zipfile
- Other module-level changes
- Optimizations
- Build and C API Changes
- Deprecated
  - New Keywords
  - Deprecated Python Behavior
  - Unsupported Operating Systems
  - Deprecated Python modules, functions and methods
- Removed
  - API and Feature Removals
- Porting to Python 3.5
- Changes in Python behavior
- Changes in the Python API
- Changes in the C API

What’s New In Python 3.4
- Summary – Release Highlights
- New Features
  - PEP 453: Explicit Bootstrapping of PIP in Python Installations
    - Bootstrapping pip By Default
    - Documentation Changes
  - PEP 446: Newly Created File Descriptors Are Non-Inheritable
  - Improvements to Codec Handling
  - PEP 451: A ModuleSpec Type for the Import System
  - Other Language Changes
- New Modules
  - asyncio
  - ensurepip
  - enum
  - pathlib
  - selectors
  - statistics
  - tracemalloc
- Improved Modules
  - abc
  - aifc
  - argparse
  - audioop
  - base64
  - collections
  - colorsys
  - contextlib
  - dbm
  - dis
- doctest
- email
- filecmp
- functools
- gc
- glob
- hashlib
- hmac
- html
- http
- idlelib and IDLE
- importlib
- inspect
- ipaddress
- logging
- marshal
- mmap
- multiprocessing
- operator
- os
- pdb
- pickle
- plistlib
- poplib
- pprint
- pty
- pydoc
- re
- resource
- select
- shelve
- shutil
- smtpd
- smtplib
- socket
- sqlite3
- ssl
- stat
- struct
- subprocess
- sunau
- sys
- tarfile
- textwrap
- threading
- traceback
- types
- urllib
- unittest
- venv
- wave
- weakref
- xml.etree
- zipfile

- CPython Implementation Changes
  - PEP 445: Customization of CPython Memory Allocators
  - PEP 442: Safe Object Finalization
  - PEP 456: Secure and Interchangeable Hash Algorithm
  - PEP 436: Argument Clinic
  - Other Build and C API Changes
  - Other Improvements
  - Significant Optimizations

- Deprecated
  - Deprecations in the Python API
  - Deprecated Features

- Removed
- Operating Systems No Longer Supported
- API and Feature Removals
- Code Cleanups
- Porting to Python 3.4
  - Changes in ‘python’ Command Behavior
  - Changes in the Python API
  - Changes in the C API
- Changed in 3.4.3
  - PEP 476: Enabling certificate verification by default for stdlib http clients
- What’s New In Python 3.3
  - Summary – Release highlights
  - PEP 405: Virtual Environments
  - PEP 420: Implicit Namespace Packages
  - PEP 3118: New memoryview implementation and buffer protocol documentation
    - Features
    - API changes
  - PEP 393: Flexible String Representation
    - Functionality
    - Performance and resource usage
  - PEP 397: Python Launcher for Windows
  - PEP 3151: Reworking the OS and IO exception hierarchy
  - PEP 380: Syntax for Delegating to a Subgenerator
  - PEP 409: Suppressing exception context
  - PEP 414: Explicit Unicode literals
  - PEP 3155: Qualified name for classes and functions
  - PEP 412: Key-Sharing Dictionary
  - PEP 362: Function Signature Object
  - PEP 421: Adding sys.implementation
    - SimpleNamespace
  - Using importlib as the Implementation of Import
    - New APIs
Visible Changes

Other Language Changes

A Finer-Grained Import Lock

Builtin functions and types

New Modules
  - faulthandler
  - ipaddress
  - lzma

Improved Modules
  - abc
  - array
  - base64
  - binascii
  - bz2
  - codecs
  - collections
  - contextlib
  - crypt
  - curses
  - datetime
  - decimal
    - Features
    - API changes
  - email
    - Policy Framework
    - Provisional Policy with New Header API
    - Other API Changes

- Optimizations
- Build and C API Changes
- Deprecated
  - Unsupported Operating Systems
  - Deprecated Python modules, functions and methods
  - Deprecated functions and types of the C API
  - Deprecated features

- Porting to Python 3.3
  - Porting Python code
  - Porting C code
  - Building C extensions
  - Command Line Switch Changes

○ What's New In Python 3.2
  - PEP 384: Defining a Stable ABI
  - PEP 389: Argparse Command Line Parsing Module
  - PEP 391: Dictionary Based Configuration for Logging
  - PEP 3148: The concurrent.futures module
  - PEP 3147: PYC Repository Directories
  - PEP 3149: ABI Version Tagged .so Files
  - PEP 3333: Python Web Server Gateway Interface v1.0.1

- Other Language Changes
- New, Improved, and Deprecated Modules
  - email
  - elementtree
  - functools
  - itertools
  - collections
  - threading
  - datetime and time
- math
- abc
- io
- reprlib
- logging
- csv
- contextlib
- decimal and fractions
- ftp
- popen
- select
- gzip and zipfile

- hashlib
- ast
- os
- shutil
- sqlite3
- html
- socket
- ssl
- nntplib
- certificates
- imaplib
- http.client
- unittest
- random
- poplib
- asyncore
- tempfile
- inspect
- pydoc
- dis
- dbm
- ctypes
- site
- sysconfig
- pdb
- configparser
- urllib.parse
- mailbox
- turtledemo

- Multi-threading
- Optimizations
- Unicode
- Codecs
- Documentation
- IDLE
- Code Repository
- Build and C API Changes
- Porting to Python 3.2

○ What's New In Python 3.1
  - PEP 372: Ordered Dictionaries
  - PEP 378: Format Specifier for Thousands Separator
  - Other Language Changes
  - New, Improved, and Deprecated Modules
  - Optimizations
  - IDLE
  - Build and C API Changes
  - Porting to Python 3.1

○ What's New In Python 3.0
  - Common Stumbling Blocks
    - Print Is A Function
    - Views And Iterators Instead Of Lists
    - Ordering Comparisons
    - Integers
    - Text Vs. Data Instead Of Unicode Vs. 8-bit
  - Overview Of Syntax Changes
- New Syntax
- Changed Syntax
- Removed Syntax
- Changes Already Present In Python 2.6
- Library Changes
  - PEP 3101: A New Approach To String Formatting
  - Changes To Exceptions
  - Miscellaneous Other Changes
  - Operators And Special Methods
  - Builtins
- Build and C API Changes
- Performance
- Porting To Python 3.0
- What's New in Python 2.7
  - The Future for Python 2.x
  - Changes to the Handling of Deprecation Warnings
  - Python 3.1 Features
  - PEP 372: Adding an Ordered Dictionary to collections
  - PEP 378: Format Specifier for Thousands Separator
  - PEP 389: The argparse Module for Parsing Command Lines
  - PEP 391: Dictionary-Based Configuration For Logging
  - PEP 3106: Dictionary Views
  - PEP 3137: The memoryview Object
- Other Language Changes
  - Interpreter Changes
  - Optimizations
- New and Improved Modules
  - New module: importlib
  - New module: sysconfig
  - ttk: Themed Widgets for Tk
  - Updated module: unittest
  - Updated module: ElementTree 1.3
- Build and C API Changes
- Capsules
- Port-Specific Changes: Windows
- Port-Specific Changes: Mac OS X
- Port-Specific Changes: FreeBSD

Other Changes and Fixes
- Porting to Python 2.7
- New Features Added to Python 2.7 Maintenance Releases
  - PEP 434: IDLE Enhancement Exception for All Branches
  - PEP 466: Network Security Enhancements for Python 2.7

Acknowledgements
- What's New in Python 2.6
  - Python 3.0
  - Changes to the Development Process
    - New Issue Tracker: Roundup
    - New Documentation Format: reStructuredText Using Sphinx
  - PEP 343: The ‘with’ statement
    - Writing Context Managers
    - The contextlib module
  - PEP 366: Explicit Relative Imports From a Main Module
  - PEP 370: Per-user site-packages Directory
  - PEP 371: The multiprocessing Package
  - PEP 3101: Advanced String Formatting
  - PEP 3105: print As a Function
  - PEP 3110: Exception-Handling Changes
  - PEP 3112: Byte Literals
  - PEP 3116: New I/O Library
  - PEP 3118: Revised Buffer Protocol
  - PEP 3119: Abstract Base Classes
  - PEP 3127: Integer Literal Support and Syntax
  - PEP 3129: Class Decorators
- **PEP 3141**: A Type Hierarchy for Numbers
  - The `fractions` Module
- **Other Language Changes**
  - Optimizations
  - Interpreter Changes
- **New and Improved Modules**
  - The `ast` module
  - The `future_builtins` module
  - The `json` module: JavaScript Object Notation
  - The `plistlib` module: A Property-List Parser
  - `ctypes` Enhancements
  - Improved SSL Support
- **Deprecations and Removals**
- **Build and C API Changes**
  - Port-Specific Changes: Windows
  - Port-Specific Changes: Mac OS X
  - Port-Specific Changes: IRIX
- **Porting to Python 2.6**
- **Acknowledgements**
  - **What's New in Python 2.5**
    - PEP 308: Conditional Expressions
    - PEP 309: Partial Function Application
    - PEP 314: Metadata for Python Software Packages v1.1
    - PEP 328: Absolute and Relative Imports
    - PEP 338: Executing Modules as Scripts
    - PEP 341: Unified `try/except/finally`
    - PEP 342: New Generator Features
    - PEP 343: The ‘with’ statement
      - Writing Context Managers
      - The `contextlib` module
    - PEP 352: Exceptions as New-Style Classes
    - PEP 353: Using `ssize_t` as the index type
    - PEP 357: The ‘__index__’ method
    - Other Language Changes
- Interactive Interpreter Changes
- Optimizations
- New, Improved, and Removed Modules
  - The ctypes package
  - The ElementTree package
  - The hashlib package
  - The sqlite3 package
  - The wsgiref package
- Build and C API Changes
  - Port-Specific Changes
- Porting to Python 2.5
- Acknowledgements

○ What’s New in Python 2.4
  - PEP 218: Built-In Set Objects
  - PEP 237: Unifying Long Integers and Integers
  - PEP 289: Generator Expressions
  - PEP 292: Simpler String Substitutions
  - PEP 318: Decorators for Functions and Methods
  - PEP 322: Reverse Iteration
  - PEP 324: New subprocess Module
  - PEP 327: Decimal Data Type
    - Why is Decimal needed?
    - The Decimal type
    - The Context type
  - PEP 328: Multi-line Imports
  - PEP 331: Locale-Independent Float/String Conversions
- Other Language Changes
  - Optimizations
  - New, Improved, and Deprecated Modules
    - cookielib
    - doctest
- Build and C API Changes
  - Port-Specific Changes
- Porting to Python 2.4
Acknowledgements

What's New in Python 2.3
- PEP 218: A Standard Set Datatype
- PEP 255: Simple Generators
- PEP 263: Source Code Encodings
- PEP 273: Importing Modules from ZIP Archives
- PEP 277: Unicode file name support for Windows NT
- PEP 278: Universal Newline Support
- PEP 279: enumerate()
- PEP 282: The logging Package
- PEP 285: A Boolean Type
- PEP 293: Codec Error Handling Callbacks
- PEP 301: Package Index and Metadata for Distutils
- PEP 302: New Import Hooks
- PEP 305: Comma-separated Files
- PEP 307: Pickle Enhancements
- Extended Slices
- Other Language Changes
  - String Changes
  - Optimizations
- New, Improved, and Deprecated Modules
  - Date/Time Type
  - The optparse Module
- Pymalloc: A Specialized Object Allocator
- Build and C API Changes
  - Port-Specific Changes
- Other Changes and Fixes
- Porting to Python 2.3
- Acknowledgements

What's New in Python 2.2
- Introduction
- PEPs 252 and 253: Type and Class Changes
  - Old and New Classes
  - Descriptors
Multiple Inheritance: The Diamond Rule
- Attribute Access
- Related Links
- PEP 234: Iterators
- PEP 255: Simple Generators
- PEP 237: Unifying Long Integers and Integers
- PEP 238: Changing the Division Operator
- Unicode Changes
- PEP 227: Nested Scopes
- New and Improved Modules
- Interpreter Changes and Fixes
- Other Changes and Fixes
- Acknowledgements

What's New in Python 2.1
- Introduction
- PEP 227: Nested Scopes
- PEP 236: __future__ Directives
- PEP 207: Rich Comparisons
- PEP 230: Warning Framework
- PEP 229: New Build System
- PEP 205: Weak References
- PEP 232: Function Attributes
- PEP 235: Importing Modules on Case-Insensitive Platforms
- PEP 217: Interactive Display Hook
- PEP 208: New Coercion Model
- PEP 241: Metadata in Python Packages
- New and Improved Modules
- Other Changes and Fixes
- Acknowledgements

What's New in Python 2.0
- Introduction
- What About Python 1.6?
- New Development Process
- Unicode
- List Comprehensions
- Augmented Assignment
- String Methods
- Garbage Collection of Cycles
- Other Core Changes
  - Minor Language Changes
  - Changes to Built-in Functions
- Porting to 2.0
- Extending/Embedding Changes
- Distutils: Making Modules Easy to Install
- XML Modules
  - SAX2 Support
  - DOM Support
  - Relationship to PyXML
- Module changes
- New modules
- IDLE Improvements
- Deleted and Deprecated Modules
- Acknowledgements

6. Expressions

6.1. Arithmetic conversions

6.2. Atoms
   - 6.2.1. Identifiers (Names)
   - 6.2.2. Literals
   - 6.2.3. Parenthesized forms
   - 6.2.4. Displays for lists, sets and dictionaries
   - 6.2.5. List displays
   - 6.2.6. Set displays
   - 6.2.7. Dictionary displays
   - 6.2.8. Generator expressions
   - 6.2.9. Yield expressions
     - 6.2.9.1. Generator-iterator methods
     - 6.2.9.2. Examples
     - 6.2.9.3. Asynchronous generator functions
     - 6.2.9.4. Asynchronous generator-iterator methods

6.3. Primaries
   - 6.3.1. Attribute references
   - 6.3.2. Subscriptions
   - 6.3.3. Slicings
   - 6.3.4. Calls

6.4. Await expression

6.5. The power operator

6.6. Unary arithmetic and bitwise operations

6.7. Binary arithmetic operations

6.8. Shifting operations

6.9. Binary bitwise operations

6.10. Comparisons
   - 6.10.1. Value comparisons
   - 6.10.2. Membership test operations
   - 6.10.3. Identity comparisons
6.11. Boolean operations
6.12. Conditional expressions
6.13. Lambdas
6.14. Expression lists
6.15. Evaluation order
6.16. Operator precedence

7. Simple statements
   7.1. Expression statements
   7.2. Assignment statements
      - 7.2.1. Augmented assignment statements
      - 7.2.2. Annotated assignment statements
   7.3. The assert statement
   7.4. The pass statement
   7.5. The del statement
   7.6. The return statement
   7.7. The yield statement
   7.8. The raise statement
   7.9. The break statement
   7.10. The continue statement
   7.11. The import statement
      - 7.11.1. Future statements
   7.12. The global statement
   7.13. The nonlocal statement

8. Compound statements
   8.1. The if statement
   8.2. The while statement
   8.3. The for statement
   8.4. The try statement
   8.5. The with statement
   8.6. Function definitions
   8.7. Class definitions
   8.8. Coroutines
      - 8.8.1. Coroutine function definition
8.8.2. The async for statement
8.8.3. The async with statement

9. Top-level components
  9.1. Complete Python programs
  9.2. File input
  9.3. Interactive input
  9.4. Expression input

10. Full Grammar specification

The Python Standard Library
  1. Introduction
  2. Built-in Functions
  3. Built-in Constants
    3.1. Constants added by the site module
  4. Built-in Types
    4.1. Truth Value Testing
    4.2. Boolean Operations — and, or, not
    4.3. Comparisons
    4.4. Numeric Types — int, float, complex
      4.4.1. Bitwise Operations on Integer Types
      4.4.2. Additional Methods on Integer Types
      4.4.3. Additional Methods on Float
      4.4.4. Hashing of numeric types
    4.5. Iterator Types
      4.5.1. Generator Types
    4.6. Sequence Types — list, tuple, range
      4.6.1. Common Sequence Operations
      4.6.2. Immutable Sequence Types
      4.6.3. Mutable Sequence Types
      4.6.4. Lists
      4.6.5. Tuples
      4.6.6. Ranges
    4.7. Text Sequence Type — str
      4.7.1. String Methods
      4.7.2. printf-style String Formatting
4.8. Binary Sequence Types — bytes, bytearray, memoryview
  • 4.8.1. Bytes Objects
  • 4.8.2. Bytearray Objects
  • 4.8.3. Bytes and Bytearray Operations
  • 4.8.4. printf-style Bytes Formatting
  • 4.8.5. Memory Views
4.9. Set Types — set, frozenset
4.10. Mapping Types — dict
  • 4.10.1. Dictionary view objects
4.11. Context Manager Types
4.12. Other Built-in Types
  • 4.12.1. Modules
  • 4.12.2. Classes and Class Instances
  • 4.12.3. Functions
  • 4.12.4. Methods
  • 4.12.5. Code Objects
  • 4.12.6. Type Objects
  • 4.12.7. The Null Object
  • 4.12.8. The Ellipsis Object
  • 4.12.9. The NotImplemented Object
  • 4.12.10. Boolean Values
  • 4.12.11. Internal Objects
4.13. Special Attributes
5. Built-in Exceptions
  • 5.1. Base classes
  • 5.2. Concrete exceptions
    • 5.2.1. OS exceptions
  • 5.3. Warnings
  • 5.4. Exception hierarchy
6. Text Processing Services
  • 6.1. string — Common string operations
    • 6.1.1. String constants
    • 6.1.2. Custom String Formatting
6.1.3. Format String Syntax
   - 6.1.3.1. Format Specification Mini-Language
   - 6.1.3.2. Format examples
6.1.4. Template strings
6.1.5. Helper functions

6.2. re — Regular expression operations
   - 6.2.1. Regular Expression Syntax
   - 6.2.2. Module Contents
   - 6.2.3. Regular Expression Objects
   - 6.2.4. Match Objects
   - 6.2.5. Regular Expression Examples
     - 6.2.5.1. Checking for a Pair
     - 6.2.5.2. Simulating scanf()
     - 6.2.5.3. search() vs. match()
     - 6.2.5.4. Making a Phonebook
     - 6.2.5.5. Text Munging
     - 6.2.5.6. Finding all Adverbs
     - 6.2.5.7. Finding all Adverbs and their Positions
     - 6.2.5.8. Raw String Notation
     - 6.2.5.9. Writing a Tokenizer

6.3. difflib — Helpers for computing deltas
   - 6.3.1. SequenceMatcher Objects
   - 6.3.2. SequenceMatcher Examples
   - 6.3.3. Differ Objects
   - 6.3.4. Differ Example
   - 6.3.5. A command-line interface to difflib

6.4. textwrap — Text wrapping and filling

6.5. unicodedata — Unicode Database

6.6. stringprep — Internet String Preparation

6.7. readline — GNU readline interface
   - 6.7.1. Init file
   - 6.7.2. Line buffer
   - 6.7.3. History file
   - 6.7.4. History list
- 6.7.5. Startup hooks
- 6.7.6. Completion
- 6.7.7. Example

- 6.8. rlcompleter — Completion function for GNU readline
  - 6.8.1. Completer Objects

- 7. Binary Data Services
  - 7.1. struct — Interpret bytes as packed binary data
    - 7.1.1. Functions and Exceptions
    - 7.1.2. Format Strings
      - 7.1.2.1. Byte Order, Size, and Alignment
      - 7.1.2.2. Format Characters
      - 7.1.2.3. Examples
    - 7.1.3. Classes
  
  - 7.2. codecs — Codec registry and base classes
    - 7.2.1. Codec Base Classes
      - 7.2.1.1. Error Handlers
      - 7.2.1.2. Stateless Encoding and Decoding
      - 7.2.1.3. Incremental Encoding and Decoding
        - 7.2.1.3.1. IncrementalEncoder Objects
        - 7.2.1.3.2. IncrementalDecoder Objects
      - 7.2.1.4. Stream Encoding and Decoding
        - 7.2.1.4.1. StreamWriter Objects
        - 7.2.1.4.2. StreamReader Objects
        - 7.2.1.4.3. StreamReaderWriter Objects
        - 7.2.1.4.4. StreamRecoder Objects
    - 7.2.2. Encodings and Unicode
    - 7.2.3. Standard Encodings
    - 7.2.4. Python Specific Encodings
      - 7.2.4.1. Text Encodings
      - 7.2.4.2. Binary Transforms
      - 7.2.4.3. Text Transforms
    - 7.2.5. encodings.idna — Internationalized Domain Names in Applications
7.2.6. encodings.mbc — Windows ANSI codepage
7.2.7. encodings.utf_8_sig — UTF-8 codec with BOM signature

8. Data Types
8.1. datetime — Basic date and time types
  8.1.1. Available Types
  8.1.2. timedelta Objects
  8.1.3. date Objects
  8.1.4. datetime Objects
  8.1.5. time Objects
  8.1.6. tzinfo Objects
  8.1.7. timezone Objects
  8.1.8. strftime() and strptime() Behavior
8.2. calendar — General calendar-related functions
8.3. collections — Container datatypes
  8.3.1. ChainMap objects
    8.3.1.1. ChainMap Examples and Recipes
  8.3.2. Counter objects
  8.3.3. deque objects
    8.3.3.1. deque Recipes
  8.3.4. defaultdict objects
    8.3.4.1. defaultdict Examples
  8.3.5. namedtuple() Factory Function for Tuples with Named Fields
  8.3.6. OrderedDict objects
    8.3.6.1. OrderedDict Examples and Recipes
  8.3.7. UserDict objects
  8.3.8. UserList objects
  8.3.9. UserString objects
8.4. collections.abc — Abstract Base Classes for Containers
- 8.4.1. Collections Abstract Base Classes
- 8.5. heapq — Heap queue algorithm
  - 8.5.1. Basic Examples
  - 8.5.2. Priority Queue Implementation Notes
  - 8.5.3. Theory
- 8.6. bisect — Array bisection algorithm
  - 8.6.1. Searching Sorted Lists
  - 8.6.2. Other Examples
- 8.7. array — Efficient arrays of numeric values
- 8.8. weakref — Weak references
  - 8.8.1. Weak Reference Objects
  - 8.8.2. Example
  - 8.8.3. Finalizer Objects
  - 8.8.4. Comparing finalizers with __del__() methods
- 8.9. types — Dynamic type creation and names for built-in types
  - 8.9.1. Dynamic Type Creation
  - 8.9.2. Standard Interpreter Types
  - 8.9.3. Additional Utility Classes and Functions
  - 8.9.4. Coroutine Utility Functions
- 8.10. copy — Shallow and deep copy operations
- 8.11. pprint — Data pretty printer
  - 8.11.1. PrettyPrinter Objects
  - 8.11.2. Example
- 8.12. reprlib — Alternate repr() implementation
  - 8.12.1. Repr Objects
  - 8.12.2. Subclassing Repr Objects
- 8.13. enum — Support for enumerations
  - 8.13.1. Module Contents
  - 8.13.2. Creating an Enum
  - 8.13.3. Programmatic access to enumeration members and their attributes
- 8.13.4. Duplicating enum members and values
- 8.13.5. Ensuring unique enumeration values
- 8.13.6. Using automatic values
- 8.13.7. Iteration
- 8.13.8. Comparisons
- 8.13.9. Allowed members and attributes of enumerations
- 8.13.10. Restricted subclassing of enumerations
- 8.13.11. Pickling
- 8.13.12. Functional API
- 8.13.13. Derived Enumerations
  - 8.13.13.1. IntEnum
  - 8.13.13.2. IntFlag
  - 8.13.13.3. Flag
  - 8.13.13.4. Others
    - 8.13.14.1.3. Using a descriptive string
    - 8.13.14.1.4. Using a custom __new__() function
  - 8.13.14.2. OrderedEnum
  - 8.13.14.3. DuplicateFreeEnum
  - 8.13.14.4. Planet
- 8.13.15. How are Enums different?
  - 8.13.15.1. Enum Classes
  - 8.13.15.2. Enum Members (aka instances)
  - 8.13.15.3. Finer Points
    - 8.13.15.3.1. Supported __dunder__ names
    - 8.13.15.3.2. Supported _sunder_ names
    - 8.13.15.3.3. Enum member type
    - 8.13.15.3.4. Boolean value of Enum classes and members
- 8.13.15.3.5. Enum classes with methods
- 8.13.15.3.6. Combining members of Flag

9. Numeric and Mathematical Modules
- 9.1. numbers — Numeric abstract base classes
  - 9.1.1. The numeric tower
  - 9.1.2. Notes for type implementors
    - 9.1.2.1. Adding More Numeric ABCs
    - 9.1.2.2. Implementing the arithmetic operations
- 9.2. math — Mathematical functions
  - 9.2.1. Number-theoretic and representation functions
  - 9.2.2. Power and logarithmic functions
  - 9.2.3. Trigonometric functions
  - 9.2.4. Angular conversion
  - 9.2.5. Hyperbolic functions
  - 9.2.6. Special functions
  - 9.2.7. Constants
- 9.3. cmath — Mathematical functions for complex numbers
  - 9.3.1. Conversions to and from polar coordinates
  - 9.3.2. Power and logarithmic functions
  - 9.3.3. Trigonometric functions
  - 9.3.4. Hyperbolic functions
  - 9.3.5. Classification functions
  - 9.3.6. Constants
- 9.4. decimal — Decimal fixed point and floating point arithmetic
  - 9.4.1. Quick-start Tutorial
  - 9.4.2. Decimal objects
    - 9.4.2.1. Logical operands
  - 9.4.3. Context objects
  - 9.4.4. Constants
  - 9.4.5. Rounding modes
  - 9.4.6. Signals
9.4.7. Floating Point Notes
  9.4.7.1. Mitigating round-off error with increased precision
  9.4.7.2. Special values
9.4.8. Working with threads
9.4.9. Recipes
9.4.10. Decimal FAQ

9.5. fractions — Rational numbers
9.6. random — Generate pseudo-random numbers
  9.6.1. Bookkeeping functions
  9.6.2. Functions for integers
  9.6.3. Functions for sequences
  9.6.4. Real-valued distributions
  9.6.5. Alternative Generator
  9.6.6. Notes on Reproducibility
  9.6.7. Examples and Recipes
9.7. statistics — Mathematical statistics functions
  9.7.1. Averages and measures of central location
  9.7.2. Measures of spread
  9.7.3. Function details
  9.7.4. Exceptions

10. Functional Programming Modules
  10.1. itertools — Functions creating iterators for efficient looping
    10.1.1. Itertool functions
    10.1.2. Itertools Recipes
  10.2. functools — Higher-order functions and operations on callable objects
    10.2.1. partial Objects
  10.3. operator — Standard operators as functions
    10.3.1. Mapping Operators to Functions
    10.3.2. Inplace Operators

11. File and Directory Access
  11.1. pathlib — Object-oriented filesystem paths
- 11.1.1. Basic use
- 11.1.2. Pure paths
  - 11.1.2.1. General properties
  - 11.1.2.2. Operators
  - 11.1.2.3. Accessing individual parts
  - 11.1.2.4. Methods and properties
- 11.1.3. Concrete paths
  - 11.1.3.1. Methods
- 11.2. os.path — Common pathname manipulations
- 11.3. fileinput — Iterate over lines from multiple input streams
- 11.4. stat — Interpreting stat() results
- 11.5. filecmp — File and Directory Comparisons
  - 11.5.1. The dircmp class
- 11.6. tempfile — Generate temporary files and directories
  - 11.6.1. Examples
  - 11.6.2. Deprecated functions and variables
- 11.7. glob — Unix style pathname pattern expansion
- 11.8. fnmatch — Unix filename pattern matching
- 11.9. linecache — Random access to text lines
- 11.10. shutil — High-level file operations
  - 11.10.1. Directory and files operations
    - 11.10.1.1. copytree example
    - 11.10.1.2. rmtree example
  - 11.10.2. Archiving operations
    - 11.10.2.1. Archiving example
  - 11.10.3. Querying the size of the output terminal
- 11.11. macpath — Mac OS 9 path manipulation functions
- 12. Data Persistence
  - 12.1. pickle — Python object serialization
    - 12.1.1. Relationship to other Python modules
- 12.1.1.1. Comparison with marshal
- 12.1.1.2. Comparison with json
- 12.1.2. Data stream format
- 12.1.3. Module Interface
- 12.1.4. What can be pickled and unpickled?
- 12.1.5. Pickling Class Instances
  - 12.1.5.1. Persistence of External Objects
  - 12.1.5.2. Dispatch Tables
  - 12.1.5.3. Handling Stateful Objects
- 12.1.6. Restricting Globals
- 12.1.7. Performance
- 12.1.8. Examples
- 12.2. copyreg — Register pickle support functions
  - 12.2.1. Example
- 12.3. shelve — Python object persistence
  - 12.3.1. Restrictions
  - 12.3.2. Example
- 12.4. marshal — Internal Python object serialization
- 12.5. dbm — Interfaces to Unix “databases”
  - 12.5.1. dbm.gnu — GNU’s reinterpretation of dbm
  - 12.5.2. dbm.ndbm — Interface based on ndbm
  - 12.5.3. dbm.dumb — Portable DBM implementation
- 12.6. sqlite3 — DB-API 2.0 interface for SQLite databases
  - 12.6.1. Module functions and constants
  - 12.6.2. Connection Objects
  - 12.6.3. Cursor Objects
  - 12.6.4. Row Objects
  - 12.6.5. Exceptions
  - 12.6.6. SQLite and Python types
    - 12.6.6.1. Introduction
    - 12.6.6.2. Using adapters to store additional Python types in SQLite databases
- 12.6.6.2.1. Letting your object adapt itself
- 12.6.6.2.2. Registering an adapter callable
- 12.6.6.3. Converting SQLite values to custom Python types
- 12.6.6.4. Default adapters and converters
- 12.6.7. Controlling Transactions
- 12.6.8. Using sqlite3 efficiently
  - 12.6.8.1. Using shortcut methods
  - 12.6.8.2. Accessing columns by name instead of by index
  - 12.6.8.3. Using the connection as a context manager
- 12.6.9. Common issues
  - 12.6.9.1. Multithreading

13. Data Compression and Archiving
- 13.1. zlib — Compression compatible with gzip
- 13.2. gzip — Support for gzip files
  - 13.2.1. Examples of usage
- 13.3. bz2 — Support for bzip2 compression
  - 13.3.1. (De)compression of files
  - 13.3.2. Incremental (de)compression
  - 13.3.3. One-shot (de)compression
- 13.4. lzma — Compression using the LZMA algorithm
  - 13.4.1. Reading and writing compressed files
  - 13.4.2. Compressing and decompressing data in memory
  - 13.4.3. Miscellaneous
  - 13.4.4. Specifying custom filter chains
  - 13.4.5. Examples
- 13.5. zipfile — Work with ZIP archives
  - 13.5.1. ZipFile Objects
  - 13.5.2. PyZipFile Objects
  - 13.5.3. ZipInfo Objects
  - 13.5.4. Command-Line Interface
13.5.4.1. Command-line options

13.6. tarfile — Read and write tar archive files
   - 13.6.1. TarFile Objects
   - 13.6.2. TarInfo Objects
   - 13.6.3. Command-Line Interface
     - 13.6.3.1. Command-line options
   - 13.6.4. Examples
   - 13.6.5. Supported tar formats
   - 13.6.6. Unicode issues

14. File Formats
   - 14.1. csv — CSV File Reading and Writing
     - 14.1.1. Module Contents
     - 14.1.2. Dialects and Formatting Parameters
     - 14.1.3. Reader Objects
     - 14.1.4. Writer Objects
     - 14.1.5. Examples
   - 14.2. configparser — Configuration file parser
     - 14.2.1. Quick Start
     - 14.2.2. Supported Datatypes
     - 14.2.3. Fallback Values
     - 14.2.4. Supported INI File Structure
     - 14.2.5. Interpolation of values
     - 14.2.6. Mapping Protocol Access
     - 14.2.7. Customizing Parser Behaviour
     - 14.2.8. Legacy API Examples
     - 14.2.9. ConfigParser Objects
     - 14.2.10. RawConfigParser Objects
     - 14.2.11. Exceptions
   - 14.3. netrc — netrc file processing
     - 14.3.1. netrc Objects
   - 14.4. xdrlib — Encode and decode XDR data
     - 14.4.1. Packer Objects
     - 14.4.2. Unpacker Objects
     - 14.4.3. Exceptions
- **14.5. plistlib** — Generate and parse Mac OS X .plist files
  - 14.5.1. Examples

- **15. Cryptographic Services**
  - **15.1. hashlib** — Secure hashes and message digests
    - 15.1.1. Hash algorithms
    - 15.1.2. SHAKE variable length digests
    - 15.1.3. Key derivation
    - 15.1.4. BLAKE2
      - 15.1.4.1. Creating hash objects
      - 15.1.4.2. Constants
      - 15.1.4.3. Examples
        - 15.1.4.3.1. Simple hashing
        - 15.1.4.3.2. Using different digest sizes
        - 15.1.4.3.3. Keyed hashing
        - 15.1.4.3.4. Randomized hashing
        - 15.1.4.3.5. Personalization
        - 15.1.4.3.6. Tree mode
      - 15.1.4.4. Credits
  - **15.2. hmac** — Keyed-Hashing for Message Authentication
  - **15.3. secrets** — Generate secure random numbers for managing secrets
    - 15.3.1. Random numbers
    - 15.3.2. Generating tokens
      - 15.3.2.1. How many bytes should tokens use?
    - 15.3.3. Other functions
    - 15.3.4. Recipes and best practices

- **16. Generic Operating System Services**
  - **16.1. os** — Miscellaneous operating system interfaces
    - 16.1.1. File Names, Command Line Arguments, and Environment Variables
    - 16.1.2. Process Parameters
    - 16.1.3. File Object Creation
- 16.1.4. File Descriptor Operations
  - 16.1.4.1. Querying the size of a terminal
  - 16.1.4.2. Inheritance of File Descriptors
- 16.1.5. Files and Directories
  - 16.1.5.1. Linux extended attributes
- 16.1.6. Process Management
- 16.1.7. Interface to the scheduler
- 16.1.8. Miscellaneous System Information
- 16.1.9. Random numbers
- 16.2. io — Core tools for working with streams
  - 16.2.1. Overview
    - 16.2.1.1. Text I/O
    - 16.2.1.2. Binary I/O
    - 16.2.1.3. Raw I/O
  - 16.2.2. High-level Module Interface
    - 16.2.2.1. In-memory streams
  - 16.2.3. Class hierarchy
    - 16.2.3.1. I/O Base Classes
    - 16.2.3.2. Raw File I/O
    - 16.2.3.3. Buffered Streams
    - 16.2.3.4. Text I/O
  - 16.2.4. Performance
    - 16.2.4.1. Binary I/O
    - 16.2.4.2. Text I/O
    - 16.2.4.3. Multi-threading
    - 16.2.4.4. Reentrancy
- 16.3. time — Time access and conversions
- 16.4. argparse — Parser for command-line options, arguments and sub-commands
  - 16.4.1. Example
    - 16.4.1.1. Creating a parser
    - 16.4.1.2. Adding arguments
    - 16.4.1.3. Parsing arguments
  - 16.4.2. ArgumentParser objects
16.4.2.1. prog
16.4.2.2. usage
16.4.2.3. description
16.4.2.4. epilog
16.4.2.5. parents
16.4.2.6. formatter_class
16.4.2.7. prefix_chars
16.4.2.8. fromfile_prefix_chars
16.4.2.9. argument_default
16.4.2.10. allow_abbrev
16.4.2.11. conflict_handler
16.4.2.12. add_help

16.4.3. The add_argument() method
  16.4.3.1. name or flags
  16.4.3.2. action
  16.4.3.3. nargs
  16.4.3.4. const
  16.4.3.5. default
  16.4.3.6. type
  16.4.3.7. choices
  16.4.3.8. required
  16.4.3.9. help
  16.4.3.10. metavar
  16.4.3.11. dest
  16.4.3.12. Action classes

16.4.4. The parse_args() method
  16.4.4.1. Option value syntax
  16.4.4.2. Invalid arguments
  16.4.4.3. Arguments containing -
  16.4.4.4. Argument abbreviations (prefix matching)
  16.4.4.5. Beyond sys.argv
  16.4.4.6. The Namespace object

16.4.5. Other utilities
- 16.4.5.1. Sub-commands
- 16.4.5.2. FileType objects
- 16.4.5.3. Argument groups
- 16.4.5.4. Mutual exclusion
- 16.4.5.5. Parser defaults
- 16.4.5.6. Printing help
- 16.4.5.7. Partial parsing
- 16.4.5.8. Customizing file parsing
- 16.4.5.9. Exiting methods
- 16.4.6. Upgrading optparse code
- 16.5. getopt — C-style parser for command line options

  - 16.6.8. LoggerAdapter Objects
  - 16.6.9. Thread Safety
  - 16.6.10. Module-Level Functions
  - 16.6.11. Module-Level Attributes
  - 16.6.12. Integration with the warnings module
- 16.7. logging.config — Logging configuration
  - 16.7.1. Configuration functions
  - 16.7.2. Configuration dictionary schema
    - 16.7.2.1. Dictionary Schema Details
    - 16.7.2.2. Incremental Configuration
    - 16.7.2.3. Object connections
    - 16.7.2.4. User-defined objects
    - 16.7.2.5. Access to external objects
    - 16.7.2.6. Access to internal objects
- 16.7.2.7. Import resolution and custom importers
  - 16.7.3. Configuration file format
- 16.8. logging.handlers — Logging handlers
  - 16.8.1. StreamHandler
  - 16.8.2. FileHandler
  - 16.8.3. NullHandler
  - 16.8.4. WatchedFileHandler
  - 16.8.5. BaseRotatingHandler
  - 16.8.6. RotatingFileHandler
  - 16.8.7. TimedRotatingFileHandler
  - 16.8.8. SocketHandler
  - 16.8.9. DatagramHandler
  - 16.8.10. SysLogHandler
  - 16.8.11. NTEventLogHandler
  - 16.8.12. SMTPHandler
  - 16.8.13. MemoryHandler
  - 16.8.14. HTTPHandler
  - 16.8.15. QueueHandler
  - 16.8.16. QueueListener
- 16.9. getpass — Portable password input
- 16.10. curses — Terminal handling for character-cell displays
  - 16.10.1. Functions
  - 16.10.2. Window Objects
  - 16.10.3. Constants
- 16.11. curses.textpad — Text input widget for curses programs
  - 16.11.1. Textbox objects
- 16.12. curses.ascii — Utilities for ASCII characters
- 16.13. curses.panel — A panel stack extension for curses
  - 16.13.1. Functions
  - 16.13.2. Panel Objects
• 16.14. platform — Access to underlying platform’s identifying data
  • 16.14.2. Java Platform
  • 16.14.3. Windows Platform

18.5.1.10. Resolve host name
18.5.1.11. Connect pipes
18.5.1.12. UNIX signals
18.5.1.13. Executor
18.5.1.14. Error Handling API
18.5.1.15. Debug mode
18.5.1.16. Server
18.5.1.17. Handle
18.5.1.18. Event loop examples
   18.5.1.18.1. Hello World with call_soon()
   18.5.1.18.2. Display the current date with call_later()
   18.5.1.18.3. Watch a file descriptor for read events
   18.5.1.18.4. Set signal handlers for SIGINT and SIGTERM

18.5.2. Event loops
   18.5.2.1. Event loop functions
   18.5.2.2. Available event loops
   18.5.2.3. Platform support
      18.5.2.3.1. Windows
      18.5.2.3.2. Mac OS X
   18.5.2.4. Event loop policies and the default policy
   18.5.2.5. Event loop policy interface
   18.5.2.6. Access to the global loop policy

18.5.3. Tasks and coroutines
   18.5.3.1. Coroutines
      18.5.3.1.1. Example: Hello World coroutine
      18.5.3.1.2. Example: Coroutine displaying the current date
      18.5.3.1.3. Example: Chain coroutines
   18.5.3.2. InvalidStateError
18.5.3.3. TimeoutError

18.5.3.4. Future
   - 18.5.3.4.1. Example: Future with run_until_complete()
   - 18.5.3.4.2. Example: Future with run_forever()

18.5.3.5. Task
   - 18.5.3.5.1. Example: Parallel execution of tasks

18.5.3.6. Task functions

18.5.4. Transports and protocols (callback based API)
   - 18.5.4.1. Transports
     - 18.5.4.1.1. BaseTransport
     - 18.5.4.1.2. ReadTransport
     - 18.5.4.1.3. WriteTransport
     - 18.5.4.1.4. DatagramTransport
     - 18.5.4.1.5. BaseSubprocessTransport
   - 18.5.4.2. Protocols
     - 18.5.4.2.1. Protocol classes
     - 18.5.4.2.2. Connection callbacks
     - 18.5.4.2.3. Streaming protocols
     - 18.5.4.2.4. Datagram protocols
     - 18.5.4.2.5. Flow control callbacks
     - 18.5.4.2.6. Coroutines and protocols
   - 18.5.4.3. Protocol examples
     - 18.5.4.3.1. TCP echo client protocol
     - 18.5.4.3.2. TCP echo server protocol
     - 18.5.4.3.3. UDP echo client protocol
     - 18.5.4.3.4. UDP echo server protocol
     - 18.5.4.3.5. Register an open socket to wait for data using a protocol

18.5.5. Streams (coroutine based API)
   - 18.5.5.1. Stream functions
18.5.5.2. StreamReader
18.5.5.3. StreamWriter
18.5.5.4. StreamReaderProtocol
18.5.5.5. IncompleteReadError
18.5.5.6. LimitOverrunError
18.5.5.7. Stream examples
   18.5.5.7.1. TCP echo client using streams
   18.5.5.7.2. TCP echo server using streams
   18.5.5.7.3. Get HTTP headers
   18.5.5.7.4. Register an open socket to wait for data using streams
18.5.6. Subprocess
   18.5.6.1. Windows event loop
   18.5.6.2. Create a subprocess: high-level API using Process
   18.5.6.3. Create a subprocess: low-level API using subprocess.Popen
   18.5.6.4. Constants
   18.5.6.5. Process
   18.5.6.6. Subprocess and threads
   18.5.6.7. Subprocess examples
      18.5.6.7.1. Subprocess using transport and protocol
      18.5.6.7.2. Subprocess using streams
18.5.7. Synchronization primitives
   18.5.7.1. Locks
      18.5.7.1.1. Lock
      18.5.7.1.2. Event
      18.5.7.1.3. Condition
   18.5.7.2. Semaphores
      18.5.7.2.1. Semaphore
      18.5.7.2.2. BoundedSemaphore
18.5.8. Queues
   18.5.8.1. Queue
- 18.5.8.2. PriorityQueue
- 18.5.8.3. LifoQueue
  - 18.5.8.3.1. Exceptions
- 18.5.9. Develop with asyncio
  - 18.5.9.1. Debug mode of asyncio
  - 18.5.9.2. Cancellation
  - 18.5.9.3. Concurrency and multithreading
  - 18.5.9.4. Handle blocking functions correctly
  - 18.5.9.5. Logging
  - 18.5.9.6. Detect coroutine objects never scheduled
  - 18.5.9.7. Detect exceptions never consumed
  - 18.5.9.8. Chain coroutines correctly
  - 18.5.9.9. Pending task destroyed
  - 18.5.9.10. Close transports and event loops
- 18.6. asyncore — Asynchronous socket handler
  - 18.6.1. asyncore Example basic HTTP client
  - 18.6.2. asyncore Example basic echo server
- 18.7. asynchat — Asynchronous socket command/response handler
  - 18.7.1. asynchat Example
- 18.8. signal — Set handlers for asynchronous events
  - 18.8.1. General rules
    - 18.8.1.1. Execution of Python signal handlers
    - 18.8.1.2. Signals and threads
  - 18.8.2. Module contents
  - 18.8.3. Example
- 18.9. mmap — Memory-mapped file support
- 19. Internet Data Handling
  - 19.1. email — An email and MIME handling package
    - 19.1.1. email.message: Representing an email message
    - 19.1.2. email.parser: Parsing email messages
      - 19.1.2.1. FeedParser API
19.1.2.2. Parser API
19.1.2.3. Additional notes
19.1.3. email.generator: Generating MIME documents
19.1.4. email.policy: Policy Objects
19.1.5. email.errors: Exception and Defect classes
19.1.6. email.headerregistry: Custom Header Objects
19.1.7. email.contentmanager: Managing MIME Content
  19.1.7.1. Content Manager Instances
19.1.8. email: Examples
19.1.9. email.message.Message: Representing an email message using the compat32 API
19.1.10. email.mime: Creating email and MIME objects from scratch
19.1.11. email.header: Internationalized headers
19.1.12. email.charset: Representing character sets
19.1.13. email.encoders: Encoders
19.1.14. email.utils: Miscellaneous utilities
19.1.15. email.iterators: Iterators

19.2. json — JSON encoder and decoder
19.2.1. Basic Usage
19.2.2. Encoders and Decoders
19.2.3. Exceptions
19.2.4. Standard Compliance and Interoperability
  19.2.4.1. Character Encodings
  19.2.4.2. Infinite and NaN Number Values
  19.2.4.3. Repeated Names Within an Object
  19.2.4.4. Top-level Non-Object, Non-Array Values
- 19.2.4.5. Implementation Limitations
- 19.2.5. Command Line Interface
  - 19.2.5.1. Command line options
- 19.3. mailcap — Mailcap file handling
- 19.4. mailbox — Manipulate mailboxes in various formats
  - 19.4.1. Mailbox objects
    - 19.4.1.1. Maildir
    - 19.4.1.2. mbox
    - 19.4.1.3. MH
    - 19.4.1.4. Babyl
    - 19.4.1.5. MMDF
  - 19.4.2. Message objects
    - 19.4.2.1. MaildirMessage
    - 19.4.2.2. mboxMessage
    - 19.4.2.3. MHMessage
    - 19.4.2.4. BabylMessage
    - 19.4.2.5. MMDFMessage
  - 19.4.3. Exceptions
  - 19.4.4. Examples
- 19.5. mimetypes — Map filenames to MIME types
  - 19.5.1. MimeTypes Objects
- 19.6. base64 — Base16, Base32, Base64, Base85 Data Encodings
- 19.7. binhex — Encode and decode binhex4 files
  - 19.7.1. Notes
- 19.8. binascii — Convert between binary and ASCII
- 19.9. quopri — Encode and decode MIME quoted-printable data
- 19.10. uu — Encode and decode uuencode files

- 20. Structured Markup Processing Tools
  - 20.1. html — HyperText Markup Language support
20.2. html.parser — Simple HTML and XHTML parser
   20.2.1. Example HTML Parser Application
   20.2.2. HTMLParser Methods
   20.2.3. Examples
20.3. html.entities — Definitions of HTML general entities
20.4. XML Processing Modules
   20.4.1. XML vulnerabilities
   20.4.2. The defusedxml and defusedexpat Packages
20.5. xml.etree.ElementTree — The ElementTree XML API
   20.5.1. Tutorial
      20.5.1.1. XML tree and elements
      20.5.1.2. Parsing XML
      20.5.1.3. Pull API for non-blocking parsing
      20.5.1.4. Finding interesting elements
      20.5.1.5. Modifying an XML File
      20.5.1.6. Building XML documents
      20.5.1.7. Parsing XML with Namespaces
      20.5.1.8. Additional resources
   20.5.2. XPath support
      20.5.2.1. Example
      20.5.2.2. Supported XPath syntax
   20.5.3. Reference
      20.5.3.1. Functions
      20.5.3.2. Element Objects
      20.5.3.3. ElementTree Objects
      20.5.3.4. QName Objects
      20.5.3.5. TreeBuilder Objects
      20.5.3.6. XMLParser Objects
      20.5.3.7. XMLPullParser Objects
      20.5.3.8. Exceptions
20.6. xml.dom — The Document Object Model API
  • 20.6.1. Module Contents
  • 20.6.2. Objects in the DOM
    • 20.6.2.1. DOMImplementation Objects
    • 20.6.2.2. Node Objects
    • 20.6.2.3. NodeList Objects
    • 20.6.2.4. DocumentType Objects
    • 20.6.2.5. Document Objects
    • 20.6.2.6. Element Objects
    • 20.6.2.7. Attr Objects
    • 20.6.2.8. NamedNodeMap Objects
    • 20.6.2.9. Comment Objects
    • 20.6.2.10. Text and CDATASection Objects
    • 20.6.2.11. ProcessingInstruction Objects
    • 20.6.2.12. Exceptions
  • 20.6.3. Conformance
    • 20.6.3.1. Type Mapping
    • 20.6.3.2. Accessor Methods
  • 20.7. xml.dom.minidom — Minimal DOM implementation
    • 20.7.1. DOM Objects
    • 20.7.2. DOM Example
    • 20.7.3. minidom and the DOM standard
  • 20.8. xml.dom.pulldom — Support for building partial DOM trees
    • 20.8.1. DOMEventStream Objects
  • 20.9. xml.sax — Support for SAX2 parsers
    • 20.9.1. SAXException Objects
  • 20.10. xml.sax.handler — Base classes for SAX handlers
    • 20.10.1. ContentHandler Objects
    • 20.10.2. DTDHandler Objects
    • 20.10.3. EntityResolver Objects
    • 20.10.4. ErrorHandler Objects
- **20.11. `xml.sax.saxutils` — SAX Utilities**
- **20.12. `xml.sax.xmlreader` — Interface for XML parsers**
  - 20.12.1. XMLReader Objects
  - 20.12.2. IncrementalParser Objects
  - 20.12.3. Locator Objects
  - 20.12.4. InputSource Objects
  - 20.12.5. The Attributes Interface
  - 20.12.6. The AttributesNS Interface
- **20.13. `xml.parsers.expat` — Fast XML parsing using Expat**
  - 20.13.1. XMLParser Objects
  - 20.13.2. ExpatError Exceptions
  - 20.13.3. Example
  - 20.13.4. Content Model Descriptions
  - 20.13.5. Expat error constants
- **21. Internet Protocols and Support**
  - **21.1. `webbrowser` — Convenient Web-browser controller**
    - 21.1.1. Browser Controller Objects
  - **21.2. `cgi` — Common Gateway Interface support**
    - 21.2.1. Introduction
    - 21.2.2. Using the `cgi` module
    - 21.2.3. Higher Level Interface
    - 21.2.4. Functions
    - 21.2.5. Caring about security
    - 21.2.6. Installing your CGI script on a Unix system
    - 21.2.7. Testing your CGI script
    - 21.2.8. Debugging CGI scripts
    - 21.2.9. Common problems and solutions
  - **21.3. `cgitb` — Traceback manager for CGI scripts**
  - **21.4. `wsgiref` — WSGI Utilities and Reference Implementation**
- 21.4.1. `wsgiref.util` — WSGI environment utilities
- 21.4.2. `wsgiref.headers` — WSGI response header tools
- 21.4.3. `wsgiref.simple_server` — a simple WSGI HTTP server
- 21.4.4. `wsgiref.validate` — WSGI conformance checker
- 21.4.5. `wsgiref.handlers` — server/gateway base classes
- 21.4.6. Examples
- 21.5. `urllib` — URL handling modules
- 21.6. `urllib.request` — Extensible library for opening URLs
  - 21.6.1. Request Objects
  - 21.6.2. OpenerDirector Objects
  - 21.6.3. BaseHandler Objects
  - 21.6.4. HTTPRedirectHandler Objects
  - 21.6.5. HTTPCookieProcessor Objects
  - 21.6.6. ProxyHandler Objects
  - 21.6.7. HTTPPasswordMgr Objects
  - 21.6.8. HTTPPasswordMgrWithPriorAuth Objects
  - 21.6.9. AbstractBasicAuthHandler Objects
  - 21.6.10. HTTPBasicAuthHandler Objects
  - 21.6.11. ProxyBasicAuthHandler Objects
  - 21.6.13. HTTPDigestAuthHandler Objects
  - 21.6.15. HTTPHandler Objects
  - 21.6.16. HTTPSHandler Objects
  - 21.6.17. FileHandler Objects
  - 21.6.18. DataHandler Objects
  - 21.6.19. FTPHandler Objects
  - 21.6.20. CacheFTPHandler Objects
21.6.21. UnknownHandler Objects
21.6.22. HTTPErrorProcessor Objects
21.6.23. Examples
21.6.24. Legacy interface
21.6.25. urllib.request Restrictions
21.7. urllib.response — Response classes used by urllib
21.8. urllib.parse — Parse URLs into components
   21.8.1. URL Parsing
   21.8.2. Parsing ASCII Encoded Bytes
   21.8.3. Structured Parse Results
   21.8.4. URL Quoting
21.9. urllib.error — Exception classes raised by urllib.request
21.10. urllib.robotparser — Parser for robots.txt
21.11. http — HTTP modules
   21.11.1. HTTP status codes
   21.12.1. HTTPConnection Objects
   21.12.2. HTTPResponse Objects
   21.12.3. Examples
   21.12.4. HTTPMessage Objects
21.13. ftplib — FTP protocol client
   21.13.1. FTP Objects
   21.13.2. FTP_TLS Objects
21.14. poplib — POP3 protocol client
   21.14.1. POP3 Objects
   21.14.2. POP3 Example
21.15. imaplib — IMAP4 protocol client
   21.15.1. IMAP4 Objects
   21.15.2. IMAP4 Example
21.16. nntplib — NNTP protocol client
   21.16.1. NNTP Objects
- 21.16.1.1. Attributes
- 21.16.1.2. Methods
- 21.16.2. Utility functions
- 21.17. smtplib — SMTP protocol client
  - 21.17.1. SMTP Objects
  - 21.17.2. SMTP Example
- 21.18. smtpd — SMTP Server
  - 21.18.1. SMTPServer Objects
  - 21.18.2. DebuggingServer Objects
  - 21.18.3. PureProxy Objects
  - 21.18.4. MailmanProxy Objects
  - 21.18.5. SMTPChannel Objects
- 21.19. telnetlib — Telnet client
  - 21.19.1. Telnet Objects
  - 21.19.2. Telnet Example
- 21.20. uuid — UUID objects according to RFC 4122
  - 21.20.1. Example
- 21.21. socketserver — A framework for network servers
  - 21.21.1. Server Creation Notes
  - 21.21.2. Server Objects
  - 21.21.3. Request Handler Objects
  - 21.21.4. Examples
    - 21.21.4.1. socketserver.TCPServer Example
    - 21.21.4.2. socketserver.UDPServer Example
    - 21.21.4.3. Asynchronous Mixins
- 21.22. http.server — HTTP servers
- 21.23. http.cookies — HTTP state management
  - 21.23.1. Cookie Objects
  - 21.23.2. Morsel Objects
  - 21.23.3. Example
- **21.24. http.cookiejar** — Cookie handling for HTTP clients
  - 21.24.2. FileCookieJar subclasses and co-operation with web browsers
  - 21.24.3. CookiePolicy Objects
  - 21.24.4. DefaultCookiePolicy Objects
  - 21.24.5. Cookie Objects
  - 21.24.6. Examples
- **21.25. xmlrpc** — XMLRPC server and client modules
- **21.26. xmlrpc.client** — XML-RPC client access
  - 21.26.2. DateTime Objects
  - 21.26.3. Binary Objects
  - 21.26.4. Fault Objects
  - 21.26.6. MultiCall Objects
  - 21.26.7. Convenience Functions
- **21.27. xmlrpc.server** — Basic XML-RPC servers
  - 21.27.1. SimpleXMLRPCServer Objects
    - 21.27.1.1. SimpleXMLRPCServer Example
  - 21.27.2. CGIHTTPRequestHandler
  - 21.27.3. Documenting XMLRPC server
  - 21.27.4. DocXMLRPCServer Objects
  - 21.27.5. DocCGIHTTPRequestHandler
- **21.28. ipaddress** — IPv4/IPv6 manipulation library
  - 21.28.1. Convenience factory functions
  - 21.28.2. IP Addresses
    - 21.28.2.1. Address objects
    - 21.28.2.2. Conversion to Strings and Integers
    - 21.28.2.3. Operators
      - 21.28.2.3.1. Comparison operators
21.28.2.3.2. Arithmetic operators

21.28.3. IP Network definitions
   21.28.3.1. Prefix, net mask and host mask
   21.28.3.2. Network objects
   21.28.3.3. Operators
      21.28.3.3.1. Logical operators
      21.28.3.3.2. Iteration
      21.28.3.3.3. Networks as containers of addresses

21.28.4. Interface objects

21.28.5. Other Module Level Functions

21.28.6. Custom Exceptions

22. Multimedia Services
   22.1. audioop — Manipulate raw audio data
   22.2. aifc — Read and write AIFF and AIFC files
   22.3. sunau — Read and write Sun AU files
      22.3.1. AU_read Objects
      22.3.2. AU_write Objects
   22.4. wave — Read and write WAV files
      22.4.1. Wave_read Objects
      22.4.2. Wave_write Objects
   22.5. chunk — Read IFF chunked data
   22.6. colorsys — Conversions between color systems
   22.7. imghdr — Determine the type of an image
   22.8. sndhdr — Determine type of sound file
   22.9. ossaudiodev — Access to OSS-compatible audio devices
      22.9.1. Audio Device Objects
      22.9.2. Mixer Device Objects

23. Internationalization
   23.1. gettext — Multilingual internationalization services
      23.1.1. GNU gettext API
- 23.1.2. Class-based API
  - 23.1.2.1. The NullTranslations class
  - 23.1.2.2. The GNUTranslations class
  - 23.1.2.3. Solaris message catalog support
  - 23.1.2.4. The Catalog constructor
- 23.1.3. Internationalizing your programs and modules
  - 23.1.3.1. Localizing your module
  - 23.1.3.2. Localizing your application
  - 23.1.3.3. Changing languages on the fly
  - 23.1.3.4. Deferred translations
- 23.1.4. Acknowledgements
- 23.2. locale — Internationalization services
  - 23.2.1. Background, details, hints, tips and caveats
  - 23.2.2. For extension writers and programs that embed Python
  - 23.2.3. Access to message catalogs
- 24. Program Frameworks
  - 24.1. turtle — Turtle graphics
    - 24.1.1. Introduction
    - 24.1.2. Overview of available Turtle and Screen methods
      - 24.1.2.1. Turtle methods
      - 24.1.2.2. Methods of TurtleScreen/Screen
    - 24.1.3. Methods of RawTurtle/Turtle and corresponding functions
      - 24.1.3.1. Turtle motion
      - 24.1.3.2. Tell Turtle's state
      - 24.1.3.3. Settings for measurement
      - 24.1.3.4. Pen control
        - 24.1.3.4.1. Drawing state
        - 24.1.3.4.2. Color control
        - 24.1.3.4.3. Filling
        - 24.1.3.4.4. More drawing control
- 24.1.3.5. Turtle state
  - 24.1.3.5.1. Visibility
  - 24.1.3.5.2. Appearance
- 24.1.3.6. Using events
- 24.1.3.7. Special Turtle methods
- 24.1.3.8. Compound shapes
- 24.1.4. Methods of TurtleScreen/Screen and corresponding functions
  - 24.1.4.1. Window control
  - 24.1.4.2. Animation control
  - 24.1.4.3. Using screen events
  - 24.1.4.4. Input methods
  - 24.1.4.5. Settings and special methods
  - 24.1.4.6. Methods specific to Screen, not inherited from TurtleScreen
- 24.1.5. Public classes
- 24.1.6. Help and configuration
  - 24.1.6.1. How to use help
  - 24.1.6.2. Translation of docstrings into different languages
  - 24.1.6.3. How to configure Screen and Turtles
- 24.1.7. turtledemo — Demo scripts
- 24.1.8. Changes since Python 2.6
- 24.1.9. Changes since Python 3.0
- 24.2. cmd — Support for line-oriented command interpreters
  - 24.2.1. Cmd Objects
  - 24.2.2. Cmd Example
- 24.3. shlex — Simple lexical analysis

• Python Frequently Asked Questions
  ○ General Python FAQ
    ▪ General Information
    ▪ Python in the real world
  ○ Programming FAQ
    ▪ General Questions
    ▪ Core Language
    ▪ Numbers and strings
    ▪ Performance
    ▪ Sequences (Tuples/Lists)
    ▪ Dictionaries
    ▪ Objects
    ▪ Modules
  ○ Design and History FAQ
    ▪ Why does Python use indentation for grouping of statements?
    ▪ Why am I getting strange results with simple arithmetic operations?
    ▪ Why are floating-point calculations so inaccurate?
    ▪ Why are Python strings immutable?
    ▪ Why must ‘self’ be used explicitly in method definitions and calls?
    ▪ Why can’t I use an assignment in an expression?
    ▪ Why does Python use methods for some functionality (e.g. list.index()) but functions for other (e.g. len(list))?
    ▪ Why is join() a string method instead of a list or tuple method?
    ▪ How fast are exceptions?
    ▪ Why isn’t there a switch or case statement in Python?
    ▪ Can’t you emulate threads in the interpreter instead of relying on an OS-specific thread implementation?
    ▪ Why can’t lambda expressions contain statements?
    ▪ Can Python be compiled to machine code, C or some
other language?
- How does Python manage memory?
- Why doesn’t CPython use a more traditional garbage collection scheme?
- Why isn’t all memory freed when CPython exits?
- Why are there separate tuple and list data types?
- How are lists implemented?
- How are dictionaries implemented?
- Why must dictionary keys be immutable?
- Why doesn’t list.sort() return the sorted list?
- How do you specify and enforce an interface spec in Python?
- Why is there no goto?
- Why can’t raw strings (r-strings) end with a backslash?
- Why doesn’t Python have a “with” statement for attribute assignments?
- Why are colons required for the if/while/def/class statements?
- Why does Python allow commas at the end of lists and tuples?

</tbody>
</table>
the abstract base class Command. This class is subclassed by the
modules in the distutils.command subpackage.

distutils.command

This subpackage contains one module for each standard Distutils
command.

distutils.command.bdist

Build a binary installer for a package

distutils.command.bdist_dumb

Build a "dumb" installer - a simple archive of files

distutils.command.bdist_msi

Build a binary distribution as a Windows MSI file

distutils.command.bdist_packager

Abstract base class for packagers

distutils.command.bdist_rpm

Build a binary distribution as a Redhat RPM and SRPM

distutils.command.bdist_wininst

Build a Windows installer

distutils.command.build

Build all files of a package

distutils.command.build_clib

Build any C libraries in a package

distutils.command.build_ext

Build any extensions in a package

distutils.command.build_py

Build the .py/.pyc files of a package

distutils.command.build_scripts

Build the scripts of a package
distutils.command.check  
Check the metadata of a package

distutils.command.clean  
Clean a package build area

distutils.command.config  
Perform package configuration

distutils.command.install  
Install a package

distutils.command.install_data  
Install data files from a package

distutils.command.install_headers  
Install C/C++ header files from a package

distutils.command.install_lib  
Install library files from a package

distutils.command.install_scripts  
Install script files from a package

distutils.command.register  
Register a module with the Python Package Index

distutils.command.sdist  
Build a source distribution

distutils.core  
The core Distutils functionality

distutils.cygwinccompiler  
Provides the debug flag for distutils

distutils.debug  
Utility functions for simple dependency checking

distutils.dep_util  
Utility functions for operating on directories and directory trees

distutils.dir_util  
Provides the Distribution class, which represents the module distribution being
<table>

<tr>
<td><strong>email.mime</strong></td>
<td>Build MIME messages.</td>
</tr>
<tr>
<td><strong>email.parser</strong></td>
<td>Parse flat text email messages to produce a message object</td>
</tr>
</tbody>
</table>
email.policy

Controlling the parsing and generating of messages.

email.utils

Miscellaneous email package utilities.

encodings

encodings.idna

Internationalized Domain Names implementation

encodings.mbc

Windows ANSI codepage

encodings.utf_8_sig

UTF-8 codec with BOM signature

ensurepip

Bootstrapping the "pip" installer into an existing Python installation or virtual environment.

enum

Implementation of an enumeration class.

errno

Standard errno system symbols.

faulthandler

Dump the Python traceback.

fcnt1 (Unix)

The fcntl() and ioctl() system calls.

filecmp

Compare files efficiently.

fileinput

Loop over standard input or a list of files.

fnmatch

Unix shell style filename pattern

- **secrets**
  Generate secure random numbers for managing secrets.

- **select**
  Wait for I/O completion on multiple streams.

- **selectors**
  High-level I/O multiplexing.

- **shelve**
  Python object persistence.

- **shlex**
  Simple lexical analysis for Unix shell-like languages.

- **shutil**
  High-level file operations, including copying.

- **signal**
  Set handlers for asynchronous events.

- **site**
  Module responsible for site-specific configuration.

- **smtpd**
  A SMTP server implementation in Python.

- **smtplib**
  SMTP protocol client (requires sockets).

- **sndhdr**
  Determine type of a sound file.

- **socket**
  Low-level networking interface.

- **socketserver**
  A framework for network servers.

- **spwd (Unix)**
  The shadow password database (getspnam() and friends).

tokenize
Lexical scanner for Python source code.

trace
Trace or track Python statement execution.

traceback
Print or retrieve a stack traceback.

tracemalloc
Trace memory allocations.

tty (Unix)
Utility functions that perform common terminal control operations.

turtle
An educational framework for simple graphics applications.

turtledemo
A viewer for example turtle scripts.

types
Names for built-in types.

typing
Support for type hints (see PEP 484).

u
Access the Unicode Database.

unicodedata

unittest
Unit testing framework for Python.

unittest.mock
Mock object library.

urllib

urllib.error
Exception classes raised by urllib.request.

urllib.parse
Parse URLs into or assemble them from
**urllib.request**
Extensible library for opening URLs.

**urllib.response**
Response classes used by urllib.

**urllib.robotparser**
Load a robots.txt file and answer questions about fetchability of other URLs.

**uu**
Encode and decode files in uuencode format.

**uuid**
UUID objects (universally unique identifiers) according to RFC 4122.

**venv**
Creation of virtual environments.

**warnings**
Issue warning messages and control their disposition.

**wave**
Provide an interface to the WAV sound format.

**weakref**
Support for weak references and weak dictionaries.

**webbrowser**
Easy-to-use controller for Web browsers.

**winreg (Windows)**
Routines and objects for manipulating the Windows registry.

Indices and tables:
What’s New In Python 3.6

Editors: Elvis Pranskevichus <elvis@magic.io>, Yury Selivanov <yury@magic.io>

This article explains the new features in Python 3.6, compared to 3.5. Python 3.6 was released on December 23, 2016. For full details, see the changelog.

See also: PEP 494 - Python 3.6 Release Schedule
Summary – Release highlights

New syntax features:

- **PEP 498**, formatted string literals.
- **PEP 515**, underscores in numeric literals.
- **PEP 526**, syntax for variable annotations.
- **PEP 525**, asynchronous generators.
- **PEP 530**: asynchronous comprehensions.

New library modules:

- **secrets**: **PEP 506** – Adding A Secrets Module To The Standard Library.

CPython implementation improvements:

- The **dict** type has been reimplemented to use a more compact representation based on a proposal by Raymond Hettinger and similar to the **PyPy dict implementation**. This resulted in dictionaries using 20% to 25% less memory when compared to Python 3.5.
- Customization of class creation has been simplified with the **new protocol**.
- The class attribute definition order is now preserved.
- The order of elements in **kwargs** now corresponds to the order in which keyword arguments were passed to the function.
- DTrace and SystemTap **probing support** has been added.
- The new **PYTHONMALLOC** environment variable can now be used to debug the interpreter memory allocation and access errors.

Significant improvements in the standard library:
- The *asyncio* module has received new features, significant usability and performance improvements, and a fair amount of bug fixes. Starting with Python 3.6 the *asyncio* module is no longer provisional and its API is considered stable.
- A new file system path protocol has been implemented to support path-like objects. All standard library functions operating on paths have been updated to work with the new protocol.
- The *datetime* module has gained support for Local Time Disambiguation.
- The *typing* module received a number of improvements.
- The *tracemalloc* module has been significantly reworked and is now used to provide better output for *ResourceWarning* as well as provide better diagnostics for memory allocation errors. See the PYTHONMALLOC section for more information.

Security improvements:

- The new *secrets* module has been added to simplify the generation of cryptographically strong pseudo-random numbers suitable for managing secrets such as account authentication, tokens, and similar.
- On Linux, *os.urandom()* now blocks until the system urandom entropy pool is initialized to increase the security. See the PEP 524 for the rationale.
- The *hashlib* and *ssl* modules now support OpenSSL 1.1.0.
- The default settings and feature set of the *ssl* module have been improved.
- The *hashlib* module received support for the BLAKE2, SHA-3 and SHAKE hash algorithms and the *scrypt()* key derivation function.

Windows improvements:

- PEP 528 and PEP 529, Windows filesystem and console
The `py.exe` launcher, when used interactively, no longer prefers Python 2 over Python 3 when the user doesn’t specify a version (via command line arguments or a config file). Handling of shebang lines remains unchanged - “python” refers to Python 2 in that case.

`python.exe` and `pythonw.exe` have been marked as long-path aware, which means that the 260 character path limit may no longer apply. See removing the MAX_PATH limitation for details.

A `.pth` file can be added to force isolated mode and fully specify all search paths to avoid registry and environment lookup. See the documentation for more information.

A `python36.zip` file now works as a landmark to infer `PYTHONHOME`. See the documentation for more information.
New Features

PEP 498: Formatted string literals

**PEP 498** introduces a new kind of string literals: *f-strings*, or *formatted string literals*.

Formatted string literals are prefixed with `f` and are similar to the format strings accepted by `str.format()`. They contain replacement fields surrounded by curly braces. The replacement fields are expressions, which are evaluated at run time, and then formatted using the `format()` protocol:

```python
>>> name = "Fred"
>>> f"He said his name is {name}."
'He said his name is Fred.'
>>> width = 10
>>> precision = 4
>>> value = decimal.Decimal("12.34567")
>>> f"result: {value:>{width}.{precision}}"  # nested
'result: 12.35'
```

See also:

**PEP 498** – *Literal String Interpolation.*
PEP written and implemented by Eric V. Smith.

*Feature documentation.*

PEP 526: Syntax for variable annotations

**PEP 484** introduced the standard for type annotations of function
parameters, a.k.a. type hints. This PEP adds syntax to Python for annotating the types of variables including class variables and instance variables:

```python
primes: List[int] = []
captain: str  # Note: no initial value!
class Starship:
    stats: Dict[str, int] = {}
```

Just as for function annotations, the Python interpreter does not attach any particular meaning to variable annotations and only stores them in the `__annotations__` attribute of a class or module.

In contrast to variable declarations in statically typed languages, the goal of annotation syntax is to provide an easy way to specify structured type metadata for third party tools and libraries via the abstract syntax tree and the `__annotations__` attribute.

See also:

**PEP 526 – Syntax for variable annotations.**

Tools that use or will use the new syntax: `mypy`, `pytype`, PyCharm, etc.

**PEP 515: Underscores in Numeric Literals**

**PEP 515** adds the ability to use underscores in numeric literals for
improved readability. For example:

```python
>>> 1_000_000_000_000_000
1000000000000000
>>> 0x_FF_FF_FF_FF
4294967295
```

Single underscores are allowed between digits and after any base specifier. Leading, trailing, or multiple underscores in a row are not allowed.

The string formatting language also now has support for the `_` option to signal the use of an underscore for a thousands separator for floating point presentation types and for integer presentation type `'d'`. For integer presentation types `'b'`, `'o'`, `'x'`, and `'X'`, underscores will be inserted every 4 digits:

```python
>>> '{:_}'.format(1000000)
'1_000_000'
>>> '{:_x}'.format(0xFFFFFFFF)
'ffff_ffff'
```

See also:

**PEP 515 – Underscores in Numeric Literals**
PEP written by Georg Brandl and Serhiy Storchaka.

**PEP 525: Asynchronous Generators**

PEP 492 introduced support for native coroutines and `async / await` syntax to Python 3.5. A notable limitation of the Python 3.5 implementation is that it was not possible to use `await` and `yield` in the same function body. In Python 3.6 this restriction has been lifted,
making it possible to define *asynchronous generators*:

```python
async def ticker(delay, to):
    """Yield numbers from 0 to *to* every *delay* seconds.""
    for i in range(to):
        yield i
    await asyncio.sleep(delay)
```

The new syntax allows for faster and more concise code.

See also:

**PEP 525** – *Asynchronous Generators*

PEP written and implemented by Yury Selivanov.

**PEP 530: Asynchronous Comprehensions**

**PEP 530** adds support for using `async for` in list, set, dict comprehensions and generator expressions:

```python
result = [i async for i in aiter() if i % 2]
```

Additionally, `await` expressions are supported in all kinds of comprehensions:

```python
result = [await fun() for fun in funcs if await condition]
```

See also:

**PEP 530** – *Asynchronous Comprehensions*

PEP written and implemented by Yury Selivanov.
PEP 487: Simpler customization of class creation

It is now possible to customize subclass creation without using a metaclass. The new `__init_subclass__` classmethod will be called on the base class whenever a new subclass is created:

```python
class PluginBase:
    subclasses = []

    def __init_subclass__(cls, **kwargs):
        super().__init_subclass__(**kwargs)
        cls.subclasses.append(cls)

class Plugin1(PluginBase):
    pass

class Plugin2(PluginBase):
    pass
```

In order to allow zero-argument `super()` calls to work correctly from `__init_subclass__()` implementations, custom metaclasses must ensure that the new `__classcell__` namespace entry is propagated to `type.__new__` (as described in Creating the class object).

See also:

**PEP 487 – Simpler customization of class creation**

PEP written and implemented by Martin Teichmann.

Feature documentation

PEP 487: Descriptor Protocol Enhancements
PEP 487 extends the descriptor protocol to include the new optional __set_name__() method. Whenever a new class is defined, the new method will be called on all descriptors included in the definition, providing them with a reference to the class being defined and the name given to the descriptor within the class namespace. In other words, instances of descriptors can now know the attribute name of the descriptor in the owner class:

```python
class IntField:
    def __get__(self, instance, owner):
        return instance.__dict__[self.name]

    def __set__(self, instance, value):
        if not isinstance(value, int):
            raise ValueError(f'expecting integer in instance.__dict__[self.name] = value

    # this is the new initializer:
    def __set_name__(self, owner, name):
        self.name = name

class Model:
    int_field = IntField()```

See also:

**PEP 487 – Simpler customization of class creation**

PEP written and implemented by Martin Teichmann.

**Feature documentation**

PEP 519: Adding a file system path protocol
File system paths have historically been represented as `str` or `bytes` objects. This has led to people who write code which operate on file system paths to assume that such objects are only one of those two types (an `int` representing a file descriptor does not count as that is not a file path). Unfortunately that assumption prevents alternative object representations of file system paths like `pathlib` from working with pre-existing code, including Python's standard library.

To fix this situation, a new interface represented by `os.PathLike` has been defined. By implementing the `__fspath__()` method, an object signals that it represents a path. An object can then provide a low-level representation of a file system path as a `str` or `bytes` object. This means an object is considered path-like if it implements `os.PathLike` or is a `str` or `bytes` object which represents a file system path. Code can use `os.fspath()`, `os.fsdecode()`, or `os.fsencode()` to explicitly get a `str` and/or `bytes` representation of a path-like object.

The built-in `open()` function has been updated to accept `os.PathLike` objects, as have all relevant functions in the `os` and `os.path` modules, and most other functions and classes in the standard library. The `os.DirEntry` class and relevant classes in `pathlib` have also been updated to implement `os.PathLike`.

The hope is that updating the fundamental functions for operating on file system paths will lead to third-party code to implicitly support all path-like objects without any code changes, or at least very minimal ones (e.g. calling `os.fspath()` at the beginning of code before operating on a path-like object).

Here are some examples of how the new interface allows for `pathlib.Path` to be used more easily and transparently with pre-
existing code:

```python
>>> import pathlib
>>> with open(pathlib.Path("README")) as f:
...     contents = f.read()
...
>>> import os.path
>>> os.path.splitext(pathlib.Path("some_file.txt"))
('some_file', '.txt')
>>> os.path.join("/a/b", pathlib.Path("c"))
'/a/b/c'
>>> import os
>>> os.fspath(pathlib.Path("some_file.txt"))
'some_file.txt'
```

(Implemented by Brett Cannon, Ethan Furman, Dusty Phillips, and Jelle Zijlstra.)

See also:

**PEP 519** – Adding a file system path protocol

PEP written by Brett Cannon and Koos Zevenhoven.

**PEP 495**: Local Time Disambiguation

In most world locations, there have been and will be times when local clocks are moved back. In those times, intervals are introduced in which local clocks show the same time twice in the same day. In these situations, the information displayed on a local clock (or stored in a Python datetime instance) is insufficient to identify a particular moment in time.

**PEP 495** adds the new `fold` attribute to instances of `datetime.datetime` and `datetime.time` classes to differentiate
between two moments in time for which local times are the same:

```python
>>> u0 = datetime(2016, 11, 6, 4, tzinfo=timezone.utc)
>>> for i in range(4):
...    u = u0 + i*HOUR
...    t = u.astimezone(Eastern)
...    print(u.time(), 'UTC =', t.time(), t.tzname(),
...         04:00:00 UTC = 00:00:00 EDT 0
05:00:00 UTC = 01:00:00 EDT 0
06:00:00 UTC = 01:00:00 EST 1
07:00:00 UTC = 02:00:00 EST 0
```

The values of the `fold` attribute have the value 0 for all instances except those that represent the second (chronologically) moment in time in an ambiguous case.

See also:

**PEP 495 – Local Time Disambiguation**

PEP written by Alexander Belopolsky and Tim Peters, implementation by Alexander Belopolsky.

**PEP 529: Change Windows filesystem encoding to UTF-8**

Representing filesystem paths is best performed with `str` (Unicode) rather than bytes. However, there are some situations where using bytes is sufficient and correct.

Prior to Python 3.6, data loss could result when using bytes paths on Windows. With this change, using bytes to represent paths is now supported on Windows, provided those bytes are encoded with the
encoding returned by `sys.getfilesystemencoding()`, which now defaults to 'utf-8'.

Applications that do not use `str` to represent paths should use `os.fsencode()` and `os.fsdecode()` to ensure their bytes are correctly encoded. To revert to the previous behaviour, set `PYTHONLEGACYWINDOWSFSENCODING` or call `sys._enablelegacywindowsfsencoding()`.

See [PEP 529](https://www.python.org/dev/peps/pep-0529/) for more information and discussion of code modifications that may be required.

**PEP 528: Change Windows console encoding to UTF-8**

The default console on Windows will now accept all Unicode characters and provide correctly read `str` objects to Python code. `sys.stdin`, `sys.stdout` and `sys.stderr` now default to utf-8 encoding.

This change only applies when using an interactive console, and not when redirecting files or pipes. To revert to the previous behaviour for interactive console use, set `PYTHONLEGACYWINDOWSSTDIO`.

**See also:**

[PEP 528 – Change Windows console encoding to UTF-8](https://www.python.org/dev/peps/pep-0528/)

PEP written and implemented by Steve Dower.

**PEP 520: Preserving Class Attribute Definition Order**
Attributes in a class definition body have a natural ordering: the same order in which the names appear in the source. This order is now preserved in the new class's `__dict__` attribute.

Also, the effective default class execution namespace (returned from `type.__prepare__()`) is now an insertion-order-preserving mapping.

See also:

**PEP 520 – Preserving Class Attribute Definition Order**
PEP written and implemented by Eric Snow.

**PEP 468: Preserving Keyword Argument Order**

**kwargs in a function signature is now guaranteed to be an insertion-order-preserving mapping.

See also:

**PEP 468 – Preserving Keyword Argument Order**
PEP written and implemented by Eric Snow.

**New dict implementation**

The `dict` type now uses a “compact” representation based on a proposal by Raymond Hettinger which was first implemented by PyPy. The memory usage of the new `dict()` is between 20% and 25% smaller compared to Python 3.5.

The order-preserving aspect of this new implementation is considered an implementation detail and should not be relied upon (this may change in the future, but it is desired to have this new dict
implementation in the language for a few releases before changing the language spec to mandate order-preserving semantics for all current and future Python implementations; this also helps preserve backwards-compatibility with older versions of the language where random iteration order is still in effect, e.g. Python 3.5).

(Contributed by INADA Naoki in bpo-27350. Idea originally suggested by Raymond Hettinger.)

PEP 523: Adding a frame evaluation API to CPython

While Python provides extensive support to customize how code executes, one place it has not done so is in the evaluation of frame objects. If you wanted some way to intercept frame evaluation in Python there really wasn’t any way without directly manipulating function pointers for defined functions.

PEP 523 changes this by providing an API to make frame evaluation pluggable at the C level. This will allow for tools such as debuggers and JITs to intercept frame evaluation before the execution of Python code begins. This enables the use of alternative evaluation implementations for Python code, tracking frame evaluation, etc.

This API is not part of the limited C API and is marked as private to signal that usage of this API is expected to be limited and only applicable to very select, low-level use-cases. Semantics of the API will change with Python as necessary.

See also:

PEP 523 – Adding a frame evaluation API to CPython
PEP written by Brett Cannon and Dino Viehland.
The new `PYTHONMALLOC` environment variable allows setting the Python memory allocators and installing debug hooks.

It is now possible to install debug hooks on Python memory allocators on Python compiled in release mode using `PYTHONMALLOC=debug`. Effects of debug hooks:

- Newly allocated memory is filled with the byte `0xCB`
- Freed memory is filled with the byte `0xDB`
- Detect violations of the Python memory allocator API. For example, `PyObject_Free()` called on a memory block allocated by `PyMem_Malloc()`.
- Detect writes before the start of a buffer (buffer underflows)
- Detect writes after the end of a buffer (buffer overflows)
- Check that the GIL is held when allocator functions of `PYMEM_DOMAIN_OBJ` (ex: `PyObject_Malloc()`) and `PYMEM_DOMAIN_MEM` (ex: `PyMem_Malloc()`) domains are called.

Checking if the GIL is held is also a new feature of Python 3.6.

See the `PyMem_SetupDebugHooks()` function for debug hooks on Python memory allocators.

It is now also possible to force the usage of the `malloc()` allocator of the C library for all Python memory allocations using `PYTHONMALLOC=malloc`. This is helpful when using external memory debuggers like Valgrind on a Python compiled in release mode.

On error, the debug hooks on Python memory allocators now use the
tracemalloc module to get the traceback where a memory block was allocated.

Example of fatal error on buffer overflow using python3.6 -X tracemalloc=5 (store 5 frames in traces):

```
Debug memory block at address p=0x7fbcd41666f8: API 4 bytes originally requested
   The 7 pad bytes at p-7 are FORBIDDENBYTE, as expected
   The 8 pad bytes at tail=0x7fbcd41666fc are not all at tail+0: 0x02 *** OUCH

   File "unittest/case.py", line 648 in __call__
   File "unittest/suite.py", line 122 in run
   File "unittest/suite.py", line 84 in __call__
```
DTrace and SystemTap probing support

Python can now be built with `--with-dtrace` which enables static markers for the following events in the interpreter:

- function call/return
- garbage collection started/finished
- line of code executed.

This can be used to instrument running interpreters in production, without the need to recompile specific debug builds or providing application-specific profiling/debugging code.

More details in Instrumenting CPython with DTrace and SystemTap.

The current implementation is tested on Linux and macOS. Additional markers may be added in the future.

(Contributed by Łukasz Langa in bpo-21590, based on patches by Jesús Cea Avión, David Malcolm, and Nikhil Benesch.)
Other Language Changes

Some smaller changes made to the core Python language are:

- A `global` or `nonlocal` statement must now textually appear before the first use of the affected name in the same scope. Previously this was a SyntaxWarning.
- It is now possible to set a special method to `None` to indicate that the corresponding operation is not available. For example, if a class sets `__iter__()` to `None`, the class is not iterable. (Contributed by Andrew Barnert and Ivan Levkivskyi in bpo-25958.)
- Long sequences of repeated traceback lines are now abbreviated as "[Previous line repeated {count} more times]" (see traceback for an example). (Contributed by Emanuel Barry in bpo-26823.)
- Import now raises the new exception `ModuleNotFoundError` (subclass of `ImportError`) when it cannot find a module. Code that currently checks for `ImportError` (in try-except) will still work. (Contributed by Eric Snow in bpo-15767.)
- Class methods relying on zero-argument `super()` will now work correctly when called from metaclass methods during class creation. (Contributed by Martin Teichmann in bpo-23722.)
New Modules

secrets

The main purpose of the new secrets module is to provide an obvious way to reliably generate cryptographically strong pseudo-random values suitable for managing secrets, such as account authentication, tokens, and similar.

**Warning:** Note that the pseudo-random generators in the random module should *NOT* be used for security purposes. Use secrets on Python 3.6+ and os.urandom() on Python 3.5 and earlier.

**See also:**

**PEP 506** – Adding A Secrets Module To The Standard Library

PEP written and implemented by Steven D’Aprano.
Improved Modules

array

Exhausted iterators of `array.array` will now stay exhausted even if the iterated array is extended. This is consistent with the behavior of other mutable sequences.

Contributed by Serhiy Storchaka in bpo-26492.

ast

The new `ast.Constant` AST node has been added. It can be used by external AST optimizers for the purposes of constant folding.

Contributed by Victor Stinner in bpo-26146.

asyncio

Starting with Python 3.6 the `asyncio` module is no longer provisional and its API is considered stable.

Notable changes in the `asyncio` module since Python 3.5.0 (all backported to 3.5.x due to the provisional status):

- The `get_event_loop()` function has been changed to always return the currently running loop when called from coroutines and callbacks. (Contributed by Yury Selivanov in bpo-28613.)
- The `ensure_future()` function and all functions that use it, such as `loop.run_until_complete()`, now accept all kinds of `awaitable objects`. (Contributed by Yury Selivanov.)
- New `run_coroutine_threadsafe()` function to submit
coroutines to event loops from other threads. (Contributed by Vincent Michel.)

- New `Transport.is_closing()` method to check if the transport is closing or closed. (Contributed by Yury Selivanov.)
- The `loop.create_server()` method can now accept a list of hosts. (Contributed by Yann Sionneau.)
- New `loop.create_future()` method to create Future objects. This allows alternative event loop implementations, such as `uvloop`, to provide a faster `asyncio.Future` implementation. (Contributed by Yury Selivanov in bpo-27041.)
- New `loop.get_exception_handler()` method to get the current exception handler. (Contributed by Yury Selivanov in bpo-27040.)
- New `StreamReader.readuntil()` method to read data from the stream until a separator bytes sequence appears. (Contributed by Mark Korenberg.)
- The performance of `StreamReader.readexactly()` has been improved. (Contributed by Mark Korenberg in bpo-28370.)
- The `loop.getaddrinfo()` method is optimized to avoid calling the system `getaddrinfo` function if the address is already resolved. (Contributed by A. Jesse Jiryu Davis.)
- The `loop.stop()` method has been changed to stop the loop immediately after the current iteration. Any new callbacks scheduled as a result of the last iteration will be discarded. (Contributed by Guido van Rossum in bpo-25593.)
- `Future.set_exception` will now raise `TypeError` when passed an instance of the `StopIteration` exception. (Contributed by Chris Angelico in bpo-26221.)
- New `loop.connect_accepted_socket()` method to be used by servers that accept connections outside of asyncio, but that use asyncio to handle them. (Contributed by Jim Fulton in bpo-27392.)
- `TCP_NODELAY` flag is now set for all TCP transports by default.
New `loop.shutdown_asyncgens()` to properly close pending asynchronous generators before closing the loop. (Contributed by Yury Selivanov in bpo-28003.)

**Future** and **Task** classes now have an optimized C implementation which makes asyncio code up to 30% faster. (Contributed by Yury Selivanov and INADA Naoki in bpo-26081 and bpo-28544.)

**binascii**

The `b2a_base64()` function now accepts an optional `newline` keyword argument to control whether the newline character is appended to the return value. (Contributed by Victor Stinner in bpo-25357.)

**cmath**

The new `cmath.tau` ($\tau$) constant has been added. (Contributed by Lisa Roach in bpo-12345, see PEP 628 for details.)

New constants: `cmath.inf` and `cmath.nan` to match `math.inf` and `math.nan`, and also `cmath.infj` and `cmath.nanj` to match the format used by complex repr. (Contributed by Mark Dickinson in bpo-23229.)

**collections**

The new **Collection** abstract base class has been added to represent sized iterable container classes. (Contributed by Ivan Levkovskyi, docs by Neil Girdhar in bpo-27598.)
The new `Reversible` abstract base class represents iterable classes that also provide the `__reversed__()` method. (Contributed by Ivan Levkivskyi in bpo-25987.)

The new `AsyncGenerator` abstract base class represents asynchronous generators. (Contributed by Yury Selivanov in bpo-28720.)

The `namedtuple()` function now accepts an optional keyword argument `module`, which, when specified, is used for the `__module__` attribute of the returned named tuple class. (Contributed by Raymond Hettinger in bpo-17941.)

The `verbose` and `rename` arguments for `namedtuple()` are now keyword-only. (Contributed by Raymond Hettinger in bpo-25628.)

Recursive `collections.deque` instances can now be pickled. (Contributed by Serhiy Storchaka in bpo-26482.)

**concurrent.futures**

The `ThreadPoolExecutor` class constructor now accepts an optional `thread_name_prefix` argument to make it possible to customize the names of the threads created by the pool. (Contributed by Gregory P. Smith in bpo-27664.)

**contextlib**

The `contextlib.AbstractContextManager` class has been added to provide an abstract base class for context managers. It provides a sensible default implementation for `__enter__()` which returns `self` and leaves `__exit__()` an abstract method. A matching
class has been added to the typing module as typing.ContextManager. (Contributed by Brett Cannon in bpo-25609.)

datetime

The datetime and time classes have the new fold attribute used to disambiguate local time when necessary. Many functions in the datetime have been updated to support local time disambiguation. See Local Time Disambiguation section for more information. (Contributed by Alexander Belopolsky in bpo-24773.)

The datetime.strptime() and date.strptime() methods now support ISO 8601 date directives %G, %u and %V. (Contributed by Ashley Anderson in bpo-12006.)

The datetime.isoformat() function now accepts an optional timespec argument that specifies the number of additional components of the time value to include. (Contributed by Alessandro Cucci and Alexander Belopolsky in bpo-19475.)

The datetime.combine() now accepts an optional tzinfo argument. (Contributed by Alexander Belopolsky in bpo-27661.)

decimal

New Decimal.as_integer_ratio() method that returns a pair \((n, d)\) of integers that represent the given Decimal instance as a fraction, in lowest terms and with a positive denominator:

```python
>>> Decimal('-3.14').as_integer_ratio()
(-157, 50)
```
distutils

The `default_format` attribute has been removed from `distutils.command.sdist.sdist` and the `formats` attribute defaults to `['gztar']`. Although not anticipated, any code relying on the presence of `default_format` may need to be adapted. See `bpo-27819` for more details.

email

The new email API, enabled via the `policy` keyword to various constructors, is no longer provisional. The `email` documentation has been reorganized and rewritten to focus on the new API, while retaining the old documentation for the legacy API. (Contributed by R. David Murray in `bpo-24277`.)

The `email.mime` classes now all accept an optional `policy` keyword. (Contributed by Berker Peksag in `bpo-27331`.)

The `DecodedGenerator` now supports the `policy` keyword.

There is a new `policy` attribute, `message_factory`, that controls what class is used by default when the parser creates new message objects. For the `email.policy.compat32` policy this is `Message`, for the new policies it is `EmailMessage`. (Contributed by R. David Murray in `bpo-20476`.)

encodings
On Windows, added the 'oem' encoding to use CP_OEMCP, and the 'ansi' alias for the existing 'mbcs' encoding, which uses the CP_ACP code page. (Contributed by Steve Dower in bpo-27959.)

**enum**

Two new enumeration base classes have been added to the `enum` module: `Flag` and `IntFlags`. Both are used to define constants that can be combined using the bitwise operators. (Contributed by Ethan Furman in bpo-23591.)

Many standard library modules have been updated to use the `IntFlags` class for their constants.

The new `enum.auto` value can be used to assign values to enum members automatically:

```python
>>> from enum import Enum, auto
>>> class Color(Enum):
...     red = auto()
...     blue = auto()
...     green = auto()
... >>> list(Color)
[<Color.red: 1>, <Color.blue: 2>, <Color.green: 3>]
```

**faulthandler**

On Windows, the `faulthandler` module now installs a handler for Windows exceptions: see `faulthandler.enable()`. (Contributed by Victor Stinner in bpo-23848.)
fileinput

`hook_encoded()` now supports the `errors` argument. (Contributed by Joseph Hackman in bpo-25788.)

hashlib

`hashlib` supports OpenSSL 1.1.0. The minimum recommend version is 1.0.2. (Contributed by Christian Heimes in bpo-26470.)

BLAKE2 hash functions were added to the module. `blake2b()` and `blake2s()` are always available and support the full feature set of BLAKE2. (Contributed by Christian Heimes in bpo-26798 based on code by Dmitry Chestnykh and Samuel Neves. Documentation written by Dmitry Chestnykh.)

The SHA-3 hash functions `sha3_224()`, `sha3_256()`, `sha3_384()`, `sha3_512()`, and SHAKE hash functions `shake_128()` and `shake_256()` were added. (Contributed by Christian Heimes in bpo-16113. Keccak Code Package by Guido Bertoni, Joan Daemen, Michaël Peeters, Gilles Van Assche, and Ronny Van Keer.)

The password-based key derivation function `scrypt()` is now available with OpenSSL 1.1.0 and newer. (Contributed by Christian Heimes in bpo-27928.)

http.client

`HTTPConnection.request()` and `endheaders()` both now support chunked encoding request bodies. (Contributed by Demian
idlelib and IDLE

The idlelib package is being modernized and refactored to make IDLE look and work better and to make the code easier to understand, test, and improve. Part of making IDLE look better, especially on Linux and Mac, is using ttk widgets, mostly in the dialogs. As a result, IDLE no longer runs with tcl/tk 8.4. It now requires tcl/tk 8.5 or 8.6. We recommend running the latest release of either.

‘Modernizing’ includes renaming and consolidation of idlelib modules. The renaming of files with partial uppercase names is similar to the renaming of, for instance, Tkinter and TkFont to tkinter and tkinter.font in 3.0. As a result, imports of idlelib files that worked in 3.5 will usually not work in 3.6. At least a module name change will be needed (see idlelib/README.txt), sometimes more. (Name changes contributed by Al Swiegart and Terry Reedy in bpo-24225. Most idlelib patches since have been and will be part of the process.)

In compensation, the eventual result with be that some idlelib classes will be easier to use, with better APIs and docstrings explaining them. Additional useful information will be added to idlelib when available.

importlib

Import now raises the new exception `ModuleNotFoundError` (subclass of `ImportError`) when it cannot find a module. Code that current checks for `ImportError` (in try-except) will still work. (Contributed by Eric Snow in bpo-15767.)

`importlib.util.LazyLoader` now calls `create_module()` on
the wrapped loader, removing the restriction that `importlib.machinery.BuiltinImporter` and `importlib.machinery.ExtensionFileLoader` couldn’t be used with `importlib.util.LazyLoader`.

`importlib.util.cache_from_source()`, `importlib.util.source_from_cache()`, and `importlib.util.spec_from_file_location()` now accept a path-like object.

**inspect**

The `inspect.signature()` function now reports the implicit .0 parameters generated by the compiler for comprehension and generator expression scopes as if they were positional-only parameters called `implicit0`. (Contributed by Jelle Zijlstra in bpo-19611.)

To reduce code churn when upgrading from Python 2.7 and the legacy `inspect.getargspec()` API, the previously documented deprecation of `inspect.getfullargspec()` has been reversed. While this function is convenient for single/source Python 2/3 code bases, the richer `inspect.signature()` interface remains the recommended approach for new code. (Contributed by Nick Coghlan in bpo-27172)

**json**

`json.load()` and `json.loads()` now support binary input. Encoded JSON should be represented using either UTF-8, UTF-16, or UTF-32. (Contributed by Serhiy Storchaka in bpo-17909.)
logging

The new `WatchedFileHandler.reopenIfNeeded()` method has been added to add the ability to check if the log file needs to be reopened. (Contributed by Marian Horban in bpo-24884.)

math

The tau (τ) constant has been added to the `math` and `cmath` modules. (Contributed by Lisa Roach in bpo-12345, see PEP 628 for details.)

multiprocessing

Proxy Objects returned by `multiprocessing.Manager()` can now be nested. (Contributed by Davin Potts in bpo-6766.)

OS

See the summary of PEP 519 for details on how the `os` and `os.path` modules now support path-like objects.

`scandir()` now supports bytes paths on Windows.

A new `close()` method allows explicitly closing a `scandir()` iterator. The `scandir()` iterator now supports the context manager protocol. If a `scandir()` iterator is neither exhausted nor explicitly closed a `ResourceWarning` will be emitted in its destructor. (Contributed by Serhiy Storchaka in bpo-25994.)

On Linux, `os.urandom()` now blocks until the system urandom
entropy pool is initialized to increase the security. See the PEP 524 for the rationale.

The Linux getrandom() syscall (get random bytes) is now exposed as the new os.getrandom() function. (Contributed by Victor Stinner, part of the PEP 524)

pathlib

`pathlib` now supports path-like objects. (Contributed by Brett Cannon in bpo-27186.)

See the summary of PEP 519 for details.

pdb

The `Pdb` class constructor has a new optional `readrc` argument to control whether `.pdbrc` files should be read.

pickle

Objects that need `__new__` called with keyword arguments can now be pickled using `pickle protocols` older than protocol version 4. Protocol version 4 already supports this case. (Contributed by Serhiy Storchaka in bpo-24164.)

pickletools

`pickletools.dis()` now outputs the implicit memo index for the MEMOIZE opcode. (Contributed by Serhiy Storchaka in bpo-25382.)
**pydoc**

The `pydoc` module has learned to respect the `MANPAGER` environment variable. (Contributed by Matthias Klose in [bpo-8637](https://bugs.python.org/issue8637).)

`help()` and `pydoc` can now list named tuple fields in the order they were defined rather than alphabetically. (Contributed by Raymond Hettinger in [bpo-24879](https://bugs.python.org/issue24879).)

**random**

The new `choices()` function returns a list of elements of specified size from the given population with optional weights. (Contributed by Raymond Hettinger in [bpo-18844](https://bugs.python.org/issue18844).)

**re**

Added support of modifier spans in regular expressions. Examples: `(?i:p)ython` matches 'python' and 'Python', but not 'PYTHON'; `(?i)g(?-i:v)r` matches 'GvR' and 'gvr', but not 'GVR'. (Contributed by Serhiy Storchaka in [bpo-433028](https://bugs.python.org/issue433028).)

Match object groups can be accessed by `__getitem__`, which is equivalent to `group()`. So `mo['name']` is now equivalent to `mo.group('name')`. (Contributed by Eric Smith in [bpo-24454](https://bugs.python.org/issue24454).)

Match objects now support `index-like objects` as group indices. (Contributed by Jeroen Demeyer and Xiang Zhang in [bpo-27177](https://bugs.python.org/issue27177).)

**readline**
Added `set_auto_history()` to enable or disable automatic addition of input to the history list. (Contributed by Tyler Crompton in bpo-26870.)

**rlcompleter**

Private and special attribute names now are omitted unless the prefix starts with underscores. A space or a colon is added after some completed keywords. (Contributed by Serhiy Storchaka in bpo-25011 and bpo-25209.)

**shlex**

The `shlex` has much improved shell compatibility through the new `punctuation_chars` argument to control which characters are treated as punctuation. (Contributed by Vinay Sajip in bpo-1521950.)

**site**

When specifying paths to add to `sys.path` in a `.pth` file, you may now specify file paths on top of directories (e.g. zip files). (Contributed by Wolfgang Langner in bpo-26587).

**sqlite3**

`sqlite3.Cursor.lastrowid` now supports the REPLACE statement. (Contributed by Alex LordThorsen in bpo-16864.)

**socket**
The `ioctl()` function now supports the `SIO_LOOPBACK_FAST_PATH` control code. (Contributed by Daniel Stokes in bpo-26536.)

The `getsockopt()` constants `SO_DOMAIN`, `SO_PROTOCOL`, `SO_PEERSEC`, and `SO_PASSSEC` are now supported. (Contributed by Christian Heimes in bpo-26907.)

The `setsockopt()` now supports the `setsockopt(level, optname, None, optlen: int)` form. (Contributed by Christian Heimes in bpo-27744.)

The socket module now supports the address family `AF_ALG` to interface with Linux Kernel crypto API. `ALG_*`, `SOL_ALG` and `sendmsg_afalg()` were added. (Contributed by Christian Heimes in bpo-27744 with support from Victor Stinner.)

New Linux constants `TCP_USER_TIMEOUT` and `TCP_CONGESTION` were added. (Contributed by Omar Sandoval, issue:26273).

**socketserver**

Servers based on the `socketserver` module, including those defined in `http.server`, `xmlrpc.server` and `wsgiref.simple_server`, now support the context manager protocol. (Contributed by Aviv Palivoda in bpo-26404.)

The `wfile` attribute of `StreamRequestHandler` classes now implements the `io.BufferedIOBase` writable interface. In particular, calling `write()` is now guaranteed to send the data in full. (Contributed by Martin Panter in bpo-26721.)
ssl

ssl supports OpenSSL 1.1.0. The minimum recommend version is 1.0.2. (Contributed by Christian Heimes in bpo-26470.)

3DES has been removed from the default cipher suites and ChaCha20 Poly1305 cipher suites have been added. (Contributed by Christian Heimes in bpo-27850 and bpo-27766.)

SSLContext has better default configuration for options and ciphers. (Contributed by Christian Heimes in bpo-28043.)

SSL session can be copied from one client-side connection to another with the new SSLSession class. TLS session resumption can speed up the initial handshake, reduce latency and improve performance (Contributed by Christian Heimes in bpo-19500 based on a draft by Alex Warhawk.)

The new get_ciphers() method can be used to get a list of enabled ciphers in order of cipher priority.

All constants and flags have been converted to IntEnum and IntFlags. (Contributed by Christian Heimes in bpo-28025.)

Server and client-side specific TLS protocols for SSLContext were added. (Contributed by Christian Heimes in bpo-28085.)

statistics

A new harmonic_mean() function has been added. (Contributed by Steven D'Aprano in bpo-27181.)
struct

struct now supports IEEE 754 half-precision floats via the 'e' format specifier. (Contributed by Eli Stevens, Mark Dickinson in bpo-11734.)

subprocess

subprocess.Popen destructor now emits a ResourceWarning warning if the child process is still running. Use the context manager protocol (with proc: ...) or explicitly call the wait() method to read the exit status of the child process. (Contributed by Victor Stinner in bpo-26741.)

The subprocess.Popen constructor and all functions that pass arguments through to it now accept encoding and errors arguments. Specifying either of these will enable text mode for the stdin, stdout and stderr streams. (Contributed by Steve Dower in bpo-6135.)

sys

The new getfilesystemencodeerrors() function returns the name of the error mode used to convert between Unicode filenames and bytes filenames. (Contributed by Steve Dower in bpo-27781.)

On Windows the return value of the getwindowsversion() function now includes the platform_version field which contains the accurate major version, minor version and build number of the current operating system, rather than the version that is being emulated for the process (Contributed by Steve Dower in bpo-27932.)
telnetlib

Telnet is now a context manager (contributed by Stéphane Wirtel in bpo-25485).

time

The struct_time attributes tm_gmtoff and tm_zone are now available on all platforms.

timeit

The new Timer.autorange() convenience method has been added to call Timer.timeit() repeatedly so that the total run time is greater or equal to 200 milliseconds. (Contributed by Steven D'Aprano in bpo-6422.)

timeit now warns when there is substantial (4x) variance between best and worst times. (Contributed by Serhiy Storchaka in bpo-23552.)

tkinter

Added methods trace_add(), trace_remove() and trace_info() in the tkinter.Variable class. They replace old methods trace_variable(), trace(), trace_vdelete() and trace_vinfo() that use obsolete Tcl commands and might not work in future versions of Tcl. (Contributed by Serhiy Storchaka in bpo-22115).

traceback
Both the traceback module and the interpreter’s builtin exception display now abbreviate long sequences of repeated lines in tracebacks as shown in the following example:

```python
>>> def f(): f()
...
>>> f()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 1, in f
  File "<stdin>", line 1, in f
  File "<stdin>", line 1, in f
  [Previous line repeated 995 more times]
RecursionError: maximum recursion depth exceeded
```

(Contributed by Emanuel Barry in bpo-26823.)

tracemalloc

The tracemalloc module now supports tracing memory allocations in multiple different address spaces.

The new DomainFilter filter class has been added to filter block traces by their address space (domain).

(Contributed by Victor Stinner in bpo-26588.)

typing

Since the typing module is provisional, all changes introduced in Python 3.6 have also been backported to Python 3.5.x.

The typing module has a much improved support for generic type
aliases. For example `Dict[str, Tuple[S, T]]` is now a valid type annotation. (Contributed by Guido van Rossum in Github #195.)

The `typing.ContextManager` class has been added for representing `contextlib(AbstractContextManager).` (Contributed by Brett Cannon in bpo-25609.)

The `typing.Collection` class has been added for representing `collections.abc.Collection`. (Contributed by Ivan Levkivskyi in bpo-27598.)

The `typing.ClassVar` type construct has been added to mark class variables. As introduced in PEP 526, a variable annotation wrapped in ClassVar indicates that a given attribute is intended to be used as a class variable and should not be set on instances of that class. (Contributed by Ivan Levkivskyi in Github #280.)

A new `TYPE_CHECKING` constant that is assumed to be `True` by the static type chekers, but is `False` at runtime. (Contributed by Guido van Rossum in Github #230.)

A new `NewType()` helper function has been added to create lightweight distinct types for annotations:

```python
from typing import NewType

UserId = NewType('UserId', int)
some_id = UserId(524313)
```

The static type checker will treat the new type as if it were a subclass of the original type. (Contributed by Ivan Levkivskyi in Github #189.)

`unicodedata`
The `unicodedata` module now uses data from Unicode 9.0.0. (Contributed by Benjamin Peterson.)

**unittest.mock**

The `Mock` class has the following improvements:

- Two new methods, `Mock.assert_called()` and `Mock.assert_called_once()` to check if the mock object was called. (Contributed by Amit Saha in bpo-26323.)
- The `Mock.reset_mock()` method now has two optional keyword only arguments: `return_value` and `side_effect`. (Contributed by Kushal Das in bpo-21271.)

**urllib.request**

If a HTTP request has a file or iterable body (other than a bytes object) but no `Content-Length` header, rather than throwing an error, `AbstractHTTPErrorHandler` now falls back to use chunked transfer encoding. (Contributed by Demian Brecht and Rolf Krahl in bpo-12319.)

**urllib.robotparser**

`RobotFileParser` now supports the `Crawl-delay` and `Request-rate` extensions. (Contributed by Nikolay Bogoychev in bpo-16099.)

**venv**

`venv` accepts a new parameter `--prompt`. This parameter provides an alternative prefix for the virtual environment. (Proposed by Łukasz
warnings

A new optional *source* parameter has been added to the `warnings.warn_explicit()` function: the destroyed object which emitted a `ResourceWarning`. A *source* attribute has also been added to `warnings.WarningMessage` (contributed by Victor Stinner in bpo-26568 and bpo-26567).

When a `ResourceWarning` warning is logged, the `tracemalloc` module is now used to try to retrieve the traceback where the destroyed object was allocated.

Example with the script `example.py`:

```python
import warnings

def func():
    return open(__file__)

f = func()
f = None
```

Output of the command `python3.6 -Wd -X tracemalloc=5 example.py`:

```
example.py:7: ResourceWarning: unclosed file <_io.TextIOWrapper ... >
  f = None
Object allocated at (most recent call first):
  File "example.py", lineno 4
    return open(__file__)
  File "example.py", lineno 6
    f = func()
```
The “Object allocated at” traceback is new and is only displayed if `tracemalloc` is tracing Python memory allocations and if the `warnings` module was already imported.

**winreg**

Added the 64-bit integer type `REG_QWORD`. (Contributed by Clement Rouault in *bpo-23026*.)

**winsound**

Allowed keyword arguments to be passed to `Beep`, `MessageBeep`, and `PlaySound` (*bpo-27982*).

**xmlrpc.client**

The `xmlrpc.client` module now supports unmarshalling additional data types used by the Apache XML-RPC implementation for numerics and `None`. (Contributed by Serhiy Storchaka in *bpo-26885*.)

**zipfile**

A new `ZipInfo.from_file()` class method allows making a `ZipInfo` instance from a filesystem file. A new `ZipInfo.is_dir()` method can be used to check if the `ZipInfo` instance represents a directory. (Contributed by Thomas Kluyver in *bpo-26039*.)

The `ZipFile.open()` method can now be used to write data into a ZIP file, as well as for extracting data. (Contributed by Thomas Kluyver
The `compress()` and `decompress()` functions now accept keyword arguments. (Contributed by Aviv Palivoda in bpo-26243 and Xiang Zhang in bpo-16764 respectively.)
Optimizations

- The Python interpreter now uses a 16-bit wordcode instead of bytecode which made a number of opcode optimizations possible. (Contributed by Demur Rumed with input and reviews from Serhiy Storchaka and Victor Stinner in bpo-26647 and bpo-28050.)
- The `asyncio.Future` class now has an optimized C implementation. (Contributed by Yury Selivanov and INADA Naoki in bpo-26081.)
- The `asyncio.Task` class now has an optimized C implementation. (Contributed by Yury Selivanov in bpo-28544.)
- Various implementation improvements in the `typing` module (such as caching of generic types) allow up to 30 times performance improvements and reduced memory footprint.
- The ASCII decoder is now up to 60 times as fast for error handlers `surrogateescape`, `ignore` and `replace` (Contributed by Victor Stinner in bpo-24870).
- The ASCII and the Latin1 encoders are now up to 3 times as fast for the error handler `surrogateescape` (Contributed by Victor Stinner in bpo-25227).
- The UTF-8 encoder is now up to 75 times as fast for error handlers `ignore`, `replace`, `surrogateescape`, `surrogatepass` (Contributed by Victor Stinner in bpo-25267).
- The UTF-8 decoder is now up to 15 times as fast for error handlers `ignore`, `replace` and `surrogateescape` (Contributed by Victor Stinner in bpo-25301).
- `bytes % args` is now up to 2 times faster. (Contributed by Victor Stinner in bpo-25349).
- `bytearray % args` is now between 2.5 and 5 times faster. (Contributed by Victor Stinner in bpo-25399).
- Optimize `bytes.fromhex()` and `bytearray.fromhex()`: they are now between 2x and 3.5x faster. (Contributed by Victor
Optimize `bytes.replace(b'', b'.')` and `bytearray.replace(b'', b'.')`: up to 80% faster. (Contributed by Josh Snider in bpo-26574).

Allocator functions of the `PyMem_Malloc()` domain (`PYMEM_DOMAIN_MEM`) now use the `pymalloc` memory allocator instead of `malloc()` function of the C library. The `pymalloc` allocator is optimized for objects smaller or equal to 512 bytes with a short lifetime, and use `malloc()` for larger memory blocks. (Contributed by Victor Stinner in bpo-26249).

`pickle.load()` and `pickle.loads()` are now up to 10% faster when deserializing many small objects (Contributed by Victor Stinner in bpo-27056).

Passing keyword arguments to a function has an overhead in comparison with passing positional arguments. Now in extension functions implemented with using Argument Clinic this overhead is significantly decreased. (Contributed by Serhiy Storchaka in bpo-27574).

Optimized `glob()` and `iglob()` functions in the `glob` module; they are now about 3–6 times faster. (Contributed by Serhiy Storchaka in bpo-25596).

Optimized globbing in `pathlib` by using `os.scandir()`; it is now about 1.5–4 times faster. (Contributed by Serhiy Storchaka in bpo-26032).

`xml.etree.ElementTree` parsing, iteration and deepcopy performance has been significantly improved. (Contributed by Serhiy Storchaka in bpo-25638, bpo-25873, and bpo-25869.)

Creation of `fractions.Fraction` instances from floats and decimals is now 2 to 3 times faster. (Contributed by Serhiy Storchaka in bpo-25971.)
Build and C API Changes

- Python now requires some C99 support in the toolchain to build. Most notably, Python now uses standard integer types and macros in place of custom macros like PY_LONG_LONG. For more information, see PEP 7 and bpo-17884.
- Cross-compiling CPython with the Android NDK and the Android API level set to 21 (Android 5.0 Lollipop) or greater runs successfully. While Android is not yet a supported platform, the Python test suite runs on the Android emulator with only about 16 tests failures. See the Android meta-issue bpo-26865.
- The --enable-optimizations configure flag has been added. Turning it on will activate expensive optimizations like PGO. (Original patch by Aleksandru Patrascu of Intel in bpo-26359.)
- The GIL must now be held when allocator functions of PYMEM_DOMAIN_OBJ (ex: PyObject_Malloc()) and PYMEM_DOMAIN_MEM (ex: PyMem_Malloc()) domains are called.
- New Py_FinalizeEx() API which indicates if flushing buffered data failed. (Contributed by Martin Panter in bpo-5319.)
- PyArg_ParseTupleAndKeywords() now supports positional-only parameters. Positional-only parameters are defined by empty names. (Contributed by Serhiy Storchaka in bpo-26282.)
- PyTraceback_Print method now abbreviates long sequences of repeated lines as "[Previous line repeated {count} more times]". (Contributed by Emanuel Barry in bpo-26823.)
- The new PyErr_SetImportErrorSubclass() function allows for specifying a subclass of ImportError to raise. (Contributed by Eric Snow in bpo-15767.)
- The new PyErr_ResourceWarning() function can be used to generate a ResourceWarning providing the source of the resource allocation. (Contributed by Victor Stinner in bpo-26567.)
- The new `PyOS_FSPath()` function returns the file system representation of a path-like object. (Contributed by Brett Cannon in bpo-27186.)
- The `PyUnicode_FSCConverter()` and `PyUnicode_FSDecoder()` functions will now accept path-like objects.
Other Improvements

- When `--version` (short form: `-V`) is supplied twice, Python prints `sys.version` for detailed information.

```bash
./python -VV
Python 3.6.0b4+ (3.6:223967b49e49+, Nov 21 2016, 20:55:04) # GCC 4.2.1 Compatible Apple LLVM 8.0.0 (clang-800)
```
Deprecated

New Keywords

`async` and `await` are not recommended to be used as variable, class, function or module names. Introduced by PEP 492 in Python 3.5, they will become proper keywords in Python 3.7. Starting in Python 3.6, the use of `async` or `await` as names will generate a `DeprecationWarning`.

Deprecated Python behavior

Raising the `StopIteration` exception inside a generator will now generate a `DeprecationWarning`, and will trigger a `RuntimeError` in Python 3.7. See PEP 479: Change StopIteration handling inside generators for details.

The `__aiter__()` method is now expected to return an asynchronous iterator directly instead of returning an awaitable as previously. Doing the former will trigger a `DeprecationWarning`. Backward compatibility will be removed in Python 3.7. (Contributed by Yury Selivanov in bpo-27243.)

A backslash-character pair that is not a valid escape sequence now generates a `DeprecationWarning`. Although this will eventually become a `SyntaxError`, that will not be for several Python releases. (Contributed by Emanuel Barry in bpo-27364.)

When performing a relative import, falling back on `__name__` and `__path__` from the calling module when `__spec__` or `__package__` are not defined now raises an `ImportWarning`. 
Deprecated Python modules, functions and methods

asynchat

The `asynchat` has been deprecated in favor of `asyncio`. (Contributed by Mariatta in bpo-25002.)

asyncore

The `asyncore` has been deprecated in favor of `asyncio`. (Contributed by Mariatta in bpo-25002.)

dbm

Unlike other `dbm` implementations, the `dbm.dumb` module creates databases with the `'rw'` mode and allows modifying the database opened with the `'r'` mode. This behavior is now deprecated and will be removed in 3.8. (Contributed by Serhiy Storchaka in bpo-21708.)
distutils

The undocumented `extra_path` argument to the Distribution constructor is now considered deprecated and will raise a warning if set. Support for this parameter will be removed in a future Python release. See bpo-27919 for details.
grp

The support of non-integer arguments in `getgrgid()` has been
deprecated. (Contributed by Serhiy Storchaka in bpo-26129.)

importlib

The `importlib.machinery.SourceFileLoader.load_module()` and `importlib.machinery.SourcelessFileLoader.load_module` methods are now deprecated. They were the only remaining implementations of `importlib.abc.Loader.load_module()` in `importlib` that had not been deprecated in previous versions of Python in favour of `importlib.abc.Loader.exec_module()`.

The `importlib.machinery.WindowsRegistryFinder` class is now deprecated. As of 3.6.0, it is still added to `sys.meta_path` by default (on Windows), but this may change in future releases.

os

Undocumented support of general `bytes-like objects` as paths in `os` functions, `compile()` and similar functions is now deprecated. (Contributed by Serhiy Storchaka in bpo-25791 and bpo-26754.)

re

Support for inline flags (\?letters) in the middle of the regular expression has been deprecated and will be removed in a future Python version. Flags at the start of a regular expression are still allowed. (Contributed by Serhiy Storchaka in bpo-22493.)

ssl
OpenSSL 0.9.8, 1.0.0 and 1.0.1 are deprecated and no longer supported. In the future the ssl module will require at least OpenSSL 1.0.2 or 1.1.0.

SSL-related arguments like certfile, keyfile and check_hostname in ftplib, http.client, imaplib, poplib, and smtplib have been deprecated in favor of context. (Contributed by Christian Heimes in bpo-28022.)

A couple of protocols and functions of the ssl module are now deprecated. Some features will no longer be available in future versions of OpenSSL. Other features are deprecated in favor of a different API. (Contributed by Christian Heimes in bpo-28022 and bpo-26470.)

tkinter

The tkinter.tix module is now deprecated. tkinter users should use tkinter.ttk instead.

venv

The pyvenv script has been deprecated in favour of python3 -m venv. This prevents confusion as to what Python interpreter pyvenv is connected to and thus what Python interpreter will be used by the virtual environment. (Contributed by Brett Cannon in bpo-25154.)

Deprecated functions and types of the C API

Undocumented functions PyUnicode_AsEncodedObject(), PyUnicode_AsDecodedObject(),
PyUnicode_AsEncodedUnicode() and PyUnicode_AsDecodedUnicode() are deprecated now. Use the generic codec based API instead.

**Deprecated Build Options**

The `--with-system-ffi` configure flag is now on by default on non-macos UNIX platforms. It may be disabled by using `--without-system-ffi`, but using the flag is deprecated and will not be accepted in Python 3.7. macOS is unaffected by this change. Note that many OS distributors already use the `--with-system-ffi` flag when building their system Python.
Removed

API and Feature Removals

- Unknown escapes consisting of '\' and an ASCII letter in regular expressions will now cause an error. In replacement templates for `re.sub()` they are still allowed, but deprecated. The `re.LOCALE` flag can now only be used with binary patterns.
- `inspect.getmoduleinfo()` was removed (was deprecated since CPython 3.3). `inspect.getmodulename()` should be used for obtaining the module name for a given path. (Contributed by Yury Selivanov in bpo-13248.)
- `traceback.Ignore` class and `traceback.usage`, `traceback.modname`, `traceback.fullmodname`, `traceback.find_lines_from_code`, `traceback.find_lines`, `traceback.find_strings`, `traceback.find_executable_lines` methods were removed from the `traceback` module. They were undocumented methods deprecated since Python 3.2 and equivalent functionality is available from private methods.
- The `tk_menuBar()` and `tk_bindForTraversal()` dummy methods in `tkinter` widget classes were removed (corresponding Tk commands were obsolete since Tk 4.0).
- The `open()` method of the `zipfile.ZipFile` class no longer supports the 'U' mode (was deprecated since Python 3.4). Use `io.TextIOWrapper` for reading compressed text files in universal newlines mode.
- The undocumented `IN`, `CDROM`, `DLFCN`, `TYPES`, `CDIO`, and `STROPTS` modules have been removed. They had been available in the platform specific `Lib/plat-*` directories, but were chronically out of date, inconsistently available across platforms, and unmaintained. The script that created these modules is still
available in the source distribution at `Tools/scripts/h2py.py`.

- The deprecated `asynchat.fifo` class has been removed.
Porting to Python 3.6

This section lists previously described changes and other bugfixes that may require changes to your code.

Changes in ‘python’ Command Behavior

- The output of a special Python build with defined `COUNT_ALLOCS`, `SHOW_ALLOC_COUNT` or `SHOW_TRACK_COUNT` macros is now off by default. It can be re-enabled using the `-X showallococount` option. It now outputs to `stderr` instead of `stdout`. (Contributed by Serhiy Storchaka in bpo-23034.)

Changes in the Python API

- `open()` will no longer allow combining the `'U'` mode flag with `'+` `. (Contributed by Jeff Balogh and John O'Connor in bpo-2091.)

- `sqlite3` no longer implicitly commits an open transaction before DDL statements.

- On Linux, `os.urandom()` now blocks until the system urandom entropy pool is initialized to increase the security.

- When `importlib.abc.Loader.exec_module()` is defined, `importlib.abc.Loader.create_module()` must also be defined.

- `PyErr_SetImportError()` now sets `TypeError` when its `msg` argument is not set. Previously only `NULL` was returned.
The format of the `co_lnotab` attribute of code objects changed to support a negative line number delta. By default, Python does not emit bytecode with a negative line number delta. Functions using `frame.f_lineno`, `PyFrame_GetLineNumber()` or `PyCode_Addr2Line()` are not affected. Functions directly decoding `co_lnotab` should be updated to use a signed 8-bit integer type for the line number delta, but this is only required to support applications using a negative line number delta. See `Objects/lnotab_notes.txt` for the `co_lnotab` format and how to decode it, and see the PEP 511 for the rationale.

The functions in the `compileall` module now return booleans instead of 1 or 0 to represent success or failure, respectively. Thanks to booleans being a subclass of integers, this should only be an issue if you were doing identity checks for 1 or 0. See bpo-25768.

Reading the port attribute of `urlib.parse.urlsplit()` and `urlparse()` results now raises `ValueError` for out-of-range values, rather than returning `None`. See bpo-20059.

The `imp` module now raises a `DeprecationWarning` instead of `PendingDeprecationWarning`.

The following modules have had missing APIs added to their `__all__` attributes to match the documented APIs: `calendar`, `cgi`, `csv`, `ElementTree`, `enum`, `fileinput`, `ftplib`, `logging`, `mailbox`, `mimetypes`, `optparse`, `plistlib`, `smtplib`, `subprocess`, `tarfile`, `threading` and `wave`. This means they will export new symbols when `import *` is used. (Contributed by Joel Taddei and Jacek Kołodziej in bpo-23883.)
When performing a relative import, if __package__ does not compare equal to __spec__.parent then ImportWarning is raised. (Contributed by Brett Cannon in bpo-25791.)

When a relative import is performed and no parent package is known, then ImportError will be raised. Previously, SystemError could be raised. (Contributed by Brett Cannon in bpo-18018.)

Servers based on the socketserver module, including those defined in http.server, xmlrpc.server and wsgiref.simple_server, now only catch exceptions derived from Exception. Therefore if a request handler raises an exception like SystemExit or KeyboardInterrupt, handle_error() is no longer called, and the exception will stop a single-threaded server. (Contributed by Martin Panter in bpo-23430.)

spwd.getspnam() now raises a PermissionError instead of KeyError if the user doesn't have privileges.

The socket.socket.close() method now raises an exception if an error (e.g. EBADF) was reported by the underlying system call. (Contributed by Martin Panter in bpo-26685.)

The decode_data argument for the smtpd.SMTPChannel and smtpd.SMTPServer constructors is now False by default. This means that the argument passed to process_message() is now a bytes object by default, and process_message() will be passed keyword arguments. Code that has already been updated in accordance with the deprecation warning generated by 3.5 will not be affected.
All optional arguments of the `dump()`, `dumps()`, `load()` and `loads()` functions and `JSONEncoder` and `JSONDecoder` class constructors in the `json` module are now keyword-only. (Contributed by Serhiy Storchaka in bpo-18726.)

Subclasses of `type` which don’t override `type.__new__` may no longer use the one-argument form to get the type of an object.

As part of PEP 487, the handling of keyword arguments passed to `type` (other than the metaclass hint, `metaclass`) is now consistently delegated to `object.__init_subclass__()`. This means that `type.__new__()` and `type.__init__()` both now accept arbitrary keyword arguments, but `object.__init_subclass__()` (which is called from `type.__new__()`) will reject them by default. Custom metaclasses accepting additional keyword arguments will need to adjust their calls to `type.__new__()` (whether direct or via `super`) accordingly.

In `distutils.command.sdist.sdist`, the `default_format` attribute has been removed and is no longer honored. Instead, the gzipped tarfile format is the default on all platforms and no platform-specific selection is made. In environments where distributions are built on Windows and zip distributions are required, configure the project with a `setup.cfg` file containing the following:

```
[sdist]
formats=zip
```

This behavior has also been backported to earlier Python versions by Setuptools 26.0.0.
In the `urllib.request` module and the `http.client.HTTPConnection.request()` method, if no Content-Length header field has been specified and the request body is a file object, it is now sent with HTTP 1.1 chunked encoding. If a file object has to be sent to a HTTP 1.0 server, the Content-Length value now has to be specified by the caller. (Contributed by Demian Brecht and Rolf Krahl with tweaks from Martin Panter in bpo-12319.)

The `DictReader` now returns rows of type `OrderedDict`. (Contributed by Steve Holden in bpo-27842.)

The `crypt.METHOD_CRYPT` will no longer be added to `crypt.methods` if unsupported by the platform. (Contributed by Victor Stinner in bpo-25287.)

The `verbose` and `rename` arguments for `namedtuple()` are now keyword-only. (Contributed by Raymond Hettinger in bpo-25628.)

On Linux, `ctypes.util.find_library()` now looks in `LD_LIBRARY_PATH` for shared libraries. (Contributed by Vinay Sajip in bpo-9998.)

The `imaplib.IMAP4` class now handles flags containing the `'[]'` character in messages sent from the server to improve real-world compatibility. (Contributed by Lita Cho in bpo-21815.)

The `mmap.write()` function now returns the number of bytes written like other write methods. (Contributed by Jakub Stasiak in bpo-26335.)

The `pkgutil.iter_modules()` and `pkgutil.walk_packages()` functions now return
ModuleInfo named tuples. (Contributed by Ramchandra Apte in bpo-17211.)

- `re.sub()` now raises an error for invalid numerical group references in replacement templates even if the pattern is not found in the string. The error message for invalid group references now includes the group index and the position of the reference. (Contributed by SilentGhost, Serhiy Storchaka in bpo-25953.)

- `zipfile.ZipFile` will now raise `NotImplementedError` for unrecognized compression values. Previously a plain `RuntimeError` was raised. Additionally, calling `ZipFile` methods on a closed `ZipFile` or calling the `write()` method on a `ZipFile` created with mode `'r'` will raise a `ValueError`. Previously, a `RuntimeError` was raised in those scenarios.

- when custom metaclasses are combined with zero-argument `super()` or direct references from methods to the implicit `__class__` closure variable, the implicit `__classcell__` namespace entry must now be passed up to `type.__new__` for initialisation. Failing to do so will result in a `DeprecationWarning` in 3.6 and a `RuntimeWarning` in the future.

Changes in the C API

- The `PyMem_Malloc()` allocator family now uses the `pymalloc allocator` rather than the system `malloc()`. Applications calling `PyMem_Malloc()` without holding the GIL can now crash. Set the `PYTHONMALLOC` environment variable to `debug` to validate the usage of memory allocators in your application. See bpo-
Py_Exit() (and the main interpreter) now override the exit status with 120 if flushing buffered data failed. See bpo-5319.

CPython bytecode changes

There have been several major changes to the bytecode in Python 3.6.

- The Python interpreter now uses a 16-bit wordcode instead of bytecode. (Contributed by Demur Rumed with input and reviews from Serhiy Storchaka and Victor Stinner in bpo-26647 and bpo-28050.)
- The new FORMAT_VALUE and BUILD_STRING opcodes as part of the formatted string literal implementation. (Contributed by Eric Smith in bpo-25483 and Serhiy Storchaka in bpo-27078.)
- The new BUILD_CONST_KEY_MAP opcode to optimize the creation of dictionaries with constant keys. (Contributed by Serhiy Storchaka in bpo-27140.)
- The function call opcodes have been heavily reworked for better performance and simpler implementation. The MAKE_FUNCTION, CALL_FUNCTION, CALL_FUNCTION_Kw and BUILD_MAP_UNPACK_WITH_CALL opcodes have been modified, the new CALL_FUNCTION_EX and BUILD_TUPLE_UNPACK_WITH_CALL have been added, and CALL_FUNCTION_VAR, CALL_FUNCTION_VAR_Kw and MAKE_CLOSURE opcodes have been removed. (Contributed by Demur Rumed in bpo-27095, and Serhiy Storchaka in bpo-27213, bpo-28257.)
- The new SETUP_ANNOTATIONS and STORE_ANNOTATION opcodes have been added to support the new variable annotation syntax. (Contributed by Ivan Levkivskyi in bpo-27985.)
Notable changes in Python 3.6.2

New make regen-all build target

To simplify cross-compilation, and to ensure that CPython can reliably be compiled without requiring an existing version of Python to already be available, the autotools-based build system no longer attempts to implicitly recompile generated files based on file modification times.

Instead, a new make regen-all command has been added to force regeneration of these files when desired (e.g. after an initial version of Python has already been built based on the pregenerated versions).

More selective regeneration targets are also defined - see Makefile.pre.in for details.

(Contributed by Victor Stinner in bpo-23404.)

New in version 3.6.2.

Removal of make touch build target

The make touch build target previously used to request implicit regeneration of generated files by updating their modification times has been removed.

It has been replaced by the new make regen-all target.

(Contributed by Victor Stinner in bpo-23404.)

Changed in version 3.6.2.
What’s New In Python 3.5

Editors: Elvis Pranskevichus <elvis@magic.io>, Yury Selivanov <yury@magic.io>

This article explains the new features in Python 3.5, compared to 3.4. Python 3.5 was released on September 13, 2015. See the changelog for a full list of changes.

See also: PEP 478 - Python 3.5 Release Schedule
Summary – Release highlights

New syntax features:

- PEP 492, coroutines with async and await syntax.
- PEP 465, a new matrix multiplication operator: $a \circ b$.
- PEP 448, additional unpacking generalizations.

New library modules:

- typing: PEP 484 – Type Hints.
- zipapp: PEP 441 Improving Python ZIP Application Support.

New built-in features:

- bytes \% args, bytearray \% args: PEP 461 – Adding \% formatting to bytes and bytearray.
- New \texttt{bytes.hex()}, \texttt{bytearray.hex()} and \texttt{memoryview.hex()} methods. (Contributed by Arnon Yaari in \texttt{bpo-9951}).
- memoryview now supports tuple indexing (including multi-dimensional). (Contributed by Antoine Pitrou in \texttt{bpo-23632}).
- Generators have a new \texttt{gi_yieldfrom} attribute, which returns the object being iterated by yield from expressions. (Contributed by Benno Leslie and Yury Selivanov in \texttt{bpo-24450}).
- A new \texttt{RecursionError} exception is now raised when maximum recursion depth is reached. (Contributed by Georg Brandl in \texttt{bpo-19235}).

CPython implementation improvements:

- When the \texttt{LC\_TYPE} locale is the POSIX locale (C locale), \texttt{sys.stdin} and \texttt{sys.stdout} now use the surrogateescape
error handler, instead of the strict error handler. (Contributed by Victor Stinner in bpo-19977.)

- .pyo files are no longer used and have been replaced by a more flexible scheme that includes the optimization level explicitly in .pyc name. (See PEP 488 overview.)
- Built-in and extension modules are now initialized in a multi-phase process, which is similar to how Python modules are loaded. (See PEP 489 overview.)

Significant improvements in the standard library:

- `collections.OrderedDict` is now implemented in C, which makes it 4 to 100 times faster.
- The `ssl` module gained support for Memory BIO, which decouples SSL protocol handling from network IO.
- The new `os.scandir()` function provides a better and significantly faster way of directory traversal.
- `functools.lru_cache()` has been mostly reimplemented in C, yielding much better performance.
- The new `subprocess.run()` function provides a streamlined way to run subprocesses.
- The `traceback` module has been significantly enhanced for improved performance and developer convenience.

Security improvements:

- SSLv3 is now disabled throughout the standard library. It can still be enabled by instantiating a `ssl.SSLContext` manually. (See bpo-22638 for more details; this change was backported to CPython 3.4 and 2.7.)
- HTTP cookie parsing is now stricter, in order to protect against potential injection attacks. (Contributed by Antoine Pitrou in bpo-22796.)
Windows improvements:

- A new installer for Windows has replaced the old MSI. See Using Python on Windows for more information.
- Windows builds now use Microsoft Visual C++ 14.0, and extension modules should use the same.

Please read on for a comprehensive list of user-facing changes, including many other smaller improvements, CPython optimizations, deprecations, and potential porting issues.
New Features

PEP 492 - Coroutines with async and await syntax

PEP 492 greatly improves support for asynchronous programming in Python by adding awaitable objects, coroutine functions, asynchronous iteration, and asynchronous context managers.

Coroutine functions are declared using the new async def syntax:

```python
>>> async def coro():
...    return 'spam'
```

Inside a coroutine function, the new await expression can be used to suspend coroutine execution until the result is available. Any object can be awaited, as long as it implements the awaitable protocol by defining the __await__() method.

PEP 492 also adds async for statement for convenient iteration over asynchronous iterables.

An example of a rudimentary HTTP client written using the new syntax:

```python
import asyncio

async def http_get(domain):
    reader, writer = await asyncio.open_connection(domain)

    writer.write(b'
'.join([
        b'GET / HTTP/1.1',
        b'Host: %b % domain.encode('latin-1'),
        b'Connection: close',
        b'', b''
    ])
```
async for line in reader:
    print('>>>', line)

writer.close()

loop = asyncio.get_event_loop()
try:
    loop.run_until_complete(http_get('example.com'))
finally:
    loop.close()

Similarly to asynchronous iteration, there is a new syntax for asynchronous context managers. The following script:

```python
import asyncio

async def coro(name, lock):
    print('coro {}: waiting for lock'.format(name))
    async with lock:
        print('coro {}: holding the lock'.format(name))
        await asyncio.sleep(1)
        print('coro {}: releasing the lock'.format(name))

loop = asyncio.get_event_loop()
lock = asyncio.Lock()
coros = asyncio.gather(coro(1, lock), coro(2, lock))
try:
    loop.run_until_complete(coros)
finally:
    loop.close()
```

will output:
Note that both `async for` and `async with` can only be used inside a coroutine function declared with `async def`.

Coroutine functions are intended to be run inside a compatible event loop, such as the `asyncio` loop.

**Note:**

*Changed in version 3.5.2:* Starting with CPython 3.5.2, `__aiter__` can directly return asynchronous iterators. Returning an `awaitable` object will result in a `PendingDeprecationWarning`.

See more details in the Asynchronous Iterators documentation section.

**See also:**

- **PEP 492** – Coroutines with async and await syntax
  PEP written and implemented by Yury Selivanov.

PEP 465 - A dedicated infix operator for matrix multiplication

**PEP 465** adds the `@` infix operator for matrix multiplication. Currently, no builtin Python types implement the new operator, however, it can be
implemented by defining __matmul__(), __rmatmul__(), and __imatmul__() for regular, reflected, and in-place matrix multiplication. The semantics of these methods is similar to that of methods defining other infix arithmetic operators.

Matrix multiplication is a notably common operation in many fields of mathematics, science, engineering, and the addition of @ allows writing cleaner code:

\[
S = (H @ beta - r).T @ inv(H @ V @ H.T) @ (H @ beta)
\]

instead of:

\[
S = \text{dot}((\text{dot}(H, beta) - r).T, \\
\text{dot}(\text{inv}(\text{dot}(\text{dot}(H, V), H.T)), \text{dot}(H, beta) - b))
\]

NumPy 1.10 has support for the new operator:

```bash
>>> import numpy

>>> x = numpy.ones(3)
>>> x
array([[ 1.,  1.,  1.]])

>>> m = numpy.eye(3)
>>> m
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])

>>> x @ m
array([[ 1.,  1.,  1.]])
```
**See also:**

**PEP 465** – A dedicated infix operator for matrix multiplication

PEP written by Nathaniel J. Smith; implemented by Benjamin Peterson.

**PEP 448** - Additional Unpacking Generalizations

**PEP 448** extends the allowed uses of the `*` iterable unpacking operator and `**` dictionary unpacking operator. It is now possible to use an arbitrary number of unpackings in function calls:

```python
>>> print(*[1], *[2], 3, *[4, 5])
1 2 3 4 5

>>> def fn(a, b, c, d):
...     print(a, b, c, d)
...

>>> fn(**{'a': 1, 'c': 3}, **{'b': 2, 'd': 4})
1 2 3 4
```

Similarly, tuple, list, set, and dictionary displays allow multiple unpackings (see Expression lists and Dictionary displays):

```python
>>> *range(4), 4
(0, 1, 2, 3, 4)

>>> [*range(4), 4]
[0, 1, 2, 3, 4]

>>> {*range(4), 4, *(5, 6, 7)}
{0, 1, 2, 3, 4, 5, 6, 7}
```
See also:

**PEP 448 – Additional Unpacking Generalizations**
PEP written by Joshua Landau; implemented by Neil Girdhar, Thomas Wouters, and Joshua Landau.

PEP 461 - percent formatting support for bytes and bytearray

**PEP 461** adds support for the % interpolation operator to bytes and bytearray.

While interpolation is usually thought of as a string operation, there are cases where interpolation on bytes or bytearrays makes sense, and the work needed to make up for this missing functionality detracts from the overall readability of the code. This issue is particularly important when dealing with wire format protocols, which are often a mixture of binary and ASCII compatible text.

Examples:

```
>>> b'Hello %b!' % b'World'
b'Hello World'

>>> b'x=%i y=%f' % (1, 2.5)
b'x=1 y=2.500000'
```

Unicode is not allowed for %b, but it is accepted by %a (equivalent of `repr(obj).encode('ascii', 'backslashreplace')`):
>>> b"Hello %b!" % 'World'
>>> b"price: %a % '10€'

Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: %b requires bytes, or an object that implements __bytes__, not 'str'

Note that %s and %r conversion types, although supported, should only be used in codebases that need compatibility with Python 2.

See also:

**PEP 461** – Adding % formatting to bytes and bytearray
  PEP written by Ethan Furman; implemented by Neil Schemenauer and Ethan Furman.

**PEP 484** - Type Hints

Function annotation syntax has been a Python feature since version 3.0 (**PEP 3107**), however the semantics of annotations has been left undefined.

Experience has shown that the majority of function annotation uses were to provide type hints to function parameters and return values. It became evident that it would be beneficial for Python users, if the standard library included the base definitions and tools for type annotations.

**PEP 484** introduces a provisional module to provide these standard definitions and tools, along with some conventions for situations where annotations are not available.
For example, here is a simple function whose argument and return type are declared in the annotations:

```python
def greeting(name: str) -> str:
    return 'Hello ' + name
```

While these annotations are available at runtime through the usual `__annotations__` attribute, no automatic type checking happens at runtime. Instead, it is assumed that a separate off-line type checker (e.g. mypy) will be used for on-demand source code analysis.

The type system supports unions, generic types, and a special type named `Any` which is consistent with (i.e. assignable to and from) all types.

  PEP written by Guido van Rossum, Jukka Lehtosalo, and Łukasz Langa; implemented by Guido van Rossum.
- **PEP 483 – The Theory of Type Hints**
  PEP written by Guido van Rossum

PEP 471 - os.scandir() function – a better and faster directory iterator

PEP 471 adds a new directory iteration function, `os.scandir()`, to the standard library. Additionally, `os.walk()` is now implemented using `scandir`, which makes it 3 to 5 times faster on POSIX systems and 7 to 20 times faster on Windows systems. This is largely achieved
by greatly reducing the number of calls to `os.stat()` required to walk a directory tree.

Additionally, `scandir` returns an iterator, as opposed to returning a list of file names, which improves memory efficiency when iterating over very large directories.

The following example shows a simple use of `os.scandir()` to display all the files (excluding directories) in the given `path` that don't start with `.''. The `entry.is_file()` call will generally not make an additional system call:

```python
for entry in os.scandir(path):
    if not entry.name.startswith('.') and entry.is_file():
        print(entry.name)
```

See also:

**PEP 471** – `os.scandir()` function – a better and faster directory iterator

PEP written and implemented by Ben Hoyt with the help of Victor Stinner.

**PEP 475: Retry system calls failing with EINTR**

An `errno.EINTR` error code is returned whenever a system call, that is waiting for I/O, is interrupted by a signal. Previously, Python would raise `InterruptedError` in such cases. This meant that, when writing a Python application, the developer had two choices:

1. Ignore the `InterruptedError`.
2. Handle the `InterruptedError` and attempt to restart the
interrupted system call at every call site.

The first option makes an application fail intermittently. The second option adds a large amount of boilerplate that makes the code nearly unreadable. Compare:

```python
print("Hello World")
```

and:

```python
while True:
    try:
        print("Hello World")
    break
    except InterruptedError:
        continue
```

**PEP 475** implements automatic retry of system calls on `EINTR`. This removes the burden of dealing with `EINTR` or `InterruptedError` in user code in most situations and makes Python programs, including the standard library, more robust. Note that the system call is only retried if the signal handler does not raise an exception.

Below is a list of functions which are now retried when interrupted by a signal:

- `open()` and `io.open()`;
- functions of the `faulthandler` module;
- `os` functions: `fchdir()`, `fchmod()`, `fchown()`, `fdatasync()`, `fstat()`, `fstatvfs()`, `fsync()`, `ftruncate()`, `mkfifo()`, `mknod()`, `open()`, `posix_fadvise()`, `posix_fallocate()`, `pread()`, `pwrite()`, `read()`, `readv()`, `sendfile()`, `wait3()`, `wait4()`, `wait()`, `waitid()`, `waitpid()`, `write()`,
writev();

- special cases: os.close() and os.dup2() now ignore EINTR errors; the syscall is not retried (see the PEP for the rationale);
- select functions: devpoll.poll(), epoll.poll(), kqueue.control(), poll.poll(), select();
- methods of the socket class: accept(), connect() (except for non-blocking sockets), recv(), recvfrom(), recvmsg(), send(), sendall(), sendmsg(), sendto();
- signal.sigtimedwait() and signal.sigwaitinfo();
- time.sleep().

See also:

**PEP 475** – Retry system calls failing with EINTR

PEP and implementation written by Charles-François Natali and Victor Stinner, with the help of Antoine Pitrou (the French connection).

**PEP 479: Change StopIteration handling inside generators**

The interaction of generators and StopIteration in Python 3.4 and earlier was sometimes surprising, and could conceal obscure bugs. Previously, StopIteration raised accidentally inside a generator function was interpreted as the end of the iteration by the loop construct driving the generator.

**PEP 479** changes the behavior of generators: when a StopIteration exception is raised inside a generator, it is replaced with a RuntimeError before it exits the generator frame. The main goal of this change is to ease debugging in the situation where an unguarded next() call raises StopIteration and causes the
iteration controlled by the generator to terminate silently. This is particularly pernicious in combination with the `yield from` construct.

This is a backwards incompatible change, so to enable the new behavior, a `__future__` import is necessary:

```python
>>> from __future__ import generator_stop

>>> def gen():
>>>     next(iter([]))
>>>     yield

>>> next(gen())
```

```
Traceback (most recent call last):
  File "<stdin>", line 2, in gen
StopIteration
```

The above exception was the direct cause of the following exception:

```
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
RuntimeError: generator raised StopIteration
```

Without a `__future__` import, a `PendingDeprecationWarning` will be raised whenever a `StopIteration` exception is raised inside a generator.

**See also:**

**PEP 479 – Change StopIteration handling inside generators**

PEP written by Chris Angelico and Guido van Rossum. Implemented by Chris Angelico, Yury Selivanov and Nick Coghlan.
PEP 485: A function for testing approximate equality

PEP 485 adds the `math.isclose()` and `cmath.isclose()` functions which tell whether two values are approximately equal or “close” to each other. Whether or not two values are considered close is determined according to given absolute and relative tolerances. Relative tolerance is the maximum allowed difference between `isclose` arguments, relative to the larger absolute value:

```python
>>> import math
>>> a = 5.0
>>> b = 4.99998
>>> math.isclose(a, b, rel_tol=1e-5)
True
>>> math.isclose(a, b, rel_tol=1e-6)
False
```

It is also possible to compare two values using absolute tolerance, which must be a non-negative value:

```python
>>> import math
>>> a = 5.0
>>> b = 4.99998
>>> math.isclose(a, b, abs_tol=0.00003)
True
>>> math.isclose(a, b, abs_tol=0.00001)
False
```

See also:

PEP 485 – A function for testing approximate equality
PEP written by Christopher Barker; implemented by Chris Barker
and Tal Einat.

PEP 486: Make the Python Launcher aware of virtual environments

**PEP 486** makes the Windows launcher (see **PEP 397**) aware of an active virtual environment. When the default interpreter would be used and the `VIRTUAL_ENV` environment variable is set, the interpreter in the virtual environment will be used.

**See also:**

**PEP 486** – Make the Python Launcher aware of virtual environments  
PEP written and implemented by Paul Moore.

PEP 488: Elimination of PYO files

**PEP 488** does away with the concept of `.pyo` files. This means that `.pyc` files represent both unoptimized and optimized bytecode. To prevent the need to constantly regenerate bytecode files, `.pyc` files now have an optional `opt-` tag in their name when the bytecode is optimized. This has the side-effect of no more bytecode file name clashes when running under either `-O` or `-OO`. Consequently, bytecode files generated from `-O`, and `-OO` may now exist simultaneously. `importlib.util.cache_from_source()` has an updated API to help with this change.

**See also:**

**PEP 488** – Elimination of PYO files
PEP 489 updates extension module initialization to take advantage of the two step module loading mechanism introduced by PEP 451 in Python 3.4.

This change brings the import semantics of extension modules that opt-in to using the new mechanism much closer to those of Python source and bytecode modules, including the ability to use any valid identifier as a module name, rather than being restricted to ASCII.
Other Language Changes

Some smaller changes made to the core Python language are:

- Added the "namereplace" error handlers. The "backslashreplace" error handlers now work with decoding and translating. (Contributed by Serhiy Storchaka in bpo-19676 and bpo-22286.)
- The -b option now affects comparisons of bytes with int. (Contributed by Serhiy Storchaka in bpo-23681.)
- New Kazakh kz1048 and Tajik koi8_t codecs. (Contributed by Serhiy Storchaka in bpo-22682 and bpo-22681.)
- Property docstrings are now writable. This is especially useful for collections.namedtuple() docstrings. (Contributed by Berker Peksag in bpo-24064.)
- Circular imports involving relative imports are now supported. (Contributed by Brett Cannon and Antoine Pitrou in bpo-17636.)
New Modules

typing

The new `typing provisional` module provides standard definitions and tools for function type annotations. See [Type Hints](#) for more information.

zipapp

The new `zipapp` module (specified in [PEP 441](#)) provides an API and command line tool for creating executable Python Zip Applications, which were introduced in Python 2.6 in [bpo-1739468](#), but which were not well publicized, either at the time or since.

With the new module, bundling your application is as simple as putting all the files, including a `__main__.py` file, into a directory `myapp` and running:

```
$ python -m zipapp myapp
$ python myapp.pyz
```

The module implementation has been contributed by Paul Moore in [bpo-23491](#).

See also: [PEP 441](#) – Improving Python ZIP Application Support
Improved Modules

argparse

The ArgumentParser class now allows disabling abbreviated usage of long options by setting allow_abbrev to False. (Contributed by Jonathan Paugh, Steven Bethard, paul j3 and Daniel Eriksson in bpo-14910.)

asyncio

Since the asyncio module is provisional, all changes introduced in Python 3.5 have also been backported to Python 3.4.x.

Notable changes in the asyncio module since Python 3.4.0:

- New debugging APIs: loop.set_debug() and loop.get_debug() methods. (Contributed by Victor Stinner.)
- The proactor event loop now supports SSL. (Contributed by Antoine Pitrou and Victor Stinner in bpo-22560.)
- A new loop.is_closed() method to check if the event loop is closed. (Contributed by Victor Stinner in bpo-21326.)
- A new loop.create_task() to conveniently create and schedule a new Task for a coroutine. The create_task method is also used by all asyncio functions that wrap coroutines into tasks, such as asyncio.wait(), asyncio.gather(), etc. (Contributed by Victor Stinner.)
- A new transport.get_write_buffer_limits() method to inquire for high- and low- water limits of the flow control. (Contributed by Victor Stinner.)
- The async() function is deprecated in favor of ensure_future(). (Contributed by Yury Selivanov.)
- New `loop.set_task_factory()` and `loop.get_task_factory()` methods to customize the task factory that `loop.create_task()` method uses. (Contributed by Yury Selivanov.)
- New `Queue.join()` and `Queue.task_done()` queue methods. (Contributed by Victor Stinner.)
- The `JoinableQueue` class was removed, in favor of the `asyncio.Queue` class. (Contributed by Victor Stinner.)

Updates in 3.5.1:

- The `ensure_future()` function and all functions that use it, such as `loop.run_until_complete()`, now accept all kinds of `awaitable objects`. (Contributed by Yury Selivanov.)
- New `run_coroutine_threadsafe()` function to submit coroutines to event loops from other threads. (Contributed by Vincent Michel.)
- New `Transport.is_closing()` method to check if the transport is closing or closed. (Contributed by Yury Selivanov.)
- The `loop.create_server()` method can now accept a list of hosts. (Contributed by Yann Sionneau.)

Updates in 3.5.2:

- New `loop.create_future()` method to create Future objects. This allows alternative event loop implementations, such as `uvloop`, to provide a faster `asyncio.Future` implementation. (Contributed by Yury Selivanov.)
- New `loop.get_exception_handler()` method to get the current exception handler. (Contributed by Yury Selivanov.)
- New `StreamReader.readuntil()` method to read data from the stream until a separator bytes sequence appears. (Contributed by Mark Korenberg.)
- The `loop.create_connection()` and
loop.create_server() methods are optimized to avoid calling the system `getaddrinfo` function if the address is already resolved. (Contributed by A. Jesse Jiryu Davis.)

- The `loop.sock_connect(sock, address)` no longer requires the `address` to be resolved prior to the call. (Contributed by A. Jesse Jiryu Davis.)

bz2

The `BZ2Decompressor.decompress` method now accepts an optional `max_length` argument to limit the maximum size of decompressed data. (Contributed by Nikolaus Rath in bpo-15955.)

cgi

The `FieldStorage` class now supports the context manager protocol. (Contributed by Berker Peksag in bpo-20289.)

cmath

A new function `isclose()` provides a way to test for approximate equality. (Contributed by Chris Barker and Tal Einat in bpo-24270.)

code

The `InteractiveInterpreter.showtraceback()` method now prints the full chained traceback, just like the interactive interpreter. (Contributed by Claudiu Popa in bpo-17442.)

collections
The **OrderedDict** class is now implemented in C, which makes it 4 to 100 times faster. (Contributed by Eric Snow in [bpo-16991](https://www.python.org/dev/peps/pep-0169/).)

```
OrderedDict.items(),              OrderedDict.keys(),
OrderedDict.values() views now support **reversed()** iteration.
(Contributed by Serhiy Storchaka in [bpo-19505](https://www.python.org/dev/peps/pep-0195/).)
```

The **deque** class now defines **index()**, **insert()**, and **copy()**, and supports the `+` and `*` operators. This allows deques to be recognized as a **MutableSequence** and improves their substitutability for lists. (Contributed by Raymond Hettinger in [bpo-23704](https://www.python.org/dev/peps/pep-0237/).)

Docstrings produced by **namedtuple()** can now be updated:

```python
Point = namedtuple('Point', ['x', 'y'])
Point.__doc__ += ': Cartesian coordinate'
Point.x.__doc__ = 'abscissa'
Point.y.__doc__ = 'ordinate'
```

(Contributed by Berker Peksag in [bpo-24064](https://www.python.org/dev/peps/pep-0240/).)

The **UserString** class now implements the **__getnewargs__()**, **__rmod__()**, **casefold()**, **format_map()**, **isprintable()**, and **maketrans()** methods to match the corresponding methods of **str**. (Contributed by Joe Jevnik in [bpo-22189](https://www.python.org/dev/peps/pep-0221/).)

**collections.abc**

The **Sequence.index()** method now accepts **start** and **stop** arguments to match the corresponding methods of **tuple**, **list**, etc. (Contributed by Devin Jeanpierre in [bpo-23086](https://www.python.org/dev/peps/pep-0230/).)
A new `Generator` abstract base class. (Contributed by Stefan Behnel in bpo-24018.)

New `Awaitable`, `Coroutine`, `AsyncIterator`, and `AsyncIterable` abstract base classes. (Contributed by Yury Selivanov in bpo-24184.)

For earlier Python versions, a backport of the new ABCs is available in an external PyPI package.

**compileall**

A new `compileall` option, `-j N`, allows running N workers simultaneously to perform parallel bytecode compilation. The `compile_dir()` function has a corresponding `workers` parameter. (Contributed by Claudiu Popa in bpo-16104.)

Another new option, `-r`, allows controlling the maximum recursion level for subdirectories. (Contributed by Claudiu Popa in bpo-19628.)

The `-q` command line option can now be specified more than once, in which case all output, including errors, will be suppressed. The corresponding `quiet` parameter in `compile_dir()`, `compile_file()`, and `compile_path()` can now accept an integer value indicating the level of output suppression. (Contributed by Thomas Kluyver in bpo-21338.)

**concurrent.futures**

The `Executor.map()` method now accepts a `chunksize` argument to allow batching of tasks to improve performance when `ProcessPoolExecutor()` is used. (Contributed by Dan O'Reilly in
The number of workers in the `ThreadPoolExecutor` constructor is optional now. The default value is 5 times the number of CPUs. (Contributed by Claudiu Popa in bpo-21527.)

`configparser` now provides a way to customize the conversion of values by specifying a dictionary of converters in the `ConfigParser` constructor, or by defining them as methods in `ConfigParser` subclasses. Converters defined in a parser instance are inherited by its section proxies.

Example:

```python
>>> import configparser
>>> conv = {}
>>> conv['list'] = lambda v: [e.strip() for e in v.split()]  # Example converter
>>> cfg = configparser.ConfigParser(converters=conv)
>>> cfg.read_string("...
... list = a b c d e f g
...
")
>>> cfg.get('s', 'list')
'a b c d e f g'
>>> cfg.getlist('s', 'list')
['a', 'b', 'c', 'd', 'e', 'f', 'g']
>>> section = cfg['s']
>>> section.getlist('list')
['a', 'b', 'c', 'd', 'e', 'f', 'g']
```

(Contributed by Łukasz Langa in bpo-18159.)
contextlib

The new `redirect_stderr()` context manager (similar to `redirect_stdout()`) makes it easier for utility scripts to handle inflexible APIs that write their output to `sys.stderr` and don't provide any options to redirect it:

```python
>>> import contextlib, io, logging
>>> f = io.StringIO()
>>> with contextlib.redirect_stderr(f):
...    logging.warning('warning')
...    ...
>>> f.getvalue()
'WARNING:root:warning\n'
```

(Contributed by Berker Peksag in bpo-22389.)

CSV

The `writerow()` method now supports arbitrary iterables, not just sequences. (Contributed by Serhiy Storchaka in bpo-23171.)

curses

The new `update_lines_cols()` function updates the LINES and COLS environment variables. This is useful for detecting manual screen resizing. (Contributed by Arnon Yaari in bpo-4254.)

dbm

dumb.open always creates a new database when the flag has the
value "n". (Contributed by Claudiu Popa in bpo-18039.)

difflib

The charset of HTML documents generated by `HtmlDiff.make_file()` can now be customized by using a new `charset` keyword-only argument. The default charset of HTML document changed from "ISO-8859-1" to "utf-8". (Contributed by Berker Peksag in bpo-2052.)

The `diff_bytes()` function can now compare lists of byte strings. This fixes a regression from Python 2. (Contributed by Terry J. Reedy and Greg Ward in bpo-17445.)

distutils

Both the `build` and `build_ext` commands now accept a `-j` option to enable parallel building of extension modules. (Contributed by Antoine Pitrou in bpo-5309.)

The `distutils` module now supports xz compression, and can be enabled by passing `xztar` as an argument to `bdist --format`. (Contributed by Serhiy Storchaka in bpo-16314.)

doctest

The `DocTestSuite()` function returns an empty `unittest.TestSuite` if `module` contains no docstrings, instead of raising `ValueError`. (Contributed by Glenn Jones in bpo-15916.)

e-mail
A new policy option `Policy.mangle_from_` controls whether or not lines that start with "From " in email bodies are prefixed with a ">" character by generators. The default is True for `compat32` and False for all other policies. (Contributed by Milan Oberkirch in bpo-20098.)

A new `Message.get_content_disposition()` method provides easy access to a canonical value for the `Content-Disposition` header. (Contributed by Abhilash Raj in bpo-21083.)

A new policy option `EmailPolicy.utf8` can be set to True to encode email headers using the UTF-8 charset instead of using encoded words. This allows Messages to be formatted according to RFC 6532 and used with an SMTP server that supports the RFC 6531 SMTPUTF8 extension. (Contributed by R. David Murray in bpo-24211.)

The `mime.text.MIMEText` constructor now accepts a `charset.Charset` instance. (Contributed by Claude Paroz and Berker Peksag in bpo-16324.)

**enum**

The `Enum` callable has a new parameter `start` to specify the initial number of enum values if only `names` are provided:

```python
>>> Animal = enum.Enum('Animal', 'cat dog', start=10)
>>> Animal.cat
<Animal.cat: 10>
>>> Animal.dog
<Animal.dog: 11>
```
(Contributed by Ethan Furman in bpo-21706.)

faulthandler

The `enable()`, `register()`, `dump_traceback()` and `dump_traceback_later()` functions now accept file descriptors in addition to file-like objects. (Contributed by Wei Wu in bpo-23566.)

functools

Most of the `lru_cache()` machinery is now implemented in C, making it significantly faster. (Contributed by Matt Joiner, Alexey Kachayev, and Serhiy Storchaka in bpo-14373.)

glob

The `iglob()` and `glob()` functions now support recursive search in subdirectories, using the "***" pattern. (Contributed by Serhiy Storchaka in bpo-13968.)

gzip

The `mode` argument of the `GzipFile` constructor now accepts "x" to request exclusive creation. (Contributed by Tim Heaney in bpo-19222.)

heapq

Element comparison in `merge()` can now be customized by passing a `key function` in a new optional `key` keyword argument, and a new optional `reverse` keyword argument can be used to reverse element
comparison:

```python
>>> import heapq
>>> a = ['9', '777', '55555']
>>> b = ['88', '6666']
>>> list(heapq.merge(a, b, key=len))
['9', '88', '777', '6666', '55555']
>>> list(heapq.merge(reversed(a), reversed(b), key=len))
['55555', '6666', '777', '88', '9']
```

(Contributed by Raymond Hettinger in bpo-13742.)

http

A new HTTPStatus enum that defines a set of HTTP status codes, reason phrases and long descriptions written in English. (Contributed by Demian Brecht in bpo-21793.)

http.client

HTTPConnection.getresponse() now raises a RemoteDisconnected exception when a remote server connection is closed unexpectedly. Additionally, if a ConnectionError (of which RemoteDisconnected is a subclass) is raised, the client socket is now closed automatically, and will reconnect on the next request:

```python
import http.client
conn = http.client.HTTPConnection('www.python.org')
for retries in range(3):
    try:
        conn.request('GET', '/')
        resp = conn.getresponse()
    except http.client.RemoteDisconnected:
```
(Contributed by Martin Panter in bpo-3566.)

idlelib and IDLE

Since idlelib implements the IDLE shell and editor and is not intended for import by other programs, it gets improvements with every release. See Lib/idlelib/NEWS.txt for a cumulative list of changes since 3.4.0, as well as changes made in future 3.5.x releases. This file is also available from the IDLE Help ➤ About IDLE dialog.

imaplib

The IMAP4 class now supports the context manager protocol. When used in a with statement, the IMAP4 LOGOUT command will be called automatically at the end of the block. (Contributed by Tarek Ziadé and Serhiy Storchaka in bpo-4972.)

The imaplib module now supports RFC 5161 (ENABLE Extension) and RFC 6855 (UTF-8 Support) via the IMAP4.enable() method. A new IMAP4.utf8_enabled attribute tracks whether or not RFC 6855 support is enabled. (Contributed by Milan Oberkirch, R. David Murray, and Maciej Szulik in bpo-21800.)

The imaplib module now automatically encodes non-ASCII string usernames and passwords using UTF-8, as recommended by the RFCs. (Contributed by Milan Oberkirch in bpo-21800.)

imghdr
The `what()` function now recognizes the OpenEXR format (contributed by Martin Vignali and Claudiu Popa in `bpo-20295`), and the WebP format (contributed by Fabrice Aneche and Claudiu Popa in `bpo-20197`).

**importlib**

The `util.LazyLoader` class allows for lazy loading of modules in applications where startup time is important. (Contributed by Brett Cannon in `bpo-17621`.)

The `abc.InspectLoader.source_to_code()` method is now a static method. This makes it easier to initialize a module object with code compiled from a string by running `exec(code, module.__dict__)`. (Contributed by Brett Cannon in `bpo-21156`.)

The new `util.module_from_spec()` function is now the preferred way to create a new module. As opposed to creating a `types.ModuleType` instance directly, this new function will set the various import-controlled attributes based on the passed-in spec object. (Contributed by Brett Cannon in `bpo-20383`.)

**inspect**

Both the `Signature` and `Parameter` classes are now picklable and hashable. (Contributed by Yury Selivanov in `bpo-20726` and `bpo-20334`.)

A new `BoundArguments.apply_defaults()` method provides a way to set default values for missing arguments:

```python
>>> def foo(a, b='ham', *args): pass
```
A new class method `Signature.from_callable()` makes subclassing of `Signature` easier. (Contributed by Yury Selivanov and Eric Snow in bpo-17373.)

The `signature()` function now accepts a `follow_wrapped` optional keyword argument, which, when set to `False`, disables automatic following of `__wrapped__` links. (Contributed by Yury Selivanov in bpo-20691.)

A set of new functions to inspect coroutine functions and coroutine objects has been added: `iscoroutine()`, `iscoroutinefunction()`, `isawaitable()`, `getcoroutinelocals()`, and `getcoroutinestate()`. (Contributed by Yury Selivanov in bpo-24017 and bpo-24400.)

The `stack()`, `trace()`, `getouterframes()`, and `getinnerframes()` functions now return a list of named tuples. (Contributed by Daniel Shahaf in bpo-16808.)

A new `BufferedIOBase.readinto1()` method, that uses at most one call to the underlying raw stream's `RawIOBase.read()` or `RawIOBase.readinto()` methods. (Contributed by Nikolaus Rath in bpo-20578.)
Both the `IPv4Network` and `IPv6Network` classes now accept an `(address, netmask)` tuple argument, so as to easily construct network objects from existing addresses:

```python
>>> import ipaddress
>>> ipaddress.IPv4Network(('127.0.0.0', 8))
IPv4Network('127.0.0.0/8')
>>> ipaddress.IPv4Network(('127.0.0.0', '255.0.0.0'))
IPv4Network('127.0.0.0/8')
```

(Contributed by Peter Moody and Antoine Pitrou in bpo-16531.)

A new `reverse_pointer` attribute for the `IPv4Network` and `IPv6Network` classes returns the name of the reverse DNS PTR record:

```python
>>> import ipaddress
>>> addr = ipaddress.IPv4Address('127.0.0.1')
>>> addr.reverse_pointer
'1.0.0.127.in-addr.arpa'
>>> addr6 = ipaddress.IPv6Address('::1')
>>> addr6.reverse_pointer
'1.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.ip6.arpa'
```

(Contributed by Leon Weber in bpo-20480.)

**json**

The `json.tool` command line interface now preserves the order of keys in JSON objects passed in input. The new `--sort-keys` option
can be used to sort the keys alphabetically. (Contributed by Berker Peksag in bpo-21650.)

JSON decoder now raises `JSONDecodeError` instead of `ValueError` to provide better context information about the error. (Contributed by Serhiy Storchaka in bpo-19361.)

**linecache**

A new `lazycache()` function can be used to capture information about a non-file-based module to permit getting its lines later via `getline()`. This avoids doing I/O until a line is actually needed, without having to carry the module globals around indefinitely. (Contributed by Robert Collins in bpo-17911.)

**locale**

A new `delocalize()` function can be used to convert a string into a normalized number string, taking the `LC_NUMERIC` settings into account:

```python
>>> import locale
>>> locale.setlocale(locale.LC_NUMERIC, 'de_DE.UTF-8')
'de_DE.UTF-8'
>>> locale.delocalize('1.234,56')
'1234.56'
>>> locale.setlocale(locale.LC_NUMERIC, 'en_US.UTF-8')
'en_US.UTF-8'
>>> locale.delocalize('1,234.56')
'1234.56'
```

(Contributed by Cédric Krier in bpo-13918.)
logging

All logging methods (Logger log(), exception(), critical(), debug(), etc.), now accept exception instances as an exc_info argument, in addition to boolean values and exception tuples:

```python
>>> import logging
d>>> try:
...     1/0
... except ZeroDivisionError as ex:
...     logging.error('exception', exc_info=ex)
ERROR:root:exception
```

(Contributed by Yury Selivanov in bpo-20537.)

The handlers.HTTPHandler class now accepts an optional ssl.SSLContext instance to configure SSL settings used in an HTTP connection. (Contributed by Alex Gaynor in bpo-22788.)

The handlers.QueueListener class now takes a respect_handler_level keyword argument which, if set to True, will pass messages to handlers taking handler levels into account. (Contributed by Vinay Sajip.)

Izma

The LZMADecompressor.decompress() method now accepts an optional max_length argument to limit the maximum size of decompressed data. (Contributed by Martin Panter in bpo-15955.)

math
Two new constants have been added to the `math` module: `inf` and `nan`. (Contributed by Mark Dickinson in bpo-23185.)

A new function `isclose()` provides a way to test for approximate equality. (Contributed by Chris Barker and Tal Einat in bpo-24270.)

A new `gcd()` function has been added. The `fractions.gcd()` function is now deprecated. (Contributed by Mark Dickinson and Serhiy Storchaka in bpo-22486.)

**multiprocessing**

`sharedctypes.synchronized()` objects now support the context manager protocol. (Contributed by Charles-François Natali in bpo-21565.)

**operator**

`attrgetter()`, `itemgetter()`, and `methodcaller()` objects now support pickling. (Contributed by Josh Rosenberg and Serhiy Storchaka in bpo-22955.)

New `matmul()` and `imatmul()` functions to perform matrix multiplication. (Contributed by Benjamin Peterson in bpo-21176.)

**OS**

The new `scandir()` function returning an iterator of `DirEntry` objects has been added. If possible, `scandir()` extracts file attributes while scanning a directory, removing the need to perform subsequent system calls to determine file type or attributes, which may
significantly improve performance. (Contributed by Ben Hoyt with the help of Victor Stinner in bpo-22524.)

On Windows, a new `stat_result.st_file_attributes` attribute is now available. It corresponds to the `dwFileAttributes` member of the `BY_HANDLE_FILE_INFORMATION` structure returned by `GetFileInformationByHandle()`. (Contributed by Ben Hoyt in bpo-21719.)

The `urandom()` function now uses the `getrandom()` syscall on Linux 3.17 or newer, and `getentropy()` on OpenBSD 5.6 and newer, removing the need to use `/dev/urandom` and avoiding failures due to potential file descriptor exhaustion. (Contributed by Victor Stinner in bpo-22181.)

New `get_blocking()` and `set_blocking()` functions allow getting and setting a file descriptor's blocking mode (`O_NONBLOCK`). (Contributed by Victor Stinner in bpo-22054.)

The `truncate()` and `ftruncate()` functions are now supported on Windows. (Contributed by Steve Dower in bpo-23668.)

There is a new `os.path.commonpath()` function returning the longest common sub-path of each passed pathname. Unlike the `os.path.commonprefix()` function, it always returns a valid path:

```python
>>> os.path.commonprefix(['/usr/lib', '/usr/local/lib', '/usr/l'])
''
```

(Contributed by Rafik Draoui and Serhiy Storchaka in bpo-10395.)
The new `Path.samefile()` method can be used to check whether the path points to the same file as another path, which can be either another `Path` object, or a string:

```python
>>> import pathlib
>>> p1 = pathlib.Path('/etc/hosts')
>>> p2 = pathlib.Path('/etc/../etc/hosts')
>>> p1.samefile(p2)
True
```

(Contributed by Vajrasky Kok and Antoine Pitrou in bpo-19775.)

The `Path.mkdir()` method now accepts a new optional `exist_ok` argument to match `mkdir -p` and `os.makedirs()` functionality. (Contributed by Berker Peksag in bpo-21539.)

There is a new `Path.expanduser()` method to expand `~` and `~user` prefixes. (Contributed by Serhiy Storchaka and Claudiu Popa in bpo-19776.)

A new `Path.home()` class method can be used to get a `Path` instance representing the user’s home directory. (Contributed by Victor Salgado and Mayank Tripathi in bpo-19777.)

New `Path.write_text()`, `Path.read_text()`, `Path.write_bytes()`, `Path.read_bytes()` methods to simplify read/write operations on files.

The following code snippet will create or rewrite existing file `~/spam42`:
>>> import pathlib
>>> p = pathlib.Path('~/spam42')
>>> p.expanduser().write_text('ham')
3

(Contributed by Christopher Welborn in bpo-20218.)

pickle

Nested objects, such as unbound methods or nested classes, can now be pickled using pickle protocols older than protocol version 4. Protocol version 4 already supports these cases. (Contributed by Serhiy Storchaka in bpo-23611.)

poplib

A new POP3.utf8() command enables RFC 6856 (Internationalized Email) support, if a POP server supports it. (Contributed by Milan OberKirch in bpo-21804.)

re

References and conditional references to groups with fixed length are now allowed in lookbehind assertions:

>>> import re
>>> pat = re.compile(r'(a|b).(?<=\1)c')
>>> pat.match('aac')
<_sre.SRE_Match object; span=(0, 3), match='aac'>
>>> pat.match('bbc')
<_sre.SRE_Match object; span=(0, 3), match='bbc'>
The number of capturing groups in regular expressions is no longer limited to 100. (Contributed by Serhiy Storchaka in bpo-22437.)

The `sub()` and `subn()` functions now replace unmatched groups with empty strings instead of raising an exception. (Contributed by Serhiy Storchaka in bpo-1519638.)

The `re.error` exceptions have new attributes, `msg`, `pattern`, `pos`, `lineno`, and `colno`, that provide better context information about the error:

```python
>>> re.compile("""
... (?x)
... .++
... """
)
Traceback (most recent call last):
... 
sre_constants.error: multiple repeat at position 16
```

(Contributed by Serhiy Storchaka in bpo-22578.)

**readline**

A new `append_history_file()` function can be used to append the specified number of trailing elements in history to the given file. (Contributed by Bruno Cauet in bpo-22940.)

**selectors**

The new `DevpollSelector` supports efficient `/dev/poll` polling
on Solaris. (Contributed by Giampaolo Rodola’ in bpo-18931.)

shutil

The `move()` function now accepts a `copy_function` argument, allowing, for example, the `copy()` function to be used instead of the default `copy2()` if there is a need to ignore file metadata when moving. (Contributed by Claudiu Popa in bpo-19840.)

The `make_archive()` function now supports the *xz* format. (Contributed by Serhiy Storchaka in bpo-5411.)

signal

On Windows, the `set_wakeup_fd()` function now also supports socket handles. (Contributed by Victor Stinner in bpo-22018.)

Various SIG* constants in the `signal` module have been converted into ` Enums`. This allows meaningful names to be printed during debugging, instead of integer “magic numbers”. (Contributed by Giampaolo Rodola’ in bpo-21076.)

smtpd

Both the `SMTPServer` and `SMTPChannel` classes now accept a `decode_data` keyword argument to determine if the DATA portion of the SMTP transaction is decoded using the "utf-8" codec or is instead provided to the `SMTPServer.process_message()` method as a byte string. The default is True for backward compatibility reasons, but will change to False in Python 3.6. If `decode_data` is set to False, the `process_message` method must be prepared to
accept keyword arguments. (Contributed by Maciej Szulik in bpo-19662.)

The SMTPServer class now advertises the 8BITMIME extension (RFC 6152) if decode_data has been set True. If the client specifies BODY=8BITMIME on the MAIL command, it is passed to SMTPServer.process_message() via the mail_options keyword. (Contributed by Milan Oberkirch and R. David Murray in bpo-21795.)

The SMTPServer class now also supports the SMTPUTF8 extension (RFC 6531: Internationalized Email). If the client specified SMTPUTF8 BODY=8BITMIME on the MAIL command, they are passed to SMTPServer.process_message() via the mail_options keyword. It is the responsibility of the process_message method to correctly handle the SMTPUTF8 data. (Contributed by Milan Oberkirch in bpo-21725.)

It is now possible to provide, directly or via name resolution, IPv6 addresses in the SMTPServer constructor, and have it successfully connect. (Contributed by Milan Oberkirch in bpo-14758.)

smtplib

A new SMTP.auth() method provides a convenient way to implement custom authentication mechanisms. (Contributed by Milan Oberkirch in bpo-15014.)

The SMTP.set_debuglevel() method now accepts an additional debuglevel (2), which enables timestamps in debug messages. (Contributed by Gavin Chappell and Maciej Szulik in bpo-16914.)

Both the SMTP.sendmail() and SMTP.send_message() methods
now support RFC 6531 (SMTPUTF8). (Contributed by Milan Oberkirch and R. David Murray in bpo-22027.)

sndhdr

The what() and whathdr() functions now return a namedtuple(). (Contributed by Claudiu Popa in bpo-18615.)

socket

Functions with timeouts now use a monotonic clock, instead of a system clock. (Contributed by Víctor Stinner in bpo-22043.)

A new socket.sendfile() method allows sending a file over a socket by using the high-performance os.sendfile() function on UNIX, resulting in uploads being from 2 to 3 times faster than when using plain socket.send(). (Contributed by Giampaolo Rodola' in bpo-17552.)

The socket.sendall() method no longer resets the socket timeout every time bytes are received or sent. The socket timeout is now the maximum total duration to send all data. (Contributed by Victor Stinner in bpo-23853.)

The backlog argument of the socket.listen() method is now optional. By default it is set to SOMAXCONN or to 128, whichever is less. (Contributed by Charles-François Natali in bpo-21455.)

ssl

Memory BIO Support
The new **SSLObject** class has been added to provide SSL protocol support for cases when the network I/O capabilities of **SSLSocket** are not necessary or are suboptimal. **SSLObject** represents an SSL protocol instance, but does not implement any network I/O methods, and instead provides a memory buffer interface. The new **MemoryBIO** class can be used to pass data between Python and an SSL protocol instance.

The memory BIO SSL support is primarily intended to be used in frameworks implementing asynchronous I/O for which **SSLSocket**'s readiness model ("select/poll") is inefficient.

A new **SSLContext.wrap_bio()** method can be used to create a new **SSLObject** instance.

**Application-Layer Protocol Negotiation Support**

Where OpenSSL support is present, the **ssl** module now implements the *Application-Layer Protocol Negotiation* TLS extension as described in **RFC 7301**.

The new **SSLContext.set_alpn_protocols()** can be used to specify which protocols a socket should advertise during the TLS handshake.

The new **SSLSocket.selected_alpn_protocol()** returns the protocol that was selected during the TLS handshake. The **HAS_ALPN** flag indicates whether ALPN support is present.
Other Changes

There is a new `SSLSocket.version()` method to query the actual protocol version in use. (Contributed by Antoine Pitrou in bpo-20421.)

The `SSLSocket` class now implements a `SSLSocket.sendfile()` method. (Contributed by Giampaolo Rodola’ in bpo-17552.)

The `SSLSocket.send()` method now raises either the `ssl.SSLWantReadError` or `ssl.SSLWantWriteError` exception on a non-blocking socket if the operation would block. Previously, it would return `0`. (Contributed by Nikolaus Rath in bpo-20951.)

The `cert_time_to_seconds()` function now interprets the input time as UTC and not as local time, per RFC 5280. Additionally, the return value is always an `int`. (Contributed by Akira Li in bpo-19940.)

New `SSLObject.shared_ciphers()` and `SSLSocket.shared_ciphers()` methods return the list of ciphers sent by the client during the handshake. (Contributed by Benjamin Peterson in bpo-23186.)

The `SSLSocket.do_handshake()`, `SSLSocket.read()`, `SSLSocket.shutdown()`, and `SSLSocket.write()` methods of the `SSLSocket` class no longer reset the socket timeout every time bytes are received or sent. The socket timeout is now the maximum total duration of the method. (Contributed by Victor Stinner in bpo-23853.)

The `match_hostname()` function now supports matching of IP addresses. (Contributed by Antoine Pitrou in bpo-23239.)
sqlite3

The Row class now fully supports the sequence protocol, in particular reversed() iteration and slice indexing. (Contributed by Claudiu Popa in bpo-10203; by Lucas Sinclair, Jessica McKellar, and Serhiy Storchaka in bpo-13583.)

subprocess

The new run() function has been added. It runs the specified command and returns a CompletedProcess object, which describes a finished process. The new API is more consistent and is the recommended approach to invoking subprocesses in Python code that does not need to maintain compatibility with earlier Python versions. (Contributed by Thomas Kluyver in bpo-23342.)

Examples:

```python
>>> subprocess.run(['ls', '-l'])  # doesn't capture output
CompletedProcess(args=['ls', '-l'], returncode=0)

>>> subprocess.run('exit 1', shell=True, check=True)
Traceback (most recent call last):
  ... subprocess.CalledProcessError: Command 'exit 1' returned non-zero exit status 1

>>> subprocess.run(['ls', '-l', '/dev/null'], stdout=subprocess.PIPE)
CompletedProcess(args=['ls', '-l', '/dev/null'], returncode=0, stdout=b'crw-rw-rw- 1 root root 1, 3 Jan 23 16:23 /dev/null')
```

sys
A new `set_coroutine_wrapper()` function allows setting a global hook that will be called whenever a coroutine object is created by an `async def` function. A corresponding `get_coroutine_wrapper()` can be used to obtain a currently set wrapper. Both functions are provisional, and are intended for debugging purposes only. (Contributed by Yury Selivanov in bpo-24017.)

A new `is_finalizing()` function can be used to check if the Python interpreter is shutting down. (Contributed by Antoine Pitrou in bpo-22696.)

**sysconfig**

The name of the user scripts directory on Windows now includes the first two components of the Python version. (Contributed by Paul Moore in bpo-23437.)

**tarfile**

The `mode` argument of the `open()` function now accepts "x" to request exclusive creation. (Contributed by Berker Peksag in bpo-21717.)

The `TarFile.extractall()` and `TarFile.extract()` methods now take a keyword argument `numeric_owner`. If set to `True`, the extracted files and directories will be owned by the numeric `uid` and `gid` from the tarfile. If set to `False` (the default, and the behavior in versions prior to 3.5), they will be owned by the named user and group in the tarfile. (Contributed by Michael Vogt and Eric Smith in bpo-23193.)
The `TarFile.list()` now accepts an optional `members` keyword argument that can be set to a subset of the list returned by `TarFile.getmembers()`. (Contributed by Serhiy Storchaka in bpo-21549.)

**threading**

Both the `Lock.acquire()` and `RLock.acquire()` methods now use a monotonic clock for timeout management. (Contributed by Victor Stinner in bpo-22043.)

**time**

The `monotonic()` function is now always available. (Contributed by Victor Stinner in bpo-22043.)

**timeit**

A new command line option `-u` or `--unit=U` can be used to specify the time unit for the timer output. Supported options are `usec`, `msec`, or `sec`. (Contributed by Julian Gindi in bpo-18983.)

The `timeit()` function has a new `globals` parameter for specifying the namespace in which the code will be running. (Contributed by Ben Roberts in bpo-2527.)

**tkinter**

The tkinter._fix module used for setting up the Tcl/Tk environment on Windows has been replaced by a private function in
the _tkinter module which makes no permanent changes to environment variables. (Contributed by Zachary Ware in bpo-20035.)

traceback

New walk_stack() and walk_tb() functions to conveniently traverse frame and traceback objects. (Contributed by Robert Collins in bpo-17911.)

New lightweight classes: TracebackException, StackSummary, and FrameSummary. (Contributed by Robert Collins in bpo-17911.)

Both the print_tb() and print_stack() functions now support negative values for the limit argument. (Contributed by Dmitry Kazakov in bpo-22619.)

types

A new coroutine() function to transform generator and generator-like objects into awaitables. (Contributed by Yury Selivanov in bpo-24017.)

A new type called CoroutineType, which is used for coroutine objects created by async def functions. (Contributed by Yury Selivanov in bpo-24400.)

unicodedata

The unicodedata module now uses data from Unicode 8.0.0.

unittest
The `TestLoader.loadTestsFromModule()` method now accepts a keyword-only argument `pattern` which is passed to `load_tests` as the third argument. Found packages are now checked for `load_tests` regardless of whether their path matches `pattern`, because it is impossible for a package name to match the default pattern. (Contributed by Robert Collins and Barry A. Warsaw in bpo-16662.)

Unittest discovery errors now are exposed in the `TestLoader.errors` attribute of the `TestLoader` instance. (Contributed by Robert Collins in bpo-19746.)

A new command line option `--locals` to show local variables in tracebacks. (Contributed by Robert Collins in bpo-22936.)

```text
unittest.mock
```

The `Mock` class has the following improvements:

- The class constructor has a new `unsafe` parameter, which causes mock objects to raise `AttributeError` on attribute names starting with "assert". (Contributed by Kushal Das in bpo-21238.)
- A new `Mock.assert_not_called()` method to check if the mock object was called. (Contributed by Kushal Das in bpo-21262.)

The `MagicMock` class now supports `__truediv__()`, `__divmod__()` and `__matmul__()` operators. (Contributed by Johannes Baiter in bpo-20968, and Håkan Lövdahl in bpo-23581 and bpo-23568.)

It is no longer necessary to explicitly pass `create=True` to the
patch() function when patching builtin names. (Contributed by Kushal Das in bpo-17660.)

urllib

A new request.HTTPPasswordMgrWithPriorAuth class allows HTTP Basic Authentication credentials to be managed so as to eliminate unnecessary 401 response handling, or to unconditionally send credentials on the first request in order to communicate with servers that return a 404 response instead of a 401 if the Authorization header is not sent. (Contributed by Matej Cepl in bpo-19494 and Akshit Khurana in bpo-7159.)

A new quote_via argument for the parse.urlencode() function provides a way to control the encoding of query parts if needed. (Contributed by Samwyse and Arnon Yaari in bpo-13866.)

The request.urlopen() function accepts an ssl.SSLContext object as a context argument, which will be used for the HTTPS connection. (Contributed by Alex Gaynor in bpo-22366.)

The parse.urljoin() was updated to use the RFC 3986 semantics for the resolution of relative URLs, rather than RFC 1808 and RFC 2396. (Contributed by Demian Brecht and Senthil Kumaran in bpo-22118.)

wsgiref

The headers argument of the headers.Headers class constructor is now optional. (Contributed by Pablo Torres Navarrete and SilentGhost in bpo-5800.)
xmlrpc

The `client.ServerProxy` class now supports the context manager protocol. (Contributed by Claudiu Popa in bpo-20627.)

The `client.ServerProxy` constructor now accepts an optional `ssl.SSLContext` instance. (Contributed by Alex Gaynor in bpo-22960.)

xml.sax

SAX parsers now support a character stream of the `xmlreader.InputSource` object. (Contributed by Serhiy Storchaka in bpo-2175.)

`parseString()` now accepts a `str` instance. (Contributed by Serhiy Storchaka in bpo-10590.)

zipfile

ZIP output can now be written to unseekable streams. (Contributed by Serhiy Storchaka in bpo-23252.)

The `mode` argument of `ZipFile.open()` method now accepts "x" to request exclusive creation. (Contributed by Serhiy Storchaka in bpo-21717.)
Other module-level changes

Many functions in the \texttt{mmap}, \texttt{ossaudiodev}, \texttt{socket}, \texttt{ssl}, and \texttt{codecs} modules now accept writable \texttt{bytes-like objects}. (Contributed by Serhiy Storchaka in \texttt{bpo-23001}.)
Optimizations

The `os.walk()` function has been sped up by 3 to 5 times on POSIX systems, and by 7 to 20 times on Windows. This was done using the new `os.scandir()` function, which exposes file information from the underlying `readdir` or `FindFirstFile/FindNextFile` system calls. (Contributed by Ben Hoyt with help from Victor Stinner in bpo-23605.)

Construction of `bytes(int)` (filled by zero bytes) is faster and uses less memory for large objects. `calloc()` is used instead of `malloc()` to allocate memory for these objects. (Contributed by Victor Stinner in bpo-21233.)

Some operations on `ipaddress IPv4Network` and `IPv6Network` have been massively sped up, such as `subnets()`, `supernet()`, `summarize_address_range()`, `collapse_addresses()`. The speed up can range from 3 to 15 times. (Contributed by Antoine Pitrou, Michel Albert, and Markus in bpo-21486, bpo-21487, bpo-20826, bpo-23266.)

Pickling of `ipaddress` objects was optimized to produce significantly smaller output. (Contributed by Serhiy Storchaka in bpo-23133.)

Many operations on `io.BytesIO` are now 50% to 100% faster. (Contributed by Serhiy Storchaka in bpo-15381 and David Wilson in bpo-22003.)

The `marshal.dumps()` function is now faster: 65–85% with versions 3 and 4, 20–25% with versions 0 to 2 on typical data, and up to 5 times in best cases. (Contributed by Serhiy Storchaka in bpo-20416)
and bpo-23344.)

The UTF-32 encoder is now 3 to 7 times faster. (Contributed by Serhiy Storchaka in bpo-15027.)

Regular expressions are now parsed up to 10% faster. (Contributed by Serhiy Storchaka in bpo-19380.)

The json.dumps() function was optimized to run with ensure_ascii=False as fast as with ensure_ascii=True. (Contributed by Naoki Inada in bpo-23206.)

The PyObject_IsInstance() and PyObject_IsSubclass() functions have been sped up in the common case that the second argument has type as its metaclass. (Contributed Georg Brandl by in bpo-22540.)

Method caching was slightly improved, yielding up to 5% performance improvement in some benchmarks. (Contributed by Antoine Pitrou in bpo-22847.)

Objects from the random module now use 50% less memory on 64-bit builds. (Contributed by Serhiy Storchaka in bpo-23488.)

The property() getter calls are up to 25% faster. (Contributed by Joe Jevnik in bpo-23910.)

Instantiation of fractions.Fraction is now up to 30% faster. (Contributed by Stefan Behnel in bpo-22464.)

String methods find(), rfind(), split(), partition() and the in string operator are now significantly faster for searching 1-character substrings. (Contributed by Serhiy Storchaka in bpo-23573.)
Build and C API Changes

New calloc functions were added:

- `PyMem_RawCalloc()`,
- `PyMem_Calloc()`,
- `PyObject_Calloc()`.

(Contributed by Victor Stinner in bpo-21233.)

New encoding/decoding helper functions:

- `Py_DecodeLocale()` (replaced `_Py_char2wchar()`),
- `Py_EncodeLocale()` (replaced `_Py_wchar2char()`).

(Contributed by Victor Stinner in bpo-18395.)

A new `PyCodec_NameReplaceErrors()` function to replace the unicode encode error with \N{...} escapes. (Contributed by Serhiy Storchaka in bpo-19676.)

A new `PyErr_FormatV()` function similar to `PyErr_Format()`, but accepts a `va_list` argument. (Contributed by Antoine Pitrou in bpo-18711.)

A new `PyExc_RecursionError` exception. (Contributed by Georg Brandl in bpo-19235.)

New `PyModule_FromDefAndSpec()`, `PyModule_FromDefAndSpec2()`, and `PyModule_ExecDef()` functions introduced by PEP 489 – multi-phase extension module initialization. (Contributed by Petr Viktorin in bpo-24268.)
New `PyNumber_MatrixMultiply()` and `PyNumber_InPlaceMatrixMultiply()` functions to perform matrix multiplication. (Contributed by Benjamin Peterson in bpo-21176. See also PEP 465 for details.)

The `PyTypeObject.tp_finalize` slot is now part of the stable ABI.

Windows builds now require Microsoft Visual C++ 14.0, which is available as part of Visual Studio 2015.

Extension modules now include a platform information tag in their filename on some platforms (the tag is optional, and CPython will import extensions without it, although if the tag is present and mismatched, the extension won’t be loaded):

- On Linux, extension module filenames end with `.cpython-<major><minor>m-<architecture>-<os>.pyd`:
  - `<major>` is the major number of the Python version; for Python 3.5 this is 3.
  - `<minor>` is the minor number of the Python version; for Python 3.5 this is 5.
  - `<architecture>` is the hardware architecture the extension module was built to run on. It's most commonly either `i386` for 32-bit Intel platforms or `x86_64` for 64-bit Intel (and AMD) platforms.
  - `<os>` is always `linux-gnu`, except for extensions built to talk to the 32-bit ABI on 64-bit platforms, in which case it is `linux-gnu32` (and `<architecture>` will be `x86_64`).
- On Windows, extension module filenames end with `<debug>.cp<major><minor>-<platform>.pyd`:
  - `<major>` is the major number of the Python version; for Python 3.5 this is 3.
- `<minor>` is the minor number of the Python version; for Python 3.5 this is 5.
- `<platform>` is the platform the extension module was built for, either `win32` for Win32, `win_amd64` for Win64, `win_ia64` for Windows Itanium 64, and `win_arm` for Windows on ARM.
- If built in debug mode, `<debug>` will be `_d`, otherwise it will be blank.
  - On OS X platforms, extension module filenames now end with `-darwin.so`.
  - On all other platforms, extension module filenames are the same as they were with Python 3.4.
Deprecated

New Keywords

async and await are not recommended to be used as variable, class, function or module names. Introduced by PEP 492 in Python 3.5, they will become proper keywords in Python 3.7.

Deprecated Python Behavior

Raising the StopIteration exception inside a generator will now generate a silent PendingDeprecationWarning, which will become a non-silent deprecation warning in Python 3.6 and will trigger a RuntimeError in Python 3.7. See PEP 479: Change StopIteration handling inside generators for details.

Unsupported Operating Systems

Windows XP is no longer supported by Microsoft, thus, per PEP 11, CPython 3.5 is no longer officially supported on this OS.

Deprecated Python modules, functions and methods

The formatter module has now graduated to full deprecation and is still slated for removal in Python 3.6.

The asyncio.async() function is deprecated in favor of ensure_future().
The `smtpd` module has in the past always decoded the DATA portion of email messages using the `utf-8` codec. This can now be controlled by the new `decode_data` keyword to `SMTPServer`. The default value is `True`, but this default is deprecated. Specify the `decode_data` keyword with an appropriate value to avoid the deprecation warning.

Directly assigning values to the `key`, `value` and `coded_value` of `http.cookies.Morsel` objects is deprecated. Use the `set()` method instead. In addition, the undocumented `LegalChars` parameter of `set()` is deprecated, and is now ignored.

Passing a format string as keyword argument `format_string` to the `format()` method of the `string.Formatter` class has been deprecated. (Contributed by Serhiy Storchaka in `bpo-23671`.)

The `platform.dist()` and `platform.linux_distribution()` functions are now deprecated. Linux distributions use too many different ways of describing themselves, so the functionality is left to a package. (Contributed by Vajrasky Kok and Berker Peksag in `bpo-1322`.)

The previously undocumented `from_function` and `from_builtin` methods of `inspect.Signature` are deprecated. Use the new `Signature.from_callable()` method instead. (Contributed by Yury Selivanov in `bpo-24248`.)

The `inspect.getargspec()` function is deprecated and scheduled to be removed in Python 3.6. (See `bpo-20438` for details.)

The `inspect.getfullargspec()`, `getcallargs()`, and `formatargspec()` functions are deprecated in favor of the
inspect.signature() API. (Contributed by Yury Selivanov in bpo-20438.)

getargvalues() and formatargvalues() functions were inadvertently marked as deprecated with the release of Python 3.5.0.

Use of re.LOCALE flag with str patterns or re.ASCII is now deprecated. (Contributed by Serhiy Storchaka in bpo-22407.)

Use of unrecognized special sequences consisting of '\\' and an ASCII letter in regular expression patterns and replacement patterns now raises a deprecation warning and will be forbidden in Python 3.6. (Contributed by Serhiy Storchaka in bpo-23622.)

The undocumented and unofficial use_load_tests default argument of the unittest.TestLoader.loadTestsFromModule() method now is deprecated and ignored. (Contributed by Robert Collins and Barry A. Warsaw in bpo-16662.)
Removed

API and Feature Removals

The following obsolete and previously deprecated APIs and features have been removed:

- The `__version__` attribute has been dropped from the email package. The email code hasn’t been shipped separately from the stdlib for a long time, and the `__version__` string was not updated in the last few releases.
- The internal `Netrc` class in the `ftpplib` module was deprecated in 3.4, and has now been removed. (Contributed by Matt Chaput in `bpo-6623`.)
- The concept of `.pyo` files has been removed.
- The `JoinableQueue` class in the provisional `asyncio` module was deprecated in 3.4.4 and is now removed. (Contributed by A. Jesse Jiryu Davis in `bpo-23464`.)
Porting to Python 3.5

This section lists previously described changes and other bugfixes that may require changes to your code.

Changes in Python behavior

- Due to an oversight, earlier Python versions erroneously accepted the following syntax:

  ```python
  f(1 for x in [1], *args)
  f(1 for x in [1], **kwargs)
  ```

  Python 3.5 now correctly raises a `SyntaxError`, as generator expressions must be put in parentheses if not a sole argument to a function.

Changes in the Python API

- **PEP 475**: System calls are now retried when interrupted by a signal instead of raising `InterruptedError` if the Python signal handler does not raise an exception.
- Before Python 3.5, a `datetime.time` object was considered to be false if it represented midnight in UTC. This behavior was considered obscure and error-prone and has been removed in Python 3.5. See [bpo-13936](https://bugs.python.org/issue13936) for full details.
- The `ssl.SSLSocket.send()` method now raises either `ssl.SSLWantReadError` or `ssl.SSLWantWriteError` on a non-blocking socket if the operation would block. Previously, it would return 0. (Contributed by Nikolaus Rath in [bpo-20951](https://bugs.python.org/issue20951).)
- The `__name__` attribute of generators is now set from the
function name, instead of being set from the code name. Use \texttt{gen.gi_code.co_name} to retrieve the code name. Generators also have a new \texttt{__qualname__} attribute, the qualified name, which is now used for the representation of a generator (\texttt{repr(gen)}). (Contributed by Victor Stinner in \texttt{bpo-21205}.)

- The deprecated “strict” mode and argument of \texttt{HTMLParser}, \texttt{HTMLParser.error()}, and the \texttt{HTMLParserError} exception have been removed. (Contributed by Ezio Melotti in \texttt{bpo-15114}.) The \texttt{convert_charrefs} argument of \texttt{HTMLParser} is now \texttt{True} by default. (Contributed by Berker Peksag in \texttt{bpo-21047}.)

- Although it is not formally part of the API, it is worth noting for porting purposes (ie: fixing tests) that error messages that were previously of the form “sometype does not support the buffer protocol” are now of the form “a \texttt{bytes-like object} is required, not ‘sometype’”. (Contributed by Ezio Melotti in \texttt{bpo-16518}.)

- If the current directory is set to a directory that no longer exists then \texttt{FileNotFoundError} will no longer be raised and instead \texttt{find_spec()} will return \texttt{None} \texttt{without} caching \texttt{None} in \texttt{sys.path_importer_cache}, which is different than the typical case (\texttt{bpo-22834}).

- HTTP status code and messages from \texttt{http.client} and \texttt{http.server} were refactored into a common \texttt{HTTPStatus} enum. The values in \texttt{http.client} and \texttt{http.server} remain available for backwards compatibility. (Contributed by Demian Brecht in \texttt{bpo-21793}.)

- When an import loader defines \texttt{importlib.machinery.Loader.exec_module()} it is now expected to also define \texttt{create_module()} (raises a \texttt{DeprecationWarning} now, will be an error in Python 3.6). If the loader inherits from \texttt{importlib.abc.Loader} then there is nothing to do, else simply define \texttt{create_module()} to return \texttt{None}. (Contributed by Brett Cannon in \texttt{bpo-23014}.)

- The \texttt{re.split()} function always ignored empty pattern
matches, so the "x*" pattern worked the same as "x+", and the "\b" pattern never worked. Now re.split() raises a warning if the pattern could match an empty string. For compatibility, use patterns that never match an empty string (e.g. "x+" instead of "x*"). Patterns that could only match an empty string (such as "\b") now raise an error. (Contributed by Serhiy Storchaka in bpo-22818.)

- The http.cookies.Morsel dict-like interface has been made self consistent: morsel comparison now takes the key and value into account, copy() now results in a Morsel instance rather than a dict, and update() will now raise an exception if any of the keys in the update dictionary are invalid. In addition, the undocumented LegalChars parameter of set() is deprecated and is now ignored. (Contributed by Demian Brecht in bpo-2211.)

- PEP 488 has removed .pyo files from Python and introduced the optional opt- tag in .pyc file names. The importlib.util.cache_from_source() has gained an optimization parameter to help control the opt- tag. Because of this, the debug_override parameter of the function is now deprecated. .pyo files are also no longer supported as a file argument to the Python interpreter and thus serve no purpose when distributed on their own (i.e. sourcless code distribution). Due to the fact that the magic number for bytecode has changed in Python 3.5, all old .pyo files from previous versions of Python are invalid regardless of this PEP.

- The socket module now exports the CAN_RAW_FD_FRAMES constant on linux 3.6 and greater.

- The ssl.cert_time_to_seconds() function now interprets the input time as UTC and not as local time, per RFC 5280. Additionally, the return value is always an int. (Contributed by Akira Li in bpo-19940.)

- The pygettext.py Tool now uses the standard +NNNN format for timezones in the POT-Creation-Date header.
• The `smtplib` module now uses `sys.stderr` instead of the previous module-level `stderr` variable for debug output. If your (test) program depends on patching the module-level variable to capture the debug output, you will need to update it to capture `sys.stderr` instead.

• The `str.startswith()` and `str.endswith()` methods no longer return `True` when finding the empty string and the indexes are completely out of range. (Contributed by Serhiy Storchaka in bpo-24284.)

• The `inspect.getdoc()` function now returns documentation strings inherited from base classes. Documentation strings no longer need to be duplicated if the inherited documentation is appropriate. To suppress an inherited string, an empty string must be specified (or the documentation may be filled in). This change affects the output of the `pydoc` module and the `help()` function. (Contributed by Serhiy Storchaka in bpo-15582.)

• Nested `functools.partial()` calls are now flattened. If you were relying on the previous behavior, you can now either add an attribute to a `functools.partial()` object or you can create a subclass of `functools.partial()`. (Contributed by Alexander Belopolsky in bpo-7830.)

Changes in the C API

• The undocumented format member of the (non-public) `PyMemoryViewObject` structure has been removed. All extensions relying on the relevant parts in `memoryobject.h` must be rebuilt.

• The `PyMemAllocator` structure was renamed to `PyMemAllocatorEx` and a new `calloc` field was added.

• Removed non-documentated macro `PyObject_REPR` which leaked references. Use format character `%R` in
PyUnicode_FromFormat()-like functions to format the `repr()` of the object. (Contributed by Serhiy Storchaka in bpo-22453.)

- Because the lack of the `__module__` attribute breaks pickling and introspection, a deprecation warning is now raised for builtin types without the `__module__` attribute. This would be an AttributeError in the future. (Contributed by Serhiy Storchaka in bpo-20204.)

- As part of the PEP 492 implementation, the `tp_reserved` slot of `PyTypeObject` was replaced with a `tp_as_async` slot. Refer to Coroutine Objects for new types, structures and functions.
What’s New In Python 3.4

Author: R. David Murray <rdmurray@bitdance.com> (Editor)

This article explains the new features in Python 3.4, compared to 3.3. Python 3.4 was released on March 16, 2014. For full details, see the changelog.

See also: PEP 429 – Python 3.4 Release Schedule
Summary – Release Highlights

New syntax features:

- No new syntax features were added in Python 3.4.

Other new features:

- pip should always be available (PEP 453).
- Newly created file descriptors are non-inheritable (PEP 446).
- command line option for isolated mode (bpo-16499).
- improvements in the handling of codecs that are not text encodings (multiple issues).
- A ModuleSpec Type for the Import System (PEP 451). (Affects importer authors.)
- The marshal format has been made more compact and efficient (bpo-16475).

New library modules:

- asyncio: New provisional API for asynchronous IO (PEP 3156).
- ensurepip: Bootstrapping the pip installer (PEP 453).
- enum: Support for enumeration types (PEP 435).
- pathlib: Object-oriented filesystem paths (PEP 428).
- selectors: High-level and efficient I/O multiplexing, built upon the select module primitives (part of PEP 3156).
- statistics: A basic numerically stable statistics library (PEP 450).
- tracemalloc: Trace Python memory allocations (PEP 454).

Significantly improved library modules:

- Single-dispatch generic functions in functools (PEP 443).
- New pickle protocol 4 (PEP 3154).
- multiprocessing now has an option to avoid using os.fork on Unix (bpo-8713).
- email has a new submodule, contentmanager, and a new Message subclass (EmailMessage) that simplify MIME handling (bpo-18891).
- The inspect and pydoc modules are now capable of correct introspection of a much wider variety of callable objects, which improves the output of the Python help() system.
- The ipaddress module API has been declared stable

Security improvements:

- Secure and interchangeable hash algorithm (PEP 456).
- Make newly created file descriptors non-inheritable (PEP 446) to avoid leaking file descriptors to child processes.
- New command line option for isolated mode, (bpo-16499).
- multiprocessing now has an option to avoid using os.fork on Unix. spawn and forkserver are more secure because they avoid sharing data with child processes.
- multiprocessing child processes on Windows no longer inherit all of the parent's inheritable handles, only the necessary ones.
- A new hashlib.pbkdf2_hmac() function provides the PKCS#5 password-based key derivation function 2.
- TLSv1.1 and TLSv1.2 support for ssl.
- Retrieving certificates from the Windows system cert store support for ssl.
- Server-side SNI (Server Name Indication) support for ssl.
- The ssl.SSLContext class has a lot of improvements.
- All modules in the standard library that support SSL now support server certificate verification, including hostname matching (ssl.match_hostname()) and CRLs (Certificate Revocation lists, see ssl.SSLContext.load_verify_locations()).
CPython implementation improvements:

- Safe object finalization (PEP 442).
- Leveraging PEP 442, in most cases module globals are no longer set to None during finalization (bpo-18214).
- Configurable memory allocators (PEP 445).
- Argument Clinic (PEP 436).

Please read on for a comprehensive list of user-facing changes, including many other smaller improvements, CPython optimizations, deprecations, and potential porting issues.
New Features

PEP 453: Explicit Bootstrapping of PIP in Python Installations

Bootstrapping pip By Default

The new `ensurepip` module (defined in PEP 453) provides a standard cross-platform mechanism to bootstrap the pip installer into Python installations and virtual environments. The version of `pip` included with Python 3.4.0 is `pip 1.5.4`, and future 3.4.x maintenance releases will update the bundled version to the latest version of `pip` that is available at the time of creating the release candidate.

By default, the commands `pipX` and `pipX.Y` will be installed on all platforms (where X.Y stands for the version of the Python installation), along with the `pip` Python package and its dependencies. On Windows and in virtual environments on all platforms, the unversioned `pip` command will also be installed. On other platforms, the system wide unversioned `pip` command typically refers to the separately installed Python 2 version.

The `pyvenv` command line utility and the `venv` module make use of the `ensurepip` module to make `pip` readily available in virtual environments. When using the command line utility, `pip` is installed by default, while when using the `venv` module API installation of `pip` must be requested explicitly.

For CPython source builds on POSIX systems, the make `install` and `make altinstall` commands bootstrap `pip` by default. This behaviour can be controlled through configure options, and overridden
through Makefile options.

On Windows and Mac OS X, the CPython installers now default to installing `pip` along with CPython itself (users may opt out of installing it during the installation process). Window users will need to opt in to the automatic `PATH` modifications to have `pip` available from the command line by default, otherwise it can still be accessed through the Python launcher for Windows as `py -m pip`.

As discussed in the PEP, platform packagers may choose not to install these commands by default, as long as, when invoked, they provide clear and simple directions on how to install them on that platform (usually using the system package manager).

**Note:** To avoid conflicts between parallel Python 2 and Python 3 installations, only the versioned `pip3` and `pip3.4` commands are bootstrapped by default when `ensurepip` is invoked directly - the `-default-pip` option is needed to also request the unversioned `pip` command. `pyvenv` and the Windows installer ensure that the unqualified `pip` command is made available in those environments, and `pip` can always be invoked via the `-m` switch rather than directly to avoid ambiguity on systems with multiple Python installations.

**Documentation Changes**

As part of this change, the Installing Python Modules and Distributing Python Modules sections of the documentation have been completely redesigned as short getting started and FAQ documents. Most packaging documentation has now been moved out to the Python Packaging Authority maintained Python Packaging User Guide and the documentation of the individual projects.
However, as this migration is currently still incomplete, the legacy versions of those guides remaining available as Installing Python Modules (Legacy version) and Distributing Python Modules (Legacy version).

**See also:**

**PEP 453** – Explicit bootstrapping of pip in Python installations
PEP written by Donald Stufft and Nick Coghlan, implemented by Donald Stufft, Nick Coghlan, Martin von Löwis and Ned Deily.

**PEP 446** makes newly created file descriptors non-inheritable. In general, this is the behavior an application will want: when launching a new process, having currently open files also open in the new process can lead to all sorts of hard to find bugs, and potentially to security issues.

However, there are occasions when inheritance is desired. To support these cases, the following new functions and methods are available:

- `os.get_inheritable()`, `os.set_inheritable()`
- `os.get_handle_inheritable()`, `os.set_handle_inheritable()`
- `socket.socket.get_inheritable()`, `socket.socket.set_inheritable()`

**See also:**

**PEP 446** – Make newly created file descriptors non-inheritable
Improvements to Codec Handling

Since it was first introduced, the `codecs` module has always been intended to operate as a type-neutral dynamic encoding and decoding system. However, its close coupling with the Python text model, especially the type restricted convenience methods on the built-in `str`, `bytes` and `bytearray` types, has historically obscured that fact.

As a key step in clarifying the situation, the `codecs.encode()` and `codecs.decode()` convenience functions are now properly documented in Python 2.7, 3.3 and 3.4. These functions have existed in the `codecs` module (and have been covered by the regression test suite) since Python 2.4, but were previously only discoverable through runtime introspection.

Unlike the convenience methods on `str`, `bytes` and `bytearray`, the `codecs` convenience functions support arbitrary codecs in both Python 2 and Python 3, rather than being limited to Unicode text encodings (in Python 3) or `basestring <-> basestring` conversions (in Python 2).

In Python 3.4, the interpreter is able to identify the known non-text encodings provided in the standard library and direct users towards these general purpose convenience functions when appropriate:

```python
>>> b"abcdef".decode("hex")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
LookupError: 'hex' is not a text encoding; use codecs
```
In a related change, whenever it is feasible without breaking backwards compatibility, exceptions raised during encoding and decoding operations are wrapped in a chained exception of the same type that mentions the name of the codec responsible for producing the error:

```python
>>> import codecs

>>> codecs.decode(b"abcdefg\h", "hex")
Traceback (most recent call last):
  File "/usr/lib/python3.4/encodings/hex_codec.py", line 128, in decode
    return (binascii.a2b_hex(input), len(input))
binascii.Error: Non-hexadecimal digit found

The above exception was the direct cause of the following exception:

Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
binascii.Error: decoding with 'hex' codec failed (Error: Non-hexadecimal digit found)

```
return comp.compress(data) + comp.flush()

TypeError: 'str' does not support the buffer interface

The above exception was the direct cause of the following exception:

Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: encoding with 'bz2' codec failed (TypeError: 'str' does not support the buffer interface)

Finally, as the examples above show, these improvements have permitted the restoration of the convenience aliases for the non-Unicode codecs that were themselves restored in Python 3.2. This means that encoding binary data to and from its hexadecimal representation (for example) can now be written as:

```python
>>> from codecs import encode, decode
>>> encode(b"hello", "hex")
b'68656c6c6f'
>>> decode(b'68656c6c6f', "hex")
b'hello'
```

The binary and text transforms provided in the standard library are detailed in Binary Transforms and Text Transforms.

(Contributed by Nick Coghlan in bpo-7475, bpo-17827, bpo-17828 and bpo-19619.)

PEP 451: A ModuleSpec Type for the Import System

PEP 451 provides an encapsulation of the information about a module that the import machinery will use to load it (that is, a module specification). This helps simplify both the import implementation and
several import-related APIs. The change is also a stepping stone for several future import-related improvements.

The public-facing changes from the PEP are entirely backward-compatible. Furthermore, they should be transparent to everyone but importer authors. Key finder and loader methods have been deprecated, but they will continue working. New importers should use the new methods described in the PEP. Existing importers should be updated to implement the new methods. See the Deprecated section for a list of methods that should be replaced and their replacements.

Other Language Changes

Some smaller changes made to the core Python language are:

- Unicode database updated to UCD version 6.3.
- \(\text{min}()\) and \(\text{max}()\) now accept a default keyword-only argument that can be used to specify the value they return if the iterable they are evaluating has no elements. (Contributed by Julian Berman in bpo-18111.)
- Module objects are now weakref’able.
- Module \texttt{__file__} attributes (and related values) should now always contain absolute paths by default, with the sole exception of \texttt{__main__.\_\_file\_\_} when a script has been executed directly using a relative path. (Contributed by Brett Cannon in bpo-18416.)
- All the UTF-* codecs (except UTF-7) now reject surrogates during both encoding and decoding unless the surrogatepass error handler is used, with the exception of the UTF-16 decoder (which accepts valid surrogate pairs) and the UTF-16 encoder (which produces them while encoding non-BMP characters). (Contributed by Victor Stinner, Kang-Hao (Kenny) Lu and Serhiy Storchaka in bpo-12892.)
- New German EBCDIC `codec cp273`. (Contributed by Michael Bierenfeld and Andrew Kuchling in bpo-1097797.)
- New Ukrainian `codec cp1125`. (Contributed by Serhiy Storchaka in bpo-19668.)
- `bytes.join()` and `bytearray.join()` now accept arbitrary buffer objects as arguments. (Contributed by Antoine Pitrou in bpo-15958.)
- The `int` constructor now accepts any object that has an `__index__` method for its `base` argument. (Contributed by Mark Dickinson in bpo-16772.)
- Frame objects now have a `clear()` method that clears all references to local variables from the frame. (Contributed by Antoine Pitrou in bpo-17934.)
- `memoryview` is now registered as a `Sequence`, and supports the `reversed()` builtin. (Contributed by Nick Coghlan and Claudiu Popa in bpo-18690 and bpo-19078.)
- Signatures reported by `help()` have been modified and improved in several cases as a result of the introduction of Argument Clinic and other changes to the `inspect` and `pydoc` modules.
- `__length_hint__()` is now part of the formal language specification (see PEP 424). (Contributed by Armin Ronacher in bpo-16148.)
New Modules

asyncio

The new asyncio module (defined in PEP 3156) provides a standard pluggable event loop model for Python, providing solid asynchronous IO support in the standard library, and making it easier for other event loop implementations to interoperate with the standard library and each other.

For Python 3.4, this module is considered a provisional API.

See also:

PEP 3156 – Asynchronous IO Support Rebooted: the “asyncio” Module

PEP written and implementation led by Guido van Rossum.

guaranteepip

The new guaranteepip module is the primary infrastructure for the PEP 453 implementation. In the normal course of events end users will not need to interact with this module, but it can be used to manually bootstrap pip if the automated bootstrapping into an installation or virtual environment was declined.

guaranteepip includes a bundled copy of pip, up-to-date as of the first release candidate of the release of CPython with which it ships (this applies to both maintenance releases and feature releases). guaranteepip does not access the internet. If the installation has Internet access, after guaranteepip is run the bundled pip can be used
to upgrade `pip` to a more recent release than the bundled one. (Note that such an upgraded version of `pip` is considered to be a separately installed package and will not be removed if Python is uninstalled.)

The module is named `ensurepip` because if called when `pip` is already installed, it does nothing. It also has an `--upgrade` option that will cause it to install the bundled copy of `pip` if the existing installed version of `pip` is older than the bundled copy.

**enum**

The new `enum` module (defined in [PEP 435](https://www.python.org/dev/peps/pep-0435/)) provides a standard implementation of enumeration types, allowing other modules (such as `socket`) to provide more informative error messages and better debugging support by replacing opaque integer constants with backwards compatible enumeration values.

**See also:**

[PEP 435 – Adding an Enum type to the Python standard library](https://www.python.org/dev/peps/pep-0435/)

PEP written by Barry Warsaw, Eli Bendersky and Ethan Furman, implemented by Ethan Furman.

**pathlib**

The new `pathlib` module offers classes representing filesystem paths with semantics appropriate for different operating systems. Path classes are divided between `pure paths`, which provide purely computational operations without I/O, and `concrete paths`, which inherit from pure paths but also provide I/O operations.
For Python 3.4, this module is considered a **provisional API**.

**See also:**

**PEP 428** – The pathlib module – object-oriented filesystem paths
  PEP written and implemented by Antoine Pitrou.

**selectors**

The new **selectors** module (created as part of implementing **PEP 3156**) allows high-level and efficient I/O multiplexing, built upon the **select** module primitives.

**statistics**

The new **statistics** module (defined in **PEP 450**) offers some core statistics functionality directly in the standard library. This module supports calculation of the mean, median, mode, variance and standard deviation of a data series.

**See also:**

**PEP 450** – Adding A Statistics Module To The Standard Library
  PEP written and implemented by Steven D’Aprano

**tracemalloc**

The new **tracemalloc** module (defined in **PEP 454**) is a debug tool to trace memory blocks allocated by Python. It provides the following information:
- Trace where an object was allocated
- Statistics on allocated memory blocks per filename and per line number: total size, number and average size of allocated memory blocks
- Compute the differences between two snapshots to detect memory leaks

See also:

**PEP 454** – Add a new tracemalloc module to trace Python memory allocations
  PEP written and implemented by Victor Stinner
Improved Modules

abc

New function **abc.get_cache_token()** can be used to know when to invalidate caches that are affected by changes in the object graph. (Contributed by Łukasz Langa in [bpo-16832](https://bugs.python.org/issue16832).)

New class **ABC** has **ABCMeta** as its meta class. Using **ABC** as a base class has essentially the same effect as specifying `metaclass=abc.ABCMeta`, but is simpler to type and easier to read. (Contributed by Bruno Dupuis in [bpo-16049](https://bugs.python.org/issue16049).)

aifc

The **getparams()** method now returns a namedtuple rather than a plain tuple. (Contributed by Claudiu Popa in [bpo-17818](https://bugs.python.org/issue17818).)

**aifc.open()** now supports the context management protocol: when used in a **with** block, the **close()** method of the returned object will be called automatically at the end of the block. (Contributed by Serhiy Storchacha in [bpo-16486](https://bugs.python.org/issue16486).)

The **writeframesraw()** and **writeframes()** methods now accept any bytes-like object. (Contributed by Serhiy Storchaka in [bpo-8311](https://bugs.python.org/issue8311).)

argparse

The **FileType** class now accepts **encoding** and **errors** arguments, which are passed through to **open()**. (Contributed by Lucas Maystre in [bpo-11175](https://bugs.python.org/issue11175).)
audioop

audioop now supports 24-bit samples. (Contributed by Serhiy Storchaka in bpo-12866.)

New byteswap() function converts big-endian samples to little-endian and vice versa. (Contributed by Serhiy Storchaka in bpo-19641.)

All audioop functions now accept any bytes-like object. Strings are not accepted: they didn’t work before, now they raise an error right away. (Contributed by Serhiy Storchaka in bpo-16685.)

base64

The encoding and decoding functions in base64 now accept any bytes-like object in cases where it previously required a bytes or bytearray instance. (Contributed by Nick Coghlan in bpo-17839.)

New functions a85encode(), a85decode(), b85encode(), and b85decode() provide the ability to encode and decode binary data from and to Ascii85 and the git/mercurial Base85 formats, respectively. The a85 functions have options that can be used to make them compatible with the variants of the Ascii85 encoding, including the Adobe variant. (Contributed by Martin Morrison, the Mercurial project, Serhiy Storchaka, and Antoine Pitrou in bpo-17618.)

collections

The ChainMap.new_child() method now accepts an $m$ argument specifying the child map to add to the chain. This allows an existing
mapping and/or a custom mapping type to be used for the child. (Contributed by Vinay Sajip in bpo-16613.)

colorsys

The number of digits in the coefficients for the RGB — YIQ conversions have been expanded so that they match the FCC NTSC versions. The change in results should be less than 1% and may better match results found elsewhere. (Contributed by Brian Landers and Serhiy Storchaka in bpo-14323.)

contextlib

The new contextlib.suppress context manager helps to clarify the intent of code that deliberately suppresses exceptions from a single statement. (Contributed by Raymond Hettinger in bpo-15806 and Zero Piraeus in bpo-19266.)

The new contextlib.redirect_stdout() context manager makes it easier for utility scripts to handle inflexible APIs that write their output to sys.stdout and don’t provide any options to redirect it. Using the context manager, the sys.stdout output can be redirected to any other stream or, in conjunction with io.StringIO, to a string. The latter can be especially useful, for example, to capture output from a function that was written to implement a command line interface. It is recommended only for utility scripts because it affects the global state of sys.stdout. (Contributed by Raymond Hettinger in bpo-15805.)

The contextlib documentation has also been updated to include a discussion of the differences between single use, reusable and
reentrant context managers.

**dbm**

dbm.open() objects now support the context management protocol. When used in a with statement, the close method of the database object will be called automatically at the end of the block. (Contributed by Claudiu Popa and Nick Coghlan in bpo-19282.)

**dis**

Functions show_code(), dis(), distb(), and disassemble() now accept a keyword-only file argument that controls where they write their output.

The dis module is now built around an Instruction class that provides object oriented access to the details of each individual bytecode operation.

A new method, get_instructions(), provides an iterator that emits the Instruction stream for a given piece of Python code. Thus it is now possible to write a program that inspects and manipulates a bytecode object in ways different from those provided by the dis module itself. For example:

```python
>>> import dis
>>> for instr in dis.get_instructions(lambda x: x + ... print(instr.opname)
LOAD_FAST
LOAD_CONST
BINARY_ADD
RETURN_VALUE
```
The various display tools in the `dis` module have been rewritten to use these new components.

In addition, a new application-friendly class `Bytecode` provides an object-oriented API for inspecting bytecode in both in human-readable form and for iterating over instructions. The `Bytecode` constructor takes the same arguments that `get_instruction()` does (plus an optional `current_offset`), and the resulting object can be iterated to produce `Instruction` objects. But it also has a `dis` method, equivalent to calling `dis` on the constructor argument, but returned as a multi-line string:

```python
>>> bytecode = dis.Bytecode(lambda x: x + 1, current_offset=0)
>>> for instr in bytecode:
...    print('{} ({}),'.format(instr.opname, instr.opindex))
LOAD_FAST (124)
LOAD_CONST (100)
BINARY_ADD (23)
RETURN_VALUE (83)
```

`Bytecode` also has a class method, `from_traceback()`, that provides the ability to manipulate a traceback (that is, `print(Bytecode.from_traceback(tb).dis())` is equivalent to `distb(tb)`).

(Contributed by Nick Coghlan, Ryan Kelly and Thomas Kluyver in bpo-11816 and Claudiu Popa in bpo-17916.)
New function `stack_effect()` computes the effect on the Python stack of a given opcode and argument, information that is not otherwise available. (Contributed by Larry Hastings in bpo-19722.)

**doctest**

A new option flag, `FAIL_FAST`, halts test running as soon as the first failure is detected. (Contributed by R. David Murray and Daniel Urban in bpo-16522.)

The `doctest` command line interface now uses `argparse`, and has two new options, `-o` and `-f`. `-o` allows `doctest options` to be specified on the command line, and `-f` is a shorthand for `-o FAIL_FAST` (to parallel the similar option supported by the `unittest` CLI). (Contributed by R. David Murray in bpo-11390.)

`doctest` will now find doctests in extension module `__doc__` strings. (Contributed by Zachary Ware in bpo-3158.)

**email**

`as_string()` now accepts a `policy` argument to override the default policy of the message when generating a string representation of it. This means that `as_string` can now be used in more circumstances, instead of having to create and use a `generator` in order to pass formatting parameters to its `flatten` method. (Contributed by R. David Murray in bpo-18600.)

New method `as_bytes()` added to produce a bytes representation of the message in a fashion similar to how `as_string` produces a string representation. It does not accept the `maxheaderlen` argument,
but does accept the `unixfrom` and `policy` arguments. The `Message.__bytes__()` method calls it, meaning that `bytes(mymsg)` will now produce the intuitive result: a bytes object containing the fully formatted message. (Contributed by R. David Murray in bpo-18600.)

The `Message.set_param()` message now accepts a `replace` keyword argument. When specified, the associated header will be updated without changing its location in the list of headers. For backward compatibility, the default is `False`. (Contributed by R. David Murray in bpo-18891.)

A pair of new subclasses of `Message` have been added (`EmailMessage` and `MIMEPart`), along with a new sub-module, `contentmanager` and a new `policy` attribute `content_manager`. All documentation is currently in the new module, which is being added as part of email's new provisional API. These classes provide a number of new methods that make extracting content from and inserting content into email messages much easier. For details, see the `contentmanager` documentation and the email: Examples. These API additions complete the bulk of the work that was planned as part of the email6 project. The currently provisional API is scheduled to become final in Python 3.5 (possibly with a few minor additions in the area of error handling). (Contributed by R. David Murray in bpo-18891.)

### filecmp

A new `clear_cache()` function provides the ability to clear the `filecmp` comparison cache, which uses `os.stat()` information to determine if the file has changed since the last compare. This can be used, for example, if the file might have been changed and re-checked
in less time than the resolution of a particular filesystem’s file modification time field. (Contributed by Mark Levitt in bpo-18149.)

New module attribute DEFAULT_IGNores provides the list of directories that are used as the default value for the ignore parameter of the dircmp() function. (Contributed by Eli Bendersky in bpo-15442.)

**functools**

The new partialmethod() descriptor brings partial argument application to descriptors, just as partial() provides for normal callables. The new descriptor also makes it easier to get arbitrary callables (including partial() instances) to behave like normal instance methods when included in a class definition. (Contributed by Alon Horev and Nick Coghlan in bpo-4331.)

The new singledispatch() decorator brings support for single-dispatch generic functions to the Python standard library. Where object oriented programming focuses on grouping multiple operations on a common set of data into a class, a generic function focuses on grouping multiple implementations of an operation that allows it to work with different kinds of data.

See also:

PEP 443 – Single-dispatch generic functions
PEP written and implemented by Łukasz Langa.

total_ordering() now supports a return value of NotImplemented from the underlying comparison function. (Contributed by Katie Miller in bpo-10042.)
A pure-python version of the `partial()` function is now in the stdlib; in CPython it is overridden by the C accelerated version, but it is available for other implementations to use. (Contributed by Brian Thorne in `bpo-12428`.)

**gc**

New function `get_stats()` returns a list of three per-generation dictionaries containing the collections statistics since interpreter startup. (Contributed by Antoine Pitrou in `bpo-16351`.)

**glob**

A new function `escape()` provides a way to escape special characters in a filename so that they do not become part of the globbing expansion but are instead matched literally. (Contributed by Serhiy Storchaka in `bpo-8402`.)

**hashlib**

A new `hashlib.pbkdf2_hmac()` function provides the PKCS#5 password-based key derivation function 2. (Contributed by Christian Heimes in `bpo-18582`.)

The `name` attribute of `hashlib` hash objects is now a formally supported interface. It has always existed in CPython's `hashlib` (although it did not return lower case names for all supported hashes), but it was not a public interface and so some other Python implementations have not previously supported it. (Contributed by Jason R. Coombs in `bpo-18532`.)
**hmac**

`hmac` now accepts `bytearray` as well as `bytes` for the `key` argument to the `new()` function, and the `msg` parameter to both the `new()` function and the `update()` method now accepts any type supported by the `hashlib` module. (Contributed by Jonas Borgström in bpo-18240.)

The `digestmod` argument to the `hmac.new()` function may now be any hash digest name recognized by `hashlib`. In addition, the current behavior in which the value of `digestmod` defaults to `MD5` is deprecated: in a future version of Python there will be no default value. (Contributed by Christian Heimes in bpo-17276.)

With the addition of `block_size` and `name` attributes (and the formal documentation of the `digest_size` attribute), the `hmac` module now conforms fully to the PEP 247 API. (Contributed by Christian Heimes in bpo-18775.)

**html**

New function `unescape()` function converts HTML5 character references to the corresponding Unicode characters. (Contributed by Ezio Melotti in bpo-2927.)

`HTMLParser` accepts a new keyword argument `convert_charrefs` that, when `True`, automatically converts all character references. For backward-compatibility, its value defaults to `False`, but it will change to `True` in a future version of Python, so you are invited to set it explicitly and update your code to use this new feature. (Contributed by Ezio Melotti in bpo-13633.)
The *strict* argument of `HTMLParser` is now deprecated. (Contributed by Ezio Melotti in `bpo-15114`.)

**http**

`send_error()` now accepts an optional additional *explain* parameter which can be used to provide an extended error description, overriding the hardcoded default if there is one. This extended error description will be formatted using the `error_message_format` attribute and sent as the body of the error response. (Contributed by Karl Cow in `bpo-12921`.)

The `http.server` command line interface now has a `-b/--bind` option that causes the server to listen on a specific address. (Contributed by Malte Swart in `bpo-17764`.)

**idlelib and IDLE**

Since `idlelib` implements the IDLE shell and editor and is not intended for import by other programs, it gets improvements with every release. See `Lib/idlelib/NEWS.txt` for a cumulative list of changes since 3.3.0, as well as changes made in future 3.4.x releases. This file is also available from the IDLE Help ‣ About IDLE dialog.

**importlib**

The `InspectLoader` ABC defines a new method, `source_to_code()` that accepts source data and a path and returns a code object. The default implementation is equivalent to `compile(data, path, 'exec', dont_inherit=True)`. (Contributed by Eric Snow and Brett Cannon in `bpo-15627`. )
**InspectLoader** also now has a default implementation for the `get_code()` method. However, it will normally be desirable to override the default implementation for performance reasons. (Contributed by Brett Cannon in [bpo-18072](https://bugs.python.org/issue18072).)

The `reload()` function has been moved from `imp` to `importlib` as part of the `imp` module deprecation. (Contributed by Berker Peksag in [bpo-18193](https://bugs.python.org/issue18193).)

`importlib.util` now has a `MAGIC_NUMBER` attribute providing access to the bytecode version number. This replaces the `get_magic()` function in the deprecated `imp` module. (Contributed by Brett Cannon in [bpo-18192](https://bugs.python.org/issue18192).)

New `importlib.util` functions `cache_from_source()` and `source_from_cache()` replace the same-named functions in the deprecated `imp` module. (Contributed by Brett Cannon in [bpo-18194](https://bugs.python.org/issue18194).)

The `importlib` bootstrap NamespaceLoader now conforms to the **InspectLoader** ABC, which means that `runpy` and `python -m` can now be used with namespace packages. (Contributed by Brett Cannon in [bpo-18058](https://bugs.python.org/issue18058).)

`importlib.util` has a new function `decode_source()` that decodes source from bytes using universal newline processing. This is useful for implementing `InspectLoader.get_source()` methods.

`importlib.machinery.ExtensionFileLoader` now has a `get_filename()` method. This was inadvertently omitted in the original implementation. (Contributed by Eric Snow in [bpo-19152](https://bugs.python.org/issue19152).)
The `inspect` module now offers a basic command line interface to quickly display source code and other information for modules, classes and functions. (Contributed by Claudiu Popa and Nick Coghlan in bpo-18626.)

`unwrap()` makes it easy to unravel wrapper function chains created by `functools.wraps()` (and any other API that sets the `__wrapped__` attribute on a wrapper function). (Contributed by Daniel Urban, Aaron Iles and Nick Coghlan in bpo-13266.)

As part of the implementation of the new `enum` module, the `inspect` module now has substantially better support for custom `__dir__` methods and dynamic class attributes provided through metaclasses. (Contributed by Ethan Furman in bpo-18929 and bpo-19030.)

`getfullargspec()` and `getargspec()` now use the `signature()` API. This allows them to support a much broader range of callables, including those with `__signature__` attributes, those with metadata provided by argument clinic, `functools.partial()` objects and more. Note that, unlike `signature()`, these functions still ignore `__wrapped__` attributes, and report the already bound first argument for bound methods, so it is still necessary to update your code to use `signature()` directly if those features are desired. (Contributed by Yury Selivanov in bpo-17481.)

`signature()` now supports duck types of CPython functions, which adds support for functions compiled with Cython. (Contributed by Stefan Behnel and Yury Selivanov in bpo-17159.)

`ipaddress`
An `ipaddress` was added to the standard library in Python 3.3 as a provisional API. With the release of Python 3.4, this qualification has been removed: `ipaddress` is now considered a stable API, covered by the normal standard library requirements to maintain backwards compatibility.

A new `is_global` property is `True` if an address is globally routeable. (Contributed by Peter Moody in [bpo-17400](https://bugs.python.org/issue17400).)

**logging**

The `TimedRotatingFileHandler` has a new `atTime` parameter that can be used to specify the time of day when rollover should happen. (Contributed by Ronald Oussoren in [bpo-9556](https://bugs.python.org/issue9556).)

`SocketHandler` and `DatagramHandler` now support Unix domain sockets (by setting `port` to `None`). (Contributed by Vinay Sajip in commit `ce46195b56a9`.)

`fileConfig()` now accepts a `configparser.RawConfigParser` subclass instance for the `fname` parameter. This facilitates using a configuration file when logging configuration is just a part of the overall application configuration, or where the application modifies the configuration before passing it to `fileConfig()`. (Contributed by Vinay Sajip in [bpo-16110](https://bugs.python.org/issue16110).)

Logging configuration data received from a socket via the `logging.config.listen()` function can now be validated before being processed by supplying a verification function as the argument to the new `verify` keyword argument. (Contributed by Vinay Sajip in [bpo-15452](https://bugs.python.org/issue15452).)
marshal

The default marshal version has been bumped to 3. The code implementing the new version restores the Python2 behavior of recording only one copy of interned strings and preserving the interning on deserialization, and extends this “one copy” ability to any object type (including handling recursive references). This reduces both the size of .pyc files and the amount of memory a module occupies in memory when it is loaded from a .pyc (or .pyo) file. (Contributed by Kristján Valur Jónsson in bpo-16475, with additional speedups by Antoine Pitrou in bpo-19219.)

mmap

mmap objects can now be weakrefed. (Contributed by Valerie Lambert in bpo-4885.)

multiprocessing

On Unix two new start methods, spawn and forkserver, have been added for starting processes using multiprocessing. These make the mixing of processes with threads more robust, and the spawn method matches the semantics that multiprocessing has always used on Windows. New function get_all_start_methods() reports all start methods available on the platform, get_start_method() reports the current start method, and set_start_method() sets the start method. (Contributed by Richard Oudkerk in bpo-8713.)

multiprocessing also now has the concept of a context, which determines how child processes are created. New function
get_context() returns a context that uses a specified start method. It has the same API as the multiprocessing module itself, so you can use it to create Pools and other objects that will operate within that context. This allows a framework and an application or different parts of the same application to use multiprocessing without interfering with each other. (Contributed by Richard Oudkerk in bpo-18999.)

Except when using the old fork start method, child processes no longer inherit unneeded handles/file descriptors from their parents (part of bpo-8713).

multiprocessing now relies on runpy (which implements the -m switch) to initialise __main__ appropriately in child processes when using the spawn or forkserver start methods. This resolves some edge cases where combining multiprocessing, the -m command line switch, and explicit relative imports could cause obscure failures in child processes. (Contributed by Nick Coghlan in bpo-19946.)

**operator**

New function length_hint() provides an implementation of the specification for how the __length_hint__() special method should be used, as part of the PEP 424 formal specification of this language feature. (Contributed by Armin Ronacher in bpo-16148.)

There is now a pure-python version of the operator module available for reference and for use by alternate implementations of Python. (Contributed by Zachary Ware in bpo-16694.)

**OS**
There are new functions to get and set the *inheritable flag* of a file descriptor (*os.get_inheritable(), os.set_inheritable()* or a Windows handle (*os.get_handle_inheritable(), os.set_handle_inheritable()*).

New function *cpu_count()* reports the number of CPUs available on the platform on which Python is running (or None if the count can’t be determined). The *multiprocessing.cpu_count()* function is now implemented in terms of this function. (Contributed by Trent Nelson, Yogesh Chaudhari, Victor Stinner, and Charles-François Natali in *bpo-17914*.)

*os.path.samestat()* is now available on the Windows platform (and the *os.path.samefile()* implementation is now shared between Unix and Windows). (Contributed by Brian Curtin in *bpo-11939*.)

*os.path.ismount()* now recognizes volumes mounted below a drive root on Windows. (Contributed by Tim Golden in *bpo-9035*.)

*os.open()* supports two new flags on platforms that provide them, *O_PATH* (un-opened file descriptor), and *O_TMPFILE* (unnamed temporary file; as of 3.4.0 release available only on Linux systems with a kernel version of 3.11 or newer that have uapi headers). (Contributed by Christian Heimes in *bpo-18673* and Benjamin Peterson, respectively.)

**pdb**

*pdb* has been enhanced to handle generators, *yield*, and *yield from* in a more useful fashion. This is especially helpful when debugging *asyncio* based programs. (Contributed by Andrew
Svetlov and Xavier de Gaye in bpo-16596.)

The print command has been removed from pdb, restoring access to the Python print() function from the pdb command line. Python2's pdb did not have a print command; instead, entering print executed the print statement. In Python3 print was mistakenly made an alias for the pdb p command. p, however, prints the repr of its argument, not the str like the Python2 print command did. Worse, the Python3 pdb print command shadowed the Python3 print function, making it inaccessible at the pdb prompt. (Contributed by Connor Osborn in bpo-18764.)

pickle

pickle now supports (but does not use by default) a new pickle protocol, protocol 4. This new protocol addresses a number of issues that were present in previous protocols, such as the serialization of nested classes, very large strings and containers, and classes whose __new__() method takes keyword-only arguments. It also provides some efficiency improvements.

See also:

PEP 3154 – Pickle protocol 4
PEP written by Antoine Pitrou and implemented by Alexandre Vassalotti.

plistlib

plistlib now has an API that is similar to the standard pattern for stdlib serialization protocols, with new load(), dump(), loads(),
and `dumps()` functions. (The older API is now deprecated.) In addition to the already supported XML plist format (`FMT_XML`), it also now supports the binary plist format (`FMT_BINARY`). (Contributed by Ronald Oussoren and others in `bpo-14455`.)

**poplib**

Two new methods have been added to `poplib`: `capa()`, which returns the list of capabilities advertised by the POP server, and `stls()`, which switches a clear-text POP3 session into an encrypted POP3 session if the POP server supports it. (Contributed by Lorenzo Catucci in `bpo-4473`.)

**pprint**

The `pprint` module's `PrettyPrinter` class and its `pformat()`, and `pprint()` functions have a new option, `compact`, that controls how the output is formatted. Currently setting `compact` to `True` means that sequences will be printed with as many sequence elements as will fit within `width` on each (indented) line. (Contributed by Serhiy Storchaka in `bpo-19132`.)

Long strings are now wrapped using Python’s normal line continuation syntax. (Contributed by Antoine Pitrou in `bpo-17150`.)

**pty**

`pty.spawn()` now returns the status value from `os.waitpid()` on the child process, instead of `None`. (Contributed by Gregory P. Smith.)
pydoc

The pydoc module is now based directly on the inspect.signature() introspection API, allowing it to provide signature information for a wider variety of callable objects. This change also means that __wrapped__ attributes are now taken into account when displaying help information. (Contributed by Larry Hastings in bpo-19674.)

The pydoc module no longer displays the self parameter for already bound methods. Instead, it aims to always display the exact current signature of the supplied callable. (Contributed by Larry Hastings in bpo-20710.)

In addition to the changes that have been made to pydoc directly, its handling of custom __dir__ methods and various descriptor behaviours has also been improved substantially by the underlying changes in the inspect module.

As the help() builtin is based on pydoc, the above changes also affect the behaviour of help().

re

New fullmatch() function and regex.fullmatch() method anchor the pattern at both ends of the string to match. This provides a way to be explicit about the goal of the match, which avoids a class of subtle bugs where $ characters get lost during code changes or the addition of alternatives to an existing regular expression. (Contributed by Matthew Barnett in bpo-16203.)
The repr of regex objects now includes the pattern and the flags; the repr of match objects now includes the start, end, and the part of the string that matched. (Contributed by Hugo Lopes Tavares and Serhiy Storchaka in bpo-13592 and bpo-17087.)

resource

New prlimit() function, available on Linux platforms with a kernel version of 2.6.36 or later and glibc of 2.13 or later, provides the ability to query or set the resource limits for processes other than the one making the call. (Contributed by Christian Heimes in bpo-16595.)

On Linux kernel version 2.6.36 or later, there are also some new Linux specific constants: RLIMIT_MSGQUEUE, RLIMIT_NICE, RLIMIT_RTPRIO, RLIMIT_RTTIME, and RLIMIT_SIGPENDING. (Contributed by Christian Heimes in bpo-19324.)

On FreeBSD version 9 and later, there some new FreeBSD specific constants: RLIMIT_SBSIZE, RLIMIT_SWAP, and RLIMIT_NPTS. (Contributed by Claudiu Popa in bpo-19343.)

select

epoll objects now support the context management protocol. When used in a with statement, the close() method will be called automatically at the end of the block. (Contributed by Serhiy Storchaka in bpo-16488.)

devpoll objects now have fileno() and close() methods, as well as a new attribute closed. (Contributed by Victor Stinner in bpo-18794.)
shelve

Shelf instances may now be used in `with` statements, and will be automatically closed at the end of the `with` block. (Contributed by Filip Gruszczynski in bpo-13896.)

shutil

copyfile() now raises a specific `Error` subclass, `SameFileError`, when the source and destination are the same file, which allows an application to take appropriate action on this specific error. (Contributed by Atsuo Ishimoto and Hynek Schlawack in bpo-1492704.)

smtpd

The `SMTPServer` and `SMTPChannel` classes now accept a `map` keyword argument which, if specified, is passed in to `asynchat.async_chat` as its `map` argument. This allows an application to avoid affecting the global socket map. (Contributed by Vinay Sajip in bpo-11959.)

smtplib

`SMTPException` is now a subclass of `OSError`, which allows both socket level errors and SMTP protocol level errors to be caught in one try/except statement by code that only cares whether or not an error occurred. (Contributed by Ned Jackson Lovely in bpo-2118.)

socket
The socket module now supports the **CAN_BCM** protocol on platforms that support it. (Contributed by Brian Thorne in [bpo-15359](https://bugs.python.org/issue15359).)

Socket objects have new methods to get or set their inheritable flag, `get_inheritable()` and `set_inheritable()`.

The `socket.AF_*` and `socket.SOCK_*` constants are now enumeration values using the new `enum` module. This allows meaningful names to be printed during debugging, instead of integer “magic numbers”.

The **AF_LINK** constant is now available on BSD and OSX.

`inet_pton()` and `inet_ntop()` are now supported on Windows. (Contributed by Atsuo Ishimoto in [bpo-7171](https://bugs.python.org/issue7171).)

### sqlite3

A new boolean parameter to the `connect()` function, `uri`, can be used to indicate that the `database` parameter is a `uri` (see the SQLite URI documentation). (Contributed by poq in [bpo-13773](https://bugs.python.org/issue13773).)

### ssl

`PROTOCOL_TLSv1_1` and `PROTOCOL_TLSv1_2` (TLSv1.1 and TLSv1.2 support) have been added; support for these protocols is only available if Python is linked with OpenSSL 1.0.1 or later. (Contributed by Michele Orrù and Antoine Pitrou in [bpo-16692](https://bugs.python.org/issue16692).)

New function `create_default_context()` provides a standard way to obtain an `SSLContext` whose settings are intended to be a reasonable balance between compatibility and security. These settings
are more stringent than the defaults provided by the SSLContext constructor, and may be adjusted in the future, without prior deprecation, if best-practice security requirements change. The new recommended best practice for using stdlib libraries that support SSL is to use create_default_context() to obtain an SSLContext object, modify it if needed, and then pass it as the context argument of the appropriate stdlib API. (Contributed by Christian Heimes in bpo-19689.)

SSLContext method load_verify_locations() accepts a new optional argument cadata, which can be used to provide PEM or DER encoded certificates directly via strings or bytes, respectively. (Contributed by Christian Heimes in bpo-18138.)

New function get_default_verify_paths() returns a named tuple of the paths and environment variables that the set_default_verify_paths() method uses to set OpenSSL's default cafie and capath. This can be an aid in debugging default verification issues. (Contributed by Christian Heimes in bpo-18143.)

SSLContext has a new method, cert_store_stats(), that reports the number of loaded X.509 certs, X.509 CA certs, and certificate revocation lists (crls), as well as a get_ca_certs() method that returns a list of the loaded CA certificates. (Contributed by Christian Heimes in bpo-18147.)

If OpenSSL 0.9.8 or later is available, SSLContext has a new attribute verify_flags that can be used to control the certificate verification process by setting it to some combination of the new constants VERIFY_DEFAULT, VERIFY_CRL_CHECK_LEAF, VERIFY_CRL_CHECK_CHAIN, or VERIFY_X509 STRICT. OpenSSL does not do any CRL verification by default. (Contributed by Christien
New `SSLCertificate` method `load_default_certs()` loads a set of default "certificate authority" (CA) certificates from default locations, which vary according to the platform. It can be used to load both TLS web server authentication certificates (purpose=SERVER_AUTH) for a client to use to verify a server, and certificates for a server to use in verifying client certificates (purpose=CLIENT_AUTH). (Contributed by Christian Heimes in bpo-19292.)

Two new windows-only functions, `enum_certificates()` and `enum_crls()` provide the ability to retrieve certificates, certificate information, and CRLs from the Windows cert store. (Contributed by Christian Heimes in bpo-17134.)

Support for server-side SNI (Server Name Indication) using the new `ssl.SSLContext.set_servername_callback()` method. (Contributed by Daniel Black in bpo-8109.)

The dictionary returned by `SSLSocket.getpeercert()` contains additional X509v3 extension items: `crlDistributionPoints`, `caIssuers`, and OCSP URIs. (Contributed by Christian Heimes in bpo-18379.)

**stat**

The `stat` module is now backed by a C implementation in `_stat`. A C implementation is required as most of the values aren’t standardized and are platform-dependent. (Contributed by Christian Heimes in bpo-11016.)

The module supports new `ST_MODE` flags, `S_IFDOOR`, `S_IFPORT`,
and S_IFWHT. (Contributed by Christian Hiemes in bpo-11016.)

**struct**

New function **iter_unpack** and a new `struct.Struct.iter_unpack()` method on compiled formats provide streamed unpacking of a buffer containing repeated instances of a given format of data. (Contributed by Antoine Pitrou in bpo-17804.)

**subprocess**

`check_output()` now accepts an *input* argument that can be used to provide the contents of **stdin** for the command that is run. (Contributed by Zack Weinberg in bpo-16624.)

getstatus() and **getstatusoutput()** now work on Windows. This change was actually inadvertently made in 3.3.4. (Contributed by Tim Golden in bpo-10197.)

**sunau**

The getparams() method now returns a namedtuple rather than a plain tuple. (Contributed by Claudiu Popa in bpo-18901.)

**sunau.open()** now supports the context management protocol: when used in a **with** block, the **close** method of the returned object will be called automatically at the end of the block. (Contributed by Serhiy Storchaka in bpo-18878.)

**AU_write.setsampwidth()** now supports 24 bit samples, thus
adding support for writing 24 sample using the module. (Contributed by Serhiy Storchaka in bpo-19261.)

The writeframesraw() and writeframes() methods now accept any bytes-like object. (Contributed by Serhiy Storchaka in bpo-8311.)

**sys**

New function sys.getallocatedblocks() returns the current number of blocks allocated by the interpreter. (In CPython with the default --with-pymalloc setting, this is allocations made through the PyObject_Malloc() API.) This can be useful for tracking memory leaks, especially if automated via a test suite. (Contributed by Antoine Pitrou in bpo-13390.)

When the Python interpreter starts in interactive mode, it checks for an __interactivehook__ attribute on the sys module. If the attribute exists, its value is called with no arguments just before interactive mode is started. The check is made after the PYTHONSTARTUP file is read, so it can be set there. The site module sets it to a function that enables tab completion and history saving (in ~/.python-history) if the platform supports readline. If you do not want this (new) behavior, you can override it in PYTHONSTARTUP, sitecustomize, or usercustomize by deleting this attribute from sys (or setting it to some other callable). (Contributed by Éric Araujo and Antoine Pitrou in bpo-5845.)

**tarfile**

The tarfile module now supports a simple Command-Line Interface when called as a script directly or via -m. This can be used to
create and extract tarfile archives. (Contributed by Berker Peksag in bpo-13477.)

textwrap

The TextWrapper class has two new attributes/constructor arguments: max_lines, which limits the number of lines in the output, and placeholder, which is a string that will appear at the end of the output if it has been truncated because of max_lines. Building on these capabilities, a new convenience function shorten() collapses all of the whitespace in the input to single spaces and produces a single line of a given width that ends with the placeholder (by default, [...]). (Contributed by Antoine Pitrou and Serhiy Storchaka in bpo-18585 and bpo-18725.)

threading

The Thread object representing the main thread can be obtained from the new main_thread() function. In normal conditions this will be the thread from which the Python interpreter was started. (Contributed by Andrew Svetlov in bpo-18882.)

traceback

A new traceback.clear_frames() function takes a traceback object and clears the local variables in all of the frames it references, reducing the amount of memory consumed. (Contributed by Andrew Kuchling in bpo-1565525.)

types
A new `DynamicClassAttribute()` descriptor provides a way to define an attribute that acts normally when looked up through an instance object, but which is routed to the `class __getattr__` when looked up through the class. This allows one to have properties active on a class, and have virtual attributes on the class with the same name (see `Enum` for an example). (Contributed by Ethan Furman in `bpo-19030`.)

**urllib**

`urllib.request` now supports `data` URLs via the `DataHandler` class. (Contributed by Mathias Panzenböck in `bpo-16423`.)

The http method that will be used by a `Request` class can now be specified by setting a `method` class attribute on the subclass. (Contributed by Jason R Coombs in `bpo-18978`.)

`Request` objects are now reusable: if the `full_url` or `data` attributes are modified, all relevant internal properties are updated. This means, for example, that it is now possible to use the same `Request` object in more than one `OpenerDirector.open()` call with different `data` arguments, or to modify a `Request`’s `url` rather than recomputing it from scratch. There is also a new `remove_header()` method that can be used to remove headers from a `Request`. (Contributed by Alexey Kachayev in `bpo-16464`, Daniel Wozniak in `bpo-17485`, and Damien Brecht and Senthil Kumaran in `bpo-17272`.)

`HTTPError` objects now have a `headers` attribute that provides access to the HTTP response headers associated with the error. (Contributed by Berker Peksag in `bpo-15701`.)
unittest

The **TestCase** class has a new method, `subTest()`, that produces a context manager whose `with` block becomes a “sub-test”. This context manager allows a test method to dynamically generate subtests by, say, calling the `subTest` context manager inside a loop. A single test method can thereby produce an indefinite number of separately-identified and separately-counted tests, all of which will run even if one or more of them fail. For example:

```
class NumbersTest(unittest.TestCase):
    def test_even(self):
        for i in range(6):
            with self.subTest(i=i):
                self.assertEqual(i % 2, 0)
```

will result in six subtests, each identified in the unittest verbose output with a label consisting of the variable name `i` and a particular value for that variable (`i=0`, `i=1`, etc). See [Distinguishing test iterations using subtests](#) for the full version of this example. (Contributed by Antoine Pitrou in bpo-16997.)

`unittest.main()` now accepts an iterable of test names for `defaultTest`, where previously it only accepted a single test name as a string. (Contributed by Jyrki Pulliainen in bpo-15132.)

If `SkipTest` is raised during test discovery (that is, at the module level in the test file), it is now reported as a skip instead of an error. (Contributed by Zach Ware in bpo-16935.)

`discover()` now sorts the discovered files to provide consistent test ordering. (Contributed by Martin Melin and Jeff Ramnani in bpo-16709.)
**TestSuite** now drops references to tests as soon as the test has been run, if the test is successful. On Python interpreters that do garbage collection, this allows the tests to be garbage collected if nothing else is holding a reference to the test. It is possible to override this behavior by creating a **TestSuite** subclass that defines a custom _removeTestAtIndex method. (Contributed by Tom Wardill, Matt McClure, and Andrew Svetlov in bpo-11798.)

A new test assertion context-manager, **assertLogs()**, will ensure that a given block of code emits a log message using the **logging** module. By default the message can come from any logger and have a priority of **INFO** or higher, but both the logger name and an alternative minimum logging level may be specified. The object returned by the context manager can be queried for the *LogRecords* and/or formatted messages that were logged. (Contributed by Antoine Pitrou in bpo-18937.)

Test discovery now works with namespace packages (Contributed by Claudiu Popa in bpo-17457.)

**unittest.mock** objects now inspect their specification signatures when matching calls, which means an argument can now be matched by either position or name, instead of only by position. (Contributed by Antoine Pitrou in bpo-17015.)

mock_open() objects now have **readline** and **readlines** methods. (Contributed by Toshio Kuratomi in bpo-17467.)

**venv**

**venv** now includes activation scripts for the **csh** and **fish** shells.
EnvBuilder and the create() convenience function take a new keyword argument with_pip, which defaults to False, that controls whether or not EnvBuilder ensures that pip is installed in the virtual environment. (Contributed by Nick Coghlan in bpo-19552 as part of the PEP 453 implementation.)

wave

The getparams() method now returns a namedtuple rather than a plain tuple. (Contributed by Claudiu Popa in bpo-17487.)

wave.open() now supports the context management protocol. (Contributed by Claudiu Popa in bpo-17616.)

wave can now write output to unseekable files. (Contributed by David Jones, Guilherme Polo, and Serhiy Storchaka in bpo-5202.)

The writeframesraw() and writeframes() methods now accept any bytes-like object. (Contributed by Serhiy Storchaka in bpo-8311.)

weakref

New WeakMethod class simulates weak references to bound methods. (Contributed by Antoine Pitrou in bpo-14631.)

New finalize class makes it possible to register a callback to be invoked when an object is garbage collected, without needing to carefully manage the lifecycle of the weak reference itself. (Contributed by Richard Oudkerk in bpo-15528.)
The callback, if any, associated with a `ref` is now exposed via the `__callback__` attribute. (Contributed by Mark Dickinson in bpo-17643.)

xml.etree

A new parser, `XMLPullParser`, allows a non-blocking applications to parse XML documents. An example can be seen at Pull API for non-blocking parsing. (Contributed by Antoine Pitrou in bpo-17741.)

The `xml.etree.ElementTree tostring()` and `tostringlist()` functions, and the `ElementTree write()` method, now have a `short_empty_elements` keyword-only parameter providing control over whether elements with no content are written in abbreviated (`<tag />`) or expanded (`<tag></tag>`) form. (Contributed by Ariel Poliak and Serhiy Storchaka in bpo-14377.)

zipfile

The `writepy()` method of the `PyZipFile` class has a new `filterfunc` option that can be used to control which directories and files are added to the archive. For example, this could be used to exclude test files from the archive. (Contributed by Christian Tismer in bpo-19274.)

The `allowZip64` parameter to `ZipFile` and `PyZipfile` is now `True` by default. (Contributed by William Mallard in bpo-17201.)
CPython Implementation Changes

PEP 445: Customization of CPython Memory Allocators

**PEP 445** adds new C level interfaces to customize memory allocation in the CPython interpreter.

**See also:**
**PEP 445** – Add new APIs to customize Python memory allocators  
PEP written and implemented by Victor Stinner.

PEP 442: Safe Object Finalization

**PEP 442** removes the current limitations and quirks of object finalization in CPython. With it, objects with `__del__() `methods, as well as generators with `finally `clauses, can be finalized when they are part of a reference cycle.

As part of this change, module globals are no longer forcibly set to `None `during interpreter shutdown in most cases, instead relying on the normal operation of the cyclic garbage collector. This avoids a whole class of interpreter-shutdown-time errors, usually involving `__del__ `methods, that have plagued Python since the cyclic GC was first introduced.

**See also:**
**PEP 442** – Safe object finalization
PEP 456: Secure and Interchangeable Hash Algorithm

**PEP 456** follows up on earlier security fix work done on Python’s hash algorithm to address certain DOS attacks to which public facing APIs backed by dictionary lookups may be subject. (See [bpo-14621](https://bugs.python.org/issue14621) for the start of the current round of improvements.) The PEP unifies CPython’s hash code to make it easier for a packager to substitute a different hash algorithm, and switches Python’s default implementation to a SipHash implementation on platforms that have a 64 bit data type. Any performance differences in comparison with the older FNV algorithm are trivial.

The PEP adds additional fields to the `sys.hash_info` struct sequence to describe the hash algorithm in use by the currently executing binary. Otherwise, the PEP does not alter any existing CPython APIs.

PEP 436: Argument Clinic

“Argument Clinic” ([PEP 436](https://www.python.org/dev/peps/pep-0436/)) is now part of the CPython build process and can be used to simplify the process of defining and maintaining accurate signatures for builtins and standard library extension modules implemented in C.

Some standard library extension modules have been converted to use Argument Clinic in Python 3.4, and `pydoc` and `inspect` have been updated accordingly.

It is expected that signature metadata for programmatic introspection
will be added to additional callables implemented in C as part of Python 3.4 maintenance releases.

**Note:** The Argument Clinic PEP is not fully up to date with the state of the implementation. This has been deemed acceptable by the release manager and core development team in this case, as Argument Clinic will not be made available as a public API for third party use in Python 3.4.

See also:

**PEP 436 – The Argument Clinic DSL**

PEP written and implemented by Larry Hastings.

Other Build and C API Changes

- The new `PyType_GetSlot()` function has been added to the stable ABI, allowing retrieval of function pointers from named type slots when using the limited API. (Contributed by Martin von Löwis in bpo-17162.)
- The new `Py_SetStandardStreamEncoding()` pre-initialization API allows applications embedding the CPython interpreter to reliably force a particular encoding and error handler for the standard streams. (Contributed by Bastien Montagne and Nick Coghlan in bpo-16129.)
- Most Python C APIs that don't mutate string arguments are now correctly marked as accepting `const char *` rather than `char *`. (Contributed by Serhiy Storchaka in bpo-1772673.)
- A new shell version of `python-config` can be used even when a python interpreter is not available (for example, in cross compilation scenarios).
- `PyUnicode_FromFormat()` now supports width and precision
specifications for %s, %A, %U, %V, %S, and %R. (Contributed by Ysj Ray and Victor Stinner in bpo-7330.)

- New function PyStructSequence_InitType2() supplements the existing PyStructSequence_InitType() function. The difference is that it returns 0 on success and -1 on failure.
- The CPython source can now be compiled using the address sanity checking features of recent versions of GCC and clang: the false alarms in the small object allocator have been silenced. (Contributed by Dhiru Kholia in bpo-18596.)
- The Windows build now uses Address Space Layout Randomization and Data Execution Prevention. (Contributed by Christian Heimes in bpo-16632.)
- New function PyObject_LengthHint() is the C API equivalent of operator.length_hint(). (Contributed by Armin Ronacher in bpo-16148.)

Other Improvements

- The python command has a new option, -I, which causes it to run in “isolated mode”, which means that sys.path contains neither the script's directory nor the user's site-packages directory, and all PYTHON* environment variables are ignored (it implies both -s and -E). Other restrictions may also be applied in the future, with the goal being to isolate the execution of a script from the user’s environment. This is appropriate, for example, when Python is used to run a system script. On most POSIX systems it can and should be used in the #! line of system scripts. (Contributed by Christian Heimes in bpo-16499.)
- Tab-completion is now enabled by default in the interactive interpreter on systems that support readline. History is also enabled by default, and is written to (and read from) the file ~/.python-history. (Contributed by Antoine Pitrou and Éric Araujo in bpo-5845.)
- Invoking the Python interpreter with `--version` now outputs the version to standard output instead of standard error (bpo-18338). Similar changes were made to `argparse` (bpo-18920) and other modules that have script-like invocation capabilities (bpo-18922).
- The CPython Windows installer now adds `.py` to the PATHEXT variable when extensions are registered, allowing users to run a python script at the windows command prompt by just typing its name without the `.py` extension. (Contributed by Paul Moore in bpo-18569.)
- A new make target `coverage-report` will build python, run the test suite, and generate an HTML coverage report for the C codebase using `gcov` and `lcov`.
- The `-R` option to the `python regression test suite` now also checks for memory allocation leaks, using `sys.getallocatedblocks()`. (Contributed by Antoine Pitrou in bpo-13390.)
- `python -m` now works with namespace packages.
- The `stat` module is now implemented in C, which means it gets the values for its constants from the C header files, instead of having the values hard-coded in the python module as was previously the case.
- Loading multiple python modules from a single OS module (`.so`, `.dll`) now works correctly (previously it silently returned the first python module in the file). (Contributed by Václav Šmilauer in bpo-16421.)
- A new opcode, `LOAD_CLASSDEREF`, has been added to fix a bug in the loading of free variables in class bodies that could be triggered by certain uses of `__prepare__`. (Contributed by Benjamin Peterson in bpo-17853.)
- A number of MemoryError-related crashes were identified and fixed by Victor Stinner using his PEP 445-based `pyfailmalloc` tool (bpo-18408, bpo-18520).
- The `pyvenv` command now accepts a `--copies` option to use
copies rather than symlinks even on systems where symlinks are the default. (Contributed by Vinay Sajip in bpo-18807.)

- The `pyvenv` command also accepts a `--without-pip` option to suppress the otherwise-automatic bootstrapping of pip into the virtual environment. (Contributed by Nick Coghlan in bpo-19552 as part of the PEP 453 implementation.)

- The encoding name is now optional in the value set for the PYTHONIOENCODING environment variable. This makes it possible to set just the error handler, without changing the default encoding. (Contributed by Serhiy Storchaka in bpo-18818.)

- The `bz2`, `lzma`, and `gzip` module open functions now support `x` (exclusive creation) mode. (Contributed by Tim Heaney and Vajrasky Kok in bpo-19201, bpo-19222, and bpo-19223.)

### Significant Optimizations

- The UTF-32 decoder is now 3x to 4x faster. (Contributed by Serhiy Storchaka in bpo-14625.)

- The cost of hash collisions for sets is now reduced. Each hash table probe now checks a series of consecutive, adjacent key/hash pairs before continuing to make random probes through the hash table. This exploits cache locality to make collision resolution less expensive. The collision resolution scheme can be described as a hybrid of linear probing and open addressing. The number of additional linear probes defaults to nine. This can be changed at compile-time by defining LINEAR_PROBES to be any value. Set LINEAR_PROBES=0 to turn-off linear probing entirely. (Contributed by Raymond Hettinger in bpo-18771.)

- The interpreter starts about 30% faster. A couple of measures lead to the speedup. The interpreter loads fewer modules on startup, e.g. the `re`, `collections` and `locale` modules and their dependencies are no longer imported by default. The marshal module has been improved to load compiled Python code
faster. (Contributed by Antoine Pitrou, Christian Heimes and Victor Stinner in bpo-19219, bpo-19218, bpo-19209, bpo-19205 and bpo-9548.)

- `bz2.BZ2File` is now as fast or faster than the Python2 version for most cases. `lzma.LZMAFile` has also been optimized. (Contributed by Serhiy Storchaka and Nadeem Vawda in bpo-16034.)

- `random.getrandbits()` is 20%-40% faster for small integers (the most common use case). (Contributed by Serhiy Storchaka in bpo-16674.)

- By taking advantage of the new storage format for strings, pickling of strings is now significantly faster. (Contributed by Victor Stinner and Antoine Pitrou in bpo-15596.)

- A performance issue in `io.FileIO.readall()` has been solved. This particularly affects Windows, and significantly speeds up the case of piping significant amounts of data through `subprocess`. (Contributed by Richard Oudkerk in bpo-15758.)

- `html.escape()` is now 10x faster. (Contributed by Matt Bryant in bpo-18020.)

- On Windows, the native `VirtualAlloc` is now used instead of the CRT `malloc` in `obmalloc`. Artificial benchmarks show about a 3% memory savings.

- `os.urandom()` now uses a lazily-opened persistent file descriptor so as to avoid using many file descriptors when run in parallel from multiple threads. (Contributed by Antoine Pitrou in bpo-18756.)
Deprecation

This section covers various APIs and other features that have been deprecated in Python 3.4, and will be removed in Python 3.5 or later. In most (but not all) cases, using the deprecated APIs will produce a DeprecationWarning when the interpreter is run with deprecation warnings enabled (for example, by using `-Wd`).

Deprecations in the Python API

- As mentioned in PEP 451: A ModuleSpec Type for the Import System, a number of `importlib` methods and functions are deprecated: `importlib.find_loader()` is replaced by `importlib.util.find_spec()`;
  `importlib.machinery.PathFinder.find_module()` is replaced by
  `importlib.machinery.PathFinder.find_spec()`;
  `importlib.abc.MetaPathFinder.find_module()` is replaced by
  `importlib.abc.MetaPathFinder.find_spec()`;
  `importlib.abc.PathEntryFinder.find_loader()` and
  `find_module()` are replaced by
  `importlib.abc.PathEntryFinder.find_spec()`;
  all of the `xxxLoader` ABC `load_module` methods
  (`importlib.abc.Loader.load_module()`,
  `importlib.abc.InspectLoader.load_module()`,
  `importlib.abc.FileLoader.load_module()`,
  `importlib.abc.SourceLoader.load_module()`) should no longer be implemented, instead loaders should implement an `exec_module` method
  (`importlib.abc.Loader.exec_module()`,
  `importlib.abc.InspectLoader.exec_module()`,
  `importlib.abc.FileLoader.exec_module()`,
  `importlib.abc.SourceLoader.exec_module()`)
importlib.abc.InspectLoader.exec_module()
importlib.abc.SourceLoader.exec_module() and let
the import system take care of the rest; and
importlib.abc.Loader.module_repr(),
importlib.util.module_for_loader(),
importlib.util.set_loader(), and
importlib.util.set_package() are no longer needed
because their functions are now handled automatically by the
import system.

- The imp module is pending deprecation. To keep compatibility
  with Python 2/3 code bases, the module's removal is currently not
  scheduled.
- The formatter module is pending deprecation and is slated for
  removal in Python 3.6.
- MD5 as the default digestmod for the hmac.new() function is
deprecated. Python 3.6 will require an explicit digest name or
constructor as digestmod argument.
- The internal Netrc class in the ftplib module has been
documented as deprecated in its docstring for quite some time. It
now emits a DeprecationWarning and will be removed
completely in Python 3.5.
- The undocumented endtime argument to
  subprocess.Popen.wait() should not have been exposed
  and is hopefully not in use; it is deprecated and will mostly likely
  be removed in Python 3.5.
- The strict argument of HTMLParser is deprecated.
- The plistlib readPlist(), writePlist(),
  readPlistFromBytes(), and writePlistToBytes() functions are deprecated in favor of the corresponding new
functions load(), dump(), loads(), and dumps(). Data() is
deprecated in favor of just using the bytes constructor.
- The sysconfig key SO is deprecated, it has been replaced by
  EXT_SUFFIX.
The `U` mode accepted by various `open` functions is deprecated. In Python3 it does not do anything useful, and should be replaced by appropriate uses of `io.TextIOWrapper` (if needed) and its `newline` argument.

The `parser` argument of `xml.etree.ElementTree.iterparse()` has been deprecated, as has the `html` argument of `XMLParser()`. To prepare for the removal of the latter, all arguments to `XMLParser` should be passed by keyword.

**Deprecated Features**

- Running `IDLE` with the `-n` flag (no subprocess) is deprecated. However, the feature will not be removed until `bpo-18823` is resolved.
- The site module adding a “site-python” directory to `sys.path`, if it exists, is deprecated (`bpo-19375`).
Removed

Operating Systems No Longer Supported

Support for the following operating systems has been removed from the source and build tools:

- OS/2 (bpo-16135).
- Windows 2000 (changeset e52df05b496a).
- Windows systems where COMSPEC points to command.com (bpo-14470).
- VMS (bpo-16136).

API and Feature Removals

The following obsolete and previously deprecated APIs and features have been removed:

- The unmaintained Misc/TextMate and Misc/vim directories have been removed (see the devguide for suggestions on what to use instead).
- The S0 makefile macro is removed (it was replaced by the SHLIB_SUFFIX and EXT_SUFFIX macros) (bpo-16754).
- The PyThreadState.tick_counter field has been removed; its value has been meaningless since Python 3.2, when the “new GIL” was introduced (bpo-19199).
- PyLoader and PyPycLoader have been removed from importlib. (Contributed by Taras Lyapun in bpo-15641.)
- The strict argument to HTTPConnection and HTTPSConnection has been removed. HTTP 0.9-style “Simple Responses” are no longer supported.
- The deprecated urllib.request.Request getter and setter
methods `add_data`, `has_data`, `get_data`, `get_type`, `get_host`, `get_selector`, `set_proxy`, `get_origin_req_host`, and `is_unverifiable` have been removed (use direct attribute access instead).

- Support for loading the deprecated `TYPE_INT64` has been removed from `marshal`. (Contributed by Dan Riti in [bpo-15480](https://bugs.python.org/issue15480).)

- `inspect.Signature`: positional-only parameters are now required to have a valid name.

- `object.__format__()`, no longer accepts non-empty format strings, it now raises a `TypeError` instead. Using a non-empty string has been deprecated since Python 3.2. This change has been made to prevent a situation where previously working (but incorrect) code would start failing if an object gained a `__format__` method, which means that your code may now raise a `TypeError` if you are using an 's' format code with objects that do not have a `__format__` method that handles it. See [bpo-7994](https://bugs.python.org/issue7994) for background.

- `difflib.SequenceMatcher.isbjunk()` and `difflib.SequenceMatcher.isbpopular()` were deprecated in 3.2, and have now been removed: use `x in sm.bjunk` and `x in sm.bpopular`, where `sm` is a `SequenceMatcher` object ([bpo-13248](https://bugs.python.org/issue13248)).

**Code Cleanups**

- The unused and undocumented internal `Scanner` class has been removed from the `pydoc` module.

- The private and effectively unused `_gestalt` module has been removed, along with the private `platform` functions `_mac_ver_lookup`, `_mac_ver_gstalt`, and `_bcd2str`, which would only have ever been called on badly broken OSX systems (see [bpo-18393](https://bugs.python.org/issue18393)).
The hardcoded copies of certain `stat` constants that were included in the `tarfile` module namespace have been removed.
Porting to Python 3.4

This section lists previously described changes and other bugfixes that may require changes to your code.

Changes in ‘python’ Command Behavior

- In a posix shell, setting the PATH environment variable to an empty value is equivalent to not setting it at all. However, setting PYTHONPATH to an empty value was not equivalent to not setting it at all: setting PYTHONPATH to an empty value was equivalent to setting it to ``, which leads to confusion when reasoning by analogy to how PATH works. The behavior now conforms to the posix convention for PATH.
- The [X refs, Y blocks] output of a debug (--with-pydebug) build of the CPython interpreter is now off by default. It can be re-enabled using the -X showrefcount option. (Contributed by Ezio Melotti in bpo-17323.)
- The python command and most stdlib scripts (as well as argparse) now output --version information to stdout instead of stderr (for issue list see Other Improvements above).

Changes in the Python API

- The ABCs defined in importlib.abc now either raise the appropriate exception or return a default value instead of raising NotImplementedError blindly. This will only affect code calling super() and falling through all the way to the ABCs. For compatibility, catch both NotImplementedError or the appropriate exception as needed.
- The module type now initializes the __package__ and
__loader__ attributes to None by default. To determine if these attributes were set in a backwards-compatible fashion, use e.g. getattr(module, '__loader__', None) is not None. (bpo-17115)

importlib.util.module_for_loader() now sets __loader__ and __package__ unconditionally to properly support reloading. If this is not desired then you will need to set these attributes manually. You can use importlib.util.module_to_load() for module management.

Import now resets relevant attributes (e.g. __name__, __loader__, __package__, __file__, __cached__) unconditionally when reloading. Note that this restores a pre-3.3 behavior in that it means a module is re-found when re-loaded (bpo-19413).

Frozen packages no longer set __path__ to a list containing the package name, they now set it to an empty list. The previous behavior could cause the import system to do the wrong thing on submodule imports if there was also a directory with the same name as the frozen package. The correct way to determine if a module is a package or not is to use hasattr(module, '__path__') (bpo-18065).

Frozen modules no longer define a __file__ attribute. It's semantically incorrect for frozen modules to set the attribute as they are not loaded from any explicit location. If you must know that a module comes from frozen code then you can see if the module's __spec__.location is set to 'frozen', check if the loader is a subclass of importlib.machinery.FrozenImporter, or if Python 2 compatibility is necessary you can use imp.is_frozen().

py_compile.compile() now raises FileExistsError if the file path it would write to is a symlink or a non-regular file. This is to act as a warning that import will overwrite those files with a
regular file regardless of what type of file path they were originally.

- `importlib.abc.SourceLoader.get_source()` no longer raises `ImportError` when the source code being loaded triggers a `SyntaxError` or `UnicodeDecodeError`. As `ImportError` is meant to be raised only when source code cannot be found but it should, it was felt to be over-reaching/overloading of that meaning when the source code is found but improperly structured. If you were catching `ImportError` before and wish to continue to ignore syntax or decoding issues, catch all three exceptions now.

- `functools.update_wrapper()` and `functools.wraps()` now correctly set the `__wrapped__` attribute to the function being wrapped, even if that function also had its `__wrapped__` attribute set. This means `__wrapped__` attributes now correctly link a stack of decorated functions rather than every `__wrapped__` attribute in the chain referring to the innermost function. Introspection libraries that assumed the previous behaviour was intentional can use `inspect.unwrap()` to access the first function in the chain that has no `__wrapped__` attribute.

- `inspect.getfullargspec()` has been reimplemented on top of `inspect.signature()` and hence handles a much wider variety of callable objects than it did in the past. It is expected that additional builtin and extension module callables will gain signature metadata over the course of the Python 3.4 series. Code that assumes that `inspect.getfullargspec()` will fail on non-Python callables may need to be adjusted accordingly.

- `importlib.machinery.PathFinder` now passes on the current working directory to objects in `sys.path_hooks` for the empty string. This results in `sys.path_importer_cache` never containing `''`, thus iterating through `sys.path_importer_cache` based on `sys.path` will not find all keys. A module's `__file__` when imported in the current working directory will also now have an absolute path, including
when using `-m` with the interpreter (except for `__main__.__file__` when a script has been executed directly using a relative path) (Contributed by Brett Cannon in bpo-18416). is specified on the command-line) (bpo-18416).

- The removal of the `strict` argument to `HTTPConnection` and `HTTPSConnection` changes the meaning of the remaining arguments if you are specifying them positionally rather than by keyword. If you've been paying attention to deprecation warnings your code should already be specifying any additional arguments via keywords.

- Strings between `from __future__ import ...` statements now always raise a `SyntaxError`. Previously if there was no leading docstring, an interstitial string would sometimes be ignored. This brings CPython into compliance with the language spec; Jython and PyPy already were. (bpo-17434).

- `ssl.SSLSocket.getpeercert()` and `ssl.SSLSocket.do_handshake()` now raise an `OSError` with `ENOTCONN` when the `SSLSocket` is not connected, instead of the previous behavior of raising an `AttributeError`. In addition, `getpeercert()` will raise a `ValueError` if the handshake has not yet been done.

- `base64.b32decode()` now raises a `binascii.Error` when the input string contains non-b32-alphabet characters, instead of a `TypeError`. This particular `TypeError` was missed when the other `TypeErrors` were converted. (Contributed by Serhiy Storchaka in bpo-18011.) Note: this change was also inadvertently applied in Python 3.3.3.

- The file attribute is now automatically closed when the creating `cgi.FieldStorage` instance is garbage collected. If you were pulling the file object out separately from the `cgi.FieldStorage` instance and not keeping the instance alive, then you should either store the entire `cgi.FieldStorage` instance or read the contents of the file.
before the cgi.FieldStorage instance is garbage collected.

- Calling `read` or `write` on a closed SSL socket now raises an informative `ValueError` rather than the previous more mysterious `AttributeError` (bpo-9177).

- `slice.indices()` no longer produces an `OverflowError` for huge values. As a consequence of this fix, `slice.indices()` now raises a `ValueError` if given a negative length; previously it returned nonsense values (bpo-14794).

- The `complex` constructor, unlike the `cmath` functions, was incorrectly accepting `float` values if an object's `__complex__` special method returned one. This now raises a `TypeError` (bpo-16290).

- The `int` constructor in 3.2 and 3.3 erroneously accepts `float` values for the `base` parameter. It is unlikely anyone was doing this, but if so, it will now raise a `TypeError` (bpo-16772).

- Defaults for keyword-only arguments are now evaluated after defaults for regular keyword arguments, instead of before. Hopefully no one wrote any code that depends on the previous buggy behavior (bpo-16967).

- Stale thread states are now cleared after `fork()`. This may cause some system resources to be released that previously were incorrectly kept perpetually alive (for example, database connections kept in thread-local storage). (bpo-17094.)

- Parameter names in `__annotations__` dicts are now mangled properly, similarly to `__kwdefaults__`. (Contributed by Yury Selivanov in bpo-20625.)

- `hashlib.hash.name` now always returns the identifier in lower case. Previously some built-in hashes had uppercase names, but now that it is a formal public interface the naming has been made consistent (bpo-18532).

- Because `unittest.TestSuite` now drops references to tests after they are run, test harnesses that re-use a `TestSuite` to re-run a set of tests may fail. Test suites should not be re-used in this
fashion since it means state is retained between test runs, breaking the test isolation that unittest is designed to provide. However, if the lack of isolation is considered acceptable, the old behavior can be restored by creating a TestSuite subclass that defines a removeTestAtIndex method that does nothing (see TestSuite.__iter__()) (bpo-11798).

- unittest now uses argparse for command line parsing. There are certain invalid command forms that used to work that are no longer allowed; in theory this should not cause backward compatibility issues since the disallowed command forms didn’t make any sense and are unlikely to be in use.

- The re.split(), re.findall(), and re.sub() functions, and the group() and groups() methods of match objects now always return a bytes object when the string to be matched is a bytes-like object. Previously the return type matched the input type, so if your code was depending on the return value being, say, a bytearray, you will need to change your code.

- audioop functions now raise an error immediately if passed string input, instead of failing randomly later on (bpo-16685).

- The new convert_charrefs argument to HTMLParser currently defaults to False for backward compatibility, but will eventually be changed to default to True. It is recommended that you add this keyword, with the appropriate value, to any HTMLParser calls in your code (bpo-13633).

- Since the digestmod argument to the hmac.new() function will in the future have no default, all calls to hmac.new() should be changed to explicitly specify a digestmod (bpo-17276).

- Calling sysconfig.get_config_var() with the SO key, or looking SO up in the results of a call to sysconfig.get_config_vars() is deprecated. This key should be replaced by EXT_SUFFIX or SHLIB_SUFFIX, depending on the context (bpo-19555).

- Any calls to open functions that specify U should be modified. U
is ineffective in Python3 and will eventually raise an error if used. Depending on the function, the equivalent of its old Python2 behavior can be achieved using either a `newline` argument, or if necessary by wrapping the stream in `TextIOWrapper` to use its `newline` argument (bpo-15204).

- If you use `pyvenv` in a script and desire that pip not be installed, you must add `-without-pip` to your command invocation.
- The default behavior of `json.dump()` and `json.dumps()` when an indent is specified has changed: it no longer produces trailing spaces after the item separating commas at the ends of lines. This will matter only if you have tests that are doing white-space-sensitive comparisons of such output (bpo-16333).
- `doctest` now looks for doctests in extension module `__doc__` strings, so if your doctest test discovery includes extension modules that have things that look like doctests in them you may see test failures you've never seen before when running your tests (bpo-3158).
- The `collections.abc` module has been slightly refactored as part of the Python startup improvements. As a consequence of this, it is no longer the case that importing `collections` automatically imports `collections.abc`. If your program depended on the (undocumented) implicit import, you will need to add an explicit import `collections.abc` (bpo-20784).

Changes in the C API

- `PyEval_EvalFrameEx()`, `PyObject_Repr()`, and `PyObject_Str()`, along with some other internal C APIs, now include a debugging assertion that ensures they are not used in situations where they may silently discard a currently active exception. In cases where discarding the active exception is expected and desired (for example, because it has already been saved locally with `PyErr_Fetch()` or is being deliberately
replaced with a different exception), an explicit `PyErr_Clear()` call will be needed to avoid triggering the assertion when invoking these operations (directly or indirectly) and running against a version of Python that is compiled with assertions enabled.

- `PyErr_SetImportError()` now sets `TypeError` when its `msg` argument is not set. Previously only `NULL` was returned with no exception set.

- The result of the `PyOS_ReadlineFunctionPointer` callback must now be a string allocated by `PyMem_RawMalloc()` or `PyMem_RawRealloc()`, or `NULL` if an error occurred, instead of a string allocated by `PyMem_Malloc()` or `PyMem_Realloc()` (bpo-16742)

- `PyThread_set_key_value()` now always set the value. In Python 3.3, the function did nothing if the key already exists (if the current value is a non-NULL pointer).

- The `f_tstate` (thread state) field of the `PyFrameObject` structure has been removed to fix a bug: see bpo-14432 for the rationale.
Changed in 3.4.3

PEP 476: Enabling certificate verification by default for stdlib http clients

`http.client` and modules which use it, such as `urllib.request` and `xmlrpc.client`, will now verify that the server presents a certificate which is signed by a CA in the platform trust store and whose hostname matches the hostname being requested by default, significantly improving security for many applications.

For applications which require the old previous behavior, they can pass an alternate context:

```python
import urllib.request
import ssl

# This disables all verification
context = ssl._create_unverified_context()

# This allows using a specific certificate for the host to be in the trust store
context = ssl.create_default_context(cafile="/path/to/file.crt")

urllib.request.urlopen("https://invalid-cert", context)
```
What’s New In Python 3.3

This article explains the new features in Python 3.3, compared to 3.2. Python 3.3 was released on September 29, 2012. For full details, see the changelog.

See also: PEP 398 - Python 3.3 Release Schedule
Summary – Release highlights

New syntax features:

- New `yield from` expression for generator delegation.
- The `u'unicode'` syntax is accepted again for `str` objects.

New library modules:

- `faulthandler` (helps debugging low-level crashes)
- `ipaddress` (high-level objects representing IP addresses and masks)
- `lzma` (compress data using the XZ / LZMA algorithm)
- `unittest.mock` (replace parts of your system under test with mock objects)
- `venv` (Python virtual environments, as in the popular `virtualenv` package)

New built-in features:

- Reworked I/O exception hierarchy.

Implementation improvements:

- Rewritten import machinery based on `importlib`.
- More compact unicode strings.
- More compact attribute dictionaries.

Significantly Improved Library Modules:

- C Accelerator for the `decimal` module.
- Better unicode handling in the `email` module (provisional).

Security improvements:
• Hash randomization is switched on by default.

Please read on for a comprehensive list of user-facing changes.
Virtual environments help create separate Python setups while sharing a system-wide base install, for ease of maintenance. Virtual environments have their own set of private site packages (i.e. locally-installed libraries), and are optionally segregated from the system-wide site packages. Their concept and implementation are inspired by the popular virtualenv third-party package, but benefit from tighter integration with the interpreter core.

This PEP adds the venv module for programmatic access, and the pyvenv script for command-line access and administration. The Python interpreter checks for a pyvenv.cfg, file whose existence signals the base of a virtual environment’s directory tree.

PEP written by Carl Meyer; implementation by Carl Meyer and Vinay Sajip
PEP 420: Implicit Namespace Packages

Native support for package directories that don't require \_\_init\_.py marker files and can automatically span multiple path segments (inspired by various third party approaches to namespace packages, as described in PEP 420)

See also:

**PEP 420 - Implicit Namespace Packages**

PEP written by Eric V. Smith; implementation by Eric V. Smith and Barry Warsaw
PEP 3118: New memoryview implementation and buffer protocol documentation

The implementation of PEP 3118 has been significantly improved.

The new memoryview implementation comprehensively fixes all ownership and lifetime issues of dynamically allocated fields in the Py_buffer struct that led to multiple crash reports. Additionally, several functions that crashed or returned incorrect results for non-contiguous or multi-dimensional input have been fixed.

The memoryview object now has a PEP-3118 compliant getbufferproc() that checks the consumer’s request type. Many new features have been added, most of them work in full generality for non-contiguous arrays and arrays with suboffsets.

The documentation has been updated, clearly spelling out responsibilities for both exporters and consumers. Buffer request flags are grouped into basic and compound flags. The memory layout of non-contiguous and multi-dimensional NumPy-style arrays is explained.

Features

- All native single character format specifiers in struct module syntax (optionally prefixed with ‘@’) are now supported.
- With some restrictions, the cast() method allows changing of format and shape of C-contiguous arrays.
- Multi-dimensional list representations are supported for any array type.
- Multi-dimensional comparisons are supported for any array type.
- One-dimensional memoryviews of hashable (read-only) types with formats B, b or c are now hashable. (Contributed by Antoine Pitrou in bpo-13411.)
- Arbitrary slicing of any 1-D arrays type is supported. For example, it is now possible to reverse a memoryview in O(1) by using a negative step.

**API changes**

- The maximum number of dimensions is officially limited to 64.
- The representation of empty shape, strides and suboffsets is now an empty tuple instead of `None`.
- Accessing a memoryview element with format ‘B’ (unsigned bytes) now returns an integer (in accordance with the struct module syntax). For returning a bytes object the view must be cast to ‘c’ first.
- memoryview comparisons now use the logical structure of the operands and compare all array elements by value. All format strings in struct module syntax are supported. Views with unrecognised format strings are still permitted, but will always compare as unequal, regardless of view contents.
- For further changes see **Build and C API Changes** and **Porting C code**.

(Contributed by Stefan Krah in bpo-10181.)

**See also:** PEP 3118 - Revising the Buffer Protocol
PEP 393: Flexible String Representation

The Unicode string type is changed to support multiple internal representations, depending on the character with the largest Unicode ordinal (1, 2, or 4 bytes) in the represented string. This allows a space-efficient representation in common cases, but gives access to full UCS-4 on all systems. For compatibility with existing APIs, several representations may exist in parallel; over time, this compatibility should be phased out.

On the Python side, there should be no downside to this change.

On the C API side, PEP 393 is fully backward compatible. The legacy API should remain available at least five years. Applications using the legacy API will not fully benefit of the memory reduction, or - worse - may use a bit more memory, because Python may have to maintain two versions of each string (in the legacy format and in the new efficient storage).

Functionality

Changes introduced by PEP 393 are the following:

- Python now always supports the full range of Unicode code points, including non-BMP ones (i.e. from $\text{U+0000}$ to $\text{U+10FFFF}$). The distinction between narrow and wide builds no longer exists and Python now behaves like a wide build, even under Windows.
- With the death of narrow builds, the problems specific to narrow builds have also been fixed, for example:
  - `len()` now always returns 1 for non-BMP characters, so `len('\U0010FFFF') == 1`;
  - surrogate pairs are not recombined in string literals, so
'\\uDBFF\\uDFFF' != '\\U0010FFFF';

- indexing or slicing non-BMP characters returns the expected value, so '\\U0010FFFF'[0] now returns '\\U0010FFFF' and not '\\uDBFF';
- all other functions in the standard library now correctly handle non-BMP code points.

- The value of sys.maxunicode is now always 1114111 (0x10FFFF in hexadecimal). The PyUnicode_GetMax() function still returns either 0xFFFF or 0x10FFFF for backward compatibility, and it should not be used with the new Unicode API (see bpo-13054).
- The ./configure flag --with-wide-unicode has been removed.

Performance and resource usage

The storage of Unicode strings now depends on the highest code point in the string:

- pure ASCII and Latin1 strings (U+0000-U+00FF) use 1 byte per code point;
- BMP strings (U+0000-U+FFFF) use 2 bytes per code point;
- non-BMP strings (U+10000-U+10FFFF) use 4 bytes per code point.

The net effect is that for most applications, memory usage of string storage should decrease significantly - especially compared to former wide unicode builds - as, in many cases, strings will be pure ASCII even in international contexts (because many strings store non-human language data, such as XML fragments, HTTP headers, JSON-encoded data, etc.). We also hope that it will, for the same reasons, increase CPU cache efficiency on non-trivial applications. The memory usage of Python 3.3 is two to three times smaller than Python 3.2, and
a little bit better than Python 2.7, on a Django benchmark (see the PEP for details).

**PEP 393 - Flexible String Representation**
   PEP written by Martin von Löwis; implementation by Torsten Becker and Martin von Löwis.
PEP 397: Python Launcher for Windows

The Python 3.3 Windows installer now includes a py launcher application that can be used to launch Python applications in a version independent fashion.

This launcher is invoked implicitly when double-clicking *.py files. If only a single Python version is installed on the system, that version will be used to run the file. If multiple versions are installed, the most recent version is used by default, but this can be overridden by including a Unix-style “shebang line” in the Python script.

The launcher can also be used explicitly from the command line as the py application. Running py follows the same version selection rules as implicitly launching scripts, but a more specific version can be selected by passing appropriate arguments (such as -3 to request Python 3 when Python 2 is also installed, or -2.6 to specifically request an earlier Python version when a more recent version is installed).

In addition to the launcher, the Windows installer now includes an option to add the newly installed Python to the system PATH. (Contributed by Brian Curtin in bpo-3561.)

PEP 397 - Python Launcher for Windows

PEP written by Mark Hammond and Martin v. Löwis; implementation by Vinay Sajip.

Launcher documentation: Python Launcher for Windows

Installer PATH modification: Finding the Python executable
PEP 3151: Reworking the OS and IO exception hierarchy

The hierarchy of exceptions raised by operating system errors is now both simplified and finer-grained.

You don’t have to worry anymore about choosing the appropriate exception type between OSError, IOError, EnvironmentError, WindowsError, mmap.error, socket.error or select.error. All these exception types are now only one: OSError. The other names are kept as aliases for compatibility reasons.

Also, it is now easier to catch a specific error condition. Instead of inspecting the errno attribute (or args[0]) for a particular constant from the errno module, you can catch the adequate OSError subclass. The available subclasses are the following:

- BlockingIOError
- ChildProcessError
- ConnectionError
- FileExistsError
- FileNotFoundError
- InterruptedError
- IsADirectoryError
- NotADirectoryError
- PermissionError
- ProcessLookupError
- TimeoutError

And the ConnectionError itself has finer-grained subclasses:
• BrokenPipeError
• ConnectionAbortedError
• ConnectionRefusedError
• ConnectionResetError

Thanks to the new exceptions, common usages of the `errno` can now be avoided. For example, the following code written for Python 3.2:

```python
from errno import ENOENT, EACCES, EPERM

try:
    with open("document.txt") as f:
        content = f.read()
except IOError as err:
    if err.errno == ENOENT:
        print("document.txt file is missing")
    elif err.errno in (EACCES, EPERM):
        print("You are not allowed to read document.")
    else:
        raise
```

can now be written without the `errno` import and without manual inspection of exception attributes:

```python
try:
    with open("document.txt") as f:
        content = f.read()
except FileNotFoundError:
    print("document.txt file is missing")
except PermissionError:
    print("You are not allowed to read document.txt")
```

PEP 3151 - Reworking the OS and IO Exception Hierarchy

PEP written and implemented by Antoine Pitrou
PEP 380: Syntax for Delegating to a Subgenerator

PEP 380 adds the `yield from` expression, allowing a generator to delegate part of its operations to another generator. This allows a section of code containing `yield` to be factored out and placed in another generator. Additionally, the subgenerator is allowed to return with a value, and the value is made available to the delegating generator.

While designed primarily for use in delegating to a subgenerator, the `yield from` expression actually allows delegation to arbitrary subiterators.

For simple iterators, `yield from iterable` is essentially just a shortened form of `for item in iterable: yield item`:

```python
>>> def g(x):
...    yield from range(x, 0, -1)
...    yield from range(x)
...
>>> list(g(5))
[5, 4, 3, 2, 1, 0, 1, 2, 3, 4]
```

However, unlike an ordinary loop, `yield from` allows subgenerators to receive sent and thrown values directly from the calling scope, and return a final value to the outer generator:

```python
>>> def accumulate():
...    tally = 0
...    while 1:
...        next = yield
```
The main principle driving this change is to allow even generators that are designed to be used with the `send` and `throw` methods to be split into multiple subgenerators as easily as a single large function can be split into multiple subfunctions.

See also:

**PEP 380 - Syntax for Delegating to a Subgenerator**

PEP written by Greg Ewing; implementation by Greg Ewing, integrated into 3.3 by Renaud Blanch, Ryan Kelly and Nick Coghlan; documentation by Zbigniew Jędrzejewski-Szmek and Nick Coghlan
PEP 409: Suppressing exception context

PEP 409 introduces new syntax that allows the display of the chained exception context to be disabled. This allows cleaner error messages in applications that convert between exception types:

```python
>>> class D:
...    def __init__(self, extra):
...        self._extra_attributes = extra
...    def __getattr__(self, attr):
...        try:
...            return self._extra_attributes[attr]
...        except KeyError:
...            raise AttributeError(attr) from None

>>> D({}).x
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 8, in __getattr__
AttributeError: x
```

Without the `from None` suffix to suppress the cause, the original exception would be displayed by default:

```python
>>> class C:
...    def __init__(self, extra):
...        self._extra_attributes = extra
...    def __getattr__(self, attr):
...        try:
...            return self._extra_attributes[attr]
...        except KeyError:
...            raise AttributeError(attr)

>>> C({}).x
```
No debugging capability is lost, as the original exception context remains available if needed (for example, if an intervening library has incorrectly suppressed valuable underlying details):

```python
>>> try:
...     D({}).x
... except AttributeError as exc:
...     print(repr(exc.__context__))
... KeyError('x',)
```

See also:

**PEP 409 - Suppressing exception context**

PEP written by Ethan Furman; implemented by Ethan Furman and Nick Coghlan.
PEP 414: Explicit Unicode literals

To ease the transition from Python 2 for Unicode aware Python applications that make heavy use of Unicode literals, Python 3.3 once again supports the “u” prefix for string literals. This prefix has no semantic significance in Python 3, it is provided solely to reduce the number of purely mechanical changes in migrating to Python 3, making it easier for developers to focus on the more significant semantic changes (such as the stricter default separation of binary and text data).

See also:

PEP 414 - Explicit Unicode literals
PEP written by Armin Ronacher.
PEP 3155: Qualified name for classes and functions

Functions and class objects have a new \texttt{__qualname__} attribute representing the “path” from the module top-level to their definition. For global functions and classes, this is the same as \texttt{__name__}. For other functions and classes, it provides better information about where they were actually defined, and how they might be accessible from the global scope.

Example with (non-bound) methods:

```python
>>> class C:
...    def meth(self):
...        pass
>>> C.meth.__name__
'meth'
>>> C.meth.__qualname__
'C.meth'
```

Example with nested classes:

```python
>>> class C:
...    class D:
...        def meth(self):
...            pass
...
>>> C.D.__name__
'D'
>>> C.D.__qualname__
'C.D'
>>> C.D.meth.__name__
'meth'
>>> C.D.meth.__qualname__
```
Example with nested functions:

```python
>>> def outer():
...     def inner():
...         pass
...     return inner
...
>>> outer().__name__
'inner'
>>> outer().__qualname__
'outer.<locals>.inner'
```

The string representation of those objects is also changed to include the new, more precise information:

```python
>>> str(C.D)
"<class '__main__.C.D'>"
>>> str(C.D.meth)
'<function C.D.meth at 0x7f46b9fe31e0>'
```

See also:

**PEP 3155** - Qualified name for classes and functions

PEP written and implemented by Antoine Pitrou.
PEP 412: Key-Sharing Dictionary

Dictionaries used for the storage of objects’ attributes are now able to share part of their internal storage between each other (namely, the part which stores the keys and their respective hashes). This reduces the memory consumption of programs creating many instances of non-builtin types.

See also:

PEP 412 - Key-Sharing Dictionary
   PEP written and implemented by Mark Shannon.
PEP 362: Function Signature Object

A new function `inspect.signature()` makes introspection of python callables easy and straightforward. A broad range of callables is supported: python functions, decorated or not, classes, and `functools.partial()` objects. New classes `inspect.Signature`, `inspect.Parameter`, and `inspect.BoundArguments` hold information about the call signatures, such as, annotations, default values, parameters kinds, and bound arguments, which considerably simplifies writing decorators and any code that validates or amends calling signatures or arguments.

See also:

PEP 362: - Function Signature Object

PEP written by Brett Cannon, Yury Selivanov, Larry Hastings, Jiwon Seo; implemented by Yury Selivanov.
PEP 421: Adding sys.implementation

A new attribute on the `sys` module exposes details specific to the implementation of the currently running interpreter. The initial set of attributes on `sys.implementation` are `name`, `version`, `hexversion`, and `cache_tag`.

The intention of `sys.implementation` is to consolidate into one namespace the implementation-specific data used by the standard library. This allows different Python implementations to share a single standard library code base much more easily. In its initial state, `sys.implementation` holds only a small portion of the implementation-specific data. Over time that ratio will shift in order to make the standard library more portable.

One example of improved standard library portability is `cache_tag`. As of Python 3.3, `sys.implementation.cache_tag` is used by `importlib` to support PEP 3147 compliance. Any Python implementation that uses `importlib` for its built-in import system may use `cache_tag` to control the caching behavior for modules.

SimpleNamespace

The implementation of `sys.implementation` also introduces a new type to Python: `types.SimpleNamespace`. In contrast to a mapping-based namespace, like `dict`, `SimpleNamespace` is attribute-based, like `object`. However, unlike `object`, `SimpleNamespace` instances are writable. This means that you can add, remove, and modify the namespace through normal attribute access.
See also:

**PEP 421** - Adding `sys.implementation`

PEP written and implemented by Eric Snow.
Using importlib as the Implementation of Import

**bpo-2377** - Replace __import__ w/ importlib.__import__
**bpo-13959** - Re-implement parts of imp in pure Python
**bpo-14605** - Make import machinery explicit
**bpo-14646** - Require loaders set __loader__ and __package__

The __import__() function is now powered by importlib.__import__(). This work leads to the completion of “phase 2” of PEP 302. There are multiple benefits to this change. First, it has allowed for more of the machinery powering import to be exposed instead of being implicit and hidden within the C code. It also provides a single implementation for all Python VMs supporting Python 3.3 to use, helping to end any VM-specific deviations in import semantics. And finally it eases the maintenance of import, allowing for future growth to occur.

For the common user, there should be no visible change in semantics. For those whose code currently manipulates import or calls import programmatically, the code changes that might possibly be required are covered in the Porting Python code section of this document.

**New APIs**

One of the large benefits of this work is the exposure of what goes into making the import statement work. That means the various importers that were once implicit are now fully exposed as part of the importlib package.

The abstract base classes defined in importlib.abc have been
expanded to properly delineate between meta path finders and path entry finders by introducing `importlib.abc.MetaPathFinder` and `importlib.abc.PathEntryFinder`, respectively. The old ABC of `importlib.abc.Finder` is now only provided for backwards-compatibility and does not enforce any method requirements.

In terms of finders, `importlib.machinery.FileFinder` exposes the mechanism used to search for source and bytecode files of a module. Previously this class was an implicit member of `sys.path_hooks`.

For loaders, the new abstract base class `importlib.abc.FileLoader` helps write a loader that uses the file system as the storage mechanism for a module's code. The loader for source files (`importlib.machinery.SourceFileLoader`), sourceless bytecode files (`importlib.machinery.SourcelessFileLoader`), and extension modules (`importlib.machinery.ExtensionFileLoader`) are now available for direct use.

`ImportError` now has name and path attributes which are set when there is relevant data to provide. The message for failed imports will also provide the full name of the module now instead of just the tail end of the module's name.

The `importlib.invalidate_caches()` function will now call the method with the same name on all finders cached in `sys.path_importer_cache` to help clean up any stored state as necessary.

**Visible Changes**
For potential required changes to code, see the Porting Python code section.

Beyond the expanse of what importlib now exposes, there are other visible changes to import. The biggest is that sys.meta_path and sys.path_hooks now store all of the meta path finders and path entry hooks used by import. Previously the finders were implicit and hidden within the C code of import instead of being directly exposed. This means that one can now easily remove or change the order of the various finders to fit one’s needs.

Another change is that all modules have a __loader__ attribute, storing the loader used to create the module. PEP 302 has been updated to make this attribute mandatory for loaders to implement, so in the future once 3rd-party loaders have been updated people will be able to rely on the existence of the attribute. Until such time, though, import is setting the module post-load.

Loaders are also now expected to set the __package__ attribute from PEP 366. Once again, import itself is already setting this on all loaders from importlib and import itself is setting the attribute post-load.

None is now inserted into sys.path_importer_cache when no finder can be found on sys.path_hooks. Since imp.NullImporter is not directly exposed on sys.path_hooks it could no longer be relied upon to always be available to use as a value representing no finder found.

All other changes relate to semantic changes which should be taken into consideration when updating code for Python 3.3, and thus should be read about in the Porting Python code section of this document.
(Implementation by Brett Cannon)
Other Language Changes

Some smaller changes made to the core Python language are:

- Added support for Unicode name aliases and named sequences. Both `unicodedata.lookup()` and '\N{...}' now resolve name aliases, and `unicodedata.lookup()` resolves named sequences too.

  (Contributed by Ezio Melotti in bpo-12753.)

- Unicode database updated to UCD version 6.1.0

- Equality comparisons on `range()` objects now return a result reflecting the equality of the underlying sequences generated by those range objects. (bpo-13201)

- The `count()`, `find()`, `rfind()`, `index()`, and `rindex()` methods of `bytes` and `bytearray` objects now accept an integer between 0 and 255 as their first argument.

  (Contributed by Petri Lehtinen in bpo-12170.)

- The `rjust()`, `ljust()`, and `center()` methods of `bytes` and `bytearray` now accept a `bytearray` for the `fill` argument.

  (Contributed by Petri Lehtinen in bpo-12380.)

- New methods have been added to `list` and `bytearray`: `copy()` and `clear()` (bpo-10516). Consequently, `MutableSequence` now also defines a `clear()` method (bpo-11388).

- Raw bytes literals can now be written `rb"..."` as well as
br"...".

(Contributed by Antoine Pitrou in bpo-13748.)

- `dict.setdefault()` now does only one lookup for the given key, making it atomic when used with built-in types.

  (Contributed by Filip Gruszczynski in bpo-13521.)

- The error messages produced when a function call does not match the function signature have been significantly improved.

  (Contributed by Benjamin Peterson.)
A Finer-Grained Import Lock

Previous versions of CPython have always relied on a global import lock. This led to unexpected annoyances, such as deadlocks when importing a module would trigger code execution in a different thread as a side-effect. Clumsy workarounds were sometimes employed, such as the `PyImport_ImportModuleNoBlock()` C API function.

In Python 3.3, importing a module takes a per-module lock. This correctly serializes importation of a given module from multiple threads (preventing the exposure of incompletely initialized modules), while eliminating the aforementioned annoyances.

(Contributed by Antoine Pitrou in bpo-9260.)
Built-in functions and types

- **open()** gets a new *opener* parameter: the underlying file descriptor for the file object is then obtained by calling *opener* with *(file, flags)*. It can be used to use custom flags like `os.O_CLOEXEC` for example. The `'x'` mode was added: open for exclusive creation, failing if the file already exists.
- **print()**: added the *flush* keyword argument. If the *flush* keyword argument is true, the stream is forcibly flushed.
- **hash()**: hash randomization is enabled by default, see `object.__hash__() and PYTHONHASHSEED`.
- The `str` type gets a new *casefold() method*: return a casefolded copy of the string, casefolded strings may be used for caseless matching. For example, `'ß'.casefold()` returns `'ss'`.
- The sequence documentation has been substantially rewritten to better explain the binary/text sequence distinction and to provide specific documentation sections for the individual built-in sequence types *(bpo-4966)*.
New Modules

faulthandler

This new debug module faulthandler contains functions to dump Python tracebacks explicitly, on a fault (a crash like a segmentation fault), after a timeout, or on a user signal. Call faulthandler.enable() to install fault handlers for the SIGSEGV, SIGFPE, SIGABRT, SIGBUS, and SIGILL signals. You can also enable them at startup by setting the PYTHONFAULTHANDLER environment variable or by using -X faulthandler command line option.

Example of a segmentation fault on Linux:

```
$ python -q -X faulthandler
>>> import ctypes
>>> ctypes.string_at(0)
Fatal Python error: Segmentation fault
Current thread 0x00007fb899f39700:
  File "/home/python/cpython/Lib/ctypes/__init__.py", line 486 in string_at
  File "<stdin>", line 1 in <module>
Segmentation fault
```

ipaddress

The new ipaddress module provides tools for creating and manipulating objects representing IPv4 and IPv6 addresses, networks and interfaces (i.e. an IP address associated with a specific IP subnet).

(Contributed by Google and Peter Moody in PEP 3144.)
Izma

The newly-added *lzma* module provides data compression and decompression using the LZMA algorithm, including support for the *.xz* and *.lzma* file formats.

(Contributed by Nadeem Vawda and Per Øyvind Karlsen in [bpo-6715](http://example.com).)
Improved Modules

abc

Improved support for abstract base classes containing descriptors composed with abstract methods. The recommended approach to declaring abstract descriptors is now to provide `__isabstractmethod__` as a dynamically updated property. The built-in descriptors have been updated accordingly.

- `abc.abstractproperty` has been deprecated, use `property` with `abc.abstractmethod()` instead.
- `abc.abstractclassmethod` has been deprecated, use `classmethod` with `abc.abstractmethod()` instead.
- `abc.abstractstaticmethod` has been deprecated, use `staticmethod` with `abc.abstractmethod()` instead.

(Contributed by Darren Dale in bpo-11610.)

`abc.ABCMeta.register()` now returns the registered subclass, which means it can now be used as a class decorator (bpo-10868).

array

The `array` module supports the `long` `long` type using `q` and `Q` type codes.

(Contributed by Oren Tirosh and Hirokazu Yamamoto in bpo-1172711.)

base64

ASCII-only Unicode strings are now accepted by the decoding
functions of the base64 modern interface. For example, `base64.b64decode('YWJj')` returns `b'abc'`. (Contributed by Catalin Iacob in bpo-13641.)

binascii

In addition to the binary objects they normally accept, the a2b_ functions now all also accept ASCII-only strings as input. (Contributed by Antoine Pitrou in bpo-13637.)

bz2

The bz2 module has been rewritten from scratch. In the process, several new features have been added:

- New `bz2.open()` function: open a bzip2-compressed file in binary or text mode.

- `bz2.BZ2File` can now read from and write to arbitrary file-like objects, by means of its constructor’s `fileobj` argument.

  (Contributed by Nadeem Vawda in bpo-5863.)

- `bz2.BZ2File` and `bz2.decompress()` can now decompress multi-stream inputs (such as those produced by the pbzip2 tool). `bz2.BZ2File` can now also be used to create this type of file, using the 'a' (append) mode.

  (Contributed by Nir Aides in bpo-1625.)

- `bz2.BZ2File` now implements all of the io.BufferedIOBase API, except for the detach() and truncate() methods.
The mbcs codec has been rewritten to handle correctly replace and ignore error handlers on all Windows versions. The mbcs codec now supports all error handlers, instead of only replace to encode and ignore to decode.

A new Windows-only codec has been added: cp65001 (bpo-13216). It is the Windows code page 65001 (Windows UTF-8, CP_UTF8). For example, it is used by sys.stdout if the console output code page is set to cp65001 (e.g., using chcp 65001 command).

Multibyte CJK decoders now resynchronize faster. They only ignore the first byte of an invalid byte sequence. For example, b'\xff\n'.decode('gb2312', 'replace') now returns a \n after the replacement character.

(bpo-12016)

Incremental CJK codec encoders are no longer reset at each call to their encode() methods. For example:

```python
>>> import codecs
>>> encoder = codecs.getincrementalencoder('hz')('strict')
>>> b''.join(encoder.encode(x) for x in u'~{NpJ}l6HK!#~} Bye.'

This example gives b'~{Np~}~{J}~{16~}~{HK~}~{!#~} Bye.' with older Python versions.
```

(bpo-12100)
The `unicode_internal` codec has been deprecated.

collections

Addition of a new `ChainMap` class to allow treating a number of mappings as a single unit. (Written by Raymond Hettinger for `bpo-11089`, made public in `bpo-11297`.)

The abstract base classes have been moved in a new `collections.abc` module, to better differentiate between the abstract and the concrete collections classes. Aliases for ABCs are still present in the `collections` module to preserve existing imports. (`bpo-11085`)

The `Counter` class now supports the unary `+` and `-` operators, as well as the in-place operators `+=`, `-=`, `|=`, and `&=`. (Contributed by Raymond Hettinger in `bpo-13121`.)

contextlib

`ExitStack` now provides a solid foundation for programmatic manipulation of context managers and similar cleanup functionality. Unlike the previous `contextlib.nested` API (which was deprecated and removed), the new API is designed to work correctly regardless of whether context managers acquire their resources in their `__init__` method (for example, file objects) or in their `__enter__` method (for example, synchronisation objects from the `threading` module).

(`bpo-13585`)
crypt

Addition of salt and modular crypt format (hashing method) and the `mksalt()` function to the `crypt` module.

(bpo-10924)

curses

- If the `curses` module is linked to the ncursesw library, use Unicode functions when Unicode strings or characters are passed (e.g. `waddwstr()`), and bytes functions otherwise (e.g. `waddstr()`).
- Use the locale encoding instead of `utf-8` to encode Unicode strings.
- `curses.window` has a new `curses.window.encoding` attribute.
- The `curses.window` class has a new `get_wch()` method to get a wide character.
- The `curses` module has a new `unget_wch()` function to push a wide character so the next `get_wch()` will return it.

(Contributed by Iñigo Serna in bpo-6755.)

datetime

- Equality comparisons between naive and aware `datetime` instances now return `False` instead of raising `TypeError` (bpo-15006).
- New `datetime.datetime.timestamp()` method: Return POSIX timestamp corresponding to the `datetime` instance.
- The `datetime.datetime.strftime()` method supports
formatting years older than 1000.
- The `datetime.datetime.astimezone()` method can now be called without arguments to convert datetime instance to the system timezone.

**decimal**

**bpo-7652** - integrate fast native decimal arithmetic.
C-module and libmpdec written by Stefan Krah.

The new C version of the decimal module integrates the high speed libmpdec library for arbitrary precision correctly-rounded decimal floating point arithmetic. libmpdec conforms to IBM's General Decimal Arithmetic Specification.

Performance gains range from 10x for database applications to 100x for numerically intensive applications. These numbers are expected gains for standard precisions used in decimal floating point arithmetic. Since the precision is user configurable, the exact figures may vary. For example, in integer bignum arithmetic the differences can be significantly higher.

The following table is meant as an illustration. Benchmarks are available at [http://www.bytereef.org/mpdecimal/quickstart.html](http://www.bytereef.org/mpdecimal/quickstart.html).

<table>
<thead>
<tr>
<th></th>
<th><strong>decimal.py</strong></th>
<th><strong>_decimal</strong></th>
<th><strong>speedup</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>pi</td>
<td>42.02s</td>
<td>0.345s</td>
<td>120x</td>
</tr>
<tr>
<td>telco</td>
<td>172.19s</td>
<td>5.68s</td>
<td>30x</td>
</tr>
<tr>
<td>psycopg</td>
<td>3.57s</td>
<td>0.29s</td>
<td>12x</td>
</tr>
</tbody>
</table>

**Features**
• The **FloatOperation** signal optionally enables stricter semantics for mixing floats and Decimals.
• If Python is compiled without threads, the C version automatically disables the expensive thread local context machinery. In this case, the variable **HAVE_THREADS** is set to **False**.

**API changes**

• The C module has the following context limits, depending on the machine architecture:

<table>
<thead>
<tr>
<th></th>
<th>32-bit</th>
<th>64-bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAX_PREC</td>
<td>4250000000</td>
<td>999999999999999999</td>
</tr>
<tr>
<td>MAX_EMAX</td>
<td>4250000000</td>
<td>999999999999999999</td>
</tr>
<tr>
<td>MIN_EMIN</td>
<td>-4250000000</td>
<td>-999999999999999999</td>
</tr>
</tbody>
</table>

• In the context templates (**DefaultContext**, **BasicContext** and **ExtendedContext**) the magnitude of Emax and Emin has changed to 999999.

• The **Decimal** constructor in decimal.py does not observe the context limits and converts values with arbitrary exponents or precision exactly. Since the C version has internal limits, the following scheme is used: If possible, values are converted exactly, otherwise **InvalidOperation** is raised and the result is NaN. In the latter case it is always possible to use **create_decimal()** in order to obtain a rounded or inexact value.

• The power function in decimal.py is always correctly-rounded. In the C version, it is defined in terms of the correctly-rounded
exp() and ln() functions, but the final result is only “almost always correctly rounded”.

- In the C version, the context dictionary containing the signals is a `MutableMapping`. For speed reasons, flags and traps always refer to the same `MutableMapping` that the context was initialized with. If a new signal dictionary is assigned, flags and traps are updated with the new values, but they do not reference the RHS dictionary.

- Pickling a `Context` produces a different output in order to have a common interchange format for the Python and C versions.

- The order of arguments in the `Context` constructor has been changed to match the order displayed by `repr()`.

- The `watchexp` parameter in the `quantize()` method is deprecated.

email

Policy Framework

The email package now has a `policy` framework. A `Policy` is an object with several methods and properties that control how the email package behaves. The primary policy for Python 3.3 is the `Compat32` policy, which provides backward compatibility with the email package in Python 3.2. A `policy` can be specified when an email message is parsed by a `parser`, or when a `Message` object is created, or when an email is serialized using a `generator`. Unless overridden, a policy passed to a `parser` is inherited by all the `Message` object and sub-objects created by the `parser`. By default a `generator` will use the
policy of the Message object it is serializing. The default policy is compat32.

The minimum set of controls implemented by all policy objects are:

<table>
<thead>
<tr>
<th>Control</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>max_line_length</td>
<td>The maximum length, excluding the linesep character(s), individual lines may have when a Message is serialized. Defaults to 78.</td>
</tr>
<tr>
<td>linesep</td>
<td>The character used to separate individual lines when a Message is serialized. Defaults to \n.</td>
</tr>
<tr>
<td>cte_type</td>
<td>7bit or 8bit. 8bit applies only to a Bytes generator, and means that non-ASCII may be used where allowed by the protocol (or where it exists in the original input).</td>
</tr>
<tr>
<td>raise_on_defect</td>
<td>Causes a parser to raise error when defects are encountered instead of adding them to the Message object's defects list.</td>
</tr>
</tbody>
</table>

A new policy instance, with new settings, is created using the clone() method of policy objects. clone takes any of the above controls as keyword arguments. Any control not specified in the call retains its default value. Thus you can create a policy that uses \r\n linesep characters like this:

```python
mypolicy = compat32.clone(linesep='\r\n')
```

Policies can be used to make the generation of messages in the format needed by your application simpler. Instead of having to remember to specify linesep='\r\n' in all the places you call a generator, you can specify it once, when you set the policy used by the parser or the Message, whichever your program uses to create
Message objects. On the other hand, if you need to generate messages in multiple forms, you can still specify the parameters in the appropriate `generator` call. Or you can have custom policy instances for your different cases, and pass those in when you create the `generator`.

**Provisional Policy with New Header API**

While the policy framework is worthwhile all by itself, the main motivation for introducing it is to allow the creation of new policies that implement new features for the email package in a way that maintains backward compatibility for those who do not use the new policies. Because the new policies introduce a new API, we are releasing them in Python 3.3 as a **provisional policy**. Backwards incompatible changes (up to and including removal of the code) may occur if deemed necessary by the core developers.

The new policies are instances of `EmailPolicy`, and add the following additional controls:

<table>
<thead>
<tr>
<th>refold_source</th>
<th>Controls whether or not headers parsed by a parser are refolded by the <code>generator</code>. It can be none, long, or all. The default is long, which means that source headers with a line longer than <code>max_line_length</code> get refolded. none means no line get refolded, and all means that all lines get refolded.</th>
</tr>
</thead>
<tbody>
<tr>
<td>header_factory</td>
<td>A callable that take a name and value and produces a custom header object.</td>
</tr>
</tbody>
</table>

The `header_factory` is the key to the new features provided by the new policies. When one of the new policies is used, any header retrieved from a `Message` object is an object produced by the
header_factory, and any time you set a header on a Message it becomes an object produced by header_factory. All such header objects have a name attribute equal to the header name. Address and Date headers have additional attributes that give you access to the parsed data of the header. This means you can now do things like this:

```python
>>> m = Message(policy=SMTP)
>>> m['To'] = 'Éric <foo@example.com>'
>>> m['to']
'Éric <foo@example.com>'
>>> m['to'].addresses
(Address(display_name='Éric', username='foo', domain='example.com'),)
>>> m['to'].addresses[0].username
'foo'
>>> m['to'].addresses[0].display_name
'Éric'
>>> m['Date'] = email.utils.localtime()
>>> m['Date'].datetime
datetime.datetime(2012, 5, 25, 21, 39, 24, 465484, tzinfo=datetime.timezone(datetime.timedelta(-1, 72000), 'EDT'))
>>> m['Date']
'Fri, 25 May 2012 21:44:27 -0400'
>>> print(m)
To: =?utf-8?q?=C3=89ric?= <foo@example.com>
Date: Fri, 25 May 2012 21:44:27 -0400
```

You will note that the unicode display name is automatically encoded as utf-8 when the message is serialized, but that when the header is accessed directly, you get the unicode version. This eliminates any need to deal with the `email.header decode_header()` or `make_header()` functions.

You can also create addresses from parts:

```python
>>> m['cc'] = [Group('pals', [Address('Bob', 'bob',
```
Decoding to unicode is done automatically:

```python
>>> m2 = message_from_string(str(m))
>>> m2['to']
'Éric <foo@example.com>'
```

When you parse a message, you can use the `addresses` and `groups` attributes of the header objects to access the groups and individual addresses:

```python
>>> m2['cc'].addresses
(Address(display_name='Bob', username='bob', domain='example.com'),
 Address(display_name='Sally', username='sally', domain='example.com'),
 Address(display_name='Bonzo', username='bonz', domain='laugh.com'))
>>> m2['cc'].groups
(Group(display_name='pals', addresses=(Address(display_name='Bob',
    username='bob', domain='example.com'),
    Address(display_name='Sally', username='sally', domain='example.com'))),
 Group(display_name=None, addresses=(Address(display_name='Bonzo',
    username='bonz', domain='laugh.com'),)))
```

In summary, if you use one of the new policies, header manipulation works the way it ought to: your application works with unicode strings, and the email package transparently encodes and decodes the unicode to and from the RFC standard Content Transfer Encodings.

Other API Changes

New `BytesHeaderParser`, added to the `parser` module to complement `HeaderParser` and complete the Bytes API.

New utility functions:
• **format_datetime()**: given a `datetime`, produce a string formatted for use in an email header.

• **parsedate_to_datetime()**: given a date string from an email header, convert it into an aware `datetime`, or a naive `datetime` if the offset is `-0000`.

• **localtime()**: With no argument, returns the current local time as an aware `datetime` using the local `timezone`. Given an aware `datetime`, converts it into an aware `datetime` using the local `timezone`.

**ftplib**

• **`ftplib.FTP`** now accepts a `source_address` keyword argument to specify the `(host, port)` to use as the source address in the bind call when creating the outgoing socket. (Contributed by Giampaolo Rodolà in bpo-8594.)

• The **FTP_TLS** class now provides a new `ccc()` function to revert control channel back to plaintext. This can be useful to take advantage of firewalls that know how to handle NAT with non-secure FTP without opening fixed ports. (Contributed by Giampaolo Rodolà in bpo-12139.)

• Added **`ftplib.FTP.mlsd()`** method which provides a parsable directory listing format and deprecates `ftplib.FTP.nlst()` and `ftplib.FTP.dir()`. (Contributed by Giampaolo Rodolà in bpo-11072.)

**functools**

The **`functools.lru_cache()`** decorator now accepts a typed keyword argument (that defaults to `False` to ensure that it caches values of different types that compare equal in separate cache slots. (Contributed by Raymond Hettinger in bpo-13227.)
It is now possible to register callbacks invoked by the garbage collector before and after collection using the new `callbacks` list.

A new `compare_digest()` function has been added to prevent side channel attacks on digests through timing analysis. (Contributed by Nick Coghlan and Christian Heimes in bpo-15061.)

`http.server.BaseHTTPRequestHandler` now buffers the headers and writes them all at once when `end_headers()` is called. A new method `flush_headers()` can be used to directly manage when the accumulated headers are sent. (Contributed by Andrew Schaaf in bpo-3709.)

`http.server` now produces valid HTML 4.01 `strict` output. (Contributed by Ezio Melotti in bpo-13295.)

`http.client.HTTPResponse` now has a `readinto()` method, which means it can be used as an `io.RawIOWBase` class. (Contributed by John Kuhn in bpo-13464.)

`html.parser.HTMLParser` is now able to parse broken markup without raising errors, therefore the `strict` argument of the constructor
and the HTMLParseError exception are now deprecated. The ability to parse broken markup is the result of a number of bug fixes that are also available on the latest bug fix releases of Python 2.7/3.2. (Contributed by Ezio Melotti in bpo-15114, and bpo-14538, bpo-13993, bpo-13960, bpo-13358, bpo-1745761, bpo-755670, bpo-13357, bpo-12629, bpo-1200313, bpo-670664, bpo-13273, bpo-12888, bpo-7311.)

A new html5 dictionary that maps HTML5 named character references to the equivalent Unicode character(s) (e.g. html5['gt;'] == '>') has been added to the html.entities module. The dictionary is now also used by HTMLParser. (Contributed by Ezio Melotti in bpo-11113 and bpo-15156.)

imaplib

The IMAP4_SSL constructor now accepts an SSLContext parameter to control parameters of the secure channel.

(Contributed by Sijin Joseph in bpo-8808.)

inspect

A new getclosurevars() function has been added. This function reports the current binding of all names referenced from the function body and where those names were resolved, making it easier to verify correct internal state when testing code that relies on stateful closures.

(Contributed by Meador Inge and Nick Coghlan in bpo-13062.)

A new getgeneratorlocals() function has been added. This function reports the current binding of local variables in the generator’s stack frame, making it easier to verify correct internal state when
testing generators.

(Contributed by Meador Inge in bpo-15153.)

**io**

The `open()` function has a new 'x' mode that can be used to exclusively create a new file, and raise a `FileExistsError` if the file already exists. It is based on the C11 ‘x’ mode to `fopen()`.

(Contributed by David Townshend in bpo-12760.)

The constructor of the `TextIOWrapper` class has a new `write_through` optional argument. If `write_through` is `True`, calls to `write()` are guaranteed not to be buffered: any data written on the `TextIOWrapper` object is immediately handled to its underlying binary buffer.

**itertools**

`accumulate()` now takes an optional `func` argument for providing a user-supplied binary function.

**logging**

The `basicConfig()` function now supports an optional `handlers` argument taking an iterable of handlers to be added to the root logger.

A class level attribute `append_nul` has been added to `SysLogHandler` to allow control of the appending of the `NUL (\000)` byte to syslog records, since for some daemons it is required while for
others it is passed through to the log.

math

The math module has a new function, \( \log_2() \), which returns the base-2 logarithm of \( x \).

(Written by Mark Dickinson in bpo-11888.)

mmap

The read() method is now more compatible with other file-like objects: if the argument is omitted or specified as None, it returns the bytes from the current file position to the end of the mapping. (Contributed by Petri Lehtinen in bpo-12021.)

multiprocessing

The new multiprocessing.connection.wait() function allows polling multiple objects (such as connections, sockets and pipes) with a timeout. (Contributed by Richard Oudkerk in bpo-12328.)

multiprocessing.Connection objects can now be transferred over multiprocessing connections. (Contributed by Richard Oudkerk in bpo-4892.)

multiprocessing.Process now accepts a daemon keyword argument to override the default behavior of inheriting the daemon flag from the parent process (bpo-6064).

New attribute multiprocessing.Process.sentinel allows a program to wait on multiple Process objects at one time using the
appropriate OS primitives (for example, `select` on posix systems).

New methods `multiprocessing.pool.Pool.starmap()` and `starmap_async()` provide `itertools.starmap()` equivalents to the existing `multiprocessing.pool.Pool.map()` and `map_async()` functions. (Contributed by Hynek Schlawack in `bpo-12708`.)

**nntplib**

The `nntplib.NNTP` class now supports the context management protocol to unconditionally consume `socket.error` exceptions and to close the NNTP connection when done:

```
>>> from nntplib import NNTP
>>> with NNTP('news.gmane.org') as n:
...     n.group('gmane.comp.python.committers')
... ('211 1755 1 1755 gmane.comp.python.committers', 1755)
```

(Contributed by Giampaolo Rodolà in `bpo-9795`.)

**OS**

- The `os` module has a new `pipe2()` function that makes it possible to create a pipe with `O_CLOEXEC` or `O_NONBLOCK` flags set atomically. This is especially useful to avoid race conditions in multi-threaded programs.

- The `os` module has a new `sendfile()` function which provides an efficient “zero-copy” way for copying data from one file (or
socket) descriptor to another. The phrase “zero-copy” refers to the fact that all of the copying of data between the two descriptors is done entirely by the kernel, with no copying of data into userspace buffers. `sendfile()` can be used to efficiently copy data from a file on disk to a network socket, e.g. for downloading a file.

(Patch submitted by Ross Lagerwall and Giampaolo Rodolà in bpo-10882.)

- To avoid race conditions like symlink attacks and issues with temporary files and directories, it is more reliable (and also faster) to manipulate file descriptors instead of file names. Python 3.3 enhances existing functions and introduces new functions to work on file descriptors (bpo-4761, bpo-10755 and bpo-14626).
  - The `os` module has a new `fwalk()` function similar to `walk()` except that it also yields file descriptors referring to the directories visited. This is especially useful to avoid symlink races.
  - The following functions get new optional `dir_fd` (paths relative to directory descriptors) and/or `follow_symlinks` (not following symlinks): `access()`, `chflags()`, `chmod()`, `chown()`, `link()`, `lstat()`, `mkdir()`, `mkfifo()`, `mknod()`, `open()`, `readlink()`, `remove()`, `rename()`, `replace()`, `rmdir()`, `stat()`, `symlink()`, `unlink()`, `utime()`. Platform support for using these parameters can be checked via the sets `os.supports_dir_fd` and `os.supports_follows_symlinks`.
  - The following functions now support a file descriptor for their path argument: `chdir()`, `chmod()`, `chown()`, `execve()`, `listdir()`, `pathconf()`, `exists()`, `stat()`, `statvfs()`, `utime()`. Platform support for this can be checked via the `os.supports_fd` set.
- `access()` accepts an `effective_ids` keyword argument to turn on using the effective uid/gid rather than the real uid/gid in the access check. Platform support for this can be checked via the `supports_effective_ids` set.

- The `os` module has two new functions: `getpriority()` and `setpriority()`. They can be used to get or set process niceness/priority in a fashion similar to `os.nice()` but extended to all processes instead of just the current one.

  (Patch submitted by Giampaolo Rodolà in `bpo-10784`.)

- The new `os.replace()` function allows cross-platform renaming of a file with overwriting the destination. With `os.rename()`, an existing destination file is overwritten under POSIX, but raises an error under Windows. (Contributed by Antoine Pitrou in `bpo-8828`.)

- The `stat` family of functions (`stat()`, `fstat()`, and `lstat()`) now support reading a file's timestamps with nanosecond precision. Symmetrically, `utime()` can now write file timestamps with nanosecond precision. (Contributed by Larry Hastings in `bpo-14127`.)

- The new `os.get_terminal_size()` function queries the size of the terminal attached to a file descriptor. See also `shutil.get_terminal_size()`. (Contributed by Zbigniew Jędrzejewski-Szmek in `bpo-13609`.)

- New functions to support Linux extended attributes (`bpo-12720`): `getxattr()`, `listxattr()`, `removexattr()`, `setxattr()`.

- New interface to the scheduler. These functions control how a process is allocated CPU time by the operating system. New
functions: sched_get_priority_max(), sched_get_priority_min(), sched_getaffinity(), sched_getparam(), sched_getscheduler(), sched_rr_get_interval(), sched_setaffinity(), sched_setparam(), sched_setscheduler(), sched_yield(),

- New functions to control the file system:
  - `posix_fadvise()`: Announces an intention to access data in a specific pattern thus allowing the kernel to make optimizations.
  - `posix_fallocate()`: Ensures that enough disk space is allocated for a file.
  - `sync()`: Force write of everything to disk.

- Additional new posix functions:
  - `lockf()`: Apply, test or remove a POSIX lock on an open file descriptor.
  - `pread()`: Read from a file descriptor at an offset, the file offset remains unchanged.
  - `pwrite()`: Write to a file descriptor from an offset, leaving the file offset unchanged.
  - `readv()`: Read from a file descriptor into a number of writable buffers.
  - `truncate()`: Truncate the file corresponding to `path`, so that it is at most `length` bytes in size.
  - `waitid()`: Wait for the completion of one or more child processes.
  - `writev()`: Write the contents of `buffers` to a file descriptor, where `buffers` is an arbitrary sequence of buffers.
  - `getgrouplist()` (bpo-9344): Return list of group ids that specified user belongs to.

- `times()` and `uname()`: Return type changed from a tuple to a tuple-like object with named attributes.

- Some platforms now support additional constants for the
lseek() function, such as os.SEEK_HOLE and os.SEEK_DATA.

- New constants RTLD_LAZY, RTLD_NOW, RTLD_GLOBAL, RTLD_LOCAL, RTLD_NODELETE, RTLD_NOLOAD, and RTLD_DEEPBIND are available on platforms that support them. These are for use with the sys.setdlopenflags() function, and supersede the similar constants defined in ctypes and DLFCN. (Contributed by Victor Stinner in bpo-13226.)

- os.symlink() now accepts (and ignores) the target_is_directory keyword argument on non-Windows platforms, to ease cross-platform support.

pdb

Tab-completion is now available not only for command names, but also their arguments. For example, for the break command, function and file names are completed.

(Contributed by Georg Brandl in bpo-14210)

pickle

pickle.Pickler objects now have an optional dispatch_table attribute allowing per-pickler reduction functions to be set.

(Contributed by Richard Oudkerk in bpo-14166.)

pydoc

The Tk GUI and the serve() function have been removed from the pydoc module: pydoc -g and serve() have been deprecated in
Python 3.2.

`re`

`str` regular expressions now support \u and \U escapes.

(Contributed by Serhiy Storchaka in bpo-3665.)

`sched`

- `run()` now accepts a `blocking` parameter which when set to false makes the method execute the scheduled events due to expire soonest (if any) and then return immediately. This is useful in case you want to use the `scheduler` in non-blocking applications. (Contributed by Giampaolo Rodolà in bpo-13449.)
- `scheduler` class can now be safely used in multi-threaded environments. (Contributed by Josiah Carlson and Giampaolo Rodolà in bpo-8684.)
- `timefunc` and `delayfunc` parameters of `scheduler` class constructor are now optional and defaults to `time.time()` and `time.sleep()` respectively. (Contributed by Chris Clark in bpo-13245.)
- `enter()` and `enterabs()` `argument` parameter is now optional. (Contributed by Chris Clark in bpo-13245.)
- `enter()` and `enterabs()` now accept a `kwargs` parameter. (Contributed by Chris Clark in bpo-13245.)

`select`

Solaris and derivative platforms have a new class `select.devpoll` for high performance asynchronous sockets via `/dev/poll`. (Contributed by Jesús Cea Avión in bpo-6397.)
shlex

The previously undocumented helper function `quote` from the `pipes` modules has been moved to the `shlex` module and documented. `quote()` properly escapes all characters in a string that might be otherwise given special meaning by the shell.

shutil

- New functions:
  - `disk_usage()`: provides total, used and free disk space statistics. (Contributed by Giampaolo Rodolà in bpo-12442.)
  - `chown()`: allows one to change user and/or group of the given path also specifying the user/group names and not only their numeric ids. (Contributed by Sandro Tosi in bpo-12191.)
  - `shutil.get_terminal_size()`: returns the size of the terminal window to which the interpreter is attached. (Contributed by Zbigniew Jędrzejewski-Szmek in bpo-13609.)
- `copy2()` and `copystat()` now preserve file timestamps with nanosecond precision on platforms that support it. They also preserve file “extended attributes” on Linux. (Contributed by Larry Hastings in bpo-14127 and bpo-15238.)
- Several functions now take an optional `symlinks` argument: when that parameter is true, symlinks aren’t dereferenced and the operation instead acts on the symlink itself (or creates one, if relevant). (Contributed by Hynek Schlawack in bpo-12715.)
- When copying files to a different file system, `move()` now handles symlinks the way the posix `mv` command does, recreating the symlink rather than copying the target file contents. (Contributed by Jonathan Niehof in bpo-9993.) `move()` now also returns the `dst` argument as its result.
- `rmtree()` is now resistant to symlink attacks on platforms which
support the new \texttt{dir\_fd} parameter in \texttt{os.open()} and \texttt{os.unlink()}. (Contributed by Martin von Löwis and Hynek Schlawack in \texttt{bpo-4489}.)

**signal**

- The \texttt{signal} module has new functions:
  - \texttt{pthread\_sigmask()}: fetch and/or change the signal mask of the calling thread (Contributed by Jean-Paul Calderone in \texttt{bpo-8407});
  - \texttt{pthread\_kill()}: send a signal to a thread;
  - \texttt{sigpending()}: examine pending functions;
  - \texttt{sigwait()}: wait a signal;
  - \texttt{sigwaitinfo()}: wait for a signal, returning detailed information about it;
  - \texttt{sigtimedwait()}: like \texttt{sigwaitinfo()} but with a timeout.
- The signal handler writes the signal number as a single byte instead of a nul byte into the wakeup file descriptor. So it is possible to wait more than one signal and know which signals were raised.
- \texttt{signal.signal()} and \texttt{signal.siginterrupt()} raise an \texttt{OSError}, instead of a \texttt{RuntimeError}: \texttt{OSError} has an \texttt{errno} attribute.

**smtpd**

The \texttt{smtpd} module now supports \texttt{RFC 5321} (extended SMTP) and \texttt{RFC 1870} (size extension). Per the standard, these extensions are enabled if and only if the client initiates the session with an \texttt{EHLO} command.

(Initial \texttt{ELHO} support by Alberto Trevino. Size extension by Juhana
Jauhiainen. Substantial additional work on the patch contributed by Michele Orrù and Dan Boswell. bpo-8739)

smtplib

The **SMTP**, **SMTP_SSL**, and **LMTP** classes now accept a `source_address` keyword argument to specify the `(host, port)` to use as the source address in the bind call when creating the outgoing socket. (Contributed by Paulo Scardine in bpo-11281.)

**SMTP** now supports the context management protocol, allowing an **SMTP** instance to be used in a `with` statement. (Contributed by Giampaolo Rodolà in bpo-11289.)

The **SMTP_SSL** constructor and the `starttls()` method now accept an SSLContext parameter to control parameters of the secure channel. (Contributed by Kasun Herath in bpo-8809.)

socket

- The **socket** class now exposes additional methods to process ancillary data when supported by the underlying platform:
  - `sendmsg()`
  - `recvmsg()`
  - `recvmsg_into()`

  (Contributed by David Watson in bpo-6560, based on an earlier patch by Heiko Wundram)

- The **socket** class now supports the PF_CAN protocol family ([https://en.wikipedia.org/wiki/Socketcan](https://en.wikipedia.org/wiki/Socketcan)), on Linux

The socket class now supports the PF_SYSTEM protocol family on OS X. (Contributed by Michael Goderbauer in bpo-13777.)

New function sethostname() allows the hostname to be set on unix systems if the calling process has sufficient privileges. (Contributed by Ross Lagerwall in bpo-10866.)

socketserver

BaseServer now has an overridable method service_actions() that is called by the serve_forever() method in the service loop. ForkingMixIn now uses this to clean up zombie child processes. (Contributed by Justin Warkentin in bpo-11109.)

sqlite3

New sqlite3.Connection method set_trace_callback() can be used to capture a trace of all sqlite commands processed by sqlite. (Contributed by Torsten Landschoff in bpo-11688.)

ssl

- The ssl module has two new random generation functions:
- `RAND_bytes()`: generate cryptographically strong pseudo-random bytes.
- `RAND_pseudo_bytes()`: generate pseudo-random bytes.

(Contributed by Victor Stinner in bpo-12049.)

- The `ssl` module now exposes a finer-grained exception hierarchy in order to make it easier to inspect the various kinds of errors. (Contributed by Antoine Pitrou in bpo-11183.)

- `load_cert_chain()` now accepts a `password` argument to be used if the private key is encrypted. (Contributed by Adam Simpkins in bpo-12803.)

- Diffie-Hellman key exchange, both regular and Elliptic Curve-based, is now supported through the `load_dh_params()` and `set_ecdh_curve()` methods. (Contributed by Antoine Pitrou in bpo-13626 and bpo-13627.)

- SSL sockets have a new `get_channel_binding()` method allowing the implementation of certain authentication mechanisms such as SCRAM-SHA-1-PLUS. (Contributed by Jacek Konieczny in bpo-12551.)

- You can query the SSL compression algorithm used by an SSL socket, thanks to its new `compression()` method. The new attribute `OP_NO_COMPRESSION` can be used to disable compression. (Contributed by Antoine Pitrou in bpo-13634.)

- Support has been added for the Next Protocol Negotiation extension using the `ssl.SSLContext.set_npn_protocols()` method. (Contributed by Colin Marc in bpo-14204.)
• SSL errors can now be introspected more easily thanks to library and reason attributes. (Contributed by Antoine Pitrou in bpo-14837.)

• The get_server_certificate() function now supports IPv6. (Contributed by Charles-François Natali in bpo-11811.)

• New attribute OP_CIPHER_SERVER_PREFERENCE allows setting SSLv3 server sockets to use the server’s cipher ordering preference rather than the client’s (bpo-13635).

stat

The undocumented tarfile.filemode function has been moved to stat.filemode(). It can be used to convert a file's mode to a string of the form ‘-rwxrwxrwx’.

(Contributed by Giampaolo Rodolà in bpo-14807.)

struct

The struct module now supports ssize_t and size_t via the new codes n and N, respectively. (Contributed by Antoine Pitrou in bpo-3163.)

subprocess

Command strings can now be bytes objects on posix platforms. (Contributed by Victor Stinner in bpo-8513.)

A new constant DEVNULL allows suppressing output in a platform-independent fashion. (Contributed by Ross Lagerwall in bpo-5870.)
The `sys` module has a new `thread_info` struct sequence holding informations about the thread implementation (bpo-11223).

The `tarfile` module now supports `lzma` encoding via the `lzma` module. (Contributed by Lars Gustäbel in bpo-5689.)

`tempfile.SpooledTemporaryFile`'s `truncate()` method now accepts a `size` parameter. (Contributed by Ryan Kelly in bpo-9957.)

The `textwrap` module has a new `indent()` that makes it straightforward to add a common prefix to selected lines in a block of text (bpo-13857).

The `threading.Condition`, `threading.Semaphore`, `threading.BoundedSemaphore`, `threading.Event`, and `threading.Timer`, all of which used to be factory functions returning a class instance, are now classes and may be subclassed. (Contributed by Éric Araujo in bpo-10968.)

The `threading.Thread` constructor now accepts a `daemon`
keyword argument to override the default behavior of inheriting the deamon flag value from the parent thread (bpo-6064).

The formerly private function _thread.get_ident is now available as the public function threading.get_ident(). This eliminates several cases of direct access to the _thread module in the stdlib. Third party code that used _thread.get_ident should likewise be changed to use the new public interface.

time

The **PEP 418** added new functions to the time module:

- **get_clock_info()**: Get information on a clock.
- **monotonic()**: Monotonic clock (cannot go backward), not affected by system clock updates.
- **perf_counter()**: Performance counter with the highest available resolution to measure a short duration.
- **process_time()**: Sum of the system and user CPU time of the current process.

Other new functions:

- **clock_getres()**, **clock_gettime()** and **clock_settime()** functions with **CLOCK_xxx** constants. (Contributed by Victor Stinner in bpo-10278.)

To improve cross platform consistency, sleep() now raises a **ValueError** when passed a negative sleep value. Previously this was an error on posix, but produced an infinite sleep on Windows.

types
Add a new `types.MappingProxyType` class: Read-only proxy of a mapping. (bpo-14386)

The new functions `types.new_class()` and `types.prepare_class()` provide support for PEP 3115 compliant dynamic type creation. (bpo-14588)

**unittest**

`assertRaises(), assertRaisesRegex(), assertWarns(), and assertWarnsRegex()` now accept a keyword argument `msg` when used as context managers. (Contributed by Ezio Melotti and Winston Ewert in bpo-10775.)

`unittest.TestCase.run()` now returns the `TestResult` object.

**urllib**

The `Request` class, now accepts a `method` argument used by `get_method()` to determine what HTTP method should be used. For example, this will send a 'HEAD' request:

```python
>>> urlopen(Request('https://www.python.org', method='HEAD'))
```

(bpo-1673007)

**webbrowser**

The `webbrowser` module supports more “browsers”: Google Chrome (named `chrome`, `chromium`, `chrome-browser` or `chromium-browser` depending on the version and operating system), and the
generic launchers **xdg-open**, from the FreeDesktop.org project, and **gvfs-open**, which is the default URI handler for GNOME 3. (The former contributed by Arnaud Calmettes in bpo-13620, the latter by Matthias Klose in bpo-14493.)

### xml.etree.ElementTree

The `xml.etree.ElementTree` module now imports its C accelerator by default; there is no longer a need to explicitly import `xml.etree.cElementTree` (this module stays for backwards compatibility, but is now deprecated). In addition, the `iter` family of methods of `Element` has been optimized (rewritten in C). The module's documentation has also been greatly improved with added examples and a more detailed reference.

### zlib

New attribute `zlib.Decompress.eof` makes it possible to distinguish between a properly-formed compressed stream and an incomplete or truncated one. (Contributed by Nadeem Vawda in bpo-12646.)

New attribute `zlib.ZLIB_RUNTIME_VERSION` reports the version string of the underlying `zlib` library that is loaded at runtime. (Contributed by Torsten Landschoff in bpo-12306.)
Optimizations

Major performance enhancements have been added:

- Thanks to PEP 393, some operations on Unicode strings have been optimized:
  - the memory footprint is divided by 2 to 4 depending on the text
  - encode an ASCII string to UTF-8 doesn’t need to encode characters anymore, the UTF-8 representation is shared with the ASCII representation
  - the UTF-8 encoder has been optimized
  - repeating a single ASCII letter and getting a substring of an ASCII string is 4 times faster
- UTF-8 is now 2x to 4x faster. UTF-16 encoding is now up to 10x faster.

(Contributed by Serhiy Storchaka, bpo-14624, bpo-14738 and bpo-15026.)
Build and C API Changes

Changes to Python’s build process and to the C API include:

- **New PEP 3118** related function:
  - PyMemoryView_FromMemory()

- **PEP 393** added new Unicode types, macros and functions:
  - **High-level API:**
    - PyUnicode_CopyCharacters()
    - PyUnicode_FindChar()
    - PyUnicode_GetLength()
    - PyUnicode_GET_LENGTH
    - PyUnicode_New()
    - PyUnicode_Substring()
    - PyUnicode_ReadChar()
    - PyUnicode_WriteChar()
  - **Low-level API:**
    - Py_UCS1, Py_UCS2, Py_UCS4 types
    - PyASCIIObject and PyCompactUnicodeObject structures
    - PyUnicode_READY
    - PyUnicode_FromKindAndData()
    - PyUnicode_AsUCS4(), PyUnicode_AsUCS4Copy()
    - PyUnicode_DATA, PyUnicode_1BYTE_DATA, PyUnicode_2BYTE_DATA, PyUnicode_4BYTE_DATA
    - PyUnicode_KIND with PyUnicode_KIND enum: PyUnicode_WCHAR_KIND, PyUnicode_1BYTE_KIND, PyUnicode_2BYTE_KIND, PyUnicode_4BYTE_KIND
    - PyUnicode_READ, PyUnicode_READ_CHAR, PyUnicode_WRITE
    - PyUnicode_MAX_CHAR_VALUE
• `PyArg_ParseTuple` now accepts a `bytearray` for the `c` format (bpo-12380).
Deprecated

Unsupported Operating Systems

OS/2 and VMS are no longer supported due to the lack of a maintainer.

Windows 2000 and Windows platforms which set `COMSPEC` to `command.com` are no longer supported due to maintenance burden.

OSF support, which was deprecated in 3.2, has been completely removed.

Deprecated Python modules, functions and methods

- Passing a non-empty string to `object.__format__()` is deprecated, and will produce a `TypeError` in Python 3.4 (bpo-9856).
- The `unicode_internal` codec has been deprecated because of the PEP 393, use UTF-8, UTF-16 (`utf-16-le` or `utf-16-be`), or UTF-32 (`utf-32-le` or `utf-32-be`)
- `ftplib.FTP.nlst()` and `ftplib.FTP.dir()` use `ftplib.FTP.mlsd()`
- `platform.popen()` use the `subprocess` module. Check especially the Replacing Older Functions with the subprocess Module section (bpo-11377).
- bpo-13374: The Windows bytes API has been deprecated in the `os` module. Use Unicode filenames, instead of bytes filenames, to not depend on the ANSI code page anymore and to support any filename.
- bpo-13988: The `xml.etree.cElementTree` module is
deprecated. The accelerator is used automatically whenever available.
- The behaviour of \texttt{time.clock()} depends on the platform: use the new \texttt{time.perf_counter()} or \texttt{time.process_time()} function instead, depending on your requirements, to have a well defined behaviour.
- The \texttt{os.stat_float_times()} function is deprecated.
- \texttt{abc} module:
  - \texttt{abc.abstractproperty} has been deprecated, use \texttt{property} with \texttt{abc.abstractmethod()} instead.
  - \texttt{abc.abstractclassmethod} has been deprecated, use \texttt{classmethod} with \texttt{abc.abstractmethod()} instead.
  - \texttt{abc.abstractstaticmethod} has been deprecated, use \texttt{staticmethod} with \texttt{abc.abstractmethod()} instead.
- \texttt{importlib} package:
  - \texttt{importlib.abc.SourceLoader.path_mtime()} is now deprecated in favour of \texttt{importlib.abc.SourceLoader.path_stats()} as bytecode files now store both the modification time and size of the source file the bytecode file was compiled from.

**Deprecated functions and types of the C API**

The \texttt{Py_UNICODE} has been deprecated by \texttt{PEP 393} and will be removed in Python 4. All functions using this type are deprecated:

Unicode functions and methods using \texttt{Py_UNICODE} and \texttt{Py_UNICODE*} types:

- \texttt{PyUnicode_FromUnicode}: use \texttt{PyUnicode_FromWideChar()} or \texttt{PyUnicode_FromKindAndData()}

- `PyUnicode_AS_UNICODE`, `PyUnicode_AsUnicode()`, `PyUnicode_AsUnicodeAndSize()`: use `PyUnicode_AsWideCharString()`.
- `PyUnicode_GET_DATA_SIZE`: use `PyUnicode_GET_LENGTH(str) * PyUnicode_KIND(str)` (only work on ready strings).
- `PyUnicode_AsUnicodeCopy()`: use `PyUnicode_AsUCS4Copy()` or `PyUnicode_AsWideCharString()`.
- `PyUnicode_GetMax()`.

Functions and macros manipulating `Py_UNICODE`* strings:

- `Py_UNICODE_strlen`: use `PyUnicode_GetLength()` or `PyUnicode_GET_LENGTH`.
- `Py_UNICODE_strcat`: use `PyUnicode_CopyCharacters()` or `PyUnicode_FromFormat()`.
- `Py_UNICODE_strcpy`, `Py_UNICODE_strncpy`: use `PyUnicode_CopyCharacters()` or `PyUnicode_Substring()`.
- `Py_UNICODE_strcmp`: use `PyUnicode_Compare()`.
- `Py_UNICODE_strncmp`: use `PyUnicode_Tailmatch()`.
- `Py_UNICODE_strchr`, `Py_UNICODE_strrchr`: use `PyUnicode_FindChar()`.
- `Py_UNICODE_FILL`: use `PyUnicode_Fill()`.
- `Py_UNICODE_MATCH`.

Encoders:
- `PyUnicode_Encode()`
  - use `PyUnicode_AsEncodedObject()`
- `PyUnicode_EncodeUTF7()`
- `PyUnicode_EncodeUTF8()`
  - use `PyUnicode_AsUTF8()` or `PyUnicode_AsUTF8String()`
- `PyUnicode_EncodeUTF32()`
- `PyUnicode_EncodeUTF16()`
- `PyUnicode_EncodeUnicodeEscape()`
  - use `PyUnicode_AsUnicodeEscapeString()`
- `PyUnicode_EncodeRawUnicodeEscape()`
  - use `PyUnicode_AsRawUnicodeEscapeString()`
- `PyUnicode_EncodeLatin1()`
  - use `PyUnicode_AsLatin1String()`
- `PyUnicode_EncodeASCII()`
  - use `PyUnicode_AsASCIIString()`
- `PyUnicode_TranslateCharmap()`
- `PyUnicode_EncodeMBCS()`
  - use `PyUnicode_AsMBCSString()` or `PyUnicode_EncodeCodePage()` (with CP_ACP code_page)
- `PyUnicode_EncodeDecimal()`, `PyUnicode_TransformDecimalToASCII()`

### Deprecated features

The `array` module's `u` format code is now deprecated and will be removed in Python 4 together with the rest of the (Py_UNICODE) API.
Porting to Python 3.3

This section lists previously described changes and other bugfixes that may require changes to your code.

Porting Python code

- Hash randomization is enabled by default. Set the PYTHONHASHSEED environment variable to 0 to disable hash randomization. See also the object.__hash__() method.
- **bpo-12326**: On Linux, sys.platform doesn’t contain the major version anymore. It is now always ‘linux’, instead of ‘linux2’ or ‘linux3’ depending on the Linux version used to build Python. Replace sys.platform == ‘linux2’ with sys.platform.startswith('linux'), or directly sys.platform == ‘linux’ if you don’t need to support older Python versions.
- **bpo-13847, bpo-14180**: time and datetime: OverflowError is now raised instead of ValueError if a timestamp is out of range. OSError is now raised if C functions gmtime() or localtime() failed.
- The default finders used by import now utilize a cache of what is contained within a specific directory. If you create a Python source file or sourceless bytecode file, make sure to call importlib.invalidate_caches() to clear out the cache for the finders to notice the new file.
- ImportError now uses the full name of the module that was attempted to be imported. Doctests that check ImportErrors’ message will need to be updated to use the full name of the module instead of just the tail of the name.
- The index argument to __import__() now defaults to 0 instead of -1 and no longer support negative values. It was an oversight when PEP 328 was implemented that the default value remained
If you need to continue to perform a relative import followed by an absolute import, then perform the relative import using an index of 1, followed by another import using an index of 0. It is preferred, though, that you use `importlib.import_module()` rather than call `__import__()` directly.

- `__import__()` no longer allows one to use an index value other than 0 for top-level modules. E.g. `__import__('sys', level=1)` is now an error.
- Because `sys.meta_path` and `sys.path_hooks` now have finders on them by default, you will most likely want to use `list.insert()` instead of `list.append()` to add to those lists.
- Because `None` is now inserted into `sys.path_importer_cache`, if you are clearing out entries in the dictionary of paths that do not have a finder, you will need to remove keys paired with values of `None` and `imp.NullImporter` to be backwards-compatible. This will lead to extra overhead on older versions of Python that re-insert `None` into `sys.path_importer_cache` where it represents the use of implicit finders, but semantically it should not change anything.
- `importlib.abc.Finder` no longer specifies a `find_module()` abstract method that must be implemented. If you were relying on subclasses to implement that method, make sure to check for the method’s existence first. You will probably want to check for `find_loader()` first, though, in the case of working with path entry finders.
- `pkgutil` has been converted to use `importlib` internally. This eliminates many edge cases where the old behaviour of the PEP 302 import emulation failed to match the behaviour of the real import system. The import emulation itself is still present, but is now deprecated. The `pkgutil.iter_importers()` and `pkgutil.walk_packages()` functions special case the standard import hooks so they are still supported even though
they do not provide the non-standard `iter_modules()` method.

- A longstanding RFC-compliance bug ([bpo-1079](https://bugs.python.org/issue1079)) in the parsing done by `email.header.decode_header()` has been fixed. Code that uses the standard idiom to convert encoded headers into unicode (`str(make_header(decode_header(h)))`) will see no change, but code that looks at the individual tuples returned by `decode_header` will see that whitespace that precedes or follows ASCII sections is now included in the ASCII section. Code that builds headers using `make_header` should also continue to work without change, since `make_header` continues to add whitespace between ASCII and non-ASCII sections if it is not already present in the input strings.

- `email.utils.formataddr()` now does the correct content transfer encoding when passed non-ASCII display names. Any code that depended on the previous buggy behavior that preserved the non-ASCII unicode in the formatted output string will need to be changed ([bpo-1690608](https://bugs.python.org/issue1690608)).

- `poplib.POP3.quit()` may now raise protocol errors like all other `poplib` methods. Code that assumes `quit` does not raise `poplib.error_proto` errors may need to be changed if errors on `quit` are encountered by a particular application ([bpo-11291](https://bugs.python.org/issue11291)).

- The `strict` argument to `email.parser.Parser`, deprecated since Python 2.4, has finally been removed.

- The deprecated method `unittest.TestCase.assertSameElements` has been removed.

- The deprecated variable `time.accept2dyear` has been removed.

- The deprecated `Context._clamp` attribute has been removed from the `decimal` module. It was previously replaced by the public attribute `clamp`. (See [bpo-8540](https://bugs.python.org/issue8540).)

- The undocumented internal helper class `SSLFakeFile` has been
removed from `smtplib`, since its functionality has long been provided directly by `socket.socket.makefile()`.

- Passing a negative value to `time.sleep()` on Windows now raises an error instead of sleeping forever. It has always raised an error on posix.
- The `ast._version_` constant has been removed. If you need to make decisions affected by the AST version, use `sys.version_info` to make the decision.
- Code that used to work around the fact that the `threading` module used factory functions by subclassing the private classes will need to change to subclass the now-public classes.
- The undocumented debugging machinery in the threading module has been removed, simplifying the code. This should have no effect on production code, but is mentioned here in case any application debug frameworks were interacting with it (bpo-13550).

**Porting C code**

- In the course of changes to the buffer API the undocumented `smalltable` member of the `Py_buffer` structure has been removed and the layout of the `PyMemoryViewObject` has changed.

  All extensions relying on the relevant parts in `memoryobject.h` or `object.h` must be rebuilt.

- Due to PEP 393, the `Py_UNICODE` type and all functions using this type are deprecated (but will stay available for at least five years). If you were using low-level Unicode APIs to construct and access unicode objects and you want to benefit of the memory footprint reduction provided by PEP 393, you have to convert your
code to the new Unicode API.

However, if you only have been using high-level functions such as `PyUnicode_Concat()`, `PyUnicode_Join()` or `PyUnicode_FromFormat()`, your code will automatically take advantage of the new unicode representations.

- `PyImport_GetMagicNumber()` now returns -1 upon failure.

- As a negative value for the `level` argument to `__import__() is no longer valid, the same now holds for `PyImport_ImportModuleLevel()`. This also means that the value of `level` used by `PyImport_ImportModuleEx()` is now 0 instead of -1.

Building C extensions

- The range of possible file names for C extensions has been narrowed. Very rarely used spellings have been suppressed: under POSIX, files named `xxxmodule.so`, `xxxmodule.abi3.so` and `xxxmodule.cpython-*so` are no longer recognized as implementing the `xxx` module. If you had been generating such files, you have to switch to the other spellings (i.e., remove the module string from the file names).

  (implemented in bpo-14040.)

Command Line Switch Changes

- The `-Q` command-line flag and related artifacts have been removed. Code checking `sys.flags.division_warning` will need updating.
When `python` is started with `-S`, `import site` will no longer add site-specific paths to the module search paths. In previous versions, it did.

(Contributed by Éric Araujo.)
What’s New In Python 3.2

Author: Raymond Hettinger

This article explains the new features in Python 3.2 as compared to 3.1. It focuses on a few highlights and gives a few examples. For full details, see the Misc/NEWS file.

See also: PEP 392 - Python 3.2 Release Schedule
PEP 384: Defining a Stable ABI

In the past, extension modules built for one Python version were often not usable with other Python versions. Particularly on Windows, every feature release of Python required rebuilding all extension modules that one wanted to use. This requirement was the result of the free access to Python interpreter internals that extension modules could use.

With Python 3.2, an alternative approach becomes available: extension modules which restrict themselves to a limited API (by defining Py_LIMITED_API) cannot use many of the internals, but are constrained to a set of API functions that are promised to be stable for several releases. As a consequence, extension modules built for 3.2 in that mode will also work with 3.3, 3.4, and so on. Extension modules that make use of details of memory structures can still be built, but will need to be recompiled for every feature release.

**PEP 384 - Defining a Stable ABI**

PEP written by Martin von Löwis.
PEP 389: Argparse Command Line Parsing Module

A new module for command line parsing, `argparse`, was introduced to overcome the limitations of `optparse` which did not provide support for positional arguments (not just options), subcommands, required options and other common patterns of specifying and validating options.

This module has already had widespread success in the community as a third-party module. Being more fully featured than its predecessor, the `argparse` module is now the preferred module for command-line processing. The older module is still being kept available because of the substantial amount of legacy code that depends on it.

Here’s an annotated example parser showing features like limiting results to a set of choices, specifying a `metavar` in the help screen, validating that one or more positional arguments is present, and making a required option:

```python
import argparse
parser = argparse.ArgumentParser(
    description = 'Manage servers',
    epilog = 'Tested on Solaris and Linux')
parser.add_argument('action',
    choices = ['deploy', 'start', 'stop'],
    help = 'action on each target')
parser.add_argument('targets',
    metavar = 'HOSTNAME',
    nargs = '+',
    help = 'url for target machines')
parser.add_argument('-u', '--user',
    required = True,
```
Example of calling the parser on a command string:

```python
>>> cmd = 'deploy sneezy.example.com sleepy.example.com -u skycaptain
>>> result = parser.parse_args(cmd.split())
>>> result.action
'deploy'
>>> result.targets
['sneezy.example.com', 'sleepy.example.com']
>>> result.user
'skycaptain'
```

Example of the parser's automatically generated help:

```python
>>> parser.parse_args('-h'.split())
usage: manage_cloud.py [-h] -u USER {deploy,start,stop} HOSTNAME

Manage servers

positional arguments:
  {deploy,start,stop} action on each target
  HOSTNAME url for target machines

optional arguments:
  -h, --help        show this help message and exit
  -u USER, --user USER  login as user

Tested on Solaris and Linux
```

An especially nice `argparse` feature is the ability to define subparsers, each with their own argument patterns and help displays:
import argparse
parser = argparse.ArgumentParser(prog='HELM')
subparsers = parser.add_subparsers()

parser_l = subparsers.add_parser('launch', help='Launch Control')
parser_l.add_argument('-m', '--missiles', action='store_true')
parser_l.add_argument('-t', '--torpedos', action='store_true')

parser_m = subparsers.add_parser('move', help='Move Vessel')
parser_m.add_argument('-c', '--course', type=int, required=True)
parser_m.add_argument('-s', '--speed', type=int, default=5)

$ ./helm.py --help                      # top level help
$ ./helm.py launch --help               # help for launch
$ ./helm.py launch --missiles           # set missiles=True and torpedos=False
$ ./helm.py steer --course 180 --speed 5 # set move parameters

**PEP 389 - New Command Line Parsing Module**

PEP written by Steven Bethard.

Upgrading `optparse` code for details on the differences from `optparse`. 
PEP 391: Dictionary Based Configuration for Logging

The `logging` module provided two kinds of configuration, one style with function calls for each option or another style driven by an external file saved in a `ConfigParser` format. Those options did not provide the flexibility to create configurations from JSON or YAML files, nor did they support incremental configuration, which is needed for specifying logger options from a command line.

To support a more flexible style, the module now offers `logging.config.dictConfig()` for specifying logging configuration with plain Python dictionaries. The configuration options include formatters, handlers, filters, and loggers. Here's a working example of a configuration dictionary:

```json
{"version": 1,
 "formatters": {
     "brief": {"format": "%\(levelname\)-8s
     "full": {"format": "%\(asctime\)s %\(name\)-15s
     
     "handlers": {"console": {
         "class": "logging.StreamHandler",
         "formatter": "brief",
         "level": "INFO",
         "stream": "ext://sys.stdout"},
     
     "console_priority": {
         "class": "logging.StreamHandler",
         "formatter": "full",
         "level": "ERROR",
         "stream": "ext://sys.stderr"}
     },
     "root": {"level": "DEBUG", "handlers": ["console",
```
If that dictionary is stored in a file called `conf.json`, it can be loaded and called with code like this:

```python
>>> import json, logging.config
>>> with open('conf.json') as f:
...    conf = json.load(f)
...
>>> logging.config.dictConfig(conf)
>>> logging.info("Transaction completed normally")
INFO : root : Transaction completed normally
>>> logging.critical("Abnormal termination")
2011-02-17 11:14:36,694 root CRITICAL Abnormal termination
```

**PEP 391 - Dictionary Based Configuration for Logging**
PEP written by Vinay Sajip.
PEP 3148: The concurrent.futures module

Code for creating and managing concurrency is being collected in a new top-level namespace, `concurrent`. Its first member is a `futures` package which provides a uniform high-level interface for managing threads and processes.

The design for `concurrent.futures` was inspired by the `java.util.concurrent` package. In that model, a running call and its result are represented by a `Future` object that abstracts features common to threads, processes, and remote procedure calls. That object supports status checks (running or done), timeouts, cancellations, adding callbacks, and access to results or exceptions.

The primary offering of the new module is a pair of executor classes for launching and managing calls. The goal of the executors is to make it easier to use existing tools for making parallel calls. They save the effort needed to setup a pool of resources, launch the calls, create a results queue, add time-out handling, and limit the total number of threads, processes, or remote procedure calls.

Ideally, each application should share a single executor across multiple components so that process and thread limits can be centrally managed. This solves the design challenge that arises when each component has its own competing strategy for resource management.

Both classes share a common interface with three methods: `submit()` for scheduling a callable and returning a `Future` object; `map()` for scheduling many asynchronous calls at a time, and `shutdown()` for freeing resources. The class is a context manager
and can be used in a `with` statement to assure that resources are automatically released when currently pending futures are done executing.

A simple of example of `ThreadPoolExecutor` is a launch of four parallel threads for copying files:

```python
import concurrent.futures, shutil
with concurrent.futures.ThreadPoolExecutor(max_workers=4) as e:
    e.submit(shutil.copy, 'src1.txt', 'dest1.txt')
    e.submit(shutil.copy, 'src2.txt', 'dest2.txt')
    e.submit(shutil.copy, 'src3.txt', 'dest3.txt')
    e.submit(shutil.copy, 'src3.txt', 'dest4.txt')
```

**PEP 3148 - Futures – Execute Computations Asynchronously**

PEP written by Brian Quinlan.

**Code for Threaded Parallel URL reads**, an example using threads to fetch multiple web pages in parallel.

**Code for computing prime numbers in parallel**, an example demonstrating `ProcessPoolExecutor`. 
PEP 3147: PYC Repository Directories

Python’s scheme for caching bytecode in `.pyc` files did not work well in environments with multiple Python interpreters. If one interpreter encountered a cached file created by another interpreter, it would recompile the source and overwrite the cached file, thus losing the benefits of caching.

The issue of “pyc fights” has become more pronounced as it has become commonplace for Linux distributions to ship with multiple versions of Python. These conflicts also arise with CPython alternatives such as Unladen Swallow.

To solve this problem, Python’s import machinery has been extended to use distinct filenames for each interpreter. Instead of Python 3.2 and Python 3.3 and Unladen Swallow each competing for a file called “mymodule.pyc”, they will now look for “mymodule.cpython-32.pyc”, “mymodule.cpython-33.pyc”, and “mymodule.unladen10.pyc”. And to prevent all of these new files from cluttering source directories, the `.pyc` files are now collected in a “__pycache__” directory stored under the package directory.

Aside from the filenames and target directories, the new scheme has a few aspects that are visible to the programmer:

- Imported modules now have a `__cached__` attribute which stores the name of the actual file that was imported:

```python
>>> import collections
>>> collections.__cached__
'c:/py32/lib/__pycache__/collections.cpython-32.pyc'
```
The tag that is unique to each interpreter is accessible from the `imp` module:

```python
>>> import imp
>>> imp.get_tag()
'cpython-32'
```

Scripts that try to deduce source filename from the imported file now need to be smarter. It is no longer sufficient to simply strip the “c” from a “.pyc” filename. Instead, use the new functions in the `imp` module:

```python
>>> imp.source_from_cache('c:/py32/lib/__pycache__/collections.cpython-32.pyc', 'c:/py32/lib/collections.py')
>>> imp.cache_from_source('c:/py32/lib/collections.py', 'c:/py32/lib/__pycache__/collections.cpython-32.pyc')
```

The `py_compile` and `compileall` modules have been updated to reflect the new naming convention and target directory. The command-line invocation of `compileall` has new options: `-i` for specifying a list of files and directories to compile and `-b` which causes bytecode files to be written to their legacy location rather than `__pycache__`.

The `importlib.abc` module has been updated with new abstract base classes for loading bytecode files. The obsolete ABCs, `PyLoader` and `PyPycLoader`, have been deprecated (instructions on how to stay Python 3.1 compatible are included with the documentation).

See also:

**PEP 3147** - PYC Repository Directories
PEP written by Barry Warsaw.
PEP 3149: ABI Version Tagged .so Files

The PYC repository directory allows multiple bytecode cache files to be co-located. This PEP implements a similar mechanism for shared object files by giving them a common directory and distinct names for each version.

The common directory is “pyshared” and the file names are made distinct by identifying the Python implementation (such as CPython, PyPy, Jython, etc.), the major and minor version numbers, and optional build flags (such as “d” for debug, “m” for pymalloc, “u” for wide-unicode). For an arbitrary package “foo”, you may see these files when the distribution package is installed:

```
/usr/share/pyshared/foo.cpython-32m.so
/usr/share/pyshared/foo.cpython-33md.so
```

In Python itself, the tags are accessible from functions in the `sysconfig` module:

```
>>> import sysconfig
>>> sysconfig.get_config_var('SOABI')  # find the version tag
'cpython-32mu'
>>> sysconfig.get_config_var('EXT_SUFFIX')  # find the full filename extension
'.cpython-32mu.so'
```

See also:

PEP 3149 - ABI Version Tagged .so Files
PEP written by Barry Warsaw.
This informational PEP clarifies how bytes/text issues are to be handled by the WSGI protocol. The challenge is that string handling in Python 3 is most conveniently handled with the `str` type even though the HTTP protocol is itself bytes oriented.

The PEP differentiates so-called native strings that are used for request/response headers and metadata versus byte strings which are used for the bodies of requests and responses.

The native strings are always of type `str` but are restricted to code points between $U+0000$ through $U+00FF$ which are translatable to bytes using Latin-1 encoding. These strings are used for the keys and values in the environment dictionary and for response headers and statuses in the `start_response()` function. They must follow RFC 2616 with respect to encoding. That is, they must either be ISO-8859-1 characters or use RFC 2047 MIME encoding.

For developers porting WSGI applications from Python 2, here are the salient points:

- If the app already used strings for headers in Python 2, no change is needed.
- If instead, the app encoded output headers or decoded input headers, then the headers will need to be re-encoded to Latin-1. For example, an output header encoded in utf-8 was using `h.encode('utf-8')` now needs to convert from bytes to native strings using `h.encode('utf-8').decode('latin-1')`.
- Values yielded by an application or sent using the write() method must be byte strings. The `start_response()` function
and environ must use native strings. The two cannot be mixed.

For server implementers writing CGI-to-WSGI pathways or other CGI-style protocols, the users must to be able access the environment using native strings even though the underlying platform may have a different convention. To bridge this gap, the wsgiref module has a new function, wsgiref.handlers.read_environ() for transcoding CGI variables from os.environ into native strings and returning a new dictionary.

PEP 3333 - Python Web Server Gateway Interface v1.0.1
PEP written by Phillip Eby.
Other Language Changes

Some smaller changes made to the core Python language are:

- String formatting for `format()` and `str.format()` gained new capabilities for the format character #. Previously, for integers in binary, octal, or hexadecimal, it caused the output to be prefixed with ‘0b’, ‘0o’, or ‘0x’ respectively. Now it can also handle floats, complex, and Decimal, causing the output to always have a decimal point even when no digits follow it.

  ```python
  >>> format(20, '#o')
  '0o24'
  >>> format(12.34, '#5.0f')
  ' 12.'
  ```

  (Suggested by Mark Dickinson and implemented by Eric Smith in `bpo-7094`.)

- There is also a new `str.format_map()` method that extends the capabilities of the existing `str.format()` method by accepting arbitrary mapping objects. This new method makes it possible to use string formatting with any of Python’s many dictionary-like objects such as `defaultdict`, `Shelf`, `ConfigParser`, or `dbm`. It is also useful with custom `dict` subclasses that normalize keys before look-up or that supply a `__missing__()` method for unknown keys:

  ```python
  >>> import shelve
  >>> d = shelve.open('tmp.shl')
  >>> 'The {project_name} status is {status} as of February 15, 2011'
  'The testing project status is green as of February 15, 2011'
  ```
class LowerCasedDict(dict):
    ...    def __getitem__(self, key):
    ...        return dict.__getitem__(self, key.lower)

lcd = LowerCasedDict(part='widgets', quantity=10)
'There are {QUANTITY} {Part} in stock'.format_map(lcd)
'There are 10 widgets in stock'

class PlaceholderDict(dict):
    ...    def __missing__(self, key):
    ...        return '<{}>'.format(key)

'Hello {name}, welcome to {location}'.format_map(PlaceholderDict(name='John', location='New York'))
'Hello <name>, welcome to <location>'

(Suggested by Raymond Hettinger and implemented by Eric Smith in bpo-6081.)

- The interpreter can now be started with a quiet option, `-q`, to prevent the copyright and version information from being displayed in the interactive mode. The option can be introspected using the `sys.flags` attribute:

```bash
$ python -q
>>> sys.flags
sys.flags(debug=0, division_warning=0, inspect=0, optimize=0, dont_write_bytecode=0, no_user_site=0, ignore_environment=0, verbose=0, bytes_warning=0, quiet=1)
```

(Contributed by Marcin Wojdyr in bpo-1772833).

- The `hasattr()` function works by calling `getattr()` and detecting whether an exception is raised. This technique allows it to detect methods created dynamically by `__getattr__()` or `__getattribute__()` which would otherwise be absent from
the class dictionary. Formerly, `hasattr` would catch any exception, possibly masking genuine errors. Now, `hasattr` has been tightened to only catch `AttributeError` and let other exceptions pass through:

```python
>>> class A:
...     @property
...     def f(self):
...         return 1 // 0
... >>> a = A()
>>> hasattr(a, 'f')
Traceback (most recent call last):
... ZeroDivisionError: integer division or modulo by zero
```

(Discovered by Yury Selivanov and fixed by Benjamin Peterson; bpo-9666.)

- The `str()` of a float or complex number is now the same as its `repr()`. Previously, the `str()` form was shorter but that just caused confusion and is no longer needed now that the shortest possible `repr()` is displayed by default:

```python
>>> import math
>>> repr(math.pi)
'3.141592653589793'
>>> str(math.pi)
'3.141592653589793'
```

(Proposed and implemented by Mark Dickinson; bpo-9337.)

- `memoryview` objects now have a `release()` method and they also now support the context management protocol. This allows
timely release of any resources that were acquired when requesting a buffer from the original object.

```python
>>> with memoryview(b'abcdefgh') as v:
...   print(v.tolist())
[97, 98, 99, 100, 101, 102, 103, 104]
```

(Added by Antoine Pitrou; bpo-9757.)

- Previously it was illegal to delete a name from the local namespace if it occurs as a free variable in a nested block:

```python
def outer(x):
    def inner():
        return x
    inner()
    del x
```

This is now allowed. Remember that the target of an `except` clause is cleared, so this code which used to work with Python 2.6, raised a `SyntaxError` with Python 3.1 and now works again:

```python
def f():
    def print_error():
        print(e)
    try:
        something
    except Exception as e:
        print_error()
        # implicit "del e" here
```

(See bpo-4617.)

- The internal structsequence tool now creates subclasses of
tuples. This means that C structures like those returned by `os.stat()`, `time.gmtime()`, and `sys.version_info` now work like a named tuple and now work with functions and methods that expect a tuple as an argument. This is a big step forward in making the C structures as flexible as their pure Python counterparts:

```python
>>> import sys
>>> isinstance(sys.version_info, tuple)
True
>>> 'Version %d.%d.%d %s(%d)'
'version_info'
'Version 3.2.0 final(0)'
```

(Suggested by Arfrever Frehtes Taifersar Arahesis and implemented by Benjamin Peterson in bpo-8413.)

- Warnings are now easier to control using the `PYTHONWARNINGS` environment variable as an alternative to using `-W` at the command line:

```bash
$ export PYTHONWARNINGS='ignore::RuntimeWarning::,once::UnicodeWarning::'
```

(Suggested by Barry Warsaw and implemented by Philip Jenvey in bpo-7301.)

- A new warning category, `ResourceWarning`, has been added. It is emitted when potential issues with resource consumption or cleanup are detected. It is silenced by default in normal release builds but can be enabled through the means provided by the `warnings` module, or on the command line.

A `ResourceWarning` is issued at interpreter shutdown if the
gc.garbage list isn’t empty, and if gc.DEBUG_UNCOLLECTABLE is set, all uncollectable objects are printed. This is meant to make the programmer aware that their code contains object finalization issues.

A ResourceWarning is also issued when a file object is destroyed without having been explicitly closed. While the deallocator for such object ensures it closes the underlying operating system resource (usually, a file descriptor), the delay in deallocating the object could produce various issues, especially under Windows. Here is an example of enabling the warning from the command line:

```
$ python -q -Wdefault
>>> f = open("foo", "wb")
>>> del f
__main__:1: ResourceWarning: unclosed file <_io.BufferedWriter name='foo'>
```

(Added by Antoine Pitrou and Georg Brandl in bpo-10093 and bpo-477863.)

- range objects now support index and count methods. This is part of an effort to make more objects fully implement the collections.Sequence abstract base class. As a result, the language will have a more uniform API. In addition, range objects now support slicing and negative indices, even with values larger than sys.maxsize. This makes range more interoperable with lists:

```
>>> range(0, 100, 2).count(10)
1
>>> range(0, 100, 2).index(10)
5
```
The `callable()` built-in function from Py2.x was resurrected. It provides a concise, readable alternative to using an abstract base class in an expression like `isinstance(x, collections.Callable):

```python
>>> callable(max)
True
>>> callable(20)
False
```

Python's import mechanism can now load modules installed in directories with non-ASCII characters in the path name. This solved an aggravating problem with home directories for users with non-ASCII characters in their usernames.

(Contributed by Daniel Stutzbach in bpo-9213, by Alexander Belopolsky in bpo-2690, and by Nick Coghlan in bpo-10889.)

(See bpo-10518.)

(Required extensive work by Victor Stinner in bpo-9425.)
New, Improved, and Deprecated Modules

Python's standard library has undergone significant maintenance efforts and quality improvements.

The biggest news for Python 3.2 is that the email package, mailbox module, and nntplib modules now work correctly with the bytes/text model in Python 3. For the first time, there is correct handling of messages with mixed encodings.

Throughout the standard library, there has been more careful attention to encodings and text versus bytes issues. In particular, interactions with the operating system are now better able to exchange non-ASCII data using the Windows MBCS encoding, locale-aware encodings, or UTF-8.

Another significant win is the addition of substantially better support for SSL connections and security certificates.

In addition, more classes now implement a context manager to support convenient and reliable resource clean-up using a with statement.

e-mail

The usability of the email package in Python 3 has been mostly fixed by the extensive efforts of R. David Murray. The problem was that emails are typically read and stored in the form of bytes rather than str text, and they may contain multiple encodings within a single email. So, the email package had to be extended to parse and generate email messages in bytes format.
- New functions `message_from_bytes()` and `message_from_binary_file()`, and new classes `BytesFeedParser` and `BytesParser` allow binary message data to be parsed into model objects.

- Given bytes input to the model, `get_payload()` will by default decode a message body that has a `Content-Transfer-Encoding` of `8bit` using the charset specified in the MIME headers and return the resulting string.

- Given bytes input to the model, `Generator` will convert message bodies that have a `Content-Transfer-Encoding` of `8bit` to instead have a `7bit Content-Transfer-Encoding`.

  Headers with unencoded non-ASCII bytes are deemed to be RFC 2047-encoded using the `unknown-8bit` character set.

- A new class `BytesGenerator` produces bytes as output, preserving any unchanged non-ASCII data that was present in the input used to build the model, including message bodies with a `Content-Transfer-Encoding` of `8bit`.

- The `smtplib` SMTP class now accepts a byte string for the `msg` argument to the `sendmail()` method, and a new method, `send_message()` accepts a `Message` object and can optionally obtain the `from_addr` and `to_addrs` addresses directly from the object.

(Proposed and implemented by R. David Murray, bpo-4661 and bpo-10321.)

`elementtree`
The \texttt{xml.etree.ElementTree} package and its \texttt{xml.etree.cElementTree} counterpart have been updated to version 1.3.

Several new and useful functions and methods have been added:

- \texttt{xml.etree.ElementTree.fromstringlist()} which builds an XML document from a sequence of fragments
- \texttt{xml.etree.ElementTree.register_namespace()} for registering a global namespace prefix
- \texttt{xml.etree.ElementTree.tostringlist()} for string representation including all sublists
- \texttt{xml.etree.ElementTree.Element.extend()} for appending a sequence of zero or more elements
- \texttt{xml.etree.ElementTree.Element.iterfind()} searches an element and subelements
- \texttt{xml.etree.ElementTree.Element.itertext()} creates a text iterator over an element and its subelements
- \texttt{xml.etree.ElementTree.TreeBuilder.end()} closes the current element
- \texttt{xml.etree.ElementTree.TreeBuilder.doctype()} handles a doctype declaration

Two methods have been deprecated:

- \texttt{xml.etree.ElementTree.getchildren()} use \texttt{list(elem)} instead.
- \texttt{xml.etree.ElementTree.getiterator()} use \texttt{Element.iter} instead.

For details of the update, see Introducing ElementTree on Fredrik Lundh’s website.

(Contributed by Florent Xicluna and Fredrik Lundh, bpo-6472.)
functools

- The **functools** module includes a new decorator for caching function calls. **functools.lru_cache()** can save repeated queries to an external resource whenever the results are expected to be the same.

For example, adding a caching decorator to a database query function can save database accesses for popular searches:

```python
>>> import functools
>>> @functools.lru_cache(maxsize=300)
... def get_phone_number(name):
...     c = conn.cursor()
...     c.execute('SELECT phonenumber FROM phonelist WHERE name=?')
...     return c.fetchone()[0]
```

```python
>>> for name in user_requests:
...     get_phone_number(name)  # cached lookup
```

To help with choosing an effective cache size, the wrapped function is instrumented for tracking cache statistics:

```python
>>> get_phone_number.cache_info()
CacheInfo(hits=4805, misses=980, maxsize=300, currsize=300)
```

If the phonelist table gets updated, the outdated contents of the cache can be cleared with:

```python
>>> get_phone_number.cache_clear()
```
The `functools.wraps()` decorator now adds a `__wrapped__` attribute pointing to the original callable function. This allows wrapped functions to be introspected. It also copies `__annotations__` if defined. And now it also gracefully skips over missing attributes such as `__doc__` which might not be defined for the wrapped callable.

In the above example, the cache can be removed by recovering the original function:

```python
>>> get_phone_number = get_phone_number.__wrapped__
```

(By Nick Coghlan and Terrence Cole; bpo-9567, bpo-3445, and bpo-8814.)

To help write classes with rich comparison methods, a new decorator `functools.total_ordering()` will use existing equality and inequality methods to fill in the remaining methods.

For example, supplying `__eq__` and `__lt__` will enable `total_ordering()` to fill-in `__le__`, `__gt__` and `__ge__`:

```python
@total_ordering
class Student:
    def __eq__(self, other):
        return ((self.lastname.lower(), self.firstname.lower()), (other.lastname.lower(), other.firstname.lower()),
                self.lastname, self.firstname) == (other.lastname, other.firstname)

    def __lt__(self, other):
```
\begin{verbatim}
return ((self.lastname.lower(), self.firstname),(other.lastname.lower(), other.firstname))
\end{verbatim}

With the \textit{total\_ordering} decorator, the remaining comparison methods are filled in automatically.

(Contributed by Raymond Hettinger.)

- To aid in porting programs from Python 2, the \texttt{functools.cmp\_to\_key()} function converts an old-style comparison function to modern key function:

\begin{verbatim}
>>> # locale-aware sort order
>>> sorted(iterable, key=cmp_to_key(locale.strcoll))
\end{verbatim}

For sorting examples and a brief sorting tutorial, see the \texttt{Sorting HowTo} tutorial.

(Contributed by Raymond Hettinger.)

\textbf{itertools}

- The \texttt{itertools} module has a new \texttt{accumulate()} function modeled on APL’s \textit{scan} operator and Numpy’s \texttt{accumulate} function:

\begin{verbatim}
>>> from itertools import accumulate
>>> list(accumulate([8, 2, 50]))
[8, 10, 60]

>>> prob_dist = [0.1, 0.4, 0.2, 0.3]
>>> list(accumulate(prob_dist))  # cumulative
[0.1, 0.5, 0.7, 1.0]
\end{verbatim}
For an example using `accumulate()`, see the examples for the `random` module.

(Contributed by Raymond Hettinger and incorporating design suggestions from Mark Dickinson.)

collections

- The `collections.Counter` class now has two forms of in-place subtraction, the existing `-=` operator for saturating subtraction and the new `subtract()` method for regular subtraction. The former is suitable for multisets which only have positive counts, and the latter is more suitable for use cases that allow negative counts:

```python
>>> from collections import Counter
>>> tally = Counter(dogs=5, cats=3)
>>> tally -= Counter(dogs=2, cats=8)  # saturating subtraction
>>> tally
Counter({'dogs': 3})
```

```python
>>> tally = Counter(dogs=5, cats=3)
>>> tally.subtract(dogs=2, cats=8)  # regular subtraction
>>> tally
Counter({'dogs': 3, 'cats': -5})
```

(Contributed by Raymond Hettinger.)

- The `collections.OrderedDict` class has a new method `move_to_end()` which takes an existing key and moves it to
either the first or last position in the ordered sequence.

The default is to move an item to the last position. This is equivalent of renewing an entry with \( \text{od}[k] = \text{od}.\text{pop}(k) \).

A fast move-to-end operation is useful for resequencing entries. For example, an ordered dictionary can be used to track order of access by aging entries from the oldest to the most recently accessed.

```python
>>> from collections import OrderedDict
>>> d = OrderedDict.fromkeys(['a', 'b', 'X', 'd'])
>>> list(d)
['a', 'b', 'X', 'd', 'e']
>>> d.move_to_end('X')
>>> list(d)
['a', 'b', 'd', 'e', 'X']
```

(Contributed by Raymond Hettinger.)

- The `collections.deque` class grew two new methods `count()` and `reverse()` that make them more substitutable for `list` objects:

```python
>>> from collections import deque
>>> d = deque('simsalabim')
>>> d.count('s')
2
>>> d.reverse()
>>> d
deque(['m', 'i', 'b', 'a', 'l', 'a', 's', 'm', 'i'])
```

(Contributed by Raymond Hettinger.)
threading

The **threading** module has a new **Barrier** synchronization class for making multiple threads wait until all of them have reached a common barrier point. Barriers are useful for making sure that a task with multiple preconditions does not run until all of the predecessor tasks are complete.

Barriers can work with an arbitrary number of threads. This is a generalization of a **Rendezvous** which is defined for only two threads.

Implemented as a two-phase cyclic barrier, **Barrier** objects are suitable for use in loops. The separate **filling** and **draining** phases assure that all threads get released (drained) before any one of them can loop back and re-enter the barrier. The barrier fully resets after each cycle.

Example of using barriers:

```python
from threading import Barrier, Thread

def get_votes(site):
    ballots = conduct_election(site)
    all_polls_closed.wait()  # do not count until all polls are closed
    totals = summarize(ballots)
    publish(site, totals)

all_polls_closed = Barrier(len(sites))
for site in sites:
    Thread(target=get_votes, args=(site,)).start()
```

In this example, the barrier enforces a rule that votes cannot be counted at any polling site until all polls are closed. Notice how a
solution with a barrier is similar to one with `threading.Thread.join()`, but the threads stay alive and continue to do work (summarizing ballots) after the barrier point is crossed.

If any of the predecessor tasks can hang or be delayed, a barrier can be created with an optional `timeout` parameter. Then if the timeout period elapses before all the predecessor tasks reach the barrier point, all waiting threads are released and a `BrokenBarrierError` exception is raised:

```python
def get_votes(site):
    ballots = conduct_election(site)
    try:
        all_polls_closed.wait(timeout=midnight - time)
    except BrokenBarrierError:
        lockbox = seal_ballots(ballots)
        queue.put(lockbox)
    else:
        totals = summarize(ballots)
        publish(site, totals)
```

In this example, the barrier enforces a more robust rule. If some election sites do not finish before midnight, the barrier times-out and the ballots are sealed and deposited in a queue for later handling.

See *Barrier Synchronization Patterns* for more examples of how barriers can be used in parallel computing. Also, there is a simple but thorough explanation of barriers in *The Little Book of Semaphores*, section 3.6.

(Contributed by Kristján Valur Jónsson with an API review by Jeffrey Yasskin in *bpo-8777*.)
datetime and time

- The `datetime` module has a new type `timezone` that implements the `tzinfo` interface by returning a fixed UTC offset and timezone name. This makes it easier to create timezone-aware datetime objects:

```python
>>> from datetime import datetime, timezone
>>> datetime.now(timezone.utc)
datetime.datetime(2010, 12, 8, 21, 4, 2, 923754, tzinfo=datetime.timezone.utc)
>>> datetime.strptime("01/01/2000 12:00 +0000", "%m/%d/%Y %I:%M %Z")
datetime.datetime(2000, 1, 1, 12, 0, tzinfo=datetime.timezone.utc)
```

- Also, `timedelta` objects can now be multiplied by `float` and divided by `float` and `int` objects. And `timedelta` objects can now divide one another.

- The `datetime.date.strftime()` method is no longer restricted to years after 1900. The new supported year range is from 1000 to 9999 inclusive.

- Whenever a two-digit year is used in a time tuple, the interpretation has been governed by `time.accept2dyear`. The default is `True` which means that for a two-digit year, the century is guessed according to the POSIX rules governing the `%y` `strptime` format.

  Starting with Py3.2, use of the century guessing heuristic will emit a `DeprecationWarning`. Instead, it is recommended that `time.accept2dyear` be set to `False` so that large date ranges
can be used without guesswork:

```python
>>> import time, warnings
>>> warnings.resetwarnings()  # remove the default warning

>>> time.accept2dyear = True  # guess whether 11 means 11 or 2011
>>> time.asctime((11, 1, 12, 34, 56, 4, 1, 0))
Warning (from warnings module):
...
DeprecationWarning: Century info guessed for a 2-digit year.
Fri Jan  1 12:34:56 2011

>>> time.accept2dyear = False  # use the full range
>>> time.asctime((11, 1, 1, 12, 34, 56, 4, 1, 0))
Fri Jan  1 12:34:56 11
```

Several functions now have significantly expanded date ranges. When `time.accept2dyear` is false, the `time.asctime()` function will accept any year that fits in a C `int`, while the `time.mktime()` and `time.strftime()` functions will accept the full range supported by the corresponding operating system functions.

(Contributed by Alexander Belopolsky and Victor Stinner in bpo-1289118, bpo-5094, bpo-6641, bpo-2706, bpo-1777412, bpo-8013, and bpo-10827.)

**math**

The `math` module has been updated with six new functions inspired by the C99 standard.

The `isfinite()` function provides a reliable and fast way to detect
special values. It returns `True` for regular numbers and `False` for `Nan` or `Infinity`:

```python
>>> from math import isfinite
>>> [isfinite(x) for x in (123, 4.56, float('Nan'),)
    [True, True, False, False]
```

The `expm1()` function computes \(e^x - 1\) for small values of \(x\) without incurring the loss of precision that usually accompanies the subtraction of nearly equal quantities:

```python
>>> from math import expm1
>>> expm1(0.013671875)  # more accurate way to compute \(e^x - 1\)
0.013765762467652909
```

The `erf()` function computes a probability integral or Gaussian error function. The complementary error function, `erfc()`, is \(1 - \text{erf}(x)\):

```python
>>> from math import erf, erfc, sqrt
>>> erf(1.0/sqrt(2.0))  # portion of normal distribution
0.682689492137086
>>> erfc(1.0/sqrt(2.0))  # portion of normal distribution
0.31731050786291404
>>> erf(1.0/sqrt(2.0)) + erfc(1.0/sqrt(2.0))
1.0
```

The `gamma()` function is a continuous extension of the factorial function. See [https://en.wikipedia.org/wiki/Gamma_function](https://en.wikipedia.org/wiki/Gamma_function) for details. Because the function is related to factorials, it grows large even for small values of \(x\), so there is also a `lgamma()` function for computing the natural logarithm of the gamma function:
>>> from math import gamma, lgamma
>>> gamma(7.0) # six factorial
720.0
>>> lgamma(801.0) # log(800 factorial)
4551.950730698041

(Contributed by Mark Dickinson.)

abc

The abc module now supports abstractclassmethod() and abstractstaticmethod().

These tools make it possible to define an abstract base class that requires a particular classmethod() or staticmethod() to be implemented:

```python
class Temperature(metaclass=abc.ABCMeta):
    @abc.abstractclassmethod
    def from_fahrenheit(cls, t):
        ...

    @abc.abstractclassmethod
    def from_celsius(cls, t):
        ...
```

(Patch submitted by Daniel Urban; bpo-5867.)

io

The io.BytesIO has a new method, getbuffer(), which provides functionality similar to memoryview(). It creates an editable view of the data without making a copy. The buffer's random access and support for slice notation are well-suited to in-place editing:
>>> REC_LEN, LOC_START, LOC_LEN = 34, 7, 11

>>> def change_location(buffer, record_number, location)
...     start = record_number * REC_LEN + LOC_START
...     buffer[start: start+LOC_LEN] = location

>>> import io

>>> byte_stream = io.BytesIO(
...     b'G3805  storeroom  Main chassis  '
...     b'X7899  shipping  Reserve cog  '
...     b'L6988  receiving  Primary sprocket'  
... )

>>> buffer = byte_stream.getbuffer()
>>> change_location(buffer, 1, b'warehouse  ')
>>> change_location(buffer, 0, b'showroom  ')
>>> print(byte_stream.getvalue())

b'G3805  showroom  Main chassis  '
b'X7899  warehouse  Reserve cog  '
b'L6988  receiving  Primary sprocket'

(Contributed by Antoine Pitrou in bpo-5506.)

reprlib

When writing a __repr__() method for a custom container, it is easy to forget to handle the case where a member refers back to the container itself. Python’s builtin objects such as list and set handle self-reference by displaying “…” in the recursive part of the representation string.

To help write such __repr__() methods, the reprlib module has a new decorator, recursive_repr(), for detecting recursive calls to __repr__() and substituting a placeholder string instead:
>>> class MyList(list):
...     @recursive_repr()
...     def __repr__(self):
...         return '<' + '|'.join(map(repr, self)) + '>

>>> m = MyList('abc')
>>> m.append(m)
>>> m.append('x')
>>> print(m)
<a'|'b'|'c'|...'|'x'>

(Contributed by Raymond Hettinger in bpo-9826 and bpo-9840.)

logging

In addition to dictionary-based configuration described above, the logging package has many other improvements.

The logging documentation has been augmented by a basic tutorial, an advanced tutorial, and a cookbook of logging recipes. These documents are the fastest way to learn about logging.

The logging.basicConfig() set-up function gained a style argument to support three different types of string formatting. It defaults to “%” for traditional %-formatting, can be set to “{” for the new str.format() style, or can be set to “$” for the shell-style formatting provided by string.Template. The following three configurations are equivalent:

```python
>>> from logging import basicConfig
>>> basicConfig(style='%', format='%(name)s -> %(levelname)s
>>> basicConfig(style='{', format='{name} -> {levelname}
```
If no configuration is set-up before a logging event occurs, there is now a default configuration using a `StreamHandler` directed to `sys.stderr` for events of `WARNING` level or higher. Formerly, an event occurring before a configuration was set-up would either raise an exception or silently drop the event depending on the value of `logging.raiseExceptions`. The new default handler is stored in `logging.lastResort`.

The use of filters has been simplified. Instead of creating a `Filter` object, the predicate can be any Python callable that returns `True` or `False`.

There were a number of other improvements that add flexibility and simplify configuration. See the module documentation for a full listing of changes in Python 3.2.

**CSV**

The `csv` module now supports a new dialect, `unix_dialect`, which applies quoting for all fields and a traditional Unix style with `\n` as the line terminator. The registered dialect name is `unix`.

The `csv.DictWriter` has a new method, `writeheader()` for writing-out an initial row to document the field names:

```python
>>> import csv, sys
>>> w = csv.DictWriter(sys.stdout, ['name', 'dept'],
                    "name","dept"
>>> w.writerows([```
(New dialect suggested by Jay Talbot in bpo-5975, and the new method suggested by Ed Abraham in bpo-1537721.)

**contextlib**

There is a new and slightly mind-blowing tool `ContextDecorator` that is helpful for creating a context manager that does double duty as a function decorator.

As a convenience, this new functionality is used by `contextmanager()` so that no extra effort is needed to support both roles.

The basic idea is that both context managers and function decorators can be used for pre-action and post-action wrappers. Context managers wrap a group of statements using a `with` statement, and function decorators wrap a group of statements enclosed in a function. So, occasionally there is a need to write a pre-action or post-action wrapper that can be used in either role.

For example, it is sometimes useful to wrap functions or groups of statements with a logger that can track the time of entry and time of exit. Rather than writing both a function decorator and a context manager for the task, the `contextmanager()` provides both capabilities in a single definition:

```python
from contextlib import contextmanager
```
import logging

logging.basicConfig(level=logging.INFO)

@contextmanager
def track_entry_and_exit(name):
    logging.info('Entering: %s', name)
    yield
    logging.info('Exiting: %s', name)

Formerly, this would have only been usable as a context manager:

```
with track_entry_and_exit('widget loader'):
    print('Some time consuming activity goes here')
    load_widget()
```

Now, it can be used as a decorator as well:

```
@track_entry_and_exit('widget loader')
def activity():
    print('Some time consuming activity goes here')
    load_widget()
```

Trying to fulfill two roles at once places some limitations on the technique. Context managers normally have the flexibility to return an argument usable by a with statement, but there is no parallel for function decorators.

In the above example, there is not a clean way for the track_entry_and_exit context manager to return a logging instance for use in the body of enclosed statements.

(Contributed by Michael Foord in bpo-9110.)

decimal and fractions
Mark Dickinson crafted an elegant and efficient scheme for assuring that different numeric datatypes will have the same hash value whenever their actual values are equal (bpo-8188):

```python
assert hash(Fraction(3, 2)) == hash(1.5) == \
    hash(Decimal("1.5")) == hash(complex(1.5, 0))
```

Some of the hashing details are exposed through a new attribute, `sys.hash_info`, which describes the bit width of the hash value, the prime modulus, the hash values for `infinity` and `nan`, and the multiplier used for the imaginary part of a number:

```python
>>> sys.hash_info
sys.hash_info(width=64, modulus=2305843009213693951,
```

An early decision to limit the inter-operability of various numeric types has been relaxed. It is still unsupported (and ill-advised) to have implicit mixing in arithmetic expressions such as `Decimal('1.1') + float('1.1')` because the latter loses information in the process of constructing the binary float. However, since existing floating point value can be converted losslessly to either a decimal or rational representation, it makes sense to add them to the constructor and to support mixed-type comparisons.

- The `decimal.Decimal` constructor now accepts `float` objects directly so there in no longer a need to use the `from_float()` method (bpo-8257).
- Mixed type comparisons are now fully supported so that `Decimal` objects can be directly compared with `float` and `fractions.Fraction` (bpo-2531 and bpo-8188).
Similar changes were made to `fractions.Fraction` so that the `from_float()` and `from_decimal()` methods are no longer needed (bpo-8294):

```python
>>> from decimal import Decimal
>>> from fractions import Fraction
>>> Decimal(1.1)
Decimal('1.1000000000000000888178419700125232338905355371878211101035162
...
>>> Fraction(1.1)
Fraction(2476979795053773, 2251799813685248)
```

Another useful change for the `decimal` module is that the `Context.clamp` attribute is now public. This is useful in creating contexts that correspond to the decimal interchange formats specified in IEEE 754 (see bpo-8540).

(Contributed by Mark Dickinson and Raymond Hettinger.)

**ftp**

The `ftplib.FTP` class now supports the context management protocol to unconditionally consume `socket.error` exceptions and to close the FTP connection when done:

```python
>>> from ftplib import FTP
>>> with FTP("ftp1.at.proftpd.org") as ftp:
    ftp.login()
    ftp.dir()

'230 Anonymous login ok, restrictions apply.'
dr-xr-xr-x 9 ftp ftp 154 May 6 10:...
```
Other file-like objects such as `mmap.mmap` and `fileinput.input()` also grew auto-closing context managers:

```python
with fileinput.input(files=('log1.txt', 'log2.txt'))
    for line in f:
        process(line)
```

(Contributed by Tarek Ziadé and Giampaolo Rodolà in bpo-4972, and by Georg Brandl in bpo-8046 and bpo-1286.)

The `FTP_TLS` class now accepts a `context` parameter, which is a `ssl.SSLContext` object allowing bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure.

(Contributed by Giampaolo Rodolà; bpo-8806.)

**popen**

The `os.popen()` and `subprocess.Popen()` functions now support `with` statements for auto-closing of the file descriptors.

(Contributed by Antoine Pitrou and Brian Curtin in bpo-7461 and bpo-10554.)

**select**

The `select` module now exposes a new, constant attribute, `PIPE_BUF`, which gives the minimum number of bytes which are
guaranteed not to block when `select.select()` says a pipe is ready for writing.

>>> import select
>>> select.PIPE_BUF
512

(Available on Unix systems. Patch by Sébastien Sablé in bpo-9862)

gzip and zipfile

gzip.GzipFile now implements the `io.BufferedIOBase abstract base class` (except for `truncate()`). It also has a `peek()` method and supports unseekable as well as zero-padded file objects.

The `gzip` module also gains the `compress()` and `decompress()` functions for easier in-memory compression and decompression. Keep in mind that text needs to be encoded as `bytes` before compressing and decompressing:

```python
>>> import gzip
>>> s = 'Three shall be the number thou shalt count, '
>>> s += 'and the number of the counting shall be the
>>> b = s.encode()                          # convert
>>> len(b)
89
>>> c = gzip.compress(b)
>>> len(c)
77
>>> gzip.decompress(c).decode()[:42]       # decompress
'Three shall be the number thou shalt count'
```

(Contributed by Anand B. Pillai in bpo-3488; and by Antoine Pitrou, Nir
Aides and Brian Curtin in bpo-9962, bpo-1675951, bpo-7471 and bpo-2846.)

Also, the zipfile.ZipExtFile class was reworked internally to represent files stored inside an archive. The new implementation is significantly faster and can be wrapped in an io BufferedReader object for more speedups. It also solves an issue where interleaved calls to read and readline gave the wrong results.

(Patch submitted by Nir Aides in bpo-7610.)

tarfile

The TarFile class can now be used as a context manager. In addition, its add() method has a new option, filter, that controls which files are added to the archive and allows the file metadata to be edited.

The new filter option replaces the older, less flexible exclude parameter which is now deprecated. If specified, the optional filter parameter needs to be a keyword argument. The user-supplied filter function accepts a TarInfo object and returns an updated TarInfo object, or if it wants the file to be excluded, the function can return None:

```python
>>> import tarfile, glob

>>> def myfilter(tarinfo):
...    if tarinfo.isfile():          # only save
...        tarinfo.uname = 'monty'   # redact the
...        return tarinfo

>>> with tarfile.open(name='myarchive.tar.gz', mode= ...
...        for filename in glob.glob('*.txt'): 
```
(Proposed by Tarek Ziadé and implemented by Lars Gustäbel in bpo-6856.)

hashlib

The `hashlib` module has two new constant attributes listing the hashing algorithms guaranteed to be present in all implementations and those available on the current implementation:

```python
>>> import hashlib
>>> hashlib.algorithms_guaranteed
{'sha1', 'sha224', 'sha384', 'sha256', 'sha512', 'md5'}
>>> hashlib.algorithms_available
{'md2', 'SHA256', 'SHA512', 'dsaWithSHA', 'mdc2', 'SHA1', 'ripemd160', 'SHA', 'SHA384', 'ecdsa-with-SHA1', 'md4', 'md5', 'sha1', 'DSA-SHA', 'dsaEncryption', 'DSA', 'RIPEMD160', 'sha', 'MD5',
```

(Suggested by Carl Chenet in bpo-7418.)

ast

The `ast` module has a wonderful a general-purpose tool for safely
evaluating expression strings using the Python literal syntax. The \texttt{ast.literal_eval()} function serves as a secure alternative to the builtin \texttt{eval()} function which is easily abused. Python 3.2 adds \texttt{bytes} and \texttt{set} literals to the list of supported types: strings, bytes, numbers, tuples, lists, dicts, sets, booleans, and \texttt{None}.

```python
>>> from ast import literal_eval
>>> request = "\{'req': 3, 'func': 'pow', 'args': (2,
>>> literal_eval(request)
\{'args': (2, 0.5), 'req': 3, 'func': 'pow'}
```

```python
>>> request = "os.system('do something harmful')"
>>> literal_eval(request)
Traceback (most recent call last):
  ... ValueError: malformed node or string: <_ast.Call object at 0x101739a10>
```

(Implemented by Benjamin Peterson and Georg Brandl.)

\textbf{OS}

Different operating systems use various encodings for filenames and environment variables. The \texttt{os} module provides two new functions, \texttt{fsencode()} and \texttt{fsdecode()}, for encoding and decoding filenames:

```python
>>> import os
>>> filename = 'Sehenswürdigkeiten'
>>> os.fsencode(filename)
b'Sehenswürdigkeiten'
```

Some operating systems allow direct access to encoded bytes in the
environment. If so, the `os.supports_bytes_environ` constant will be true.

For direct access to encoded environment variables (if available), use the new `os.getenvb()` function or use `os.environb` which is a bytes version of `os.environ`.

(Contributed by Victor Stinner.)

**shutil**

The `shutil.copytree()` function has two new options:

- `ignore_dangling_symlinks`: when `symlinks=False` so that the function copies a file pointed to by a symlink, not the symlink itself. This option will silence the error raised if the file doesn’t exist.
- `copy_function`: is a callable that will be used to copy files. `shutil.copy2()` is used by default.

(Contributed by Tarek Ziadé.)

In addition, the `shutil` module now supports archiving operations for zipfiles, uncompressed tarfiles, gzipped tarfiles, and bzipped tarfiles. And there are functions for registering additional archiving file formats (such as xz compressed tarfiles or custom formats).

The principal functions are `make_archive()` and `unpack_archive()`. By default, both operate on the current directory (which can be set by `os.chdir()` and on any sub-directories. The archive filename needs to be specified with a full pathname. The archiving step is non-destructive (the original files are left unchanged).
import shutil, pprint

os.chdir('mydata')  # change to the source directory
f = shutil.make_archive('/var/backup/mydata', ... 'zip')  # archive the directory
f  # show the name of archive
'/var/backup/mydata.zip'
os.chdir('tmp')  # change to an unpacking
shutil.unpack_archive('/var/backup/mydata.zip')

pprint.pprint(shutil.get_archive_formats())  # display known formats
[[''bztar', 'bzip2\'ed tar-file"],
 ('gztar', "gzip\'ed tar-file"),
 ('tar', 'uncompressed tar file'),
 ('zip', 'ZIP file')]

shutil.register_archive_format(  # register a new archive format
    ... name='xz',
    ... function=xz.compress,  # callable archiving function
    ... extra_args=[('level', 8)],  # arguments to the function
    ... description='xz compression'
    ...
)

(Contributed by Tarek Ziadé.)

sqlite3

The sqlite3 module was updated to pysqlite version 2.6.0. It has two new capabilities.

- The sqlite3.Connection.in_transit attribute is true if there is an active transaction for uncommitted changes.
- The sqlite3.Connection.enable_load_extension() and sqlite3.Connection.load_extension() methods allow
you to load SQLite extensions from “.so” files. One well-known extension is the fulltext-search extension distributed with SQLite.

(Contributed by R. David Murray and Shashwat Anand; bpo-8845.)

html

A new html module was introduced with only a single function, escape(), which is used for escaping reserved characters from HTML markup:

```python
>>> import html
>>> html.escape('x > 2 && x < 7')
'x &gt; 2 &amp;&amp; x &lt; 7'
```

socket

The socket module has two new improvements.

- Socket objects now have a detach() method which puts the socket into closed state without actually closing the underlying file descriptor. The latter can then be reused for other purposes. (Added by Antoine Pitrou; bpo-8524.)
- socket.create_connection() now supports the context management protocol to unconditionally consume socket.error exceptions and to close the socket when done. (Contributed by Giampaolo Rodolà; bpo-9794.)

ssl

The ssl module added a number of features to satisfy common requirements for secure (encrypted, authenticated) internet
connections:

- A new class, `SSLContext`, serves as a container for persistent SSL data, such as protocol settings, certificates, private keys, and various other options. It includes a `wrap_socket()` for creating an SSL socket from an SSL context.
- A new function, `ssl.match_hostname()`, supports server identity verification for higher-level protocols by implementing the rules of HTTPS (from [RFC 2818](https://www.rfc-editor.org/rfc/rfc2818)) which are also suitable for other protocols.
- The `ssl.wrap_socket()` constructor function now takes a `ciphers` argument. The `ciphers` string lists the allowed encryption algorithms using the format described in the OpenSSL documentation.
- When linked against recent versions of OpenSSL, the `ssl` module now supports the Server Name Indication extension to the TLS protocol, allowing multiple “virtual hosts” using different certificates on a single IP port. This extension is only supported in client mode, and is activated by passing the `server_hostname` argument to `ssl.SSLContext.wrap_socket()`.
- Various options have been added to the `ssl` module, such as `OP_NO_SSLv2` which disables the insecure and obsolete SSLv2 protocol.
- The extension now loads all the OpenSSL ciphers and digest algorithms. If some SSL certificates cannot be verified, they are reported as an “unknown algorithm” error.
- The version of OpenSSL being used is now accessible using the module attributes `ssl.OPENSSL_VERSION` (a string), `ssl.OPENSSL_VERSION_INFO` (a 5-tuple), and `ssl.OPENSSL_VERSION_NUMBER` (an integer).

(Contributed by Antoine Pitrou in bpo-8850, bpo-1589, bpo-8322, bpo-5639, bpo-4870, bpo-8484, and bpo-8321.)
nnntp

The `nntplib` module has a revamped implementation with better bytes and text semantics as well as more practical APIs. These improvements break compatibility with the nntplib version in Python 3.1, which was partly dysfunctional in itself.

Support for secure connections through both implicit (using `nntplib.NNTP_SSL`) and explicit (using `nntplib.NNTP.starttls()`) TLS has also been added.

(Contributed by Antoine Pitrou in [bpo-9360](https://bugs.python.org/issue9360) and Andrew Vant in [bpo-1926](https://bugs.python.org/issue1926).)

certificates

`http.client.HTTPSConnection`, `urllib.request.HTTPSHandler` and `urllib.request.urlopen()` now take optional arguments to allow for server certificate checking against a set of Certificate Authorities, as recommended in public uses of HTTPS.

(Added by Antoine Pitrou, [bpo-9003](https://bugs.python.org/issue9003).)

imaplib

Support for explicit TLS on standard IMAP4 connections has been added through the new `imaplib.IMAP4.starttls` method.

(Contributed by Lorenzo M. Catucci and Antoine Pitrou, [bpo-4471](https://bugs.python.org/issue4471).)
http.client

There were a number of small API improvements in the http.client module. The old-style HTTP 0.9 simple responses are no longer supported and the strict parameter is deprecated in all classes.

The HTTPConnection and HTTPSConnection classes now have a source_address parameter for a (host, port) tuple indicating where the HTTP connection is made from.

Support for certificate checking and HTTPS virtual hosts were added to HTTPSConnection.

The request() method on connection objects allowed an optional body argument so that a file object could be used to supply the content of the request. Conveniently, the body argument now also accepts an iterable object so long as it includes an explicit Content-Length header. This extended interface is much more flexible than before.

To establish an HTTPS connection through a proxy server, there is a new set_tunnel() method that sets the host and port for HTTP Connect tunneling.

To match the behavior of http.server, the HTTP client library now also encodes headers with ISO-8859-1 (Latin-1) encoding. It was already doing that for incoming headers, so now the behavior is consistent for both incoming and outgoing traffic. (See work by Armin Ronacher in bpo-10980.)

unittest
The unittest module has a number of improvements supporting test discovery for packages, easier experimentation at the interactive prompt, new testcase methods, improved diagnostic messages for test failures, and better method names.

- The command-line call `python -m unittest` can now accept file paths instead of module names for running specific tests (bpo-10620). The new test discovery can find tests within packages, locating any test importable from the top-level directory. The top-level directory can be specified with the `-t` option, a pattern for matching files with `-p`, and a directory to start discovery with `-s`:

  ```
  $ python -m unittest discover -s my_proj_dir -p _test.py
  ```

  (Contributed by Michael Foord.)

- Experimentation at the interactive prompt is now easier because the `unittest.case.TestCase` class can now be instantiated without arguments:

  ```python
  >>> from unittest import TestCase
  >>> testCase().assertEqual(pow(2, 3), 8)
  ```

  (Contributed by Michael Foord.)

- The `unittest` module has two new methods, `assertWarns()` and `assertWarnsRegex()` to verify that a given warning type is triggered by the code under test:

  ```python
  with self.assertWarns(DeprecationWarning):
    legacy_function('XYZ')
  ```

  (Contributed by Antoine Pitrou, bpo-9754.)
Another new method, `assertCountEqual()` is used to compare two iterables to determine if their element counts are equal (whether the same elements are present with the same number of occurrences regardless of order):

```python
def test_anagram(self):
    self.assertCountEqual('algorithm', 'logarithm')
```

(Contributed by Raymond Hettinger.)

- A principal feature of the unittest module is an effort to produce meaningful diagnostics when a test fails. When possible, the failure is recorded along with a diff of the output. This is especially helpful for analyzing log files of failed test runs. However, since diffs can sometime be voluminous, there is a new `maxDiff` attribute that sets maximum length of diffs displayed.

- In addition, the method names in the module have undergone a number of clean-ups.

For example, `assertRegex()` is the new name for `assertRegexpMatches()` which was misnamed because the test uses `re.search()`, not `re.match()`. Other methods using regular expressions are now named using short form “Regex” in preference to “Regexp” – this matches the names used in other unittest implementations, matches Python’s old name for the `re` module, and it has unambiguous camel-casing.

(Contributed by Raymond Hettinger and implemented by Ezio Melotti.)

- To improve consistency, some long-standing method aliases are being deprecated in favor of the preferred names:
<table>
<thead>
<tr>
<th>Old Name</th>
<th>Preferred Name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assert_()</code></td>
<td><code>assertTrue()</code></td>
</tr>
<tr>
<td><code>assertEquals()</code></td>
<td><code>assertEqual()</code></td>
</tr>
<tr>
<td><code>assertNotEquals()</code></td>
<td><code>assertNotEqual()</code></td>
</tr>
<tr>
<td><code>assertAlmostEquals()</code></td>
<td><code>assertAlmostEqual()</code></td>
</tr>
<tr>
<td><code>assertNotAlmostEquals()</code></td>
<td><code>assertNotAlmostEqual()</code></td>
</tr>
</tbody>
</table>

Likewise, the `TestCase.fail*` methods deprecated in Python 3.1 are expected to be removed in Python 3.3. Also see the [Deprecated aliases](#) section in the [unittest](#) documentation.

(Contributed by Ezio Melotti; [bpo-9424](#).)

- The `assertDictContainsSubset()` method was deprecated because it was misimplemented with the arguments in the wrong order. This created hard-to-debug optical illusions where tests like `TestCase().assertDictContainsSubset({'a':1, 'b':2}, {'a':1})` would fail.

  (Contributed by Raymond Hettinger.)

**random**

The integer methods in the `random` module now do a better job of producing uniform distributions. Previously, they computed selections with `int(n*random())` which had a slight bias whenever `n` was not a power of two. Now, multiple selections are made from a range up to the next power of two and a selection is kept only when it falls within the range $0 \leq x < n$. The functions and methods affected are `randrange()`, `randint()`, `choice()`, `shuffle()` and
sample().

(Contributed by Raymond Hettinger; bpo-9025.)

poplib

POP3_SSL class now accepts a context parameter, which is a
ssl.SSLContext object allowing bundling SSL configuration options,
certificates and private keys into a single (potentially long-lived)
structure.

(Contributed by Giampaolo Rodolà; bpo-8807.)

asyncore

asyncore.dispatcher now provides a handle_accepted() method returning a (sock, addr) pair which is called when a connection
has actually been established with a new remote endpoint. This is
supposed to be used as a replacement for old handle_accept() and avoids the user to call accept() directly.

(Contributed by Giampaolo Rodolà; bpo-6706.)

tempfile

The tempfile module has a new context manager, TemporaryDirectory which provides easy deterministic cleanup of
temporary directories:

```python
with tempfile.TemporaryDirectory() as tmpdirname:
    print('created temporary dir:', tmpdirname)
```
inspect

- The `inspect` module has a new function `getgeneratorstate()` to easily identify the current state of a generator-iterator:

```python
>>> from inspect import getgeneratorstate
>>> def gen():
...     yield 'demo'
>>> g = gen()
>>> getgeneratorstate(g)
'GEN_CREATED'
>>> next(g)
'demo'
>>> getgeneratorstate(g)
'GEN_SUSPENDED'
>>> next(g, None)
>>> getgeneratorstate(g)
'GEN_CLOSED'
```

(Contributed by Rodolpho Eckhardt and Nick Coghlan, bpo-10220.)

- To support lookups without the possibility of activating a dynamic attribute, the `inspect` module has a new function, `getattr_static()`. Unlike `hasattr()`, this is a true read-only search, guaranteed not to change state while it is searching:

```python
>>> class A:
...     @property
...     def f(self):
...         print('Running')
```
return 10

a = A()
ggetattr(a, 'f')
Running
10
inspect.getattr_static(a, 'f')
<property object at 0x1022bd788>

(Contributed by Michael Foord.)

pydoc

The pydoc module now provides a much-improved Web server interface, as well as a new command-line option `-b` to automatically open a browser window to display that server:

```
$ pydoc3.2 -b
```

(Contributed by Ron Adam; bpo-2001.)

dis

The dis module gained two new functions for inspecting code, `code_info()` and `show_code()`. Both provide detailed code object information for the supplied function, method, source code string or code object. The former returns a string and the latter prints it:

```
>>> import dis, random
>>> dis.show_code(random.choice)
Name: choice
Filename: /Library/Frameworks/Python.framework/Versions/3.2/lib/python3.2/random.py
Argument count: 2
```
Kw-only arguments: 0
Number of locals: 3
Stack size: 11
Flags: OPTIMIZED, NEWLOCALS, NOFREE

Constants:
0: 'Choose a random element from a non-empty sequence.'
1: 'Cannot choose from an empty sequence.'

Names:
0: _randbelow
1: len
2: ValueError
3: IndexError

Variable names:
0: self
1: seq
2: i

In addition, the `dis()` function now accepts string arguments so that the common idiom `dis(compile(s, '', 'eval'))` can be shortened to `dis(s):

```python
>>> dis('3*x+1 if x%2==1 else x//2')
   1          0 LOAD_NAME  0 (x)
   3          3 LOAD CONST  0 (2)
   6         6 BINARY_MODULO
   7          7 LOAD CONST  1 (1)
  10        10 COMPARE_OP  2 (==)
  13      13 POP_JUMP_IF_FALSE  28
  16        16 LOAD CONST  2 (3)
  19        19 LOAD_NAME  0 (x)
  22       22 BINARY_MULTIPLY
  23        23 LOAD CONST  1 (1)
  26       26 BINARY_ADD
  27      27 RETURN VALUE
>>>  28          28 LOAD_NAME  0 (x)
```
Taken together, these improvements make it easier to explore how CPython is implemented and to see for yourself what the language syntax does under-the-hood.

(Contributed by Nick Coghlan in bpo-9147.)

dbm

All database modules now support the get() and setdefault() methods.

(Suggested by Ray Allen in bpo-9523.)

c types

A new type, c types.c_ssize_t represents the C ssize_t datatype.

site

The site module has three new functions useful for reporting on the details of a given Python installation.

- getsitepackages() lists all global site-packages directories.
- getuserbase() reports on the user's base directory where data can be stored.
- getusersitepackages() reveals the user-specific site-packages directory path.
Conveniently, some of site's functionality is accessible directly from the command-line:

```
$ python -m site --user-base
/Users/raymondhettinger/.local
$ python -m site --user-site
/Users/raymondhettinger/.local/lib/python3.2/site-packages
```

(Contributed by Tarek Ziadé in bpo-6693.)

**sysconfig**

The new *sysconfig* module makes it straightforward to discover installation paths and configuration variables that vary across platforms and installations.

The module offers access simple access functions for platform and version information:

- `get_platform()` returning values like `linux-i586` or `macosx-10.6-ppc`.
- `get_python_version()` returns a Python version string such as “3.2”.

```python
>>> import site
>>> site.getsitepackages()
['/Library/Frameworks/Python.framework/Versions/3.2/lib/python3.2/site-packages',
 '/Library/Frameworks/Python.framework/Versions/3.2/lib/site-python',
 '/Library/Python/3.2/site-packages']
>>> site.getuserbase()
'/Users/raymondhettinger/Library/Python/3.2'
>>> site.getusersitepackages()
'/Users/raymondhettinger/Library/Python/3.2/lib/python3.2/site-packages'
```
It also provides access to the paths and variables corresponding to one of seven named schemes used by distutils. Those include *posix_prefix*, *posix_home*, *posix_user*, *nt*, *nt_user*, *os2*, *os2_home*:

- **get_paths()** makes a dictionary containing installation paths for the current installation scheme.
- **get_config_vars()** returns a dictionary of platform specific variables.

There is also a convenient command-line interface:

```
C:\Python32>python -m sysconfig
Platform: "win32"
Python version: "3.2"
Current installation scheme: "nt"

Paths:
data = "C:\Python32"
include = "C:\Python32\Include"
platinclude = "C:\Python32\Include"
platlib = "C:\Python32\Lib\site-packages"
platstdlib = "C:\Python32\Lib"
purelib = "C:\Python32\Lib\site-packages"
scripts = "C:\Python32\Scripts"
stdlib = "C:\Python32\Lib"

Variables:
BINDIR = "C:\Python32"
BINLIBDEST = "C:\Python32\Lib"
EXE = ".exe"
INCLUDEPY = "C:\Python32\Include"
LIBDEST = "C:\Python32\Lib"
SO = ".pyd"
VERSION = "32"
abiflags = ""
base = "C:\Python32"
```
The `pdb` debugger module gained a number of usability improvements:

- `pdb.py` now has a `-c` option that executes commands as given in a `.pdbrc` script file.
- A `.pdbrc` script file can contain `continue` and `next` commands that continue debugging.
- The Pdb class constructor now accepts a `nosigint` argument.
- New commands: `l(list), ll(long list)` and `source` for listing source code.
- New commands: `display` and `undisplay` for showing or hiding the value of an expression if it has changed.
- New command: `interact` for starting an interactive interpreter containing the global and local names found in the current scope.
- Breakpoints can be cleared by breakpoint number.

(Contributed by Georg Brandl, Antonio Cuni and Ilya Sandler.)

`configparser`
The `configparser` module was modified to improve usability and predictability of the default parser and its supported INI syntax. The old ConfigParser class was removed in favor of SafeConfigParser which has in turn been renamed to `ConfigParser`. Support for inline comments is now turned off by default and section or option duplicates are not allowed in a single configuration source.

Config parsers gained a new API based on the mapping protocol:

```python
>>> parser = ConfigParser()
>>> parser.read_string(""
... [DEFAULT]
... location = upper left
... visible = yes
... editable = no
... color = blue
...
... [main]
... title = Main Menu
... color = green
...
... [options]
... title = Options
... ""

>>> parser['main']['color']
'green'
>>> parser['main']['editable']
'no'
>>> section = parser['options']
>>> section['title']
'Options'
>>> section['title'] = 'Options (editable: %(editable)s)
>>> section['title']
'Options (editable: no)'
```
The new API is implemented on top of the classical API, so custom parser subclasses should be able to use it without modifications.

The INI file structure accepted by config parsers can now be customized. Users can specify alternative option/value delimiters and comment prefixes, change the name of the DEFAULT section or switch the interpolation syntax.

There is support for pluggable interpolation including an additional interpolation handler ExtendedInterpolation:

```python
>>> parser = ConfigParser(interpolation=ExtendedInterpolation)
>>> parser.read_dict({'buildout': {'directory': '/home/ambv/zope9',
                                    'custom': {'prefix': '/usr/local'}}
>>> parser.read_string('"
... [buildout]
...    parts =
...    zope9
...    instance
...    find-links =
...        ${buildout:directory}/downloads/dist
...
... [zope9]
...    recipe = plone.recipe.zope9install
...    location = /opt/zope
...
... [instance]
...    recipe = plone.recipe.zope9instance
...    zope9-location = ${zope9:location}
...    zope-conf = ${custom:prefix}/etc/zope.conf
...  ""

>>> parser['buildout']['find-links']
'/home/ambv/zope9/downloads/dist'
>>> parser['instance']['zope-conf']
'/usr/local/etc/zope.conf'
>>> instance = parser['instance']
```
A number of smaller features were also introduced, like support for specifying encoding in read operations, specifying fallback values for get-functions, or reading directly from dictionaries and strings.

(All changes contributed by Łukasz Langa.)

**urllib.parse**

A number of usability improvements were made for the `urllib.parse` module.

The `urlparse()` function now supports IPv6 addresses as described in RFC 2732:

```python
>>> import urllib.parse
ParseResult(scheme='http',
    path='/foo/',
    params='',
    query='',
    fragment='')
```

The `urldefrag()` function now returns a named tuple:

```python
>>> r = urllib.parse.urldefrag('http://python.org/about/#target')
>>> r
DefragResult(url='http://python.org/about/',
    fragment='target')
```
And, the `urlencode()` function is now much more flexible, accepting either a string or bytes type for the `query` argument. If it is a string, then the `safe`, `encoding`, and `error` parameters are sent to `quote_plus()` for encoding:

```python
>>> urllib.parse.urlencode([
...     ('type', 'telenovela'),
...     ('name', '¿Dónde Está Elisa?'),
...     ('encoding', 'latin-1')],
...     encoding='latin-1')
'type=telenovela&name=%BFD%F3nde+Est%E1+Elisa%3F'
```

As detailed in Parsing ASCII Encoded Bytes, all the `urllib.parse` functions now accept ASCII-encoded byte strings as input, so long as they are not mixed with regular strings. If ASCII-encoded byte strings are given as parameters, the return types will also be an ASCII-encoded byte strings:

```python
>>> urllib.parse.urlparse(b'http://www.python.org:80/about/')
ParseResultBytes(scheme=b'http', netloc=b'www.python.org:80', path=b'/about/', params=b'', query=)
```

(Work by Nick Coghlan, Dan Mahn, and Senthil Kumaran in `bpo-2987`, `bpo-5468`, and `bpo-9873`.)

**mailbox**

Thanks to a concerted effort by R. David Murray, the `mailbox` module
has been fixed for Python 3.2. The challenge was that mailbox had been originally designed with a text interface, but email messages are best represented with bytes because various parts of a message may have different encodings.

The solution harnessed the email package's binary support for parsing arbitrary email messages. In addition, the solution required a number of API changes.

As expected, the add() method for mailbox.Mailbox objects now accepts binary input.

StringIO and text file input are deprecated. Also, string input will fail early if non-ASCII characters are used. Previously it would fail when the email was processed in a later step.

There is also support for binary output. The get_file() method now returns a file in the binary mode (where it used to incorrectly set the file to text-mode). There is also a new get_bytes() method that returns a bytes representation of a message corresponding to a given key.

It is still possible to get non-binary output using the old API's get_string() method, but that approach is not very useful. Instead, it is best to extract messages from a Message object or to load them from binary input.

(Contributed by R. David Murray, with efforts from Steffen Daode Nurpmeso and an initial patch by Victor Stinner in bpo-9124.)

turtledemo
The demonstration code for the `turtle` module was moved from the `Demo` directory to main library. It includes over a dozen sample scripts with lively displays. Being on `sys.path`, it can now be run directly from the command-line:

```
$ python -m turtledemo
```

(Moved from the Demo directory by Alexander Belopolsky in `bpo-10199`.)
Multi-threading

- The mechanism for serializing execution of concurrently running Python threads (generally known as the **GIL** or **Global Interpreter Lock**) has been rewritten. Among the objectives were more predictable switching intervals and reduced overhead due to lock contention and the number of ensuing system calls. The notion of a “check interval” to allow thread switches has been abandoned and replaced by an absolute duration expressed in seconds. This parameter is tunable through `sys.setswitchinterval()`. It currently defaults to 5 milliseconds.

  Additional details about the implementation can be read from a python-dev mailing-list message (however, “priority requests” as exposed in this message have not been kept for inclusion).

  (Contributed by Antoine Pitrou.)

- Regular and recursive locks now accept an optional `timeout` argument to their `acquire()` method. (Contributed by Antoine Pitrou; bpo-7316.)

- Similarly, `threading.Semaphore.acquire()` also gained a `timeout` argument. (Contributed by Torsten Landschoff; bpo-850728.)

- Regular and recursive lock acquisitions can now be interrupted by signals on platforms using Pthreads. This means that Python programs that deadlock while acquiring locks can be successfully killed by repeatedly sending SIGINT to the process (by pressing `Ctrl+C` in most shells). (Contributed by Reid Kleckner; bpo-8844.)
Optimizations

A number of small performance enhancements have been added:

- Python’s peephole optimizer now recognizes patterns such as \( x \in \{1, 2, 3\} \) as being a test for membership in a set of constants. The optimizer recasts the set as a `frozenset` and stores the pre-built constant.

Now that the speed penalty is gone, it is practical to start writing membership tests using set-notation. This style is both semantically clear and operationally fast:

```python
extension = name.rpartition('.')[2]
if extension in {'xml', 'html', 'xhtml', 'css'}:
    handle(name)
```

(Patch and additional tests contributed by Dave Malcolm; `bpo-6690`).

- Serializing and unserializing data using the `pickle` module is now several times faster.

  (Contributed by Alexandre Vassalotti, Antoine Pitrou and the Unladen Swallow team in `bpo-9410` and `bpo-3873`.)

- The Timsort algorithm used in `list.sort()` and `sorted()` now runs faster and uses less memory when called with a key function. Previously, every element of a list was wrapped with a temporary object that remembered the key value associated with each element. Now, two arrays of keys and values are sorted in parallel. This saves the memory consumed by the sort wrappers,
and it saves time lost to delegating comparisons.

(Patch by Daniel Stutzbach in bpo-9915.)

- JSON decoding performance is improved and memory consumption is reduced whenever the same string is repeated for multiple keys. Also, JSON encoding now uses the C speedups when the sort_keys argument is true.

  (Contributed by Antoine Pitrou in bpo-7451 and by Raymond Hettinger and Antoine Pitrou in bpo-10314.)

- Recursive locks (created with the threading.RLock() API) now benefit from a C implementation which makes them as fast as regular locks, and between 10x and 15x faster than their previous pure Python implementation.

  (Contributed by Antoine Pitrou; bpo-3001.)

- The fast-search algorithm in stringlib is now used by the split(), rsplit(), splitlines() and replace() methods on bytes, bytearray and str objects. Likewise, the algorithm is also used by rfind(), rindex(), rsplit() and rpartition().

  (Patch by Florent Xicluna in bpo-7622 and bpo-7462.)

- Integer to string conversions now work two “digits” at a time, reducing the number of division and modulo operations.

  (bpo-6713 by Gawain Bolton, Mark Dickinson, and Victor Stinner.)

There were several other minor optimizations. Set differencing now runs faster when one operand is much larger than the other (patch by
Andress Bennetts in bpo-8685). The array.repeat() method has a faster implementation (bpo-1569291 by Alexander Belopolsky). The BaseHTTPRequestHandler has more efficient buffering (bpo-3709 by Andrew Schaaf). The operator.attrgetter() function has been sped-up (bpo-10160 by Christos Georgiou). And ConfigParser loads multi-line arguments a bit faster (bpo-7113 by Łukasz Langa).
Unicode

Python has been updated to Unicode 6.0.0. The update to the standard adds over 2,000 new characters including emoji symbols which are important for mobile phones.

In addition, the updated standard has altered the character properties for two Kannada characters (U+0CF1, U+0CF2) and one New Tai Lue numeric character (U+19DA), making the former eligible for use in identifiers while disqualifying the latter. For more information, see Unicode Character Database Changes.
Codecs

Support was added for cp720 Arabic DOS encoding (bpo-1616979).

MBCS encoding no longer ignores the error handler argument. In the default strict mode, it raises an UnicodeDecodeError when it encounters an undecodable byte sequence and an UnicodeEncodeError for an unencodable character.

The MBCS codec supports 'strict' and 'ignore' error handlers for decoding, and 'strict' and 'replace' for encoding.

To emulate Python3.1 MBCS encoding, select the 'ignore' handler for decoding and the 'replace' handler for encoding.

On Mac OS X, Python decodes command line arguments with 'utf-8' rather than the locale encoding.

By default, tarfile uses 'utf-8' encoding on Windows (instead of 'mbcs') and the 'surrogateescape' error handler on all operating systems.
Documentation

The documentation continues to be improved.

- A table of quick links has been added to the top of lengthy sections such as Built-in Functions. In the case of itertools, the links are accompanied by tables of cheatsheet-style summaries to provide an overview and memory jog without having to read all of the docs.

- In some cases, the pure Python source code can be a helpful adjunct to the documentation, so now many modules now feature quick links to the latest version of the source code. For example, the functools module documentation has a quick link at the top labeled:

  **Source code** Lib/functools.py.

  (Contributed by Raymond Hettinger; see rationale.)

- The docs now contain more examples and recipes. In particular, re module has an extensive section, Regular Expression Examples. Likewise, the itertools module continues to be updated with new Itertools Recipes.

- The datetime module now has an auxiliary implementation in pure Python. No functionality was changed. This just provides an easier-to-read alternate implementation.

  (Contributed by Alexander Belopolsky in bpo-9528.)

- The unmaintained Demo directory has been removed. Some demos were integrated into the documentation, some were moved
to the `Tools/demo` directory, and others were removed altogether.

(Contributed by Georg Brandl in `bpo-7962`.)
IDLE

- The format menu now has an option to clean source files by stripping trailing whitespace.

  (Contributed by Raymond Hettinger; bpo-5150.)

- IDLE on Mac OS X now works with both Carbon AquaTk and Cocoa AquaTk.

  (Contributed by Kevin Walzer, Ned Deily, and Ronald Oussoren; bpo-6075.)
Code Repository

In addition to the existing Subversion code repository at http://svn.python.org there is now a Mercurial repository at https://hg.python.org/.

After the 3.2 release, there are plans to switch to Mercurial as the primary repository. This distributed version control system should make it easier for members of the community to create and share external changesets. See PEP 385 for details.

To learn to use the new version control system, see the tutorial by Joel Spolsky or the Guide to Mercurial Workflows.
Build and C API Changes

Changes to Python’s build process and to the C API include:

- The `idle`, `pydoc` and `2to3` scripts are now installed with a version-specific suffix on `make altinstall` (**bpo-10679**).

- The C functions that access the Unicode Database now accept and return characters from the full Unicode range, even on narrow unicode builds (Py_UNICODE_TOLOWER, Py_UNICODE_ISDECIMAL, and others). A visible difference in Python is that `unicodedata.numeric()` now returns the correct value for large code points, and `repr()` may consider more characters as printable.

  (Reported by Bupjoe Lee and fixed by Amaury Forgeot D’Arc; **bpo-5127**.)

- Computed gotos are now enabled by default on supported compilers (which are detected by the configure script). They can still be disabled selectively by specifying `--without-computed-gotos`.

  (Contributed by Antoine Pitrou; **bpo-9203**.)

- The option `--with-wctype-functions` was removed. The built-in unicode database is now used for all functions.

  (Contributed by Amaury Forgeot D’Arc; **bpo-9210**.)

- Hash values are now values of a new type, `Py_hash_t`, which is defined to be the same size as a pointer. Previously they were of type `long`, which on some 64-bit operating systems is still only 32
bits long. As a result of this fix, `set` and `dict` can now hold more than $2^{32}$ entries on builds with 64-bit pointers (previously, they could grow to that size but their performance degraded catastrophically).

(Suggested by Raymond Hettinger and implemented by Benjamin Peterson; bpo-9778.)

- A new macro `Py_VA_COPY` copies the state of the variable argument list. It is equivalent to C99 `va_copy` but available on all Python platforms (bpo-2443).

- A new C API function `PySys_SetArgvEx()` allows an embedded interpreter to set `sys.argv` without also modifying `sys.path` (bpo-5753).

- `PyEval_CallObject` is now only available in macro form. The function declaration, which was kept for backwards compatibility reasons, is now removed – the macro was introduced in 1997 (bpo-8276).

- There is a new function `PyLong_AsLongLongAndOverflow()` which is analogous to `PyLong_AsLongAndOverflow()`. They both serve to convert Python `int` into a native fixed-width type while providing detection of cases where the conversion won’t fit (bpo-7767).

- The `PyUnicode_CompareWithASCIIString()` function now returns `not equal` if the Python string is `NUL` terminated.

- There is a new function `PyErr_NewExceptionWithDoc()` that is like `PyErr_NewException()` but allows a docstring to be specified. This lets C exceptions have the same self-documenting
capabilities as their pure Python counterparts (bpo-7033).

- When compiled with the --with-valgrind option, the pymalloc allocator will be automatically disabled when running under Valgrind. This gives improved memory leak detection when running under Valgrind, while taking advantage of pymalloc at other times (bpo-2422).

- Removed the 0? format from the PyArg_Parse functions. The format is no longer used and it had never been documented (bpo-8837).

There were a number of other small changes to the C-API. See the Misc/NEWS file for a complete list.

Also, there were a number of updates to the Mac OS X build, see Mac/BuildScript/README.txt for details. For users running a 32/64-bit build, there is a known problem with the default Tcl/Tk on Mac OS X 10.6. Accordingly, we recommend installing an updated alternative such as ActiveState Tcl/Tk 8.5.9. See https://www.python.org/download/mac/tcltk/ for additional details.
Porting to Python 3.2

This section lists previously described changes and other bug fixes that may require changes to your code:

- The `configparser` module has a number of clean-ups. The major change is to replace the old ConfigParser class with long-standing preferred alternative SafeConfigParser. In addition there are a number of smaller incompatibilities:
  - The interpolation syntax is now validated on `get()` and `set()` operations. In the default interpolation scheme, only two tokens with percent signs are valid: `%(name)s` and `%%`, the latter being an escaped percent sign.
  - The `set()` and `add_section()` methods now verify that values are actual strings. Formerly, unsupported types could be introduced unintentionally.
  - Duplicate sections or options from a single source now raise either `DuplicateSectionError` or `DuplicateOptionError`. Formerly, duplicates would silently overwrite a previous entry.
  - Inline comments are now disabled by default so now the `;` character can be safely used in values.
  - Comments now can be indented. Consequently, for `;` or `#` to appear at the start of a line in multiline values, it has to be interpolated. This keeps comment prefix characters in values from being mistaken as comments.
  - `"""` is now a valid value and is no longer automatically converted to an empty string. For empty strings, use `"option" =""` in a line.
- The `nntplib` module was reworked extensively, meaning that its APIs are often incompatible with the 3.1 APIs.
- `bytearray` objects can no longer be used as filenames; instead, they should be converted to `bytes`.

- The `array.tostring()` and `array.fromstring()` have been renamed to `array.tobytes()` and `array.frombytes()` for clarity. The old names have been deprecated. (See `bpo-8990`.)

- `PyArg_Parse*()` functions:
  - “t#” format has been removed: use “s#” or “s*” instead
  - “w” and “w#” formats has been removed: use “w*” instead

- The `PyCObject` type, deprecated in 3.1, has been removed. To wrap opaque C pointers in Python objects, the `PyCapsule` API should be used instead; the new type has a well-defined interface for passing typing safety information and a less complicated signature for calling a destructor.

- The `sys.setfilesystemencoding()` function was removed because it had a flawed design.

- The `random.seed()` function and method now salt string seeds with an sha512 hash function. To access the previous version of `seed` in order to reproduce Python 3.1 sequences, set the `version` argument to 1, `random.seed(s, version=1)`.

- The previously deprecated `string.maketrans()` function has been removed in favor of the static methods `bytes.maketrans()` and `bytearray.maketrans()`. This change solves the confusion around which types were supported by the `string` module. Now, `str`, `bytes`, and `bytearray` each have their own `maketrans` and `translate` methods with intermediate translation tables of the appropriate type.
The previously deprecated `contextlib.nested()` function has been removed in favor of a plain `with` statement which can accept multiple context managers. The latter technique is faster (because it is built-in), and it does a better job finalizing multiple context managers when one of them raises an exception:

```python
with open('mylog.txt') as infile, open('a.out', 'w') as outfile:
    for line in infile:
        if '<critical>' in line:
            outfile.write(line)
```

The `xml.etree.ElementTree` class now raises an `xml.etree.ElementTree.ParseError` when a parse fails.
Previously it raised an `xml.parsers.expat.ExpatError`.

- The new, longer `str()` value on floats may break doctests which rely on the old output format.

- In `subprocess.Popen`, the default value for `close_fds` is now `True` under Unix; under Windows, it is `True` if the three standard streams are set to `None`, `False` otherwise. Previously, `close_fds` was always `False` by default, which produced difficult to solve bugs or race conditions when open file descriptors would leak into the child process.

- Support for legacy HTTP 0.9 has been removed from `urllib.request` and `http.client`. Such support is still present on the server side (in `http.server`).

  (Contributed by Antoine Pitrou, `bpo-10711`.)

- SSL sockets in timeout mode now raise `socket.timeout` when a timeout occurs, rather than a generic `SSLError`.

  (Contributed by Antoine Pitrou, `bpo-10272`.)

- The misleading functions `PyEval_AcquireLock()` and `PyEval_ReleaseLock()` have been officially deprecated. The thread-state aware APIs (such as `PyEval_SaveThread()` and `PyEval_RestoreThread()`) should be used instead.

- Due to security risks, `asyncore.handle_accept()` has been deprecated, and a new function, `asyncore.handle_accepted()`, was added to replace it.

  (Contributed by Giampaolo Rodola in `bpo-6706`.)
Due to the new GIL implementation, `PyEval_InitThreads()` cannot be called before `Py_Initialize()` anymore.
What’s New In Python 3.1

Author: Raymond Hettinger

This article explains the new features in Python 3.1, compared to 3.0.
Regular Python dictionaries iterate over key/value pairs in arbitrary order. Over the years, a number of authors have written alternative implementations that remember the order that the keys were originally inserted. Based on the experiences from those implementations, a new `collections.OrderedDict` class has been introduced.

The OrderedDict API is substantially the same as regular dictionaries but will iterate over keys and values in a guaranteed order depending on when a key was first inserted. If a new entry overwrites an existing entry, the original insertion position is left unchanged. Deleting an entry and reinserting it will move it to the end.

The standard library now supports use of ordered dictionaries in several modules. The `configparser` module uses them by default. This lets configuration files be read, modified, and then written back in their original order. The `_asdict()` method for `collections.namedtuple()` now returns an ordered dictionary with the values appearing in the same order as the underlying tuple indicies. The `json` module is being built-out with an `object_pairs_hook` to allow OrderedDicts to be built by the decoder. Support was also added for third-party tools like `PyYAML`.

---

**See also:**

**PEP 372 - Ordered Dictionaries**

PEP written by Armin Ronacher and Raymond Hettinger. Implementation written by Raymond Hettinger.
PEP 378: FormatSpecifier for Thousands Separator

The built-in `format()` function and the `str.format()` method use a mini-language that now includes a simple, non-locale aware way to format a number with a thousands separator. That provides a way to humanize a program's output, improving its professional appearance and readability:

```python
>>> format(1234567, ',d')
'1,234,567'
>>> format(1234567.89, ',.2f')
'1,234,567.89'
>>> format(12345.6 + 8901234.12j, ',f')
'12,345.600000+8,901,234.120000j'
>>> format(Decimal('1234567.89'), ',f')
'1,234,567.89'
```

The supported types are `int`, `float`, `complex` and `decimal.Decimal`.

Discussions are underway about how to specify alternative separators like dots, spaces, apostrophes, or underscores. Locale-aware applications should use the existing `n` format specifier which already has some support for thousands separators.

See also:

**PEP 378 - FormatSpecifier for Thousands Separator**

PEP written by Raymond Hettinger and implemented by Eric Smith and Mark Dickinson.
Other Language Changes

Some smaller changes made to the core Python language are:

- Directories and zip archives containing a `__main__.py` file can now be executed directly by passing their name to the interpreter. The directory/zipfile is automatically inserted as the first entry in `sys.path`. (Suggestion and initial patch by Andy Chu; revised patch by Phillip J. Eby and Nick Coghlan; bpo-1739468.)

- The `int()` type gained a `bit_length` method that returns the number of bits necessary to represent its argument in binary:

  ```python
  >>> n = 37
  >>> bin(37)
  '0b100101'
  >>> n.bit_length()
  6
  >>> n = 2**123-1
  >>> n.bit_length()
  123
  >>> (n+1).bit_length()
  124
  ```

  (Contributed by Fredrik Johansson, Victor Stinner, Raymond Hettinger, and Mark Dickinson; bpo-3439.)

- The fields in `format()` strings can now be automatically numbered:

  ```python
  >>> 'Sir {} of {}'.format('Gallahad', 'Camelot')
  'Sir Gallahad of Camelot'
  ```
Formerly, the string would have required numbered fields such as: 
'Sir {0} of {1}'

(Contributed by Eric Smith; bpo-5237.)

- The string.maketrans() function is deprecated and is replaced by new static methods, bytes.maketrans() and bytearray.maketrans(). This change solves the confusion around which types were supported by the string module. Now, str, bytes, and bytearray each have their own maketrans and translate methods with intermediate translation tables of the appropriate type.

  (Contributed by Georg Brandl; bpo-5675.)

- The syntax of the with statement now allows multiple context managers in a single statement:

  ```python
  >>> with open('mylog.txt') as infile, open('a.out', ...
  ...     for line in infile:
  ...         if '<critical>' in line:
  ...             outfile.write(line)
  ```

  With the new syntax, the contextlib.nested() function is no longer needed and is now deprecated.

  (Contributed by Georg Brandl and Mattias Brändström; appspot issue 53094.)

- round(x, n) now returns an integer if x is an integer. Previously it returned a float:

  ```python
  >>> round(1123, -2)
  ```
Python now uses David Gay’s algorithm for finding the shortest floating point representation that doesn’t change its value. This should help mitigate some of the confusion surrounding binary floating point numbers.

The significance is easily seen with a number like 1.1 which does not have an exact equivalent in binary floating point. Since there is no exact equivalent, an expression like `float('1.1')` evaluates to the nearest representable value which is 0x1.199999999999ap+0 in hex or 1.10000000000000008881784197001252323389053344726 in decimal. That nearest value was and still is used in subsequent floating point calculations.

What is new is how the number gets displayed. Formerly, Python used a simple approach. The value of `repr(1.1)` was computed as `format(1.1, '.17g')` which evaluated to '1.1000000000000001'. The advantage of using 17 digits was that it relied on IEEE-754 guarantees to assure that `eval(repr(1.1))` would round-trip exactly to its original value. The disadvantage is that many people found the output to be confusing (mistaking intrinsic limitations of binary floating point representation as being a problem with Python itself).

The new algorithm for `repr(1.1)` is smarter and returns '1.1'. Effectively, it searches all equivalent string representations (ones that get stored with the same underlying float value) and returns the shortest representation.
The new algorithm tends to emit cleaner representations when possible, but it does not change the underlying values. So, it is still the case that \( 1.1 + 2.2 \neq 3.3 \) even though the representations may suggest otherwise.

The new algorithm depends on certain features in the underlying floating point implementation. If the required features are not found, the old algorithm will continue to be used. Also, the text pickle protocols assure cross-platform portability by using the old algorithm.

(Contributed by Eric Smith and Mark Dickinson; bpo-1580)
New, Improved, and Deprecated Modules

- Added a `collections.Counter` class to support convenient counting of unique items in a sequence or iterable:

  ```python
  >>> Counter(['red', 'blue', 'red', 'green', 'blue'])
  Counter({'blue': 3, 'red': 2, 'green': 1})
  ```

  (Contributed by Raymond Hettinger; bpo-1696199.)

- Added a new module, `tkinter.ttk` for access to the Tk themed widget set. The basic idea of ttk is to separate, to the extent possible, the code implementing a widget's behavior from the code implementing its appearance.

  (Contributed by Guilherme Polo; bpo-2983.)

- The `gzip.GzipFile` and `bz2.BZ2File` classes now support the context management protocol:

  ```python
  >>> # Automatically close file after writing
  >>> with gzip.GzipFile(filename, "wb") as f:
  ...     f.write(b"xxx")
  ```

  (Contributed by Antoine Pitrou.)

- The `decimal` module now supports methods for creating a decimal object from a binary `float`. The conversion is exact but can sometimes be surprising:

  ```python
  >>> Decimal.from_float(1.1)
  Decimal('1.10000000000000008881784197001252323389
  ```
The long decimal result shows the actual binary fraction being stored for 1.1. The fraction has many digits because 1.1 cannot be exactly represented in binary.

(Contributed by Raymond Hettinger and Mark Dickinson.)

- The `itertools` module grew two new functions. The `itertools.combinations_with_replacement()` function is one of four for generating combinatorics including permutations and Cartesian products. The `itertools.compress()` function mimics its namesake from APL. Also, the existing `itertools.count()` function now has an optional `step` argument and can accept any type of counting sequence including `fractions.Fraction` and `decimal.Decimal`:

```python

>>> list(compress(data=range(10), selectors=[0, 0, 0, 0, 0, 1, 1, 0, 0, 0]))
[2, 3, 5, 7]

>>> c = count(start=Fraction(1, 2), step=Fraction(1, 2))
>>> [next(c), next(c), next(c), next(c)]
[Fraction(1, 2), Fraction(2, 3), Fraction(5, 6), Fraction(1, 1)]
```

(Contributed by Raymond Hettinger.)

- `collections.namedtuple()` now supports a keyword argument `rename` which lets invalid fieldnames be automatically converted to positional names in the form _0, _1, etc. This is useful when the field names are being created by an external source such as a CSV header, SQL field list, or user input:
>>> query = input()
SELECT region, dept, count(*) FROM main GROUP BY region, dept

>>> cursor.execute(query)

>>> query_fields = [desc[0] for desc in cursor.description]

>>> UserQuery = namedtuple('UserQuery', query_fields)

>>> pprint.pprint([UserQuery(*row) for row in cursor])
[UserQuery(region='South', dept='Shipping', __2=185),
 UserQuery(region='North', dept='Accounting', __2=37),
 UserQuery(region='West', dept='Sales', __2=419)]

(Contributed by Raymond Hettinger; bpo-1818.)

- The `re.sub()`, `re.subn()` and `re.split()` functions now accept a flags parameter.

  (Contributed by Gregory Smith.)

- The `logging` module now implements a simple `logging.NullHandler` class for applications that are not using logging but are calling library code that does. Setting-up a null handler will suppress spurious warnings such as “No handlers could be found for logger foo”:

  ```python
  >>> h = logging.NullHandler()
  >>> logging.getLogger("foo").addHandler(h)
  ```

  (Contributed by Vinay Sajip; bpo-4384).

- The `runpy` module which supports the `-m` command line switch now supports the execution of packages by looking for and executing a `__main__` submodule when a package name is supplied.
The pdb module can now access and display source code loaded via zipimport (or any other conformant PEP 302 loader).

functools.partial objects can now be pickled.

Add pydoc help topics for symbols so that help('@') works as expected in the interactive environment.

The unittest module now supports skipping individual tests or classes of tests. And it supports marking a test as an expected failure, a test that is known to be broken, but shouldn't be counted as a failure on a TestResult:

```python
class TestGizmo(unittest.TestCase):
    @unittest.skipUnless(sys.platform.startswith('win'),
                       def test_gizmo_on_windows(self):
                           ...

    @unittest.expectedFailure
    def test_gimzo_without_required_library(self):
                           ...
```

Also, tests for exceptions have been builtout to work with context managers using the with statement:
def test_division_by_zero(self):
    with self.assertRaises(ZeroDivisionError):
        x / 0

In addition, several new assertion methods were added including assertSetEqual(), assertDictEqual(), assertDictContainsSubset(), assertListEqual(), assertTupleEqual(), assertSequenceEqual(), assertRaisesRegexp(), assertIsNone(), and assertIsNotNone.

(Contributed by Benjamin Peterson and Antoine Pitrou.)

- The io module has three new constants for the seek() method SEEK_SET, SEEK_CUR, and SEEK_END.

- The sys.version_info tuple is now a named tuple:

  ```
  >>> sys.version_info
  sys.version_info(major=3, minor=1, micro=0, releaselevel='alpha', serial=2)
  ```

  (Contributed by Ross Light; bpo-4285.)

- The nntplib and imaplib modules now support IPv6.

  (Contributed by Derek Morr; bpo-1655 and bpo-1664.)

- The pickle module has been adapted for better interoperability with Python 2.x when used with protocol 2 or lower. The reorganization of the standard library changed the formal reference for many objects. For example, __builtin__.set in Python 2 is called builtins.set in Python 3. This change confounded efforts to share data between different versions of
Python. But now when protocol 2 or lower is selected, the pickler will automatically use the old Python 2 names for both loading and dumping. This remapping is turned-on by default but can be disabled with the `fix_imports` option:

```python
>>> s = {1, 2, 3}
>>> pickle.dumps(s, protocol=0)
b'c__builtin__\nset
p0\n((lp1\nL1L
aL2L
aL3L
atp2
Rp3
.'
>>> pickle.dumps(s, protocol=0, fix_imports=False)
b'cbuiltins\nset
p0\n((lp1\nL1L
aL2L
aL3L
atp2
Rp3
.'
```

An unfortunate but unavoidable side-effect of this change is that protocol 2 pickles produced by Python 3.1 won’t be readable with Python 3.0. The latest pickle protocol, protocol 3, should be used when migrating data between Python 3.x implementations, as it doesn’t attempt to remain compatible with Python 2.x.

(Contributed by Alexandre Vassalotti and Antoine Pitrou, bpo-6137.)

- A new module, `importlib` was added. It provides a complete, portable, pure Python reference implementation of the `import` statement and its counterpart, the `__import__()` function. It represents a substantial step forward in documenting and defining the actions that take place during imports.

(Contributed by Brett Cannon.)
Optimizations

Major performance enhancements have been added:

- The new I/O library (as defined in PEP 3116) was mostly written in Python and quickly proved to be a problematic bottleneck in Python 3.0. In Python 3.1, the I/O library has been entirely rewritten in C and is 2 to 20 times faster depending on the task at hand. The pure Python version is still available for experimentation purposes through the _pyio module.

  (Contributed by Amaury Forgeot d’Arc and Antoine Pitrou.)

- Added a heuristic so that tuples and dicts containing only untrackable objects are not tracked by the garbage collector. This can reduce the size of collections and therefore the garbage collection overhead on long-running programs, depending on their particular use of datatypes.

  (Contributed by Antoine Pitrou, bpo-4688.)

- Enabling a configure option named --with-computed-gotos on compilers that support it (notably: gcc, SunPro, icc), the bytecode evaluation loop is compiled with a new dispatch mechanism which gives speedups of up to 20%, depending on the system, the compiler, and the benchmark.

  (Contributed by Antoine Pitrou along with a number of other participants, bpo-4753).

- The decoding of UTF-8, UTF-16 and LATIN-1 is now two to four times faster.
The json module now has a C extension to substantially improve its performance. In addition, the API was modified so that json works only with `str`, not with `bytes`. That change makes the module closely match the JSON specification which is defined in terms of Unicode.

(Contributed by Bob Ippolito and converted to Py3.1 by Antoine Pitrou and Benjamin Peterson; bpo-4136.)

- Unpickling now interns the attribute names of pickled objects. This saves memory and allows pickles to be smaller.

(Contributed by Jake McGuire and Antoine Pitrou; bpo-5084.)
IDLE

- IDLE’s format menu now provides an option to strip trailing whitespace from a source file.

(Contributed by Roger D. Serwy; bpo-5150.)
Build and C API Changes

Changes to Python’s build process and to the C API include:

- Integers are now stored internally either in base $2^{15}$ or in base $2^{30}$, the base being determined at build time. Previously, they were always stored in base $2^{15}$. Using base $2^{30}$ gives significant performance improvements on 64-bit machines, but benchmark results on 32-bit machines have been mixed. Therefore, the default is to use base $2^{30}$ on 64-bit machines and base $2^{15}$ on 32-bit machines; on Unix, there’s a new configure option `--enable-big-digits` that can be used to override this default.

  Apart from the performance improvements this change should be invisible to end users, with one exception: for testing and debugging purposes there’s a new `sys.int_info` that provides information about the internal format, giving the number of bits per digit and the size in bytes of the C type used to store each digit:

  ```python
  >>> import sys
  >>> sys.int_info
  sys.int_info(bits_per_digit=30, sizeof_digit=4)
  ```

  (Contributed by Mark Dickinson; bpo-4258.)

- The `PyLong_AsUnsignedLongLong()` function now handles a negative `pylong` by raising `OverflowError` instead of `TypeError`.

  (Contributed by Mark Dickinson and Lisandro Dalcrin; bpo-5175.)
• Deprecated PyNumber_Int(). Use PyNumber_Long() instead.

(Contributed by Mark Dickinson; bpo-4910.)

• Added a new PyOS_string_to_double() function to replace the deprecated functions PyOS_ascii_strtod() and PyOS_ascii_atof().

(Contributed by Mark Dickinson; bpo-5914.)

• Added PyCapsule as a replacement for the PyCObject API. The principal difference is that the new type has a well defined interface for passing typing safety information and a less complicated signature for calling a destructor. The old type had a problematic API and is now deprecated.

(Contributed by Larry Hastings; bpo-5630.)
Porting to Python 3.1

This section lists previously described changes and other bugfixes that may require changes to your code:

- The new floating point string representations can break existing doctests. For example:

```python
def e():
    '''Compute the base of natural logarithms.

    >>> e()
    2.7182818284590451

    ..
    return sum(1/math.factorial(x) for x in reversed(doctest.testmod())
```

```
**********************************************************************
Failed example:
   e()
Expected:
   2.7182818284590451
Got:
   2.718281828459045
**********************************************************************
```

- The automatic name remapping in the pickle module for protocol 2 or lower can make Python 3.1 pickles unreadable in Python 3.0. One solution is to use protocol 3. Another solution is to set the `fix_imports` option to `False`. See the discussion above for more details.
What’s New In Python 3.0

Author: Guido van Rossum

This article explains the new features in Python 3.0, compared to 2.6. Python 3.0, also known as “Python 3000” or “Py3K”, is the first ever intentionally backwards incompatible Python release. There are more changes than in a typical release, and more that are important for all Python users. Nevertheless, after digesting the changes, you’ll find that Python really hasn’t changed all that much – by and large, we’re mostly fixing well-known annoyances and warts, and removing a lot of old cruft.

This article doesn’t attempt to provide a complete specification of all new features, but instead tries to give a convenient overview. For full details, you should refer to the documentation for Python 3.0, and/or the many PEPs referenced in the text. If you want to understand the complete implementation and design rationale for a particular feature, PEPs usually have more details than the regular documentation; but note that PEPs usually are not kept up-to-date once a feature has been fully implemented.

Due to time constraints this document is not as complete as it should have been. As always for a new release, the Misc/NEWS file in the source distribution contains a wealth of detailed information about every small thing that was changed.
Common Stumbling Blocks
This section lists those few changes that are most likely to trip you up
if you’re used to Python 2.5.

Print Is A Function
The print statement has been replaced with a print() function,
with keyword arguments to replace most of the special syntax of the
old print statement (PEP 3105). Examples:
Old: print "The answer is", 2*2
New: print("The answer is", 2*2)
Old: print x,
New: print(x, end=" ")

# Trailing comma suppresses newline
# Appends a space instead of a newli

Old: print
New: print()

# Prints a newline
# You must call the function!

Old: print >>sys.stderr, "fatal error"
New: print("fatal error", file=sys.stderr)
Old: print (x, y)
New: print((x, y))

# prints repr((x, y))
# Not the same as print(x, y)!

You can also customize the separator between items, e.g.:
print("There are <", 2**32, "> possibilities!", sep=

which produces:


There are <4294967296> possibilities!

Note:

- The `print()` function doesn't support the “softspace” feature of the old `print` statement. For example, in Python 2.x, `print "A\n", "B"` would write "A\nB\n"; but in Python 3.0, `print("A\n", "B")` writes "A
B
".
- Initially, you’ll be finding yourself typing the old `print x` a lot in interactive mode. Time to retrain your fingers to type `print(x)` instead!
- When using the `2to3` source-to-source conversion tool, all `print` statements are automatically converted to `print()` function calls, so this is mostly a non-issue for larger projects.

Views And Iterators Instead Of Lists

Some well-known APIs no longer return lists:

- `dict` methods `dict.keys()`, `dict.items()` and `dict.values()` return “views” instead of lists. For example, this no longer works: `k = d.keys(); k.sort()`. Use `k = sorted(d)` instead (this works in Python 2.5 too and is just as efficient).
- Also, the `dict.iterkeys()`, `dict.iteritems()` and `dict.itervalues()` methods are no longer supported.
- `map()` and `filter()` return iterators. If you really need a list and the input sequences are all of equal length, a quick fix is to wrap `map()` in `list()`, e.g. `list(map(...))`, but a better fix is often to use a list comprehension (especially when the original
code uses **lambda**), or rewriting the code so it doesn't need a list at all. Particularly tricky is **map()** invoked for the side effects of the function; the correct transformation is to use a regular **for** loop (since creating a list would just be wasteful).

If the input sequences are not of equal length, **map()** will stop at the termination of the shortest of the sequences. For full compatibility with **map()** from Python 2.x, also wrap the sequences in **itertools.zip_longest()**, e.g. `map(func, *sequences)` becomes `list(map(func, itertools.zip_longest(*sequences))).`

- **range()** now behaves like **xrange()** used to behave, except it works with values of arbitrary size. The latter no longer exists.

- **zip()** now returns an iterator.

**Ordering Comparisons**

Python 3.0 has simplified the rules for ordering comparisons:

- The ordering comparison operators (`<`, `<=`, `>=`, `>`) raise a `TypeError` exception when the operands don't have a meaningful natural ordering. Thus, expressions like `1 < ''`, `0 > None` or `len <= len` are no longer valid, and e.g. `None < None` raises `TypeError` instead of returning `False`. A corollary is that sorting a heterogeneous list no longer makes sense – all the elements must be comparable to each other. Note that this does not apply to the `==` and `!=` operators: objects of different incomparable types always compare unequal to each other.

- **builtins.sorted()** and **list.sort()** no longer accept the `cmp` argument providing a comparison function. Use the **key**
argument instead. N.B. the key and reverse arguments are now “keyword-only”.

- The cmp() function should be treated as gone, and the __cmp__() special method is no longer supported. Use __lt__() for sorting, __eq__() with __hash__(), and other rich comparisons as needed. (If you really need the cmp() functionality, you could use the expression \((a > b) - (a < b)\) as the equivalent for cmp(a, b).)

Integers

- **PEP 237**: Essentially, long renamed to int. That is, there is only one built-in integral type, named int; but it behaves mostly like the old long type.
- **PEP 238**: An expression like 1/2 returns a float. Use 1//2 to get the truncating behavior. (The latter syntax has existed for years, at least since Python 2.2.)
- The sys.maxint constant was removed, since there is no longer a limit to the value of integers. However, sys.maxsize can be used as an integer larger than any practical list or string index. It conforms to the implementation’s “natural” integer size and is typically the same as sys.maxint in previous releases on the same platform (assuming the same build options).
- The repr() of a long integer doesn't include the trailing L anymore, so code that unconditionally strips that character will chop off the last digit instead. (Use str() instead.)
- Octal literals are no longer of the form \(0720\); use \(0o720\) instead.

Text Vs. Data Instead Of Unicode Vs. 8-bit

Everything you thought you knew about binary data and Unicode has changed.
Python 3.0 uses the concepts of text and (binary) data instead of Unicode strings and 8-bit strings. All text is Unicode; however encoded Unicode is represented as binary data. The type used to hold text is str, the type used to hold data is bytes. The biggest difference with the 2.x situation is that any attempt to mix text and data in Python 3.0 raises TypeError, whereas if you were to mix Unicode and 8-bit strings in Python 2.x, it would work if the 8-bit string happened to contain only 7-bit (ASCII) bytes, but you would get UnicodeDecodeError if it contained non-ASCII values. This value-specific behavior has caused numerous sad faces over the years.

As a consequence of this change in philosophy, pretty much all code that uses Unicode, encodings or binary data most likely has to change. The change is for the better, as in the 2.x world there were numerous bugs having to do with mixing encoded and unencoded text. To be prepared in Python 2.x, start using unicode for all unencoded text, and str for binary or encoded data only. Then the 2to3 tool will do most of the work for you.

You can no longer use u"..." literals for Unicode text. However, you must use b"..." literals for binary data.

As the str and bytes types cannot be mixed, you must always explicitly convert between them. Use str.encode() to go from str to bytes, and bytes.decode() to go from bytes to str. You can also use bytes(s, encoding=...) and str(b, encoding=...), respectively.

Like str, the bytes type is immutable. There is a separate mutable type to hold buffered binary data, bytearray. Nearly all APIs that accept bytes also accept bytearray. The mutable API is based on collections.MutableSequence.

All backslashes in raw string literals are interpreted literally. This means that '\U' and '\u' escapes in raw strings are not treated specially. For example, r'\u20ac' is a string of 6 characters in Python 3.0, whereas in 2.6, ur'\u20ac' was the
single “euro” character. (Of course, this change only affects raw string literals; the euro character is \u20ac in Python 3.0.)

- The built-in basestring abstract type was removed. Use str instead. The str and bytes types don't have functionality enough in common to warrant a shared base class. The 2to3 tool (see below) replaces every occurrence of basestring with str.

- Files opened as text files (still the default mode for open()) always use an encoding to map between strings (in memory) and bytes (on disk). Binary files (opened with a b in the mode argument) always use bytes in memory. This means that if a file is opened using an incorrect mode or encoding, I/O will likely fail loudly, instead of silently producing incorrect data. It also means that even Unix users will have to specify the correct mode (text or binary) when opening a file. There is a platform-dependent default encoding, which on Unixy platforms can be set with the LANG environment variable (and sometimes also with some other platform-specific locale-related environment variables). In many cases, but not all, the system default is UTF-8; you should never count on this default. Any application reading or writing more than pure ASCII text should probably have a way to override the encoding. There is no longer any need for using the encoding-aware streams in the codecs module.

- The initial values of sys.stdin, sys.stdout and sys.stderr are now unicode-only text files (i.e., they are instances of io.TextIOWrapper). To read and write bytes data with these streams, you need to use their io.TextIOWrapper.buffer attribute.

- Filenames are passed to and returned from APIs as (Unicode) strings. This can present platform-specific problems because on some platforms filenames are arbitrary byte strings. (On the other hand, on Windows filenames are natively stored as Unicode.) As a work-around, most APIs (e.g. open()) and many functions in
the os module) that take filenames accept bytes objects as well as strings, and a few APIs have a way to ask for a bytes return value. Thus, os.listdir() returns a list of bytes instances if the argument is a bytes instance, and os.getcwd() returns the current working directory as a bytes instance. Note that when os.listdir() returns a list of strings, filenames that cannot be decoded properly are omitted rather than raising UnicodeError.

- Some system APIs like os.environ and sys.argv can also present problems when the bytes made available by the system is not interpretable using the default encoding. Setting the LANG variable and rerunning the program is probably the best approach.
- **PEP 3138**: The repr() of a string no longer escapes non-ASCII characters. It still escapes control characters and code points with non-printable status in the Unicode standard, however.
- **PEP 3120**: The default source encoding is now UTF-8.
- **PEP 3131**: Non-ASCII letters are now allowed in identifiers. (However, the standard library remains ASCII-only with the exception of contributor names in comments.)
- The StringIO and cStringIO modules are gone. Instead, import the io module and use io.StringIO or io.BytesIO for text and data respectively.
- See also the Unicode HOWTO, which was updated for Python 3.0.
Overview Of Syntax Changes

This section gives a brief overview of every syntactic change in Python 3.0.

New Syntax

- **PEP 3107**: Function argument and return value annotations. This provides a standardized way of annotating a function’s parameters and return value. There are no semantics attached to such annotations except that they can be introspected at runtime using the `__annotations__` attribute. The intent is to encourage experimentation through metaclasses, decorators or frameworks.

- **PEP 3102**: Keyword-only arguments. Named parameters occurring after `*args` in the parameter list must be specified using keyword syntax in the call. You can also use a bare `*` in the parameter list to indicate that you don’t accept a variable-length argument list, but you do have keyword-only arguments.

- Keyword arguments are allowed after the list of base classes in a class definition. This is used by the new convention for specifying a metaclass (see next section), but can be used for other purposes as well, as long as the metaclass supports it.

- **PEP 3104**: `nonlocal` statement. Using `nonlocal x` you can now assign directly to a variable in an outer (but non-global) scope. `nonlocal` is a new reserved word.

- **PEP 3132**: Extended Iterable Unpacking. You can now write
things like a, b, *rest = some_sequence. And even *rest, a = stuff. The rest object is always a (possibly empty) list; the right-hand side may be any iterable. Example:

```
(a, *rest, b) = range(5)
```

This sets a to 0, b to 4, and rest to [1, 2, 3].

- Dictionary comprehensions: `{k: v for k, v in stuff}` means the same thing as `dict(stuff)` but is more flexible. (This is PEP 274 vindicated. :-)

- Set literals, e.g. `{1, 2}`. Note that `{}` is an empty dictionary; use `set()` for an empty set. Set comprehensions are also supported; e.g., `{x for x in stuff}` means the same thing as `set(stuff)` but is more flexible.

- New octal literals, e.g. `0o720` (already in 2.6). The old octal literals (0720) are gone.

- New binary literals, e.g. `0b1010` (already in 2.6), and there is a new corresponding built-in function, `bin()`.

- Bytes literals are introduced with a leading `b` or `B`, and there is a new corresponding built-in function, `bytes()`.

**Changed Syntax**

- **PEP 3109** and **PEP 3134**: new `raise` statement syntax: `raise [expr [from expr]]`. See below.

- `as` and `with` are now reserved words. (Since 2.6, actually.)
• True, False, and None are reserved words. (2.6 partially enforced the restrictions on None already.)

• Change from except exc, var to except exc as var. See PEP 3110.

• PEP 3115: New Metaclass Syntax. Instead of:

```python
class C:
    __metaclass__ = M
...
```

you must now use:

```python
class C(metaclass=M):
    ...
```

The module-global __metaclass__ variable is no longer supported. (It was a crutch to make it easier to default to new-style classes without deriving every class from object.)

• List comprehensions no longer support the syntactic form [...] for var in item1, item2, ...]. Use [...] for var in (item1, item2, ...) instead. Also note that list comprehensions have different semantics: they are closer to syntactic sugar for a generator expression inside a list() constructor, and in particular the loop control variables are no longer leaked into the surrounding scope.

• The ellipsis (...) can be used as an atomic expression anywhere. (Previously it was only allowed in slices.) Also, it must now be spelled as . . . . (Previously it could also be spelled as . . . , by a mere accident of the grammar.)
Removed Syntax

- **PEP 3113**: Tuple parameter unpacking removed. You can no longer write `def foo(a, (b, c)): ....` Use `def foo(a, b_c): b, c = b_c` instead.
- Removed backticks (use `repr()` instead).
- Removed `<>` (use `!=` instead).
- Removed keyword: `exec()` is no longer a keyword; it remains as a function. (Fortunately the function syntax was also accepted in 2.x.) Also note that `exec()` no longer takes a stream argument; instead of `exec(f)` you can use `exec(f.read())`.
- Integer literals no longer support a trailing `l` or `L`.
- String literals no longer support a leading `u` or `U`.
- The `from module import *` syntax is only allowed at the module level, no longer inside functions.
- The only acceptable syntax for relative imports is `from [module] import name`. All `import` forms not starting with `.` are interpreted as absolute imports. *(PEP 328)*
- Classic classes are gone.
Changes Already Present In Python 2.6

Since many users presumably make the jump straight from Python 2.5 to Python 3.0, this section reminds the reader of new features that were originally designed for Python 3.0 but that were back-ported to Python 2.6. The corresponding sections in What's New in Python 2.6 should be consulted for longer descriptions.

- **PEP 343: The 'with' statement.** The `with` statement is now a standard feature and no longer needs to be imported from the `__future__`. Also check out Writing Context Managers and The contextlib module.
- **PEP 366: Explicit Relative Imports From a Main Module.** This enhances the usefulness of the `-m` option when the referenced module lives in a package.
- **PEP 370: Per-user site-packages Directory.**
- **PEP 371: The multiprocessing Package.**
- **PEP 3101: Advanced String Formatting.** Note: the 2.6 description mentions the `format()` method for both 8-bit and Unicode strings. In 3.0, only the `str` type (text strings with Unicode support) supports this method; the `bytes` type does not. The plan is to eventually make this the only API for string formatting, and to start deprecating the `%` operator in Python 3.1.
- **PEP 3105: print As a Function.** This is now a standard feature and no longer needs to be imported from `__future__`. More details were given above.
- **PEP 3110: Exception-Handling Changes.** The `except exc as var` syntax is now standard and `except exc, var` is no longer supported. (Of course, the `as var` part is still optional.)
- **PEP 3112: Byte Literals.** The `b"..."` string literal notation (and its variants like `b'...', b'''...''', and `br"..."`) now produces a literal of type `bytes`. 
- **PEP 3116: New I/O Library.** The `io` module is now the standard way of doing file I/O. The built-in `open()` function is now an alias for `io.open()` and has additional keyword arguments `encoding, errors, newline` and `closefd`. Also note that an invalid `mode` argument now raises `ValueError`, not `IOError`. The binary file object underlying a text file object can be accessed as `f.buffer` (but beware that the text object maintains a buffer of itself in order to speed up the encoding and decoding operations).

- **PEP 3118: Revised Buffer Protocol.** The old built-in `buffer()` is now really gone; the new built-in `memoryview()` provides (mostly) similar functionality.

- **PEP 3119: Abstract Base Classes.** The `abc` module and the ABCs defined in the `collections` module plays a somewhat more prominent role in the language now, and built-in collection types like `dict` and `list` conform to the `collections.MutableMapping` and `collections.MutableSequence` ABCs, respectively.

- **PEP 3127: Integer Literal Support and Syntax.** As mentioned above, the new octal literal notation is the only one supported, and binary literals have been added.

- **PEP 3129: Class Decorators.**

- **PEP 3141: A Type Hierarchy for Numbers.** The `numbers` module is another new use of ABCs, defining Python’s “numeric tower”. Also note the new `fractions` module which implements `numbers.Rational`. 
Library Changes

Due to time constraints, this document does not exhaustively cover the very extensive changes to the standard library. **PEP 3108** is the reference for the major changes to the library. Here's a capsule review:

- Many old modules were removed. Some, like gopherlib (no longer used) and md5 (replaced by **hashlib**), were already deprecated by PEP 4. Others were removed as a result of the removal of support for various platforms such as Irix, BeOS and Mac OS 9 (see PEP 11). Some modules were also selected for removal in Python 3.0 due to lack of use or because a better replacement exists. See **PEP 3108** for an exhaustive list.

- The bsddb3 package was removed because its presence in the core standard library has proved over time to be a particular burden for the core developers due to testing instability and Berkeley DB's release schedule. However, the package is alive and well, externally maintained at [https://www.jcea.es/programacion/pybsddb.htm](https://www.jcea.es/programacion/pybsddb.htm).

- Some modules were renamed because their old name disobeyed PEP 8, or for various other reasons. Here's the list:

<table>
<thead>
<tr>
<th>Old Name</th>
<th>New Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>_winreg</td>
<td>winreg</td>
</tr>
<tr>
<td>ConfigParser</td>
<td>configparser</td>
</tr>
<tr>
<td>copy_reg</td>
<td>copyreg</td>
</tr>
<tr>
<td>Queue</td>
<td>queue</td>
</tr>
<tr>
<td>SocketServer</td>
<td>socketserv</td>
</tr>
</tbody>
</table>
A common pattern in Python 2.x is to have one version of a module implemented in pure Python, with an optional accelerated version implemented as a C extension; for example, pickle and cPickle. This places the burden of importing the accelerated version and falling back on the pure Python version on each user of these modules. In Python 3.0, the accelerated versions are considered implementation details of the pure Python versions. Users should always import the standard version, which attempts to import the accelerated version and falls back to the pure Python version. The pickle / cPickle pair received this treatment. The profile module is on the list for 3.1. The StringIO module has been turned into a class in the io module.

Some related modules have been grouped into packages, and usually the submodule names have been simplified. The resulting new packages are:

- dbm (anydbm, dbhash, dbm, dumbdbm, gdbm, whichdb).
- html (HTMLParser, htmlentitydefs).
- http (httplib, BaseHTTPServer, CGIHTTPServer, SimpleHTTPServer, Cookie, cookielib).
- tkinter (all Tkinter-related modules except turtle). The target audience of turtle doesn't really care about tkinter. Also note that as of Python 2.6, the functionality of turtle has been greatly enhanced.
- urllib (urllib, urllib2, urlparse, robotparser).
- xmlrpclib, DocXMLRPCServer,
SimpleXMLRPCServer).

Some other changes to standard library modules, not covered by PEP 3108:

- Killed sets. Use the built-in `set()` class.
- Cleanup of the `sys` module: removed `sys.exitfunc()`, `sys.exc_clear()`, `sys.exc_type`, `sys.exc_value`, `sys.exc_traceback`. (Note that `sys.last_type` etc. remain.)
- Cleanup of the `array.array` type: the `read()` and `write()` methods are gone; use `fromfile()` and `tofile()` instead. Also, the `'c'` typecode for array is gone – use either `'b'` for bytes or `'u'` for Unicode characters.
- Cleanup of the `operator` module: removed `sequenceIncludes()` and `isCallable()`.
- Cleanup of the `thread` module: `acquire_lock()` and `release_lock()` are gone; use `acquire()` and `release()` instead.
- Cleanup of the `random` module: removed the `jumpahead()` API.
- The new module is gone.
- The functions `os.tmpnam()`, `os.tempnam()` and `os.tmpfile()` have been removed in favor of the `tempfile` module.
- The `tokenize` module has been changed to work with bytes. The main entry point is now `tokenize.tokenize()`, instead of `generate_tokens`.
- `string.letters` and its friends (`string.lowercase` and `string.uppercase`) are gone. Use `string.ascii_letters` etc. instead. (The reason for the removal is that `string.letters` and friends had locale-specific behavior, which is a bad idea for such attractively-named global "constants").
- Renamed module `__builtin__` to `builtins` (removing the
underscores, adding an ‘s’). The __builtins__ variable found in most global namespaces is unchanged. To modify a builtin, you should use builtins, not __builtins__!
**PEP 3101: A New Approach To String Formatting**

- A new system for built-in string formatting operations replaces the `%` string formatting operator. (However, the `%` operator is still supported; it will be deprecated in Python 3.1 and removed from the language at some later time.) Read **PEP 3101** for the full scoop.
Changes To Exceptions

The APIs for raising and catching exception have been cleaned up and new powerful features added:

- **PEP 352**: All exceptions must be derived (directly or indirectly) from `BaseException`. This is the root of the exception hierarchy. This is not new as a recommendation, but the requirement to inherit from `BaseException` is new. (Python 2.6 still allowed classic classes to be raised, and placed no restriction on what you can catch.) As a consequence, string exceptions are finally truly and utterly dead.

- Almost all exceptions should actually derive from `Exception`; `BaseException` should only be used as a base class for exceptions that should only be handled at the top level, such as `SystemExit` or `KeyboardInterrupt`. The recommended idiom for handling all exceptions except for this latter category is to use `except Exception`.

- `StandardError` was removed.

- Exceptions no longer behave as sequences. Use the `args` attribute instead.

- **PEP 3109**: Raising exceptions. You must now use `raise Exception(args)` instead of `raise Exception, args`. Additionally, you can no longer explicitly specify a traceback; instead, if you have to do this, you can assign directly to the `__traceback__` attribute (see below).

- **PEP 3110**: Catching exceptions. You must now use `except`
SomeException as variable instead of except SomeException, variable. Moreover, the variable is explicitly deleted when the except block is left.

- **PEP 3134**: Exception chaining. There are two cases: implicit chaining and explicit chaining. Implicit chaining happens when an exception is raised in an except or finally handler block. This usually happens due to a bug in the handler block; we call this a secondary exception. In this case, the original exception (that was being handled) is saved as the __context__ attribute of the secondary exception. Explicit chaining is invoked with this syntax:

```python
raise SecondaryException() from primary_exception
```

(where primary_exception is any expression that produces an exception object, probably an exception that was previously caught). In this case, the primary exception is stored on the __cause__ attribute of the secondary exception. The traceback printed when an unhandled exception occurs walks the chain of __cause__ and __context__ attributes and prints a separate traceback for each component of the chain, with the primary exception at the top. (Java users may recognize this behavior.)

- **PEP 3134**: Exception objects now store their traceback as the __traceback__ attribute. This means that an exception object now contains all the information pertaining to an exception, and there are fewer reasons to use `sys.exc_info()` (though the latter is not removed).

- A few exception messages are improved when Windows fails to load an extension module. For example, error code 193 is
now \%1 is not a valid Win32 application. Strings now deal with non-English locales.
Miscellaneous Other Changes

Operators And Special Methods

- $!=$ now returns the opposite of $==$ unless $==$ returns `NotImplemented`.
- The concept of “unbound methods” has been removed from the language. When referencing a method as a class attribute, you now get a plain function object.
- `__getslice__()`, `__setslice__()`, and `__delslice__()` were killed. The syntax `a[i:j]` now translates to `a.__getitem__(slice(i, j))` (or `__setitem__()` or `__delitem__()`), when used as an assignment or deletion target, respectively.
- **PEP 3114**: the standard `next()` method has been renamed to `__next__()`.  
- The `__oct__()` and `__hex__()` special methods are removed – `oct()` and `hex()` use `__index__()` now to convert the argument to an integer.
- Removed support for `__members__` and `__methods__`.
- The function attributes named `func_X` have been renamed to use the `__X__` form, freeing up these names in the function attribute namespace for user-defined attributes. To wit, `func_closure`, `func_code`, `func_defaults`, `func_dict`, `func_doc`, `func_globals`, `func_name` were renamed to `__closure__`, `__code__`, `__defaults__`, `__dict__`, `__doc__`, `__globals__`, `__name__`, respectively.
- `__nonzero__()` is now `__bool__()`.

Builtins
**PEP 3135**: New `super()`. You can now invoke `super()` without arguments and (assuming this is in a regular instance method defined inside a `class` statement) the right class and instance will automatically be chosen. With arguments, the behavior of `super()` is unchanged.

**PEP 3111**: `raw_input()` was renamed to `input()`. That is, the new `input()` function reads a line from `sys.stdin` and returns it with the trailing newline stripped. It raises `EOFError` if the input is terminated prematurely. To get the old behavior of `input()`, use `eval(input())`.

A new built-in function `next()` was added to call the `__next__()` method on an object.

The `round()` function rounding strategy and return type have changed. Exact halfway cases are now rounded to the nearest even result instead of away from zero. (For example, `round(2.5)` now returns 2 rather than 3.) `round(x[, n])` now delegates to `x.__round__(n)` instead of always returning a float. It generally returns an integer when called with a single argument and a value of the same type as `x` when called with two arguments.

Moved `intern()` to `sys.intern()`.

Removed: `apply()`.

Instead of `apply(f, args)` use `f(*args)`.

Removed `callable()`. Instead of `callable(f)` you can use `isinstance(f, collections.Callable)`. The `operator.isCallable()` function is also gone.

Removed `coerce()`.

This function no longer serves a purpose now that classic classes are gone.

Removed `execfile()`. Instead of `execfile(fn)` use `exec(open(fn).read())`.

Removed the file type. Use `open()`. There are now several different kinds of streams that `open` can return in the `io` module.
• Removed `reduce()`. Use `functools.reduce()` if you really need it; however, 99 percent of the time an explicit `for` loop is more readable.
• Removed `reload()`. Use `imp.reload()`.
• Removed `dict.has_key()` – use the `in` operator instead.
Build and C API Changes

Due to time constraints, here is a very incomplete list of changes to the C API.

- Support for several platforms was dropped, including but not limited to Mac OS 9, BeOS, RISCOS, Irix, and Tru64.
- **PEP 3118**: New Buffer API.
- **PEP 3121**: Extension Module Initialization & Finalization.
- **PEP 3123**: Making *PyObject* HEAD conform to standard C.
- No more C API support for restricted execution.
- *PyNumber_Coerce()*, *PyNumber_CoerceEx()*, *PyMember_Get()*, and *PyMember_Set()* C APIs are removed.
- New C API *PyImport_ImportModuleNoBlock()*, works like *PyImport_ImportModule()* but won’t block on the import lock (returning an error instead).
- Renamed the boolean conversion C-level slot and method: *nb_nonzero* is now *nb_bool*.
- Removed METH_OLDARGS and WITH_CYCLE_GC from the C API.
Performance

The net result of the 3.0 generalizations is that Python 3.0 runs the pystone benchmark around 10% slower than Python 2.5. Most likely the biggest cause is the removal of special-casing for small integers. There’s room for improvement, but it will happen after 3.0 is released!
Porting To Python 3.0

For porting existing Python 2.5 or 2.6 source code to Python 3.0, the best strategy is the following:

0. (Prerequisite:) Start with excellent test coverage.
1. Port to Python 2.6. This should be no more work than the average port from Python 2.x to Python 2.(x+1). Make sure all your tests pass.
2. (Still using 2.6:) Turn on the -3 command line switch. This enables warnings about features that will be removed (or change) in 3.0. Run your test suite again, and fix code that you get warnings about until there are no warnings left, and all your tests still pass.
3. Run the 2to3 source-to-source translator over your source code tree. (See 2to3 - Automated Python 2 to 3 code translation for more on this tool.) Run the result of the translation under Python 3.0. Manually fix up any remaining issues, fixing problems until all tests pass again.

It is not recommended to try to write source code that runs unchanged under both Python 2.6 and 3.0; you’d have to use a very contorted coding style, e.g. avoiding print statements, metaclasses, and much more. If you are maintaining a library that needs to support both Python 2.6 and Python 3.0, the best approach is to modify step 3 above by editing the 2.6 version of the source code and running the 2to3 translator again, rather than editing the 3.0 version of the source code.

For porting C extensions to Python 3.0, please see Porting Extension Modules to Python 3.
What’s New in Python 2.7

Author: A.M. Kuchling (amk at amk.ca)

This article explains the new features in Python 2.7. Python 2.7 was released on July 3, 2010.

Numeric handling has been improved in many ways, for both floating-point numbers and for the Decimal class. There are some useful additions to the standard library, such as a greatly enhanced unittest module, the argparse module for parsing command-line options, convenient OrderedDict and Counter classes in the collections module, and many other improvements.

Python 2.7 is planned to be the last of the 2.x releases, so we worked on making it a good release for the long term. To help with porting to Python 3, several new features from the Python 3.x series have been included in 2.7.

This article doesn’t attempt to provide a complete specification of the new features, but instead provides a convenient overview. For full details, you should refer to the documentation for Python 2.7 at https://docs.python.org. If you want to understand the rationale for the design and implementation, refer to the PEP for a particular new feature or the issue on https://bugs.python.org in which a change was discussed. Whenever possible, “What’s New in Python” links to the bug/patch item for each change.
The Future for Python 2.x

Python 2.7 is the last major release in the 2.x series, as the Python maintainers have shifted the focus of their new feature development efforts to the Python 3.x series. This means that while Python 2 continues to receive bug fixes, and to be updated to build correctly on new hardware and versions of supported operated systems, there will be no new full feature releases for the language or standard library.

However, while there is a large common subset between Python 2.7 and Python 3, and many of the changes involved in migrating to that common subset, or directly to Python 3, can be safely automated, some other changes (notably those associated with Unicode handling) may require careful consideration, and preferably robust automated regression test suites, to migrate effectively.

This means that Python 2.7 will remain in place for a long time, providing a stable and supported base platform for production systems that have not yet been ported to Python 3. The full expected lifecycle of the Python 2.7 series is detailed in PEP 373.

Some key consequences of the long-term significance of 2.7 are:

- As noted above, the 2.7 release has a much longer period of maintenance when compared to earlier 2.x versions. Python 2.7 is currently expected to remain supported by the core development team (receiving security updates and other bug fixes) until at least 2020 (10 years after its initial release, compared to the more typical support period of 18–24 months).
- As the Python 2.7 standard library ages, making effective use of the Python Package Index (either directly or via a redistributor) becomes more important for Python 2 users. In addition to a wide variety of third party packages for various tasks, the available
packages include backports of new modules and features from the Python 3 standard library that are compatible with Python 2, as well as various tools and libraries that can make it easier to migrate to Python 3. The Python Packaging User Guide provides guidance on downloading and installing software from the Python Package Index.

- While the preferred approach to enhancing Python 2 is now the publication of new packages on the Python Package Index, this approach doesn't necessarily work in all cases, especially those related to network security. In exceptional cases that cannot be handled adequately by publishing new or updated packages on PyPI, the Python Enhancement Proposal process may be used to make the case for adding new features directly to the Python 2 standard library. Any such additions, and the maintenance releases where they were added, will be noted in the New Features Added to Python 2.7 Maintenance Releases section below.

For projects wishing to migrate from Python 2 to Python 3, or for library and framework developers wishing to support users on both Python 2 and Python 3, there are a variety of tools and guides available to help decide on a suitable approach and manage some of the technical details involved. The recommended starting point is the Porting Python 2 Code to Python 3 HOWTO guide.
Changes to the Handling of Deprecation Warnings

For Python 2.7, a policy decision was made to silence warnings only of interest to developers by default. `DeprecationWarning` and its descendants are now ignored unless otherwise requested, preventing users from seeing warnings triggered by an application. This change was also made in the branch that became Python 3.2. (Discussed on stdlib-sig and carried out in bpo-7319.)

In previous releases, `DeprecationWarning` messages were enabled by default, providing Python developers with a clear indication of where their code may break in a future major version of Python.

However, there are increasingly many users of Python-based applications who are not directly involved in the development of those applications. `DeprecationWarning` messages are irrelevant to such users, making them worry about an application that's actually working correctly and burdening application developers with responding to these concerns.

You can re-enable display of `DeprecationWarning` messages by running Python with the `-Wdefault` (short form: `-Wd`) switch, or by setting the `PYTHONWARNINGS` environment variable to "default" (or "d") before running Python. Python code can also re-enable them by calling `warnings.simplefilter('default')`.

The `unittest` module also automatically reenables deprecation warnings when running tests.
Python 3.1 Features

Much as Python 2.6 incorporated features from Python 3.0, version 2.7 incorporates some of the new features in Python 3.1. The 2.x series continues to provide tools for migrating to the 3.x series.

A partial list of 3.1 features that were backported to 2.7:

- The syntax for set literals ({1, 2, 3} is a mutable set).
- Dictionary and set comprehensions ({i: i*2 for i in range(3)}).
- Multiple context managers in a single `with` statement.
- A new version of the `io` library, rewritten in C for performance.
- The ordered-dictionary type described in PEP 372: Adding an Ordered Dictionary to collections.
- The new `,` format specifier described in PEP 378: Format Specifier for Thousands Separator.
- The `memoryview` object.
- A small subset of the `importlib` module, described below.
- The `repr()` of a float is shorter in many cases: it's now based on the shortest decimal string that's guaranteed to round back to x. As in previous versions of Python, it's guaranteed that `float(repr(x))` recovers x.
- Float-to-string and string-to-float conversions are correctly rounded. The `round()` function is also now correctly rounded.
- The `PyCapsule` type, used to provide a C API for extension modules.
- The `PyLong_AsLongAndOverflow()` C API function.

Other new Python3-mode warnings include:

- `operator.isCallable()` and
operator.sequenceIncludes(), which are not supported in 3.x, now trigger warnings.

- The -3 switch now automatically enables the -Qwarn switch that causes warnings about using classic division with integers and long integers.
PEP 372: Adding an Ordered Dictionary to collections

Regular Python dictionaries iterate over key/value pairs in arbitrary order. Over the years, a number of authors have written alternative implementations that remember the order that the keys were originally inserted. Based on the experiences from those implementations, 2.7 introduces a new OrderedDict class in the collections module.

The OrderedDict API provides the same interface as regular dictionaries but iterates over keys and values in a guaranteed order depending on when a key was first inserted:

```python
>>> from collections import OrderedDict
>>> d = OrderedDict([('first', 1), ...
                   ('second', 2), ...
                   ('third', 3)])
>>> d.items()
[('first', 1), ('second', 2), ('third', 3)]
```

If a new entry overwrites an existing entry, the original insertion position is left unchanged:

```python
>>> d['second'] = 4
>>> d.items()
[('first', 1), ('second', 4), ('third', 3)]
```

Deleting an entry and reinserting it will move it to the end:

```python
>>> del d['second']
>>> d['second'] = 5
>>> d.items()
[('first', 1), ('third', 3), ('second', 5)]
```
The `popitem()` method has an optional last argument that defaults to `True`. If last is true, the most recently added key is returned and removed; if it's false, the oldest key is selected:

```python
>>> od = OrderedDict([(x, 0) for x in range(20)])
>>> od.popitem()
(19, 0)
>>> od.popitem()
(18, 0)
>>> od.popitem(last=False)
(0, 0)
>>> od.popitem(last=False)
(1, 0)
```

Comparing two ordered dictionaries checks both the keys and values, and requires that the insertion order was the same:

```python
>>> od1 = OrderedDict([('first', 1),
...                      ('second', 2),
...                      ('third', 3)])
>>> od2 = OrderedDict([('third', 3),
...                      ('first', 1),
...                      ('second', 2)])
>>> od1 == od2
False
>>> # Move 'third' key to the end
>>> del od2['third']; od2['third'] = 3
>>> od1 == od2
True
```

Comparing an `OrderedDict` with a regular dictionary ignores the insertion order and just compares the keys and values.

How does the `OrderedDict` work? It maintains a doubly-linked list of keys, appending new keys to the list as they're inserted. A secondary
dictionary maps keys to their corresponding list node, so deletion doesn’t have to traverse the entire linked list and therefore remains O(1).

The standard library now supports use of ordered dictionaries in several modules.

- The ConfigParser module uses them by default, meaning that configuration files can now be read, modified, and then written back in their original order.
- The \_asdict() method for \texttt{collections.namedtuple()} now returns an ordered dictionary with the values appearing in the same order as the underlying tuple indices.
- The \texttt{json} module’s \texttt{JSONDecoder} class constructor was extended with an \texttt{object\_pairs\_hook} parameter to allow \texttt{OrderedDict} instances to be built by the decoder. Support was also added for third-party tools like \texttt{PyYAML}.

\textbf{See also:}

\textbf{PEP 372 - Adding an ordered dictionary to collections}

PEP written by Armin Ronacher and Raymond Hettinger; implemented by Raymond Hettinger.
PEP 378: Format Specifier for Thousands Separator

To make program output more readable, it can be useful to add separators to large numbers, rendering them as 18,446,744,073,709,551,616 instead of 18446744073709551616.

The fully general solution for doing this is the `locale` module, which can use different separators (""," in North America, “.” in Europe) and different grouping sizes, but `locale` is complicated to use and unsuitable for multi-threaded applications where different threads are producing output for different locales.

Therefore, a simple comma-grouping mechanism has been added to the mini-language used by the `str.format()` method. When formatting a floating-point number, simply include a comma between the width and the precision:

```python
>>> '{:20,.2f}'.format(18446744073709551616.0)
'18,446,744,073,709,551,616.00'
```

When formatting an integer, include the comma after the width:

```python
>>> '{:20,d}'.format(18446744073709551616)
'18,446,744,073,709,551,616'
```

This mechanism is not adaptable at all; commas are always used as the separator and the grouping is always into three-digit groups. The comma-formatting mechanism isn't as general as the `locale` module, but it's easier to use.

See also:
PEP 378 - Format Specifier for Thousands Separator

PEP written by Raymond Hettinger; implemented by Eric Smith.
PEP 389: The argparse Module for Parsing Command Lines

The `argparse` module for parsing command-line arguments was added as a more powerful replacement for the `optparse` module.

This means Python now supports three different modules for parsing command-line arguments: `getopt`, `optparse`, and `argparse`. The `getopt` module closely resembles the C library’s `getopt()` function, so it remains useful if you’re writing a Python prototype that will eventually be rewritten in C. `optparse` becomes redundant, but there are no plans to remove it because there are many scripts still using it, and there’s no automated way to update these scripts. (Making the `argparse` API consistent with `optparse`‘s interface was discussed but rejected as too messy and difficult.)

In short, if you’re writing a new script and don’t need to worry about compatibility with earlier versions of Python, use `argparse` instead of `optparse`.

Here’s an example:

```python
import argparse

parser = argparse.ArgumentParser(description='Command-line example.')

# Add optional switches
parser.add_argument('-v', action='store_true', dest='verbose',
                    help='produce verbose output')
parser.add_argument('-o', action='store', dest='output',
                    metavar='FILE',
                    help='direct output to FILE instead of stdout')
```

parser.add_argument('-C', action='store', type=int, metavar='NUM', default=0, help='display NUM lines of added context')

# Allow any number of additional arguments.
parser.add_argument(nargs='*', action='store', dest='inputs', help='input filenames (default is stdin)')

args = parser.parse_args()
print(args.__dict__)

Unless you override it, -h and --help switches are automatically added, and produce neatly formatted output:

```
-> ./python.exe argparse-example.py --help
usage: argparse-example.py [-h] [-v] [-o FILE] [-C NUM]

Command-line example.

positional arguments:
  inputs             input filenames (default is stdin)

optional arguments:
  -h, --help         show this help message and exit
  -v                 produce verbose output
  -o FILE            direct output to FILE instead of stdout
  -C NUM             display NUM lines of added context
```

As with optparse, the command-line switches and arguments are returned as an object with attributes named by the dest parameters:

```
-> ./python.exe argparse-example.py -v
{'output': None, 'is_verbos': True, 'context': 0,}
argparse has much fancier validation than optparse; you can specify an exact number of arguments as an integer, 0 or more arguments by passing '*', 1 or more by passing '+', or an optional argument with '?'. A top-level parser can contain sub-parsers to define subcommands that have different sets of switches, as in `svn commit, svn checkout`, etc. You can specify an argument's type as `FileType`, which will automatically open files for you and understands that `-` means standard input or output.

argparse documentation
  The documentation page of the argparse module.

Upgrading optparse code
  Part of the Python documentation, describing how to convert code that uses optparse.

PEP 389 - argparse - New Command Line Parsing Module
  PEP written and implemented by Steven Bethard.
PEP 391: Dictionary-Based Configuration For Logging

The `logging` module is very flexible; applications can define a tree of logging subsystems, and each logger in this tree can filter out certain messages, format them differently, and direct messages to a varying number of handlers.

All this flexibility can require a lot of configuration. You can write Python statements to create objects and set their properties, but a complex set-up requires verbose but boring code. `logging` also supports a `fileConfig()` function that parses a file, but the file format doesn't support configuring filters, and it's messier to generate programmatically.

Python 2.7 adds a `dictConfig()` function that uses a dictionary to configure logging. There are many ways to produce a dictionary from different sources: construct one with code; parse a file containing JSON; or use a YAML parsing library if one is installed. For more information see Configuration functions.

The following example configures two loggers, the root logger and a logger named “network”. Messages sent to the root logger will be sent to the system log using the syslog protocol, and messages to the “network” logger will be written to a `network.log` file that will be rotated once the log reaches 1MB.

```python
import logging
import logging.config

configdict = {
    'version': 1,  # Configuration schema in use; mus
'formatters': {
    'standard': {
        'format': ('%(asctime)s (%(name)s)-15s ' +
                   '%(levelname)-8s %(message)s')
    }
}

'handlers': {
    'netlog': {
        'backupCount': 10,
        'class': 'logging.handlers.RotatingFileHandler',
        'filename': '/logs/network.log',
        'formatter': 'standard',
        'level': 'INFO',
        'maxBytes': 1000000,
    },
    'syslog': {
        'class': 'logging.handlers.SysLogHandler',
        'formatter': 'standard',
        'level': 'ERROR'
    }
}

# Specify all the subordinate loggers
'loggers': {
    'network': {
        'handlers': ['netlog']
    }
},

# Specify properties of the root logger
'root': {
    'handlers': ['syslog']
},

# Set up configuration
logging.config.dictConfig(configdict)

# As an example, log two error messages
logger = logging.getLogger('/')
logger.error('Database not found')

netlogger = logging.getLogger('network')
netlogger.error('Connection failed')
Three smaller enhancements to the `logging` module, all implemented by Vinay Sajip, are:

- The `SysLogHandler` class now supports syslogging over TCP. The constructor has a `socktype` parameter giving the type of socket to use, either `socket.SOCK_DGRAM` for UDP or `socket.SOCK_STREAM` for TCP. The default protocol remains UDP.
- `Logger` instances gained a `getChild()` method that retrieves a descendant logger using a relative path. For example, once you retrieve a logger by doing `log = getLogger('app')`, calling `log.getChild('network.listen')` is equivalent to `getLogger('app.network.listen')`.
- The `LoggerAdapter` class gained an `isEnabledFor()` method that takes a `level` and returns whether the underlying logger would process a message of that level of importance.

See also:

**PEP 391 - Dictionary-Based Configuration For Logging**

PEP written and implemented by Vinay Sajip.
PEP 3106: Dictionary Views

The dictionary methods `keys()`, `values()`, and `items()` are different in Python 3.x. They return an object called a `view` instead of a fully materialized list.

It’s not possible to change the return values of `keys()`, `values()`, and `items()` in Python 2.7 because too much code would break. Instead the 3.x versions were added under the new names `viewkeys()`, `viewvalues()`, and `viewitems()`.

```python
>>> d = dict((i*10, chr(65+i)) for i in range(26))
>>> d
{0: 'A', 130: 'N', 10: 'B', 140: 'O', 20: ...
```

Views can be iterated over, but the key and item views also behave like sets. The `&` operator performs intersection, and `|` performs a union:

```python
>>> d1 = dict((i*10, chr(65+i)) for i in range(26))
>>> d2 = dict((i**.5, i) for i in range(1000))
>>> d1.viewkeys() & d2.viewkeys()
set([0.0, 10.0, 20.0, 30.0])
>>> d1.viewkeys() | range(0, 30)
set([0, 1, 130, 3, 4, 5, 6, ..., 120, 250])
```

The view keeps track of the dictionary and its contents change as the dictionary is modified:

```python
>>> vk = d.viewkeys()
```
However, note that you can't add or remove keys while you're iterating over the view:

```python
>>> for k in vk:
...     d[k*2] = k
...      
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
RuntimeError: dictionary changed size during iteration
```

You can use the view methods in Python 2.x code, and the 2to3 converter will change them to the standard `keys()`, `values()`, and `items()` methods.

See also:

**PEP 3106 - Revamping dict.keys(), .values() and .items()**

PEP 3137: The memoryview Object

The `memoryview` object provides a view of another object's memory content that matches the `bytes` type's interface.

```python
>>> import string
>>> m = memoryview(string.ascii_letters)
>>> m
<memory at 0x37f850>
>>> len(m)  # Returns length of underlying object
52
>>> m[0], m[25], m[26]  # Indexing returns one byte
('a', 'z', 'A')
>>> m2 = m[0:26]  # Slicing returns another memoryview
>>> m2
<memory at 0x37f080>
```

The content of the view can be converted to a string of bytes or a list of integers:

```python
>>> m2.tobytes()
'babcdefgijklmnopqrstuvwxyz'
>>> m2.tolist()
[97, 98, 99, 100, 101, 102, 103, ..., 121, 122]
```

`memoryview` objects allow modifying the underlying object if it's a mutable object.

```python
>>> m2[0] = 75
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: cannot modify read-only memory
```
>>> b = bytearray(string.letters)  # Creating a mutable object
>>> b
bytearray(b'abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ')
>>> mb = memoryview(b)
>>> mb[0] = '*'  # Assign to view, changing the bytearray.
>>> b[0:5]  # The bytearray has been changed.
bytearray(b'*bcde')

See also:

**PEP 3137 - Immutable Bytes and Mutable Buffer**

PEP written by Guido van Rossum. Implemented by Travis Oliphant, Antoine Pitrou and others. Backported to 2.7 by Antoine Pitrou; bpo-2396.
Other Language Changes

Some smaller changes made to the core Python language are:

- The syntax for set literals has been backported from Python 3.x. Curly brackets are used to surround the contents of the resulting mutable set; set literals are distinguished from dictionaries by not containing colons and values. `{}` continues to represent an empty dictionary; use `set()` for an empty set.

```
>>> {1, 2, 3, 4, 5}
set([1, 2, 3, 4, 5])
>>> set()  # empty set
set([])
>>> {}    # empty dict
{}
```

Backported by Alexandre Vassalotti; bpo-2335.

- Dictionary and set comprehensions are another feature backported from 3.x, generalizing list/generator comprehensions to use the literal syntax for sets and dictionaries.

```
>>> {x: x*x for x in range(6)}
{0: 0, 1: 1, 2: 4, 3: 9, 4: 16, 5: 25}
>>> {('a'*x) for x in range(6)}
set(['', 'a', 'aa', 'aaa', 'aaaa', 'aaaaa'])
```

Backported by Alexandre Vassalotti; bpo-2333.

- The `with` statement can now use multiple context managers in one statement. Context managers are processed from left to right and each one is treated as beginning a new `with` statement. This
means that:

```python
with A() as a, B() as b:
    ... suite of statements ...
```

is equivalent to:

```python
with A() as a:
    with B() as b:
        ... suite of statements ...
```

The `contextlib.nested()` function provides a very similar function, so it's no longer necessary and has been deprecated.

(Proposed in https://codereview.appspot.com/53094; implemented by Georg Brandl.)

- Conversions between floating-point numbers and strings are now correctly rounded on most platforms. These conversions occur in many different places: `str()` on floats and complex numbers; the `float` and `complex` constructors; numeric formatting; serializing and deserializing floats and complex numbers using the `marshal`, `pickle` and `json` modules; parsing of float and imaginary literals in Python code; and `Decimal`-to-float conversion.

  Related to this, the `repr()` of a floating-point number `x` now returns a result based on the shortest decimal string that's guaranteed to round back to `x` under correct rounding (with round-half-to-even rounding mode). Previously it gave a string based on rounding `x` to 17 decimal digits.

  The rounding library responsible for this improvement works on
Windows and on Unix platforms using the gcc, icc, or suncc compilers. There may be a small number of platforms where correct operation of this code cannot be guaranteed, so the code is not used on such systems. You can find out which code is being used by checking `sys.float_repr_style`, which will be `short` if the new code is in use and `legacy` if it isn’t.

Implemented by Eric Smith and Mark Dickinson, using David Gay’s `dtoa.c` library; [bpo-7117](https://bugs.python.org/issue7117).

- Conversions from long integers and regular integers to floating point now round differently, returning the floating-point number closest to the number. This doesn’t matter for small integers that can be converted exactly, but for large numbers that will unavoidably lose precision, Python 2.7 now approximates more closely. For example, Python 2.6 computed the following:

```
>>> n = 295147905179352891391
>>> float(n)
2.9514790517935283e+20
>>> n - long(float(n))
65535L
```

Python 2.7’s floating-point result is larger, but much closer to the true value:

```
>>> n = 295147905179352891391
>>> float(n)
2.9514790517935289e+20
>>> n - long(float(n))
-1L
```

(Implemented by Mark Dickinson; [bpo-3166](https://bugs.python.org/issue3166).)
Integer division is also more accurate in its rounding behaviours. (Also implemented by Mark Dickinson; bpo-1811.)

- Implicit coercion for complex numbers has been removed; the interpreter will no longer ever attempt to call a \_coerce\_() method on complex objects. (Removed by Meador Inge and Mark Dickinson; bpo-5211.)

- The \texttt{str.format()} method now supports automatic numbering of the replacement fields. This makes using \texttt{str.format()} more closely resemble using \%s formatting:

```
>>> '{}:{}:{}' .format(2009, 04, 'Sunday')
'2009:4:Sunday'
>>> '{}:{}:{day}'.format(2009, 4, day='Sunday')
'2009:4:Sunday'
```

The auto-numbering takes the fields from left to right, so the first \{...\} specifier will use the first argument to \texttt{str.format()}, the next specifier will use the next argument, and so on. You can’t mix auto-numbering and explicit numbering – either number all of your specifier fields or none of them – but you can mix auto-numbering and named fields, as in the second example above. (Contributed by Eric Smith; bpo-5237.)

Complex numbers now correctly support usage with \texttt{format()}, and default to being right-aligned. Specifying a precision or comma-separation applies to both the real and imaginary parts of the number, but a specified field width and alignment is applied to the whole of the resulting \texttt{1.5+3j} output. (Contributed by Eric Smith; \texttt{bpo-1588} and \texttt{bpo-7988}.)

The ‘F’ format code now always formats its output using
uppercase characters, so it will now produce ‘INF’ and ‘NAN’.
(Contributed by Eric Smith; bpo-3382.)

A low-level change: the object.__format__() method now
triggers a PendingDeprecationWarning if it’s passed a format
string, because the __format__() method for object converts
the object to a string representation and formats that. Previously
the method silently applied the format string to the string
representation, but that could hide mistakes in Python code. If
you’re supplying formatting information such as an alignment or
precision, presumably you’re expecting the formatting to be
applied in some object-specific way. (Fixed by Eric Smith; bpo-
7994.)

• The int() and long() types gained a bit_length method
  that returns the number of bits necessary to represent its
  argument in binary:

```python
>>> n = 37
>>> bin(n)
'0b100101'
>>> n.bit_length()
6
>>> n = 2**123-1
>>> n.bit_length()
123
>>> (n+1).bit_length()
124
```

(Contributed by Fredrik Johansson and Victor Stinner; bpo-3439.)

• The import statement will no longer try an absolute import if a
  relative import (e.g. from .os import sep) fails. This fixes a
  bug, but could possibly break certain import statements that
were only working by accident. (Fixed by Meador Inge; bpo-7902.)

- It's now possible for a subclass of the built-in unicode type to override the `__unicode__()` method. (Implemented by Victor Stinner; bpo-1583863.)

- The `bytearray` type's `translate()` method now accepts `None` as its first argument. (Fixed by Georg Brandl; bpo-4759.)

- When using `@classmethod` and `@staticmethod` to wrap methods as class or static methods, the wrapper object now exposes the wrapped function as their `__func__` attribute. (Contributed by Amaury Forgeot d'Arc, after a suggestion by George Sakkis; bpo-5982.)

- When a restricted set of attributes were set using `__slots__`, deleting an unset attribute would not raise `AttributeError` as you would expect. Fixed by Benjamin Peterson; bpo-7604.)

- Two new encodings are now supported: “cp720”, used primarily for Arabic text; and “cp858”, a variant of CP 850 that adds the euro symbol. (CP720 contributed by Alexander Belchenko and Amaury Forgeot d'Arc in bpo-1616979; CP858 contributed by Tim Hatch in bpo-8016.)

- The file object will now set the `filename` attribute on the `IOError` exception when trying to open a directory on POSIX platforms (noted by Jan Kaliszewski; bpo-4764), and now explicitly checks for and forbids writing to read-only file objects instead of trusting the C library to catch and report the error (fixed by Stefan Krah; bpo-5677).

- The Python tokenizer now translates line endings itself, so the
**compile()** built-in function now accepts code using any line-ending convention. Additionally, it no longer requires that the code end in a newline.

- Extra parentheses in function definitions are illegal in Python 3.x, meaning that you get a syntax error from `def f((x)): pass`. In Python3-warning mode, Python 2.7 will now warn about this odd usage. (Noted by James Lingard; [bpo-7362](https://bugs.python.org/issue7362).)

- It’s now possible to create weak references to old-style class objects. New-style classes were always weak-referenceable. (Fixed by Antoine Pitrou; [bpo-8268](https://bugs.python.org/issue8268).)

- When a module object is garbage-collected, the module's dictionary is now only cleared if no one else is holding a reference to the dictionary ([bpo-7140](https://bugs.python.org/issue7140)).

### Interpreter Changes

A new environment variable, **PYTHONWARNINGS**, allows controlling warnings. It should be set to a string containing warning settings, equivalent to those used with the `-w` switch, separated by commas. (Contributed by Brian Curtin; [bpo-7301](https://bugs.python.org/issue7301).)

For example, the following setting will print warnings every time they occur, but turn warnings from the Cookie module into an error. (The exact syntax for setting an environment variable varies across operating systems and shells.)

```
export PYTHONWARNINGS=all,error::Cookie:0
```

### Optimizations
Several performance enhancements have been added:

- A new opcode was added to perform the initial setup for `with` statements, looking up the `__enter__()` and `__exit__()` methods. (Contributed by Benjamin Peterson.)

- The garbage collector now performs better for one common usage pattern: when many objects are being allocated without deallocating any of them. This would previously take quadratic time for garbage collection, but now the number of full garbage collections is reduced as the number of objects on the heap grows. The new logic only performs a full garbage collection pass when the middle generation has been collected 10 times and when the number of survivor objects from the middle generation exceeds 10% of the number of objects in the oldest generation. (Suggested by Martin von Löwis and implemented by Antoine Pitrou; bpo-4074.)

- The garbage collector tries to avoid tracking simple containers which can’t be part of a cycle. In Python 2.7, this is now true for tuples and dicts containing atomic types (such as ints, strings, etc.). Transitively, a dict containing tuples of atomic types won’t be tracked either. This helps reduce the cost of each garbage collection by decreasing the number of objects to be considered and traversed by the collector. (Contributed by Antoine Pitrou; bpo-4688.)

- Long integers are now stored internally either in base $2^{15}$ or in base $2^{30}$, the base being determined at build time. Previously, they were always stored in base $2^{15}$. Using base $2^{30}$ gives significant performance improvements on 64-bit machines, but benchmark results on 32-bit machines have been mixed. Therefore, the default is to use base $2^{30}$ on 64-bit machines.
and base $2^{15}$ on 32-bit machines; on Unix, there's a new configure option --enable-big-digits that can be used to override this default.

Apart from the performance improvements this change should be invisible to end users, with one exception: for testing and debugging purposes there's a new structseq `sys.long_info` that provides information about the internal format, giving the number of bits per digit and the size in bytes of the C type used to store each digit:

```python
>>> import sys
>>> sys.long_info
sys.long_info(bits_per_digit=30, sizeof_digit=4)
```

(Contributed by Mark Dickinson; bpo-4258.)

Another set of changes made long objects a few bytes smaller: 2 bytes smaller on 32-bit systems and 6 bytes on 64-bit. (Contributed by Mark Dickinson; bpo-5260.)

- The division algorithm for long integers has been made faster by tightening the inner loop, doing shifts instead of multiplications, and fixing an unnecessary extra iteration. Various benchmarks show speedups of between 50% and 150% for long integer divisions and modulo operations. (Contributed by Mark Dickinson; bpo-5512.) Bitwise operations are also significantly faster (initial patch by Gregory Smith; bpo-1087418).

- The implementation of `%` checks for the left-side operand being a Python string and special-cases it; this results in a 1–3% performance increase for applications that frequently use `%` with strings, such as templating libraries. (Implemented by Collin
List comprehensions with an `if` condition are compiled into faster bytecode. (Patch by Antoine Pitrou, back-ported to 2.7 by Jeffrey Yasskin; bpo-4715.)

Converting an integer or long integer to a decimal string was made faster by special-casing base 10 instead of using a generalized conversion function that supports arbitrary bases. (Patch by Gawain Bolton; bpo-6713.)

The `split()`, `replace()`, `rindex()`, `rpartition()`, and `rsplit()` methods of string-like types (strings, Unicode strings, and `bytearray` objects) now use a fast reverse-search algorithm instead of a character-by-character scan. This is sometimes faster by a factor of 10. (Added by Florent Xicluna; bpo-7462 and bpo-7622.)

The `pickle` and `cPickle` modules now automatically intern the strings used for attribute names, reducing memory usage of the objects resulting from unpickling. (Contributed by Jake McGuire; bpo-5084.)

The `cPickle` module now special-cases dictionaries, nearly halving the time required to pickle them. (Contributed by Collin Winter; bpo-5670.)
New and Improved Modules

As in every release, Python's standard library received a number of enhancements and bug fixes. Here's a partial list of the most notable changes, sorted alphabetically by module name. Consult the Misc/NEWS file in the source tree for a more complete list of changes, or look through the Subversion logs for all the details.

- The **bdb** module's base debugging class **Bdb** gained a feature for skipping modules. The constructor now takes an iterable containing glob-style patterns such as `django.*`; the debugger will not step into stack frames from a module that matches one of these patterns. (Contributed by Maru Newby after a suggestion by Senthil Kumaran; bpo-5142.)

- The **binascii** module now supports the buffer API, so it can be used with **memoryview** instances and other similar buffer objects. (Backported from 3.x by Florent Xicluna; bpo-7703.)

- Updated module: the **bsddb** module has been updated from 4.7.2devel9 to version 4.8.4 of the **pybsddb** package. The new version features better Python 3.x compatibility, various bug fixes, and adds several new BerkeleyDB flags and methods. (Updated by Jesús Cea Avión; bpo-8156. The pybsddb changelog can be read at http://hg.jcea.es/pybsddb/file/tip/ChangeLog.)

- The **bz2** module's **BZ2File** now supports the context management protocol, so you can write with `bz2.BZ2File(...) as f:`. (Contributed by Hagen Fürstenau; bpo-3860.)

- New class: the **Counter** class in the **collections** module is
useful for tallying data. `Counter` instances behave mostly like dictionaries but return zero for missing keys instead of raising a `KeyError`:

```python
>>> from collections import Counter
>>> c = Counter()
>>> for letter in 'here is a sample of english text'
...   c[letter] += 1
... c
Counter({' ': 6, 'e': 5, 's': 3, 'a': 2, 'i': 2, 'l': 2, 't': 2, 'g': 1, 'f': 1, 'm': 1, 'o': 1, 'n': 1, 'p': 1, 'r': 1, 'x': 1})
>>> c['e']
5
>>> c['z']
0
```

There are three additional `Counter` methods. `most_common()` returns the N most common elements and their counts. `elements()` returns an iterator over the contained elements, repeating each element as many times as its count. `subtract()` takes an iterable and subtracts one for each element instead of adding; if the argument is a dictionary or another `Counter`, the counts are subtracted.

```python
>>> c.most_common(5)
[(' ', 6), ('e', 5), ('s', 3), ('a', 2), ('i', 2)]
>>> c.elements() ->
'a', 'a', ' ', ' ', ' ', ' ', ' ', ' ', ' ', ' ', ' ', ' ', 'e', 'e', 'e', 'e', 'e', 'g', 'f', 'i', 'i', 'h', 'h', 'm', 'l', 'l', 'o', 'n', 'p', 's', 's', 's', 'r', 't', 't', 'x'
>>> c['e']
5
```
Contributed by Raymond Hettinger; bpo-1696199.

New class: `OrderedDict` is described in the earlier section PEP 372: Adding an Ordered Dictionary to collections.

New method: The `deque` data type now has a `count()` method that returns the number of contained elements equal to the supplied argument `x`, and a `reverse()` method that reverses the elements of the deque in-place. `deque` also exposes its maximum length as the read-only `maxlen` attribute. (Both features added by Raymond Hettinger.)

The `namedtuple` class now has an optional `rename` parameter. If `rename` is true, field names that are invalid because they've been repeated or aren't legal Python identifiers will be renamed to legal names that are derived from the field's position within the list of fields:

```
>>> from collections import namedtuple
>>> T = namedtuple('T', ['field1', '$illegal', 'for'])
>>> T._fields
('field1', '_1', '_2', 'field2')
```

(Added by Raymond Hettinger; bpo-1818.)

Finally, the Mapping abstract base class now returns `NotImplemented` if a mapping is compared to another type that
isn’t a Mapping. (Fixed by Daniel Stutzbach; bpo-8729.)

- Constructors for the parsing classes in the ConfigParser module now take an `allow_no_value` parameter, defaulting to false; if true, options without values will be allowed. For example:

```python
>>> import ConfigParser, StringIO
>>> sample_config = ""
... [mysqld]
... user = mysql
... pid-file = /var/run/mysqld/mysqld.pid
... skip-bdb
... ""
>>> config = ConfigParser.RawConfigParser(allow_no_value)
>>> config.readfp(StringIO.StringIO(sample_config))
>>> config.get('mysqld', 'user')
'mysql'
>>> print config.get('mysqld', 'skip-bdb')
None
>>> print config.get('mysqld', 'unknown')
Traceback (most recent call last):
  ...,
NoOptionError: No option 'unknown' in section: 'mysqld'
```

(Contributed by Mats Kindahl; bpo-7005.)

- Deprecated function: `contextlib.nested()`, which allows handling more than one context manager with a single `with` statement, has been deprecated, because the `with` statement now supports multiple context managers.

- The cookielib module now ignores cookies that have an invalid version field, one that doesn’t contain an integer value. (Fixed by John J. Lee; bpo-3924.)
The copy module's `deepcopy()` function will now correctly copy bound instance methods. (Implemented by Robert Collins; bpo-1515.)

The ctypes module now always converts None to a C NULL pointer for arguments declared as pointers. (Changed by Thomas Heller; bpo-4606.) The underlying libffi library has been updated to version 3.0.9, containing various fixes for different platforms. (Updated by Matthias Klose; bpo-8142.)

New method: the datetime module's `timedelta` class gained a `total_seconds()` method that returns the number of seconds in the duration. (Contributed by Brian Quinlan; bpo-5788.)

New method: the Decimal class gained a `from_float()` class method that performs an exact conversion of a floating-point number to a Decimal. This exact conversion strives for the closest decimal approximation to the floating-point representation's value; the resulting decimal value will therefore still include the inaccuracy, if any. For example, \( \text{Decimal.from_float(0.1)} \) returns Decimal('0.10000000000000000555111512312578270211') (Implemented by Raymond Hettinger; bpo-4796.)

Comparing instances of Decimal with floating-point numbers now produces sensible results based on the numeric values of the operands. Previously such comparisons would fall back to Python's default rules for comparing objects, which produced arbitrary results based on their type. Note that you still cannot combine Decimal and floating-point in other operations such as addition, since you should be explicitly choosing how to convert
between float and **Decimal**. (Fixed by Mark Dickinson; bpo-2531.)

The constructor for **Decimal** now accepts floating-point numbers (added by Raymond Hettinger; bpo-8257) and non-European Unicode characters such as Arabic-Indic digits (contributed by Mark Dickinson; bpo-6595).

Most of the methods of the **Context** class now accept integers as well as **Decimal** instances; the only exceptions are the **canonical()** and **is_canonical()** methods. (Patch by Juan José Conti; bpo-7633.)

When using **Decimal** instances with a string's **format()** method, the default alignment was previously left-alignment. This has been changed to right-alignment, which is more sensible for numeric types. (Changed by Mark Dickinson; bpo-6857.)

Comparisons involving a signaling NaN value (or sNAN) now signal **InvalidOperation** instead of silently returning a true or false value depending on the comparison operator. Quiet NaN values (or NaN) are now hashable. (Fixed by Mark Dickinson; bpo-7279.)

- The **difflib** module now produces output that is more compatible with modern **diff/patch** tools through one small change, using a tab character instead of spaces as a separator in the header giving the filename. (Fixed by Anatoly Techtonik; bpo-7585.)

- The Distutils **sdist** command now always regenerates the **MANIFEST** file, since even if the **MANIFEST.in** or **setup.py** files haven't been modified, the user might have created some
new files that should be included. (Fixed by Tarek Ziadé; bpo-8688.)

- The doctest module's IGNORE_EXCEPTION_DETAIL flag will now ignore the name of the module containing the exception being tested. (Patch by Lennart Regebro; bpo-7490.)

- The email module's Message class will now accept a Unicode-valued payload, automatically converting the payload to the encoding specified by output_charset. (Added by R. David Murray; bpo-1368247.)

- The Fraction class now accepts a single float or Decimal instance, or two rational numbers, as arguments to its constructor. (Implemented by Mark Dickinson; rationals added in bpo-5812, and float/decimal in bpo-8294.)

  Ordering comparisons (<, <=, >, >=) between fractions and complex numbers now raise a TypeError. This fixes an oversight, making the Fraction match the other numeric types.

- New class: FTP_TLS in the ftplib module provides secure FTP connections using TLS encapsulation of authentication as well as subsequent control and data transfers. (Contributed by Giampaolo Rodola; bpo-2054.)

  The storbinary() method for binary uploads can now restart uploads thanks to an added rest parameter (patch by Pablo Mouzo; bpo-6845.)

- New class decorator: total_ordering() in the functools module takes a class that defines an __eq__() method and one of __lt__(), __le__(), __gt__(), or __ge__(), and
generates the missing comparison methods. Since the \_\_cmp\_\_( ) method is being deprecated in Python 3.x, this decorator makes it easier to define ordered classes. (Added by Raymond Hettinger; bpo-5479.)

New function: cmp\_to\_key\() will take an old-style comparison function that expects two arguments and return a new callable that can be used as the key parameter to functions such as sorted\((),\ min\() and max\((),\ etc. The primary intended use is to help with making code compatible with Python 3.x. (Added by Raymond Hettinger.)

- New function: the gc module's is\_tracked\() returns true if a given instance is tracked by the garbage collector, false otherwise. (Contributed by Antoine Pitrou; bpo-4688.)

- The gzip module's GzipFile now supports the context management protocol, so you can write with gzip.GzipFile\(...\) as f:\ (contributed by Hagen Fürstenau; bpo-3860), and it now implements the io.BufferedIOBase ABC, so you can wrap it with io.BufferedReader for faster processing (contributed by Nir Aides; bpo-7471). It's also now possible to override the modification time recorded in a gzipped file by providing an optional timestamp to the constructor. (Contributed by Jacques Frechet; bpo-4272.)

Files in gzip format can be padded with trailing zero bytes; the gzip module will now consume these trailing bytes. (Fixed by Tadek Pietraszek and Brian Curtin; bpo-2846.)

- New attribute: the hashlib module now has an algorithms
attribute containing a tuple naming the supported algorithms. In 
Python 2.7, `hashlib.algorithms` contains ("md5", "sha1", "sha224", "sha256", "sha384", "sha512"). (Contributed by Carl Chenet; bpo-7418.)

- The default `HTTPRequest` class used by the `httpplib` module now supports buffering, resulting in much faster reading of HTTP responses. (Contributed by Kristján Valur Jónsson; bpo-4879.)

The `HTTPConnection` and `HTTPSConnection` classes now support a `source_address` parameter, a `(host, port)` 2-tuple giving the source address that will be used for the connection. (Contributed by Eldon Ziegler; bpo-3972.)

- The `ihooks` module now supports relative imports. Note that `ihooks` is an older module for customizing imports, superseded by the `imputil` module added in Python 2.0. (Relative import support added by Neil Schemenauer.)

- The `imaplib` module now supports IPv6 addresses. (Contributed by Derek Morr; bpo-1655.)

- New function: the `inspect` module's `getcallargs()` takes a callable and its positional and keyword arguments, and figures out which of the callable's parameters will receive each argument, returning a dictionary mapping argument names to their values. For example:

```python
>>> from inspect import getcallargs
>>> def f(a, b=1, *pos, **named):
...     pass
>>> getcallargs(f, 1, 2, 3)
{'a': 1, 'b': 2, 'pos': (3,), 'named': {}}
```
Contributed by George Sakkis; bpo-3135.

- **Updated module**: The `io` library has been upgraded to the version shipped with Python 3.1. For 3.1, the I/O library was entirely rewritten in C and is 2 to 20 times faster depending on the task being performed. The original Python version was renamed to the `_pyio` module.

  One minor resulting change: the `io.TextIOBase` class now has an `errors` attribute giving the error setting used for encoding and decoding errors (one of `'strict'`, `'replace'`, `'ignore'`).

  The `io.FileIO` class now raises an `OSError` when passed an invalid file descriptor. (Implemented by Benjamin Peterson; bpo-4991.) The `truncate()` method now preserves the file position; previously it would change the file position to the end of the new file. (Fixed by Pascal Chambon; bpo-6939.)

- **New function**: `itertools.compress(data, selectors)` takes two iterators. Elements of `data` are returned if the corresponding value in `selectors` is true:

  ```python
  itertools.compress('ABCDEF', [1, 0, 1, 0, 1, 1]) =>
  A, C, E, F
  ```

  New function:
**itertools.combinations_with_replacement(iter, r)** returns all the possible \( r \)-length combinations of elements from the iterable \( \text{iter} \). Unlike **combinations()**, individual elements can be repeated in the generated combinations:

```python
itertools.combinations_with_replacement('abc', 2)
# output:
# [('a', 'a'), ('a', 'b'), ('a', 'c'),
#  ('b', 'b'), ('b', 'c'), ('c', 'c')]
```

Note that elements are treated as unique depending on their position in the input, not their actual values.

The **itertools.count()** function now has a *step* argument that allows incrementing by values other than 1. **count()** also now allows keyword arguments, and using non-integer values such as floats or **Decimal** instances. (Implemented by Raymond Hettinger; **bpo-5032**.)

**itertools.combinations()** and **itertools.product()** previously raised **ValueError** for values of \( r \) larger than the input iterable. This was deemed a specification error, so they now return an empty iterator. (Fixed by Raymond Hettinger; **bpo-4816**.)

- **Updated module:** The **json** module was upgraded to version 2.0.9 of the simplejson package, which includes a C extension that makes encoding and decoding faster. (Contributed by Bob Ippolito; **bpo-4136**.)

  To support the new **collections.OrderedDict** type, **json.load()** now has an optional **object_pairs_hook** parameter that will be called with any object literal that decodes to a list of pairs. (Contributed by Raymond Hettinger; **bpo-5381**.)
The **mailbox** module's **Maildir** class now records the timestamp on the directories it reads, and only re-reads them if the modification time has subsequently changed. This improves performance by avoiding unneeded directory scans. (Fixed by A.M. Kuchling and Antoine Pitrou; [bpo-1607951, bpo-6896](https://www.python.org/dev/peps/pep-06896/).)

New functions: the **math** module gained **erf()** and **erfc()** for the error function and the complementary error function, **expm1()** which computes \( e^{x} - 1 \) with more precision than using **exp()** and subtracting 1, **gamma()** for the Gamma function, and **lgamma()** for the natural log of the Gamma function. (Contributed by Mark Dickinson and nirinA raseliarison; [bpo-3366](https://www.python.org/dev/peps/pep-03366/).)

The **multiprocessing** module's Manager* classes can now be passed a callable that will be called whenever a subprocess is started, along with a set of arguments that will be passed to the callable. (Contributed by lekma; [bpo-5585](https://www.python.org/dev/peps/pep-05585/).)

The Pool class, which controls a pool of worker processes, now has an optional **maxtasksperchild** parameter. Worker processes will perform the specified number of tasks and then exit, causing the Pool to start a new worker. This is useful if tasks may leak memory or other resources, or if some tasks will cause the worker to become very large. (Contributed by Charles Cazabon; [bpo-6963](https://www.python.org/dev/peps/pep-06963/).)

The **nntplib** module now supports IPv6 addresses. (Contributed by Derek Morr; [bpo-1664](https://www.python.org/dev/peps/pep-01664/).)

New functions: the **os** module wraps the following POSIX system calls: **getresgid()** and **getresuid()**, which return the real,
effective, and saved GIDs and UIDs; \texttt{setresgid()} and \texttt{setresuid()}), which set real, effective, and saved GIDs and UIDs to new values; \texttt{initgroups()}, which initialize the group access list for the current process. (GID/UID functions contributed by Travis H.; \texttt{bpo-6508}. Support for \texttt{initgroups} added by Jean-Paul Calderone; \texttt{bpo-7333}.)

The \texttt{os.fork()} function now re-initializes the import lock in the child process; this fixes problems on Solaris when \texttt{fork()} is called from a thread. (Fixed by Zsolt Cserna; \texttt{bpo-7242}.)

- In the \texttt{os.path} module, the \texttt{normpath()} and \texttt{abspath()} functions now preserve Unicode; if their input path is a Unicode string, the return value is also a Unicode string. (\texttt{normpath()} fixed by Matt Giuca in \texttt{bpo-5827}; \texttt{abspath()} fixed by Ezio Melotti in \texttt{bpo-3426}.)

- The \texttt{pydoc} module now has help for the various symbols that Python uses. You can now do \texttt{help('<<')} or \texttt{help('@')}, for example. (Contributed by David Laban; \texttt{bpo-4739}.)

- The \texttt{re} module's \texttt{split()}, \texttt{sub()}, and \texttt{subn()} now accept an optional \texttt{flags} argument, for consistency with the other functions in the module. (Added by Gregory P. Smith.)

- New function: \texttt{run_path()} in the \texttt{runpy} module will execute the code at a provided \texttt{path} argument. \texttt{path} can be the path of a Python source file (\texttt{example.py}), a compiled bytecode file (\texttt{example.pyc}), a directory (\texttt{./package/}), or a zip archive (\texttt{example.zip}). If a directory or zip path is provided, it will be added to the front of \texttt{sys.path} and the module \texttt{__main__} will be imported. It's expected that the directory or zip contains a
if it doesn't, some other __main__.py might be imported from a location later in sys.path. This makes more of the machinery of runpy available to scripts that want to mimic the way Python's command line processes an explicit path name. (Added by Nick Coghlan; bpo-6816.)

- New function: in the shutil module, make_archive() takes a filename, archive type (zip or tar-format), and a directory path, and creates an archive containing the directory's contents. (Added by Tarek Ziadé.)

  shutil's copyfile() and copytree() functions now raise a SpecialFileError exception when asked to copy a named pipe. Previously the code would treat named pipes like a regular file by opening them for reading, and this would block indefinitely. (Fixed by Antoine Pitrou; bpo-3002.)

- The signal module no longer re-installs the signal handler unless this is truly necessary, which fixes a bug that could make it impossible to catch the EINTR signal robustly. (Fixed by Charles-François Natali; bpo-8354.)

- New functions: in the site module, three new functions return various site- and user-specific paths. getsitepackages() returns a list containing all global site-packages directories, getusersitepackages() returns the path of the user's site-packages directory, and getuserbase() returns the value of the USER_BASE environment variable, giving the path to a directory that can be used to store data. (Contributed by Tarek Ziadé; bpo-6693.)

  The site module now reports exceptions occurring when the
sitecustomize module is imported, and will no longer catch and swallow the `KeyboardInterrupt` exception. (Fixed by Victor Stinner; bpo-3137.)

- The `create_connection()` function gained a `source_address` parameter, a `(host, port)` 2-tuple giving the source address that will be used for the connection. (Contributed by Eldon Ziegler; bpo-3972.)

The `recv_into()` and `recvfrom_into()` methods will now write into objects that support the buffer API, most usefully the `bytearray` and `memoryview` objects. (Implemented by Antoine Pitrou; bpo-8104.)

- The `SocketServer` module's `TCPServer` class now supports socket timeouts and disabling the Nagle algorithm. The `disable_nagle_algorithm` class attribute defaults to `False`; if overridden to be `true`, new request connections will have the `TCP_NODELAY` option set to prevent buffering many small sends into a single TCP packet. The `timeout` class attribute can hold a timeout in seconds that will be applied to the request socket; if no request is received within that time, `handle_timeout()` will be called and `handle_request()` will return. (Contributed by Kristján Valur Jónsson; bpo-6192 and bpo-6267.)

- Updated module: the `sqlite3` module has been updated to version 2.6.0 of the `pysqlite` package. Version 2.6.0 includes a number of bugfixes, and adds the ability to load SQLite extensions from shared libraries. Call the `enable_load_extension(True)` method to enable extensions, and then call `load_extension()` to load a particular shared library. (Updated by Gerhard Häring.)
The `ssl` module's `SSLSocket` objects now support the buffer API, which fixed a test suite failure (fix by Antoine Pitrou; `bpo-7133`) and automatically set OpenSSL's `SSL_MODE_AUTO_RETRY`, which will prevent an error code being returned from `recv()` operations that trigger an SSL renegotiation (fix by Antoine Pitrou; `bpo-8222`).

The `ssl.wrap_socket()` constructor function now takes a `ciphers` argument that’s a string listing the encryption algorithms to be allowed; the format of the string is described in the OpenSSL documentation. (Added by Antoine Pitrou; `bpo-8322`.)

Another change makes the extension load all of OpenSSL’s ciphers and digest algorithms so that they’re all available. Some SSL certificates couldn’t be verified, reporting an “unknown algorithm” error. (Reported by Beda Kosata, and fixed by Antoine Pitrou; `bpo-8484`.)

The version of OpenSSL being used is now available as the module attributes `ssl.OPENSSL_VERSION` (a string), `ssl.OPENSSL_VERSION_INFO` (a 5-tuple), and `ssl.OPENSSL_VERSION_NUMBER` (an integer). (Added by Antoine Pitrou; `bpo-8321`.)

The `struct` module will no longer silently ignore overflow errors when a value is too large for a particular integer format code (one of `bBhHiIlLqQ`); it now always raises a `struct.error` exception. (Changed by Mark Dickinson; `bpo-1523`.) The `pack()` function will also attempt to use `__index__()` to convert and pack non-integers before trying the `__int__()` method or reporting an error. (Changed by Mark Dickinson; `bpo-8300`.)
New function: the subprocess module's check_output() runs a command with a specified set of arguments and returns the command's output as a string when the command runs without error, or raises a CalledProcessError exception otherwise.

```python
>>> subprocess.check_output(['df', '-h', '.'])
'Filesystem  Size  Used  Avail  Capacity  Mounted
/dev/disk0s2  52G   49G   3.0G   94%   /
'
```

(Contributed by Gregory P. Smith.)

The subprocess module will now retry its internal system calls on receiving an EINTR signal. (Reported by several people; final patch by Gregory P. Smith in bpo-1068268.)

New function: is_declared_global() in the symtable module returns true for variables that are explicitly declared to be global, false for ones that are implicitly global. (Contributed by Jeremy Hylton.)

The syslog module will now use the value of sys.argv[0] as the identifier instead of the previous default value of 'python'. (Changed by Sean Reifschneider; bpo-8451.)

The sys.version_info value is now a named tuple, with attributes named major, minor, micro, releaselevel, and serial. (Contributed by Ross Light; bpo-4285.)

sys.getwindowsversion() also returns a named tuple, with
attributes named major, minor, build, platform, service_pack, service_pack_major, service_pack_minor, suite_mask, and product_type. (Contributed by Brian Curtin; bpo-7766.)

- The `tarfile` module's default error handling has changed, to no longer suppress fatal errors. The default error level was previously 0, which meant that errors would only result in a message being written to the debug log, but because the debug log is not activated by default, these errors go unnoticed. The default error level is now 1, which raises an exception if there's an error. (Changed by Lars Gustäbel; bpo-7357.)

  `tarfile` now supports filtering the `TarInfo` objects being added to a tar file. When you call `add()`, you may supply an optional `filter` argument that's a callable. The `filter` callable will be passed the `TarInfo` for every file being added, and can modify and return it. If the callable returns `None`, the file will be excluded from the resulting archive. This is more powerful than the existing `exclude` argument, which has therefore been deprecated. (Added by Lars Gustäbel; bpo-6856.) The `TarFile` class also now supports the context management protocol. (Added by Lars Gustäbel; bpo-7232.)

- The `wait()` method of the `threading.Event` class now returns the internal flag on exit. This means the method will usually return true because `wait()` is supposed to block until the internal flag becomes true. The return value will only be false if a timeout was provided and the operation timed out. (Contributed by Tim Lesher; bpo-1674032.)

- The Unicode database provided by the `unicodedata` module is
now used internally to determine which characters are numeric, whitespace, or represent line breaks. The database also includes information from the `Unihan.txt` data file (patch by Anders Chrigström and Amaury Forgeot d'Arc; `bpo-1571184`) and has been updated to version 5.2.0 (updated by Florent Xicluna; `bpo-8024`).

- The `urlparse` module's `urlsplit()` now handles unknown URL schemes in a fashion compliant with **RFC 3986**: if the URL is of the form "<something>://...", the text before the `://` is treated as the scheme, even if it's a made-up scheme that the module doesn't know about. This change may break code that worked around the old behaviour. For example, Python 2.6.4 or 2.5 will return the following:

```python
>>> import urlparse
>>> urlparse.urlsplit('invented://host/filename?query')
('invented', '', '//host/filename?query', '', '')
```

Python 2.7 (and Python 2.6.5) will return:

```python
>>> import urlparse
>>> urlparse.urlsplit('invented://host/filename?query')
('invented', 'host', '/filename?query', '', '')
```

(Python 2.7 actually produces slightly different output, since it returns a named tuple instead of a standard tuple.)

The `urlparse` module also supports IPv6 literal addresses as defined by **RFC 2732** (contributed by Senthil Kumaran; `bpo-2987`).
New class: the `WeakSet` class in the `weakref` module is a set that only holds weak references to its elements; elements will be removed once there are no references pointing to them. (Originally implemented in Python 3.x by Raymond Hettinger, and backported to 2.7 by Michael Foord.)

The ElementTree library, `xml.etree`, no longer escapes ampersands and angle brackets when outputting an XML processing instruction (which looks like `<?xml-stylesheet href="#style1"?>`) or comment (which looks like `<!-- comment -->`). (Patch by Neil Muller; bpo-2746.)

The XML-RPC client and server, provided by the `xmlrpc` and `SimpleXMLRPCServer` modules, have improved performance by supporting HTTP/1.1 keep-alive and by optionally using gzip encoding to compress the XML being exchanged. The gzip compression is controlled by the `encode_threshold` attribute of `SimpleXMLRPCRequestHandler`, which contains a size in bytes; responses larger than this will be compressed. (Contributed by Kristján Valur Jónsson; bpo-6267.)

The `zipfile` module's `ZipFile` now supports the context management protocol, so you can write with `zipfile.ZipFile(...) as f:`. (Contributed by Brian Curtin; bpo-5511.)

`zipfile` now also supports archiving empty directories and extracts them correctly. (Fixed by Kuba Wieczorek; bpo-4710.)
Reading files out of an archive is faster, and interleaving `read()` and `readline()` now works correctly. (Contributed by Nir Aides; bpo-7610.)

The `is_zipfile()` function now accepts a file object, in addition to the path names accepted in earlier versions. (Contributed by Gabriel Genellina; bpo-4756.)

The `writestr()` method now has an optional `compress_type` parameter that lets you override the default compression method specified in the `ZipFile` constructor. (Contributed by Ronald Oussoren; bpo-6003.)

New module: importlib

Python 3.1 includes the `importlib` package, a re-implementation of the logic underlying Python’s `import` statement. `importlib` is useful for implementors of Python interpreters and to users who wish to write new importers that can participate in the import process. Python 2.7 doesn’t contain the complete `importlib` package, but instead has a tiny subset that contains a single function, `import_module()`.

`import_module(name, package=None)` imports a module. `name` is a string containing the module or package’s name. It’s possible to do relative imports by providing a string that begins with a `.` character, such as `..utils.errors`. For relative imports, the `package` argument must be provided and is the name of the package that will be used as the anchor for the relative import. `import_module()` both inserts the imported module into `sys.modules` and returns the module object.
Here are some examples:

```python
>>> from importlib import import_module
>>> anydbm = import_module('anydbm')  # Standard absolute import
>>> anydbm
<module 'anydbm' from '/p/python/Lib/anydbm.py'>
>>> # Relative import
>>> file_util = import_module('..file_util', 'distutils.command')
>>> file_util
<module 'distutils.file_util' from '/python/Lib/distutils/file_util.pyc'>
```

`importlib` was implemented by Brett Cannon and introduced in Python 3.1.

**New module: sysconfig**

The `sysconfig` module has been pulled out of the Distutils package, becoming a new top-level module in its own right. `sysconfig` provides functions for getting information about Python’s build process: compiler switches, installation paths, the platform name, and whether Python is running from its source directory.

Some of the functions in the module are:

- `get_config_var()` returns variables from Python’s Makefile and the `pyconfig.h` file.
- `get_config_vars()` returns a dictionary containing all of the configuration variables.
- `get_path()` returns the configured path for a particular type of module: the standard library, site-specific modules, platform-specific modules, etc.
- `is_python_build()` returns true if you’re running a binary from a Python source tree, and false otherwise.
Consult the `sysconfig` documentation for more details and for a complete list of functions.

The Distutils package and `sysconfig` are now maintained by Tarek Ziadé, who has also started a Distutils2 package (source repository at https://hg.python.org/distutils2/) for developing a next-generation version of Distutils.

**ttk: Themed Widgets for Tk**

Tcl/Tk 8.5 includes a set of themed widgets that re-implement basic Tk widgets but have a more customizable appearance and can therefore more closely resemble the native platform's widgets. This widget set was originally called Tile, but was renamed to Ttk (for “themed Tk”) on being added to Tcl/Tk release 8.5.

To learn more, read the ttk module documentation. You may also wish to read the Tcl/Tk manual page describing the Ttk theme engine, available at https://www.tcl.tk/man/tcl8.5/TkCmd/ttk_intro.htm. Some screenshots of the Python/Ttk code in use are at http://code.google.com/p/python-ttk/wiki/Screenshots.

The ttk module was written by Guilherme Polo and added in bpo-2983. An alternate version called Tile.py, written by Martin Franklin and maintained by Kevin Walzer, was proposed for inclusion in bpo-2618, but the authors argued that Guilherme Polo's work was more comprehensive.

**Updated module: unittest**

The `unittest` module was greatly enhanced; many new features were added. Most of these features were implemented by Michael
Foord, unless otherwise noted. The enhanced version of the module is downloadable separately for use with Python versions 2.4 to 2.6, packaged as the unittest2 package, from https://pypi.python.org/pypi/unittest2.

When used from the command line, the module can automatically discover tests. It’s not as fancy as py.test or nose, but provides a simple way to run tests kept within a set of package directories. For example, the following command will search the test/ subdirectory for any importable test files named test*.py:

```
python -m unittest discover -s test
```

Consult the unittest module documentation for more details. (Developed in bpo-6001.)

The main() function supports some other new options:

- **-b** or **--buffer** will buffer the standard output and standard error streams during each test. If the test passes, any resulting output will be discarded; on failure, the buffered output will be displayed.

- **-c** or **--catch** will cause the control-C interrupt to be handled more gracefully. Instead of interrupting the test process immediately, the currently running test will be completed and then the partial results up to the interruption will be reported. If you’re impatient, a second press of control-C will cause an immediate interruption.

This control-C handler tries to avoid causing problems when the code being tested or the tests being run have defined a signal handler of their own, by noticing that a signal handler was already
set and calling it. If this doesn’t work for you, there’s a `removeHandler()` decorator that can be used to mark tests that should have the control-C handling disabled.

- `-f` or `--failfast` makes test execution stop immediately when a test fails instead of continuing to execute further tests. (Suggested by Cliff Dyer and implemented by Michael Foord; bpo-8074.)

The progress messages now show ‘x’ for expected failures and ‘u’ for unexpected successes when run in verbose mode. (Contributed by Benjamin Peterson.)

Test cases can raise the `SkipTest` exception to skip a test (bpo-1034053).

The error messages for `assertEqual()`, `assertTrue()`, and `assertFalse()` failures now provide more information. If you set the `longMessage` attribute of your `TestCase` classes to `true`, both the standard error message and any additional message you provide will be printed for failures. (Added by Michael Foord; bpo-5663.)

The `assertRaises()` method now returns a context handler when called without providing a callable object to run. For example, you can write this:

```python
with self.assertRaises(KeyError):
    {}['foo']
```

(Implemented by Antoine Pitrou; bpo-4444.)

Module- and class-level setup and teardown fixtures are now supported. Modules can contain `setUpModule()` and
tearDownModule() functions. Classes can have setUpClass() and tearDownClass() methods that must be defined as class methods (using @classmethod or equivalent). These functions and methods are invoked when the test runner switches to a test case in a different module or class.

The methods addCleanup() and doCleanups() were added. addCleanup() lets you add cleanup functions that will be called unconditionally (after setUp() if setUp() fails, otherwise after tearDown()). This allows for much simpler resource allocation and deallocation during tests (bpo-5679).

A number of new methods were added that provide more specialized tests. Many of these methods were written by Google engineers for use in their test suites; Gregory P. Smith, Michael Foord, and GvR worked on merging them into Python's version of unittest.

- **assertIsNone()** and **assertIsNotNone()** take one expression and verify that the result is or is not None.
- **assertIs()** and **assertIsNot()** take two values and check whether the two values evaluate to the same object or not. (Added by Michael Foord; bpo-2578.)
- **assertIsInstance()** and **assertNotIsInstance()** check whether the resulting object is an instance of a particular class, or of one of a tuple of classes. (Added by Georg Brandl; bpo-7031.)
- **assertGreater()**, **assertGreaterEqual()**, **assertLess()**, and **assertLessEqual()** compare two quantities.
- **assertMultiLineEqual()** compares two strings, and if they're not equal, displays a helpful comparison that highlights the differences in the two strings. This comparison is now used by default when Unicode strings are compared with **assertEqual()**.
assertRegexpMatches() and assertNotRegexpMatches() checks whether the first argument is a string matching or not matching the regular expression provided as the second argument (bpo-8038).

assertRaisesRegexp() checks whether a particular exception is raised, and then also checks that the string representation of the exception matches the provided regular expression.

assertIn() and assertNotIn() tests whether first is or is not in second.

assertItemsEqual() tests whether two provided sequences contain the same elements.

assertSetEqual() compares whether two sets are equal, and only reports the differences between the sets in case of error.

Similarly, assertListEqual() and assertTupleEqual() compare the specified types and explain any differences without necessarily printing their full values; these methods are now used by default when comparing lists and tuples using assertEqual(). More generally, assertSequenceEqual() compares two sequences and can optionally check whether both sequences are of a particular type.

assertDictEqual() compares two dictionaries and reports the differences; it's now used by default when you compare two dictionaries using assertEqual().

assertDictContainsSubset() checks whether all of the key/value pairs in first are found in second.

assertAlmostEqual() and assertNotAlmostEqual() test whether first and second are approximately equal. This method can either round their difference to an optionally-specified number of places (the default is 7) and compare it to zero, or require the difference to be smaller than a supplied delta value.

loadTestsFromName() properly honors the suiteClass attribute of the TestLoader. (Fixed by Mark Roddy; bpo-6866.)

A new hook lets you extend the assertEqual() method to
handle new data types. The `addTypeEqualityFunc()` method takes a type object and a function. The function will be used when both of the objects being compared are of the specified type. This function should compare the two objects and raise an exception if they don't match; it's a good idea for the function to provide additional information about why the two objects aren't matching, much as the new sequence comparison methods do.

`unittest.main()` now takes an optional `exit` argument. If false, `main()` doesn't call `sys.exit()`, allowing `main()` to be used from the interactive interpreter. (Contributed by J. Pablo Fernández; [bpo-3379](https://bugs.python.org/issue3379).)

`TestResult` has new `startTestRun()` and `stopTestRun()` methods that are called immediately before and after a test run. (Contributed by Robert Collins; [bpo-5728](https://bugs.python.org/issue5728).)

With all these changes, the `unittest.py` was becoming awkwardly large, so the module was turned into a package and the code split into several files (by Benjamin Peterson). This doesn't affect how the module is imported or used.

**See also:**

Describes the new features, how to use them, and the rationale for various design decisions. (By Michael Foord.)

**Updated module: ElementTree 1.3**

The version of the ElementTree library included with Python was updated to version 1.3. Some of the new features are:
- The various parsing functions now take a `parser` keyword argument giving an `XMLParser` instance that will be used. This makes it possible to override the file's internal encoding:

  ```
p = ET.XMLParser(encoding='utf-8')
t = ET.XML("""<root/>"""", parser=p)
  ```

  Errors in parsing XML now raise a `ParseError` exception, whose instances have a `position` attribute containing a `(line, column)` tuple giving the location of the problem.

- ElementTree's code for converting trees to a string has been significantly reworked, making it roughly twice as fast in many cases. The `ElementTree.write()` and `Element.write()` methods now have a `method` parameter that can be “xml” (the default), “html”, or “text”. HTML mode will output empty elements as `<empty></empty>` instead of `<empty/>`, and text mode will skip over elements and only output the text chunks. If you set the `tag` attribute of an element to `None` but leave its children in place, the element will be omitted when the tree is written out, so you don't need to do more extensive rearrangement to remove a single element.

Namespace handling has also been improved. All `xmlns:<whatever>` declarations are now output on the root element, not scattered throughout the resulting XML. You can set the default namespace for a tree by setting the `default_namespace` attribute and can register new prefixes with `register_namespace()`. In XML mode, you can use the `true/false xml_declaration` parameter to suppress the XML declaration.
• New `Element` method: `extend()` appends the items from a sequence to the element's children. Elements themselves behave like sequences, so it's easy to move children from one element to another:

```python
from xml.etree import ElementTree as ET

t = ET.XML('"""<list>
   <item>1</item> <item>2</item> <item>3</item>
</list>"""
new = ET.XML(''<root/>'')
new.extend(t)

# Outputs <root><item>1</item>...</root>
print ET.tostring(new)
```

• New Element method: `iter()` yields the children of the element as a generator. It's also possible to write for child in elem: to loop over an element's children. The existing method `getiterator()` is now deprecated, as is `getchildren()` which constructs and returns a list of children.

• New Element method: `itertext()` yields all chunks of text that are descendants of the element. For example:

```python
t = ET.XML('"""<list>
   <item>1</item> <item>2</item> <item>3</item>
</list>"""

# Outputs ['\n   ', '1', ' ', '2', ' ', '3', '\n
print list(t.itertext())
```

• Deprecated: using an element as a Boolean (i.e., `if elem:`)
would return true if the element had any children, or false if there were no children. This behaviour is confusing – None is false, but so is a childless element? – so it will now trigger a **FutureWarning**. In your code, you should be explicit: write `len(elem) != 0` if you’re interested in the number of children, or `elem is not None`.

Fredrik Lundh develops ElementTree and produced the 1.3 version; you can read his article describing 1.3 at [http://effbot.org/zone/elementtree-13-intro.htm](http://effbot.org/zone/elementtree-13-intro.htm). Florent Xicluna updated the version included with Python, after discussions on python-dev and on bpo-6472.)
Build and C API Changes

Changes to Python’s build process and to the C API include:

- The latest release of the GNU Debugger, GDB 7, can be scripted using Python. When you begin debugging an executable program P, GDB will look for a file named P.gdb.py and automatically read it. Dave Malcolm contributed a python-gdb.py that adds a number of commands useful when debugging Python itself. For example, `py-up` and `py-down` go up or down one Python stack frame, which usually corresponds to several C stack frames. `py-print` prints the value of a Python variable, and `py-bt` prints the Python stack trace. (Added as a result of bpo-8032.)

- If you use the `.gdbinit` file provided with Python, the “pyo” macro in the 2.7 version now works correctly when the thread being debugged doesn’t hold the GIL; the macro now acquires it before printing. (Contributed by Victor Stinner; bpo-3632.)

- `Py_AddPendingCall()` is now thread-safe, letting any worker thread submit notifications to the main Python thread. This is particularly useful for asynchronous IO operations. (Contributed by Kristján Valur Jónsson; bpo-4293.)

- New function: `PyCode_NewEmpty()` creates an empty code object; only the filename, function name, and first line number are required. This is useful for extension modules that are attempting to construct a more useful traceback stack. Previously such extensions needed to call `PyCode_New()`, which had many more arguments. (Added by Jeffrey Yasskin.)

- New function: `PyErr_NewExceptionWithDoc()` creates a new
exception class, just as the existing `PyErr_NewException()` does, but takes an extra `char*` argument containing the docstring for the new exception class. (Added by 'lekma' on the Python bug tracker; bpo-7033.)

- New function: `PyFrame_GetLineNumber()` takes a frame object and returns the line number that the frame is currently executing. Previously code would need to get the index of the bytecode instruction currently executing, and then look up the line number corresponding to that address. (Added by Jeffrey Yasskin.)

- New functions: `PyLong_AsLongAndOverflow()` and `PyLong_AsLongLongAndOverflow()` approximates a Python long integer as a C `long` or `long long`. If the number is too large to fit into the output type, an `overflow` flag is set and returned to the caller. (Contributed by Case Van Horsen; bpo-7528 and bpo-7767.)

- New function: stemming from the rewrite of string-to-float conversion, a new `PyOS_string_to_double()` function was added. The old `PyOS_ascii_strtod()` and `PyOS_ascii_atof()` functions are now deprecated.

- New function: `PySys_SetArgvEx()` sets the value of `sys.argv` and can optionally update `sys.path` to include the directory containing the script named by `sys.argv[0]` depending on the value of an `updatepath` parameter.

This function was added to close a security hole for applications that embed Python. The old function, `PySys_SetArgv()`, would always update `sys.path`, and sometimes it would add the
current directory. This meant that, if you ran an application embedding Python in a directory controlled by someone else, attackers could put a Trojan-horse module in the directory (say, a file named os.py) that your application would then import and run.

If you maintain a C/C++ application that embeds Python, check whether you’re calling PySys_SetArgv() and carefully consider whether the application should be using PySys_SetArgvEx() with updatepath set to false.

Security issue reported as CVE-2008-5983; discussed in bpo-5753, and fixed by Antoine Pitrou.

- New macros: the Python header files now define the following macros: Py_ISALNUM, Py_ISALPHA, Py_ISDIGIT, Py_ISLOWER, Py_ISSPACE, Py_ISUPPER, Py_ISXDIGIT, Py_TOLOWER, and Py_TOUPPER. All of these functions are analogous to the C standard macros for classifying characters, but ignore the current locale setting, because in several places Python needs to analyze characters in a locale-independent way. (Added by Eric Smith; bpo-5793.)

- Removed function: PyEval_CallObject is now only available as a macro. A function version was being kept around to preserve ABI linking compatibility, but that was in 1997; it can certainly be deleted by now. (Removed by Antoine Pitrou; bpo-8276.)

- New format codes: the PyFormat_FromString(), PyFormat_FromStringV(), and PyErr_Format() functions now accept %lld and %llu format codes for displaying C’s long long types. (Contributed by Mark Dickinson; bpo-7228.)
• The complicated interaction between threads and process forking has been changed. Previously, the child process created by \texttt{os.fork()} might fail because the child is created with only a single thread running, the thread performing the \texttt{os.fork()}. If other threads were holding a lock, such as Python's import lock, when the fork was performed, the lock would still be marked as “held” in the new process. But in the child process nothing would ever release the lock, since the other threads weren't replicated, and the child process would no longer be able to perform imports.

Python 2.7 acquires the import lock before performing an \texttt{os.fork()}, and will also clean up any locks created using the \texttt{threading} module. C extension modules that have internal locks, or that call \texttt{fork()} themselves, will not benefit from this clean-up.

(Fixed by Thomas Wouters; \texttt{bpo-1590864}.)

• The \texttt{Py_Finalize()} function now calls the internal \texttt{threading._shutdown()} function; this prevents some exceptions from being raised when an interpreter shuts down. (Patch by Adam Olsen; \texttt{bpo-1722344}.)

• When using the \texttt{PyMemberDef} structure to define attributes of a type, Python will no longer let you try to delete or set a \texttt{T\_STRING\_INPLACE} attribute.

• Global symbols defined by the \texttt{ctypes} module are now prefixed with \texttt{Py}, or with \texttt{_ctypes}. (Implemented by Thomas Heller; \texttt{bpo-3102}.)

• New configure option: the \texttt{--with-system-expat} switch allows
building the pyexpat module to use the system Expat library. (Contributed by Arfrever Frehtes Taifersar Arahesis; bpo-7609.)

- New configure option: the --with-valgrind option will now disable the pymalloc allocator, which is difficult for the Valgrind memory-error detector to analyze correctly. Valgrind will therefore be better at detecting memory leaks and overruns. (Contributed by James Henstridge; bpo-2422.)

- New configure option: you can now supply an empty string to --with-dbmliborder= in order to disable all of the various DBM modules. (Added by Arfrever Frehtes Taifersar Arahesis; bpo-6491.)

- The **configure** script now checks for floating-point rounding bugs on certain 32-bit Intel chips and defines a _X87_DOUBLE_ROUNDING_ preprocessor definition. No code currently uses this definition, but it’s available if anyone wishes to use it. (Added by Mark Dickinson; bpo-2937.)

  **configure** also now sets a LDCXXSHARED Makefile variable for supporting C++ linking. (Contributed by Arfrever Frehtes Taifersar Arahesis; bpo-1222585.)

- The build process now creates the necessary files for pkg-config support. (Contributed by Clinton Roy; bpo-3585.)

- The build process now supports Subversion 1.7. (Contributed by Arfrever Frehtes Taifersar Arahesis; bpo-6094.)

**Capsules**

Python 3.1 adds a new C datatype, **PyCapsule**, for providing a C API
to an extension module. A capsule is essentially the holder of a C
\texttt{void \*} pointer, and is made available as a module attribute; for
example, the \texttt{socket} module's API is exposed as \texttt{socket.CAPI},
and \texttt{unicodedata} exposes \texttt{ucnhash_CAPI}. Other extensions can
import the module, access its dictionary to get the capsule object, and
then get the \texttt{void \*} pointer, which will usually point to an array of
pointers to the module's various API functions.

There is an existing data type already used for this, \texttt{PyCObject}, but it
doesn't provide type safety. Evil code written in pure Python could
cause a segmentation fault by taking a \texttt{PyCObject} from module A
and somehow substituting it for the \texttt{PyCObject} in module B.
Capsules know their own name, and getting the pointer requires
providing the name:

\begin{verbatim}
void *vtable;

if (!PyCapsule_IsValid(capsule, "mymodule.CAPI")
    PyErr_SetString(PyExc_ValueError, "argument
default
return NULL;
}

vtable = PyCapsule_GetPointer(capsule, "mymodule.CAPI"
\end{verbatim}

You are assured that \texttt{vtable} points to whatever you're expecting. If a
different capsule was passed in, \texttt{PyCapsule_IsValid()} would
detect the mismatched name and return false. Refer to \texttt{Providing a C
API for an Extension Module} for more information on using these
objects.

Python 2.7 now uses capsules internally to provide various extension-
module APIs, but the \texttt{PyCObject_AsVoidPtr()} was modified to
handle capsules, preserving compile-time compatibility with the CObject interface. Use of PyCObject_AsVoidPtr() will signal a PendingDeprecationWarning, which is silent by default.

Implemented in Python 3.1 and backported to 2.7 by Larry Hastings; discussed in bpo-5630.

Port-Specific Changes: Windows

- The msvcrtnow module now contains some constants from the crtassem.h header file: CRT_ASSEMBLY_VERSION, VC_ASSEMBLY_PUBLICKEYTOKEN, and LIBRARIES_ASSEMBLY_NAME_PREFIX. (Contributed by David Cournapeau; bpo-4365.)
- The _winreg module for accessing the registry now implements the CreateKeyEx() and DeleteKeyEx() functions, extended versions of previously-supported functions that take several extra arguments. The DisableReflectionKey(), EnableReflectionKey(), and QueryReflectionKey() were also tested and documented. (Implemented by Brian Curtin: bpo-7347.)
- The new _beginthreadex() API is used to start threads, and the native thread-local storage functions are now used. (Contributed by Kristján Valur Jónsson; bpo-3582.)
- The os.kill() function now works on Windows. The signal value can be the constants CTRL_C_EVENT, CTRL_BREAK_EVENT, or any integer. The first two constants will send Control-C and Control-Break keystroke events to subprocesses; any other value will use the TerminateProcess() API. (Contributed by Miki Tebeka; bpo-1220212.)
- The os.listdir() function now correctly fails for an empty
The mimelib module will now read the MIME database from the Windows registry when initializing. (Patch by Gabriel Genellina; bpo-4969.)

Port-Specific Changes: Mac OS X

- The path `/Library/Python/2.7/site-packages` is now appended to `sys.path`, in order to share added packages between the system installation and a user-installed copy of the same version. (Changed by Ronald Oussoren; bpo-4865.)

Port-Specific Changes: FreeBSD

- FreeBSD 7.1's SO_SETFIB constant, used with `getsockopt()`/`setsockopt()` to select an alternate routing table, is now available in the `socket` module. (Added by Kyle VanderBeek; bpo-8235.)
Other Changes and Fixes

- Two benchmark scripts, `iobench` and `ccbench`, were added to the `Tools` directory. `iobench` measures the speed of the built-in file I/O objects returned by `open()` while performing various operations, and `ccbench` is a concurrency benchmark that tries to measure computing throughput, thread switching latency, and IO processing bandwidth when performing several tasks using a varying number of threads.
- The `Tools/i18n/msgfmt.py` script now understands plural forms in `.po` files. (Fixed by Martin von Löwis; bpo-5464.)
- When importing a module from a `.pyc` or `.pyo` file with an existing `.py` counterpart, the `co_filename` attributes of the resulting code objects are overwritten when the original filename is obsolete. This can happen if the file has been renamed, moved, or is accessed through different paths. (Patch by Ziga Seilnacht and Jean-Paul Calderone; bpo-1180193.)
- The `regrtest.py` script now takes a `--randseed=` switch that takes an integer that will be used as the random seed for the `-r` option that executes tests in random order. The `-r` option also reports the seed that was used (Added by Collin Winter.)
- Another `regrtest.py` switch is `-j`, which takes an integer specifying how many tests run in parallel. This allows reducing the total runtime on multi-core machines. This option is compatible with several other options, including the `-R` switch which is known to produce long runtimes. (Added by Antoine Pitrou, bpo-6152.) This can also be used with a new `-F` switch that runs selected tests in a loop until they fail. (Added by Antoine Pitrou; bpo-7312.)
- When executed as a script, the `py_compile.py` module now accepts `-` as an argument, which will read standard input for the list of filenames to be compiled. (Contributed by Piotr Ożarowski; bpo-8233.)
Porting to Python 2.7

This section lists previously described changes and other bugfixes that may require changes to your code:

- The `range()` function processes its arguments more consistently; it will now call `__int__()` on non-float, non-integer arguments that are supplied to it. (Fixed by Alexander Belopolsky; \[bpo-1533\].)
- The string `format()` method changed the default precision used for floating-point and complex numbers from 6 decimal places to 12, which matches the precision used by `str()`. (Changed by Eric Smith; \[bpo-5920\].)
- Because of an optimization for the `with` statement, the special methods `__enter__()` and `__exit__()` must belong to the object's type, and cannot be directly attached to the object's instance. This affects new-style classes (derived from `object`) and C extension types. (\[bpo-6101\].)
- Due to a bug in Python 2.6, the `exc_value` parameter to `__exit__()` methods was often the string representation of the exception, not an instance. This was fixed in 2.7, so `exc_value` will be an instance as expected. (Fixed by Florent Xicluna; \[bpo-7853\].)
- When a restricted set of attributes were set using `__slots__`, deleting an unset attribute would not raise `AttributeError` as you would expect. Fixed by Benjamin Peterson; \[bpo-7604\].)

In the standard library:

- Operations with `datetime` instances that resulted in a year falling outside the supported range didn’t always raise `OverflowError`. Such errors are now checked more carefully and will now raise the exception. (Reported by Mark Leander,
When using `Decimal` instances with a string's `format()` method, the default alignment was previously left-alignment. This has been changed to right-alignment, which might change the output of your programs. (Changed by Mark Dickinson; bpo-6857.)

Comparisons involving a signaling NaN value (or sNAN) now signal `InvalidOperation` instead of silently returning a true or false value depending on the comparison operator. Quiet NaN values (or NaN) are now hashable. (Fixed by Mark Dickinson; bpo-7279.)

The `ElementTree` library, `xml.etree`, no longer escapes ampersands and angle brackets when outputting an XML processing instruction (which looks like `<xml-stylesheet href="#style1"/>`) or comment (which looks like `<!– comment –>`) (Patch by Neil Muller; bpo-2746.)

The `readline()` method of `StringIO` objects now does nothing when a negative length is requested, as other file-like objects do. (bpo-7348).

The `syslog` module will now use the value of `sys.argv[0]` as the identifier instead of the previous default value of 'python'. (Changed by Sean Reifschneider; bpo-8451.)

The `tarfile` module's default error handling has changed, to no longer suppress fatal errors. The default error level was previously 0, which meant that errors would only result in a message being written to the debug log, but because the debug log is not activated by default, these errors go unnoticed. The default error
level is now 1, which raises an exception if there's an error. (Changed by Lars Gustäbel; bpo-7357.)

- The urlparse module's urlsplit() now handles unknown URL schemes in a fashion compliant with RFC 3986: if the URL is of the form "<something>://...", the text before the :// is treated as the scheme, even if it's a made-up scheme that the module doesn’t know about. This change may break code that worked around the old behaviour. For example, Python 2.6.4 or 2.5 will return the following:

```python
>>> import urlparse
>>> urlparse.urlsplit('invented://host/filename?query')
('invented', '', '//host/filename?query', '', '')
```

Python 2.7 (and Python 2.6.5) will return:

```python
>>> import urlparse
>>> urlparse.urlsplit('invented://host/filename?query')
('invented', 'host', '/filename?query', '', '')
```

(Python 2.7 actually produces slightly different output, since it returns a named tuple instead of a standard tuple.)

For C extensions:

- C extensions that use integer format codes with the PyArg_Parse* family of functions will now raise a TypeError exception instead of triggering a DeprecationWarning (bpo-5080).
- Use the new PyOS_string_to_double() function instead of the old PyOS_ascii_strtod() and PyOS_ascii_atof() functions, which are now deprecated.
For applications that embed Python:

- The `PySys_SetArgvEx()` function was added, letting applications close a security hole when the existing `PySys_SetArgv()` function was used. Check whether you're calling `PySys_SetArgv()` and carefully consider whether the application should be using `PySys_SetArgvEx()` with `updatepath` set to false.
New Features Added to Python 2.7
Maintenance Releases

New features may be added to Python 2.7 maintenance releases when the situation genuinely calls for it. Any such additions must go through the Python Enhancement Proposal process, and make a compelling case for why they can’t be adequately addressed by either adding the new feature solely to Python 3, or else by publishing it on the Python Package Index.

In addition to the specific proposals listed below, there is a general exemption allowing new `-3` warnings to be added in any Python 2.7 maintenance release.

**PEP 434: IDLE Enhancement Exception for All Branches**

**PEP 434** describes a general exemption for changes made to the IDLE development environment shipped along with Python. This exemption makes it possible for the IDLE developers to provide a more consistent user experience across all supported versions of Python 2 and 3.

For details of any IDLE changes, refer to the NEWS file for the specific release.

**PEP 466: Network Security Enhancements for Python 2.7**

**PEP 466** describes a number of network security enhancement
proposals that have been approved for inclusion in Python 2.7 maintenance releases, with the first of those changes appearing in the Python 2.7.7 release.

**PEP 466** related features added in Python 2.7.7:

- `hmac.compare_digest()` was backported from Python 3 to make a timing attack resistant comparison operation available to Python 2 applications. (Contributed by Alex Gaynor; bpo-21306.)
- OpenSSL 1.0.1g was upgraded in the official Windows installers published on python.org. (Contributed by Zachary Ware; bpo-21462.)

**PEP 466** related features added in Python 2.7.8:

- `hashlib.pbkdf2_hmac()` was backported from Python 3 to make a hashing algorithm suitable for secure password storage broadly available to Python 2 applications. (Contributed by Alex Gaynor; bpo-21304.)
- OpenSSL 1.0.1h was upgraded for the official Windows installers published on python.org. (contributed by Zachary Ware in bpo-21671 for CVE-2014-0224)

**PEP 466** related features added in Python 2.7.9:

- Most of Python 3.4’s `ssl` module was backported. This means `ssl` now supports Server Name Indication, TLS1.x settings, access to the platform certificate store, the `SSLContext` class, and other features. (Contributed by Alex Gaynor and David Reid; bpo-21308.)
- `os.urandom()` was changed to cache a file descriptor to `/dev/urandom` instead of reopening `/dev/urandom` on every call. (Contributed by Alex Gaynor; bpo-21305.)
Acknowledgements

The author would like to thank the following people for offering suggestions, corrections and assistance with various drafts of this article: Nick Coghlan, Philip Jenvey, Ryan Lovett, R. David Murray, Hugh Secker-Walker.
This article explains the new features in Python 2.6, released on October 1 2008. The release schedule is described in PEP 361.

The major theme of Python 2.6 is preparing the migration path to Python 3.0, a major redesign of the language. Whenever possible, Python 2.6 incorporates new features and syntax from 3.0 while remaining compatible with existing code by not removing older features or syntax. When it's not possible to do that, Python 2.6 tries to do what it can, adding compatibility functions in a future_builtins module and a -3 switch to warn about usages that will become unsupported in 3.0.

Some significant new packages have been added to the standard library, such as the multiprocessing and json modules, but there aren’t many new features that aren’t related to Python 3.0 in some way.

Python 2.6 also sees a number of improvements and bugfixes throughout the source. A search through the change logs finds there were 259 patches applied and 612 bugs fixed between Python 2.5 and 2.6. Both figures are likely to be underestimates.

This article doesn’t attempt to provide a complete specification of the new features, but instead provides a convenient overview. For full details, you should refer to the documentation for Python 2.6. If you want to understand the rationale for the design and implementation, refer to the PEP for a particular new feature. Whenever possible, “What’s New in Python” links to the bug/patch item for each change.
Python 3.0

The development cycle for Python versions 2.6 and 3.0 was synchronized, with the alpha and beta releases for both versions being made on the same days. The development of 3.0 has influenced many features in 2.6.

Python 3.0 is a far-ranging redesign of Python that breaks compatibility with the 2.x series. This means that existing Python code will need some conversion in order to run on Python 3.0. However, not all the changes in 3.0 necessarily break compatibility. In cases where new features won’t cause existing code to break, they’ve been backported to 2.6 and are described in this document in the appropriate place. Some of the 3.0-derived features are:

- A `__complex__()` method for converting objects to a complex number.
- Alternate syntax for catching exceptions: `except TypeError as exc`.
- The addition of `functools.reduce()` as a synonym for the built-in `reduce()` function.

Python 3.0 adds several new built-in functions and changes the semantics of some existing builtins. Functions that are new in 3.0 such as `bin()` have simply been added to Python 2.6, but existing builtins haven’t been changed; instead, the `future_builtins` module has versions with the new 3.0 semantics. Code written to be compatible with 3.0 can do `from future_builtins import hex, map` as necessary.

A new command-line switch, `-3`, enables warnings about features that will be removed in Python 3.0. You can run code with this switch to see
how much work will be necessary to port code to 3.0. The value of this switch is available to Python code as the boolean variable `sys.py3kwarning`, and to C extension code as `Py_Py3kWarningFlag`.

**See also:** The 3xxx series of PEPs, which contains proposals for Python 3.0. [PEP 3000](https://www.python.org/dev/peps/pep-0300/) describes the development process for Python 3.0. Start with [PEP 3100](https://www.python.org/dev/peps/pep-03100/) that describes the general goals for Python 3.0, and then explore the higher-numbered PEPs that propose specific features.
Changes to the Development Process

While 2.6 was being developed, the Python development process underwent two significant changes: we switched from SourceForge’s issue tracker to a customized Roundup installation, and the documentation was converted from LaTeX to reStructuredText.

New Issue Tracker: Roundup

For a long time, the Python developers had been growing increasingly annoyed by SourceForge’s bug tracker. SourceForge’s hosted solution doesn’t permit much customization; for example, it wasn’t possible to customize the life cycle of issues.

The infrastructure committee of the Python Software Foundation therefore posted a call for issue trackers, asking volunteers to set up different products and import some of the bugs and patches from SourceForge. Four different trackers were examined: Jira, Launchpad, Roundup, and Trac. The committee eventually settled on Jira and Roundup as the two candidates. Jira is a commercial product that offers no-cost hosted instances to free-software projects; Roundup is an open-source project that requires volunteers to administer it and a server to host it.

After posting a call for volunteers, a new Roundup installation was set up at https://bugs.python.org. One installation of Roundup can host multiple trackers, and this server now also hosts issue trackers for Jython and for the Python web site. It will surely find other uses in the future. Where possible, this edition of “What’s New in Python” links to the bug/patch item for each change.
Hosting of the Python bug tracker is kindly provided by Upfront Systems of Stellenbosch, South Africa. Martin von Löwis put a lot of effort into importing existing bugs and patches from SourceForge; his scripts for this import operation are at http://svn.python.org/view/tracker/importer/ and may be useful to other projects wishing to move from SourceForge to Roundup.

New Documentation Format: reStructuredText
Using Sphinx

The Python documentation was written using LaTeX since the project started around 1989. In the 1980s and early 1990s, most documentation was printed out for later study, not viewed online. LaTeX was widely used because it provided attractive printed output while remaining straightforward to write once the basic rules of the markup were learned.

Today LaTeX is still used for writing publications destined for printing, but the landscape for programming tools has shifted. We no longer print out reams of documentation; instead, we browse through it online
and HTML has become the most important format to support. Unfortunately, converting \LaTeX to HTML is fairly complicated and Fred L. Drake Jr., the long-time Python documentation editor, spent a lot of time maintaining the conversion process. Occasionally people would suggest converting the documentation into SGML and later XML, but performing a good conversion is a major task and no one ever committed the time required to finish the job.

During the 2.6 development cycle, Georg Brandl put a lot of effort into building a new toolchain for processing the documentation. The resulting package is called Sphinx, and is available from \url{http://sphinx-doc.org/}.

Sphinx concentrates on HTML output, producing attractively styled and modern HTML; printed output is still supported through conversion to \LaTeX. The input format is reStructuredText, a markup syntax supporting custom extensions and directives that is commonly used in the Python community.

Sphinx is a standalone package that can be used for writing, and almost two dozen other projects (listed on the Sphinx web site) have adopted Sphinx as their documentation tool.

PEP 343: The ‘with’ statement

The previous version, Python 2.5, added the ‘with’ statement as an optional feature, to be enabled by a from __future__ import with_statement directive. In 2.6 the statement no longer needs to be specially enabled; this means that with is now always a keyword. The rest of this section is a copy of the corresponding section from the “What's New in Python 2.5” document; if you're familiar with the ‘with’ statement from Python 2.5, you can skip this section.

The ‘with’ statement clarifies code that previously would use try...finally blocks to ensure that clean-up code is executed. In this section, I'll discuss the statement as it will commonly be used. In the next section, I'll examine the implementation details and show how to write objects for use with this statement.

The 'with' statement is a control-flow structure whose basic structure is:

```python
with expression [as variable]:
    with-block
```

The expression is evaluated, and it should result in an object that supports the context management protocol (that is, has __enter__() and __exit__() methods).

The object's __enter__() is called before with-block is executed and therefore can run set-up code. It also may return a value that is bound to the name variable, if given. (Note carefully that variable is not assigned the result of expression.)

After execution of the with-block is finished, the object's __exit__()
method is called, even if the block raised an exception, and can therefore run clean-up code.

Some standard Python objects now support the context management protocol and can be used with the `with` statement. File objects are one example:

```python
with open('/etc/passwd', 'r') as f:
    for line in f:
        print line
... more processing code ...
```

After this statement has executed, the file object in `f` will have been automatically closed, even if the `for` loop raised an exception part-way through the block.

**Note:** In this case, `f` is the same object created by `open()`, because `file.__enter__()` returns `self`.

The `threading` module's locks and condition variables also support the `with` statement:

```python
lock = threading.Lock()
with lock:
    # Critical section of code
...```

The lock is acquired before the block is executed and always released once the block is complete.

The `localcontext()` function in the `decimal` module makes it easy to save and restore the current decimal context, which encapsulates the desired precision and rounding characteristics for
computations:

```python
from decimal import Decimal, Context, localcontext

# Displays with default precision of 28 digits
v = Decimal('578')
print v.sqrt()

with localcontext(Context(prec=16)):
    # All code in this block uses a precision of 16
    # The original context is restored on exiting the block.
    print v.sqrt()
```

Writing Context Managers

Under the hood, the `with` statement is fairly complicated. Most people will only use `with` in company with existing objects and don’t need to know these details, so you can skip the rest of this section if you like. Authors of new objects will need to understand the details of the underlying implementation and should keep reading.

A high-level explanation of the context management protocol is:

- The expression is evaluated and should result in an object called a “context manager”. The context manager must have `__enter__()` and `__exit__()` methods.
- The context manager’s `__enter__()` method is called. The value returned is assigned to `VAR`. If no `as VAR` clause is present, the value is simply discarded.
- The code in `BLOCK` is executed.
- If `BLOCK` raises an exception, the context manager’s `__exit__()` method is called with three arguments, the exception details (`type`, `value`, `traceback`), the same values
returned by `sys.exc_info()`, which can also be `None` if no exception occurred). The method's return value controls whether an exception is re-raised: any false value re-raises the exception, and `True` will result in suppressing it. You'll only rarely want to suppress the exception, because if you do the author of the code containing the `with` statement will never realize anything went wrong.

- If `BLOCK` didn't raise an exception, the `__exit__()` method is still called, but `type`, `value`, and `traceback` are all `None`.

Let's think through an example. I won't present detailed code but will only sketch the methods necessary for a database that supports transactions.

(For people unfamiliar with database terminology: a set of changes to the database are grouped into a transaction. Transactions can be either committed, meaning that all the changes are written into the database, or rolled back, meaning that the changes are all discarded and the database is unchanged. See any database textbook for more information.)

Let's assume there's an object representing a database connection. Our goal will be to let the user write code like this:

```python
db_connection = DatabaseConnection()
with db_connection as cursor:
    cursor.execute('insert into ...')
    cursor.execute('delete from ...')
    # ... more operations ...
```

The transaction should be committed if the code in the block runs flawlessly or rolled back if there's an exception. Here's the basic interface for `DatabaseConnection` that I'll assume:
class DatabaseConnection:
    # Database interface
    def cursor(self):
        """Returns a cursor object and starts a new transaction"""
    def commit(self):
        "Commits current transaction"
    def rollback(self):
        "Rolls back current transaction"

The __enter__() method is pretty easy, having only to start a new transaction. For this application the resulting cursor object would be a useful result, so the method will return it. The user can then add as cursor to their 'with' statement to bind the cursor to a variable name.

class DatabaseConnection:
    ... 
    def __enter__(self):
        "# Code to start a new transaction"
        cursor = self.cursor()
        return cursor

The __exit__() method is the most complicated because it's where most of the work has to be done. The method has to check if an exception occurred. If there was no exception, the transaction is committed. The transaction is rolled back if there was an exception.

In the code below, execution will just fall off the end of the function, returning the default value of None. None is false, so the exception will be re-raised automatically. If you wished, you could be more explicit and add a return statement at the marked location.
The contextlib module

The `contextlib` module provides some functions and a decorator that are useful when writing objects for use with the `with` statement.

The decorator is called `contextmanager()`, and lets you write a single generator function instead of defining a new class. The generator should yield exactly one value. The code up to the `yield` will be executed as the `__enter__()` method, and the value yielded will be the method’s return value that will get bound to the variable in the `with` statement’s `as` clause, if any. The code after the `yield` will be executed in the `__exit__()` method. Any exception raised in the block will be raised by the `yield` statement.

Using this decorator, our database example from the previous section could be written as:

```python
from contextlib import contextmanager

@contextmanager
def db_transaction(connection):
    cursor = connection.cursor()
    try:
        yield cursor
    except:
        connection.rollback()
```

```python
def __exit__(self, type, value, tb):
    if tb is None:
        # No exception, so commit
        self.commit()
    else:
        # Exception occurred, so rollback.
        self.rollback()
        # return False
```
except:
    connection.rollback()
    raise
else:
    connection.commit()

db = DatabaseConnection()
with db_transaction(db) as cursor:
    ...

The `contextlib` module also has a `nested(mgr1, mgr2, ...)` function that combines a number of context managers so you don't need to write nested `with` statements. In this example, the single `with` statement both starts a database transaction and acquires a thread lock:

```python
lock = threading.Lock()
with nested (db_transaction(db), lock) as (cursor, l
    ...
```

Finally, the `closing()` function returns its argument so that it can be bound to a variable, and calls the argument's `close()` method at the end of the block.

```python
import urllib, sys
from contextlib import closing

with closing(urllib.urlopen('http://www.yahoo.com'))
    for line in f:
        sys.stdout.write(line)
```

PEP 343 - The “with” statement

PEP written by Guido van Rossum and Nick Coghlan; implemented by Mike Bland, Guido van Rossum, and Neal Norwitz. The PEP shows the code generated for a ‘with’ statement, which can be helpful in learning how the statement works.

The documentation for the `contextlib` module.
PEP 366: Explicit Relative Imports From a Main Module

Python's `-m` switch allows running a module as a script. When you ran a module that was located inside a package, relative imports didn't work correctly.

The fix for Python 2.6 adds a `__package__` attribute to modules. When this attribute is present, relative imports will be relative to the value of this attribute instead of the `__name__` attribute.

PEP 302-style importers can then set `__package__` as necessary. The `runpy` module that implements the `-m` switch now does this, so relative imports will now work correctly in scripts running from inside a package.
PEP 370: Per-user site-packages Directory

When you run Python, the module search path `sys.path` usually includes a directory whose path ends in "site-packages". This directory is intended to hold locally-installed packages available to all users using a machine or a particular site installation.

Python 2.6 introduces a convention for user-specific site directories. The directory varies depending on the platform:

- Unix and Mac OS X: `~/.local/`
- Windows: `%APPDATA%/Python`

Within this directory, there will be version-specific subdirectories, such as `lib/python2.6/site-packages` on Unix/Mac OS and `Python26/site-packages` on Windows.

If you don’t like the default directory, it can be overridden by an environment variable. `PYTHONUSERBASE` sets the root directory used for all Python versions supporting this feature. On Windows, the directory for application-specific data can be changed by setting the `APPDATA` environment variable. You can also modify the `site.py` file for your Python installation.

The feature can be disabled entirely by running Python with the `-s` option or setting the `PYTHONNOUSERSITE` environment variable.

PEP 370 - Per-user `site-packages` Directory

PEP written and implemented by Christian Heimes.
PEP 371: The multiprocessing Package

The new multiprocessing package lets Python programs create new processes that will perform a computation and return a result to the parent. The parent and child processes can communicate using queues and pipes, synchronize their operations using locks and semaphores, and can share simple arrays of data.

The multiprocessing module started out as an exact emulation of the threading module using processes instead of threads. That goal was discarded along the path to Python 2.6, but the general approach of the module is still similar. The fundamental class is the Process, which is passed a callable object and a collection of arguments. The start() method sets the callable running in a subprocess, after which you can call the is_alive() method to check whether the subprocess is still running and the join() method to wait for the process to exit.

Here's a simple example where the subprocess will calculate a factorial. The function doing the calculation is written strangely so that it takes significantly longer when the input argument is a multiple of 4.

```python
import time
from multiprocessing import Process, Queue

def factorial(queue, N):
    "Compute a factorial."
    # If N is a multiple of 4, this function will take longer.
    if (N % 4) == 0:
        time.sleep(.05 * N/4)
```
A Queue is used to communicate the result of the factorial. The Queue object is stored in a global variable. The child process will use the value of the variable when the child was created; because it's a Queue, parent and child can use the object to communicate. (If the parent were to change the value of the global variable, the child's value would be unaffected, and vice versa.)

Two other classes, Pool and Manager, provide higher-level interfaces. Pool will create a fixed number of worker processes, and requests can then be distributed to the workers by calling apply() or apply_async() to add a single request, and map() or map_async() to add a number of requests. The following code uses a Pool to spread requests across 5 worker processes and retrieve a
list of results:

```python
from multiprocessing import Pool

def factorial(N, dictionary):
    "Compute a factorial."
    ...
p = Pool(5)
result = p.map(factorial, range(1, 1000, 10))
for v in result:
    print v
```

This produces the following output:

```
1
39916800
51090942171709440000
822283865417792281772556288000000
33452526613163807108170062053440751665152000000000
...
```

The other high-level interface, the Manager class, creates a separate server process that can hold master copies of Python data structures. Other processes can then access and modify these data structures using proxy objects. The following example creates a shared dictionary by calling the `dict()` method; the worker processes then insert values into the dictionary. (Locking is not done for you automatically, which doesn’t matter in this example. Manager’s methods also include Lock(), RLock(), and Semaphore() to create shared locks.)

```python
import time
from multiprocessing import Pool, Manager
```
def factorial(N, dictionary):
    "Compute a factorial."
    # Calculate the result
    fact = 1L
    for i in range(1, N+1):
        fact = fact * i

    # Store result in dictionary
    dictionary[N] = fact

if __name__ == '__main__':
    p = Pool(5)
    mgr = Manager()
    d = mgr.dict()  # Create shared dictionary

    # Run tasks using the pool
    for N in range(1, 1000, 10):
        p.apply_async(factorial, (N, d))

    # Mark pool as closed -- no more tasks can be added.
p.close()

    # Wait for tasks to exit
    p.join()

    # Output results
    for k, v in sorted(d.items()):
        print k, v

This will produce the output:

1 1
11 39916800
21 51090942171709440000
31 8222838654177922817725562880000000
41 33452526613163807108170062053440751665152000000000
See also: The documentation for the `multiprocessing` module.

**PEP 371 - Addition of the multiprocessing package**

PEP written by Jesse Noller and Richard Oudkerk; implemented by Richard Oudkerk and Jesse Noller.
PEP 3101: Advanced String Formatting

In Python 3.0, the % operator is supplemented by a more powerful string formatting method, \texttt{format()}. Support for the \texttt{str.format()} method has been backported to Python 2.6.

In 2.6, both 8-bit and Unicode strings have a \texttt{.format()} method that treats the string as a template and takes the arguments to be formatted. The formatting template uses curly brackets (\{, \}) as special characters:

\begin{verbatim}
>>> # Substitute positional argument 0 into the string
>>> "User ID: \{0\}".format("root")
'User ID: root'
>>> # Use the named keyword arguments
>>> "User ID: {uid} Last seen: {last_login}".format(....uid="root",
...last_login = "5 Mar 2008 07:20")
'User ID: root Last seen: 5 Mar 2008 07:20'
\end{verbatim}

Curly brackets can be escaped by doubling them:

\begin{verbatim}
>>> "Empty dict: \{{}\}".format()
"Empty dict: {}"
\end{verbatim}

Field names can be integers indicating positional arguments, such as \{0\}, \{1\}, etc. or names of keyword arguments. You can also supply compound field names that read attributes or access dictionary keys:

\begin{verbatim}
>>> import sys
>>> print 'Platform: \{0.platform\}
Platform: darwin
Python version: 2.6a1+ (trunk:61261M, Mar 5 2008, 2
\end{verbatim}
Note that when using dictionary-style notation such as `[{.mp4}]`, you don’t need to put any quotation marks around the string; it will look up the value using `.mp4` as the key. Strings beginning with a number will be converted to an integer. You can’t write more complicated expressions inside a format string.

So far we’ve shown how to specify which field to substitute into the resulting string. The precise formatting used is also controllable by adding a colon followed by a format specifier. For example:

```python
>>> # Field 0: left justify, pad to 15 characters
>>> # Field 1: right justify, pad to 6 characters
>>> fmt = '{0:15} ${1:>6}'
>>> fmt.format('Registration', 35)
'Registration   $ 35'
>>> fmt.format('Tutorial', 50)
'Tutorial       $ 50'
>>> fmt.format('Banquet', 125)
'Banquet       $ 125'
```

Format specifiers can reference other fields through nesting:

```python
>>> fmt = '{0:{1}}'
>>> width = 15
>>> fmt.format('Invoice #1234', width)
'Invoice #1234'
>>> width = 35
>>> fmt.format('Invoice #1234', width)
'Invoice #1234'
```
The alignment of a field within the desired width can be specified:

<table>
<thead>
<tr>
<th>Character</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; (default)</td>
<td>Left-align</td>
</tr>
<tr>
<td>&gt;</td>
<td>Right-align</td>
</tr>
<tr>
<td>^</td>
<td>Center</td>
</tr>
<tr>
<td>=</td>
<td>(For numeric types only) Pad after the sign.</td>
</tr>
</tbody>
</table>

Format specifiers can also include a presentation type, which controls how the value is formatted. For example, floating-point numbers can be formatted as a general number or in exponential notation:

```python
>>> '{0:g}'.format(3.75)
'3.75'
>>> '{0:e}'.format(3.75)
'3.750000e+00'
```

A variety of presentation types are available. Consult the 2.6 documentation for a complete list; here's a sample:

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>Binary. Outputs the number in base 2.</td>
</tr>
<tr>
<td>c</td>
<td>Character. Converts the integer to the corresponding Unicode character before printing.</td>
</tr>
<tr>
<td>d</td>
<td>Decimal Integer. Outputs the number in base 10.</td>
</tr>
<tr>
<td>o</td>
<td>Octal format. Outputs the number in base 8.</td>
</tr>
<tr>
<td>x</td>
<td>Hex format. Outputs the number in base 16, using lower-case letters for the digits above 9.</td>
</tr>
<tr>
<td>e</td>
<td>Exponent notation. Prints the number in scientific notation using the letter ‘e’ to indicate the exponent.</td>
</tr>
<tr>
<td>g</td>
<td>General format. This prints the number as a fixed-point number, unless the number is too large, in which case it switches to ‘e’ exponent notation.</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>n</td>
<td>Number. This is the same as ‘g’ (for floats) or ‘d’ (for integers), except that it uses the current locale setting to insert the appropriate number separator characters.</td>
</tr>
<tr>
<td>%</td>
<td>Percentage. Multiplies the number by 100 and displays in fixed (‘f’) format, followed by a percent sign.</td>
</tr>
</tbody>
</table>

Classes and types can define a `__format__()` method to control how they’re formatted. It receives a single argument, the format specifier:

```python
def __format__(self, format_spec):
    if isinstance(format_spec, unicode):
        return unicode(str(self))
    else:
        return str(self)
```

There’s also a `format()` builtin that will format a single value. It calls the type’s `__format__()` method with the provided specifier:

```python
>>> format(75.6564, '.2f')
'75.66'
```

**See also:**

- **Format String Syntax**
  - The reference documentation for format fields.
- **PEP 3101 - Advanced String Formatting**
  - PEP written by Talin. Implemented by Eric Smith.
PEP 3105: print As a Function

The `print` statement becomes the `print()` function in Python 3.0. Making `print()` a function makes it possible to replace the function by doing `def print(...)`, or importing a new function from somewhere else.

Python 2.6 has a `__future__` import that removes `print` as language syntax, letting you use the functional form instead. For example:

```python
>>> from __future__ import print_function
>>> print('# of entries', len(dictionary), file=sys.stdout)
```

The signature of the new function is:

```python
def print(*args, sep=' ', end='
', file=None)
```

The parameters are:

- `args`: positional arguments whose values will be printed out.
- `sep`: the separator, which will be printed between arguments.
- `end`: the ending text, which will be printed after all of the arguments have been output.
- `file`: the file object to which the output will be sent.

See also:

**PEP 3105 - Make print a function**

PEP written by Georg Brandl.
PEP 3110: Exception-Handling Changes

One error that Python programmers occasionally make is writing the following code:

```python
try:
    ...
except TypeError, ValueError:  # Wrong!
    ...
```

The author is probably trying to catch both `TypeError` and `ValueError` exceptions, but this code actually does something different: it will catch `TypeError` and bind the resulting exception object to the local name "ValueError". The `ValueError` exception will not be caught at all. The correct code specifies a tuple of exceptions:

```python
try:
    ...
except (TypeError, ValueError):
    ...
```

This error happens because the use of the comma here is ambiguous: does it indicate two different nodes in the parse tree, or a single node that's a tuple?

Python 3.0 makes this unambiguous by replacing the comma with the word “as”. To catch an exception and store the exception object in the variable `exc`, you must write:

```python
try:
    ...
except TypeError as exc:
    ...
```
Python 3.0 will only support the use of “as”, and therefore interprets the first example as catching two different exceptions. Python 2.6 supports both the comma and “as”, so existing code will continue to work. We therefore suggest using “as” when writing new Python code that will only be executed with 2.6.

See also:

PEP 3110 - Catching Exceptions in Python 3000
PEP written and implemented by Collin Winter.
PEP 3112: Byte Literals

Python 3.0 adopts Unicode as the language's fundamental string type and denotes 8-bit literals differently, either as b'\texttt{string}' or using a 
\texttt{bytes} constructor. For future compatibility, Python 2.6 adds \texttt{bytes}
as a synonym for the \texttt{str} type, and it also supports the b'' notation.

The 2.6 \texttt{str} differs from 3.0's \texttt{bytes} type in various ways; most notably, the constructor is completely different. In 3.0, \texttt{bytes([65, 66, 67])} is 3 elements long, containing the bytes representing ABC; in 2.6, \texttt{bytes([65, 66, 67])} returns the 12-byte string representing the \texttt{str()} of the list.

The primary use of \texttt{bytes} in 2.6 will be to write tests of object type such as \texttt{isinstance(x, bytes)}. This will help the 2to3 converter, which can't tell whether 2.x code intends strings to contain either characters or 8-bit bytes; you can now use either \texttt{bytes} or \texttt{str} to represent your intention exactly, and the resulting code will also be correct in Python 3.0.

There's also a \texttt{__future__} import that causes all string literals to become Unicode strings. This means that \texttt{\u} escape sequences can be used to include Unicode characters:

```python
from __future__ import unicode_literals

s = (r'\u751f\u3080\u304e\u3000\u751f\u3054\u3081\u3000\u751f\u305f\u307e\u3054',
     r'\u3081\u3000\u751f\u305f\u307e\u3054')

print len(s)  # 12 Unicode characters
```

At the C level, Python 3.0 will rename the existing 8-bit string type,
called PyStringObject in Python 2.x, to `PyBytesObject`. Python 2.6 uses `#define` to support using the names `PyBytesObject()`, `PyBytes_Check()`, `PyBytes_FromStringAndSize()`, and all the other functions and macros used with strings.

Instances of the `bytes` type are immutable just as strings are. A new `bytearray` type stores a mutable sequence of bytes:

```python
>>> bytearray([65, 66, 67])
bytearray(b'ABC')
>>> b = bytearray(u'\u21ef\u3244', 'utf-8')
>>> b
bytearray(b'\xe2\x87\xaf\xe3\x89\x84')
>>> b[0] = '\xe3'
>>> b
bytearray(b'\xe3\xe2\x87\xaf\xe3\x89\x84')
>>> unicode(str(b), 'utf-8')
'u'\u31ef \u3244'
```

Byte arrays support most of the methods of string types, such as `startswith()`/`endswith()`, `find()`/`rfind()`, and some of the methods of lists, such as `append()`, `pop()`, and `reverse()`.

```python
>>> b = bytearray('ABC')
>>> b.append('d')
>>> b.append(ord('e'))
>>> b
bytearray(b'ABCde')
```

There's also a corresponding C API, with `PyByteArray_FromObject()`, `PyByteArray_FromStringAndSize()`, and various other functions.

**PEP 3112 - Bytes literals in Python 3000**

PEP written by Jason Orendorff; backported to 2.6 by Christian Heimes.
PEP 3116: New I/O Library

Python’s built-in file objects support a number of methods, but file-like objects don’t necessarily support all of them. Objects that imitate files usually support read() and write(), but they may not support readline(), for example. Python 3.0 introduces a layered I/O library in the io module that separates buffering and text-handling features from the fundamental read and write operations.

There are three levels of abstract base classes provided by the io module:

- **RawIOBase** defines raw I/O operations: read(), readinto(), write(), seek(), tell(), truncate(), and close(). Most of the methods of this class will often map to a single system call. There are also readable(), writable(), and seekable() methods for determining what operations a given object will allow.

  Python 3.0 has concrete implementations of this class for files and sockets, but Python 2.6 hasn’t restructured its file and socket objects in this way.

- **BufferedIOBase** is an abstract base class that buffers data in memory to reduce the number of system calls used, making I/O processing more efficient. It supports all of the methods of RawIOBase, and adds a raw attribute holding the underlying raw object.

  There are five concrete classes implementing this ABC. BufferedWriter and BufferedReader are for objects that support write-only or read-only usage that have a seek() method
for random access. BufferedRandom objects support read and write access upon the same underlying stream, and BufferedRWPair is for objects such as TTYs that have both read and write operations acting upon unconnected streams of data. The BytesIO class supports reading, writing, and seeking over an in-memory buffer.

- **TextIOBase**: Provides functions for reading and writing strings (remember, strings will be Unicode in Python 3.0), and supporting universal newlines. TextIOBase defines the `readline()` method and supports iteration upon objects.

  There are two concrete implementations. TextIOWrapper wraps a buffered I/O object, supporting all of the methods for text I/O and adding a buffer attribute for access to the underlying object. StringIO simply buffers everything in memory without ever writing anything to disk.

  (In Python 2.6, `io.StringIO` is implemented in pure Python, so it’s pretty slow. You should therefore stick with the existing StringIO module or cStringIO for now. At some point Python 3.0’s `io` module will be rewritten into C for speed, and perhaps the C implementation will be backported to the 2.x releases.)

  In Python 2.6, the underlying implementations haven’t been restructured to build on top of the `io` module’s classes. The module is being provided to make it easier to write code that’s forward-compatible with 3.0, and to save developers the effort of writing their own implementations of buffering and text I/O.

PEP 3116 - New I/O

PEP 3118: Revised Buffer Protocol

The buffer protocol is a C-level API that lets Python types exchange pointers into their internal representations. A memory-mapped file can be viewed as a buffer of characters, for example, and this lets another module such as `re` treat memory-mapped files as a string of characters to be searched.

The primary users of the buffer protocol are numeric-processing packages such as NumPy, which expose the internal representation of arrays so that callers can write data directly into an array instead of going through a slower API. This PEP updates the buffer protocol in light of experience from NumPy development, adding a number of new features such as indicating the shape of an array or locking a memory region.

The most important new C API function is `PyObject_GetBuffer(PyObject *obj, Py_buffer *view, int flags)`, which takes an object and a set of flags, and fills in the `Py_buffer` structure with information about the object's memory representation. Objects can use this operation to lock memory in place while an external caller could be modifying the contents, so there's a corresponding `PyBuffer_Release(Py_buffer *view)` to indicate that the external caller is done.

The `flags` argument to `PyObject_GetBuffer()` specifies constraints upon the memory returned. Some examples are:

- `PyBUF_WRITABLE` indicates that the memory must be writable.
- `PyBUF_LOCK` requests a read-only or exclusive lock on the memory.
- PyBUF_C_CONTIGUOUS and PyBUF_F_CONTIGUOUS requests a C-contiguous (last dimension varies the fastest) or Fortran-contiguous (first dimension varies the fastest) array layout.

Two new argument codes for `PyArg_ParseTuple()`, s* and z*, return locked buffer objects for a parameter.

**PEP 3118 - Revising the buffer protocol**
PEP written by Travis Oliphant and Carl Banks; implemented by Travis Oliphant.
PEP 3119: Abstract Base Classes

Some object-oriented languages such as Java support interfaces, declaring that a class has a given set of methods or supports a given access protocol. Abstract Base Classes (or ABCs) are an equivalent feature for Python. The ABC support consists of an abc module containing a metaclass called ABCMeta, special handling of this metaclass by the isinstance() and issubclass() builtins, and a collection of basic ABCs that the Python developers think will be widely useful. Future versions of Python will probably add more ABCs.

Let's say you have a particular class and wish to know whether it supports dictionary-style access. The phrase “dictionary-style” is vague, however. It probably means that accessing items with obj[1] works. Does it imply that setting items with obj[2] = value works? Or that the object will have keys(), values(), and items() methods? What about the iterative variants such as iterkeys(), copy() and update()? Iterating over the object with iter()?

The Python 2.6 collections module includes a number of different ABCs that represent these distinctions. Iterable indicates that a class defines __iter__(), and Container means the class defines a __contains__() method and therefore supports x in y expressions. The basic dictionary interface of getting items, setting items, and keys(), values(), and items(), is defined by the MutableMapping ABC.

You can derive your own classes from a particular ABC to indicate they support that ABC's interface:

```python
import collections
```
class Storage(collections.MutableMapping):
...

Alternatively, you could write the class without deriving from the desired ABC and instead register the class by calling the ABC's register() method:

```python
import collections
class Storage:
...
collections.MutableMapping.register(Storage)
```

For classes that you write, deriving from the ABC is probably clearer. The register() method is useful when you've written a new ABC that can describe an existing type or class, or if you want to declare that some third-party class implements an ABC. For example, if you defined a PrintableType ABC, it's legal to do:

```python
# Register Python's types
PrintableType.register(int)
PrintableType.register(float)
PrintableType.register(str)
```

Classes should obey the semantics specified by an ABC, but Python can't check this; it's up to the class author to understand the ABC's requirements and to implement the code accordingly.

To check whether an object supports a particular interface, you can now write:

```python
def func(d):
```
Don’t feel that you must now begin writing lots of checks as in the above example. Python has a strong tradition of duck-typing, where explicit type-checking is never done and code simply calls methods on an object, trusting that those methods will be there and raising an exception if they aren’t. Be judicious in checking for ABCs and only do it where it’s absolutely necessary.

You can write your own ABCs by using `abc.ABCMeta` as the metaclass in a class definition:

```python
from abc import ABCMeta, abstractmethod

class Drawable():
    __metaclass__ = ABCMeta

    @abstractmethod
def draw(self, x, y, scale=1.0):
        pass

    def draw_doubled(self, x, y):
        self.draw(x, y, scale=2.0)

class Square(Drawable):
    def draw(self, x, y, scale):
        ...
```

In the `Drawable` ABC above, the `draw_doubled()` method renders the object at twice its size and can be implemented in terms of other methods described in `Drawable`. Classes implementing this ABC therefore don’t need to provide their own implementation of
draw_doubled(), though they can do so. An implementation of draw() is necessary, though; the ABC can't provide a useful generic implementation.

You can apply the `@abstractmethod` decorator to methods such as draw() that must be implemented; Python will then raise an exception for classes that don't define the method. Note that the exception is only raised when you actually try to create an instance of a subclass lacking the method:

```python
>>> class Circle(Drawable):
    ...    pass
    ...
>>> c = Circle()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: Can't instantiate abstract class Circle with abstract methods draw
```

Abstract data attributes can be declared using the `@abstractproperty` decorator:

```python
from abc import abstractproperty
...

@abstractproperty
def readonly(self):
    return self._x
```

Subclasses must then define a `readonly()` property.

See also:

**PEP 3119 - Introducing Abstract Base Classes**
PEP written by Guido van Rossum and Talin. Implemented by Guido van Rossum. Backported to 2.6 by Benjamin Aranguren, with Alex Martelli.
PEP 3127: Integer Literal Support and Syntax

Python 3.0 changes the syntax for octal (base-8) integer literals, prefixing them with “0o” or “0O” instead of a leading zero, and adds support for binary (base-2) integer literals, signalled by a “0b” or “0B” prefix.

Python 2.6 doesn’t drop support for a leading 0 signalling an octal number, but it does add support for “0o” and “0b”:

```
>>> 0o21, 2*8 + 1
(17, 17)
>>> 0b101111
47
```

The `oct()` builtin still returns numbers prefixed with a leading zero, and a new `bin()` builtin returns the binary representation for a number:

```
>>> oct(42)
'052'
>>> future_builtins.oct(42)
'0o52'
>>> bin(173)
'0b10101101'
```

The `int()` and `long()` builtins will now accept the “0o” and “0b” prefixes when base-8 or base-2 are requested, or when the `base` argument is zero (signalling that the base used should be determined from the string):
See also:

PEP 3127 - Integer Literal Support and Syntax

PEP written by Patrick Maupin; backported to 2.6 by Eric Smith.
PEP 3129: Class Decorators

Decorators have been extended from functions to classes. It’s now legal to write:

```python
@foo
@bar
class A:
    pass
```

This is equivalent to:

```python
class A:
    pass
A = foo(bar(A))
```

See also:

**PEP 3129 - Class Decorators**
PEP written by Collin Winter.
PEP 3141: A Type Hierarchy for Numbers

Python 3.0 adds several abstract base classes for numeric types inspired by Scheme's numeric tower. These classes were backported to 2.6 as the *numbers* module.

The most general ABC is *Number*. It defines no operations at all, and only exists to allow checking if an object is a number by doing `isinstance(obj, Number)`.

*Complex* is a subclass of *Number*. Complex numbers can undergo the basic operations of addition, subtraction, multiplication, division, and exponentiation, and you can retrieve the real and imaginary parts and obtain a number's conjugate. Python's built-in complex type is an implementation of *Complex*.

*Real* further derives from *Complex*, and adds operations that only work on real numbers: `floor()`, `trunc()`, rounding, taking the remainder mod N, floor division, and comparisons.

*Rational* numbers derive from *Real*, have numerator and denominator properties, and can be converted to floats. Python 2.6 adds a simple rational-number class, *Fraction*, in the *fractions* module. (It's called Fraction instead of Rational to avoid a name clash with *numbers.Rational*.)

*Integral* numbers derive from *Rational*, and can be shifted left and right with `<<` and `>>`, combined using bitwise operations such as `&` and `|`, and can be used as array indexes and slice boundaries.

In Python 3.0, the PEP slightly redefines the existing builtins
round(), math.floor(), math.ceil(), and adds a new one, math.trunc(), that's been backported to Python 2.6. math.trunc() rounds toward zero, returning the closest Integral that's between the function's argument and zero.

See also:

PEP 3141 - A Type Hierarchy for Numbers
  PEP written by Jeffrey Yasskin.

Scheme's numerical tower, from the Guile manual.

Scheme's number datatypes from the R5RS Scheme specification.

The fractions Module

To fill out the hierarchy of numeric types, the fractions module provides a rational-number class. Rational numbers store their values as a numerator and denominator forming a fraction, and can exactly represent numbers such as 2/3 that floating-point numbers can only approximate.

The Fraction constructor takes two Integral values that will be the numerator and denominator of the resulting fraction.

```python
>>> from fractions import Fraction
>>> a = Fraction(2, 3)
>>> b = Fraction(2, 5)
>>> float(a), float(b)
(0.6666666666666666, 0.40000000000000002)
>>> a+b
Fraction(16, 15)
>>> a/b
```
For converting floating-point numbers to rationals, the float type now has an `as_integer_ratio()` method that returns the numerator and denominator for a fraction that evaluates to the same floating-point value:

```
>>> (2.5).as_integer_ratio()
(5, 2)
>>> (3.1415).as_integer_ratio()
(7074029114692207L, 2251799813685248L)
>>> (1./3).as_integer_ratio()
(6004799503160661L, 18014398509481984L)
```

Note that values that can only be approximated by floating-point numbers, such as 1./3, are not simplified to the number being approximated; the fraction attempts to match the floating-point value **exactly**.

The `fractions` module is based upon an implementation by Sjoerd Mullender that was in Python's Demo/classes/ directory for a long time. This implementation was significantly updated by Jeffrey Yasskin.
Other Language Changes

Some smaller changes made to the core Python language are:

- Directories and zip archives containing a `__main__.py` file can now be executed directly by passing their name to the interpreter. The directory or zip archive is automatically inserted as the first entry in `sys.path`. (Suggestion and initial patch by Andy Chu, subsequently revised by Phillip J. Eby and Nick Coghlan; bpo-1739468.)

- The `hasattr()` function was catching and ignoring all errors, under the assumption that they meant a `__getattr__()` method was failing somehow and the return value of `hasattr()` would therefore be `False`. This logic shouldn't be applied to `KeyboardInterrupt` and `SystemExit`, however; Python 2.6 will no longer discard such exceptions when `hasattr()` encounters them. (Fixed by Benjamin Peterson; bpo-2196.)

- When calling a function using the `**` syntax to provide keyword arguments, you are no longer required to use a Python dictionary; any mapping will now work:

```python
>>> def f(**kw):
...     print sorted(kw)
...
>>> ud=UserDict.UserDict()
>>> ud['a'] = 1
>>> ud['b'] = 'string'
>>> f(**ud)
[a, b]
```
It's also become legal to provide keyword arguments after a *args argument to a function call.

```python
>>> def f(*args, **kw):
    ...    print args, kw
    ...

>>> f(1, 2, 3, *(4, 5, 6), keyword=13)
(1, 2, 3, 4, 5, 6) {'keyword': 13}
```

Previously this would have been a syntax error. (Contributed by Amaury Forgeot d'Arc; bpo-3473.)

- A new builtin, `next(iterator, [default])` returns the next item from the specified iterator. If the `default` argument is supplied, it will be returned if `iterator` has been exhausted; otherwise, the `StopIteration` exception will be raised. (Backported in bpo-2719.)

- Tuples now have `index()` and `count()` methods matching the list type's `index()` and `count()` methods:

  ```python
  >>> t = (0, 1, 2, 3, 4, 0, 1, 2)
  >>> t.index(3)
  3
  >>> t.count(0)
  2
  ```

  (Contributed by Raymond Hettinger)

- The built-in types now have improved support for extended slicing syntax, accepting various combinations of `(start, stop, step)`. Previously, the support was partial and certain corner
cases wouldn’t work. (Implemented by Thomas Wouters.)

- Properties now have three attributes, getter, setter and deleter, that are decorators providing useful shortcuts for adding a getter, setter or deleter function to an existing property. You would use them like this:

```python
class C(object):
    @property
    def x(self):
        return self._x

    @x.setter
    def x(self, value):
        self._x = value

    @x.deleter
    def x(self):
        del self._x

class D(C):
    @C.x.getter
    def x(self):
        return self._x * 2

    @x.setter
    def x(self, value):
        self._x = value / 2
```

- Several methods of the built-in set types now accept multiple iterables: `intersection()`, `intersection_update()`, `union()`, `update()`, `difference()`, and `difference_update()`.

```python
>>> s=set('1234567890')
```
Many floating-point features were added. The `float()` function will now turn the string `nan` into an IEEE 754 Not A Number value, and `+inf` and `-inf` into positive or negative infinity. This works on any platform with IEEE 754 semantics. (Contributed by Christian Heimes; bpo-1635.)

Other functions in the `math` module, `isinf()` and `isnan()`, return true if their floating-point argument is infinite or Not A Number. (bpo-1640)

Conversion functions were added to convert floating-point numbers into hexadecimal strings (bpo-3008). These functions convert floats to and from a string representation without introducing rounding errors from the conversion between decimal and binary. Floats have a `hex()` method that returns a string representation, and the `float.fromhex()` method converts a string back into a number:
• A numerical nicety: when creating a complex number from two floats on systems that support signed zeros (-0 and +0), the `complex()` constructor will now preserve the sign of the zero. (Fixed by Mark T. Dickinson; bpo-1507.)

• Classes that inherit a `__hash__()` method from a parent class can set `__hash__ = None` to indicate that the class isn’t hashable. This will make `hash(obj)` raise a `TypeError` and the class will not be indicated as implementing the Hashable ABC.

  You should do this when you’ve defined a `__cmp__()` or `__eq__()` method that compares objects by their value rather than by identity. All objects have a default hash method that uses `id(obj)` as the hash value. There’s no tidy way to remove the `__hash__()` method inherited from a parent class, so assigning None was implemented as an override. At the C level, extensions can set `tp_hash` to `PyObject_HashNotImplemented()`. (Fixed by Nick Coghlan and Amaury Forgeot d’Arc; bpo-2235.)

• The `GeneratorExit` exception now subclasses `BaseException` instead of `Exception`. This means that an exception handler that does `except Exception:` will not inadvertently catch `GeneratorExit`. (Contributed by Chad Austin; bpo-1537.)

• Generator objects now have a `gi_code` attribute that refers to the original code object backing the generator. (Contributed by Collin Winter; bpo-1473257.)

• The `compile()` built-in function now accepts keyword arguments as well as positional parameters. (Contributed by
The complex() constructor now accepts strings containing parenthesized complex numbers, meaning that complex(repr(cplx)) will now round-trip values. For example, complex('(3+4j)') now returns the value (3+4j). (bpo-1491866)

The string translate() method now accepts None as the translation table parameter, which is treated as the identity transformation. This makes it easier to carry out operations that only delete characters. (Contributed by Bengt Richter and implemented by Raymond Hettinger; bpo-1193128.)

The built-in dir() function now checks for a __dir__() method on the objects it receives. This method must return a list of strings containing the names of valid attributes for the object, and lets the object control the value that dir() produces. Objects that have __getattr__() or __getattribute__() methods can use this to advertise pseudo-attributes they will honor. (bpo-1591665)

Instance method objects have new attributes for the object and function comprising the method; the new synonym for im_self is __self__, and im_func is also available as __func__. The old names are still supported in Python 2.6, but are gone in 3.0.

An obscure change: when you use the locals() function inside a class statement, the resulting dictionary no longer returns free variables. (Free variables, in this case, are variables referenced in the class statement that aren’t attributes of the class.)

Optimizations
The **warnings** module has been rewritten in C. This makes it possible to invoke warnings from the parser, and may also make the interpreter's startup faster. (Contributed by Neal Norwitz and Brett Cannon; [bpo-1631171](https://bugs.python.org/issue1631171).)

Type objects now have a cache of methods that can reduce the work required to find the correct method implementation for a particular class; once cached, the interpreter doesn't need to traverse base classes to figure out the right method to call. The cache is cleared if a base class or the class itself is modified, so the cache should remain correct even in the face of Python's dynamic nature. (Original optimization implemented by Armin Rigo, updated for Python 2.6 by Kevin Jacobs; [bpo-1700288](https://bugs.python.org/issue1700288).)

By default, this change is only applied to types that are included with the Python core. Extension modules may not necessarily be compatible with this cache, so they must explicitly add `Py_TPFLAGS_HAVE_VERSION_TAG` to the module's `tp_flags` field to enable the method cache. (To be compatible with the method cache, the extension module's code must not directly access and modify the `tp_dict` member of any of the types it implements. Most modules don't do this, but it's impossible for the Python interpreter to determine that. See [bpo-1878](https://bugs.python.org/issue1878) for some discussion.)

Function calls that use keyword arguments are significantly faster by doing a quick pointer comparison, usually saving the time of a full string comparison. (Contributed by Raymond Hettinger, after an initial implementation by Antoine Pitrou; [bpo-1819](https://bugs.python.org/issue1819).)

All of the functions in the **struct** module have been rewritten in C, thanks to work at the Need For Speed sprint. (Contributed by Raymond Hettinger.)
• Some of the standard built-in types now set a bit in their type objects. This speeds up checking whether an object is a subclass of one of these types. (Contributed by Neal Norwitz.)

• Unicode strings now use faster code for detecting whitespace and line breaks; this speeds up the split() method by about 25% and splitlines() by 35%. (Contributed by Antoine Pitrou.) Memory usage is reduced by using pymalloc for the Unicode string’s data.

• The with statement now stores the __exit__() method on the stack, producing a small speedup. (Implemented by Jeffrey Yasskin.)

• To reduce memory usage, the garbage collector will now clear internal free lists when garbage-collecting the highest generation of objects. This may return memory to the operating system sooner.

Interpreter Changes

Two command-line options have been reserved for use by other Python implementations. The -J switch has been reserved for use by Jython for Jython-specific options, such as switches that are passed to the underlying JVM. -X has been reserved for options specific to a particular implementation of Python such as CPython, Jython, or IronPython. If either option is used with Python 2.6, the interpreter will report that the option isn’t currently used.

Python can now be prevented from writing .pyc or .pyo files by supplying the -B switch to the Python interpreter, or by setting the
**PYTHONDONTWRITEBYTECODE** environment variable before running the interpreter. This setting is available to Python programs as the `sys.dont_write_bytecode` variable, and Python code can change the value to modify the interpreter’s behaviour. (Contributed by Neal Norwitz and Georg Brandl.)

The encoding used for standard input, output, and standard error can be specified by setting the **PYTHONIOENCODING** environment variable before running the interpreter. The value should be a string in the form `<encoding>` or `<encoding>:@<errorhandler>`. The `encoding` part specifies the encoding’s name, e.g. `utf-8` or `latin-1`; the optional `errorhandler` part specifies what to do with characters that can’t be handled by the encoding, and should be one of “error”, “ignore”, or “replace”. (Contributed by Martin von Löwis.)
New and Improved Modules

As in every release, Python's standard library received a number of enhancements and bug fixes. Here's a partial list of the most notable changes, sorted alphabetically by module name. Consult the Misc/NEWS file in the source tree for a more complete list of changes, or look through the Subversion logs for all the details.

- The asyncore and asynchat modules are being actively maintained again, and a number of patches and bugfixes were applied. (Maintained by Josiah Carlson; see bpo-1736190 for one patch.)

- The bsddb module also has a new maintainer, Jesús Cea Avión, and the package is now available as a standalone package. The web page for the package is www.jcea.es/programacion/pybsddb.htm. The plan is to remove the package from the standard library in Python 3.0, because its pace of releases is much more frequent than Python's.

  The bsddb.dbshelve module now uses the highest pickling protocol available, instead of restricting itself to protocol 1. (Contributed by W. Barnes.)

- The cgi module will now read variables from the query string of an HTTP POST request. This makes it possible to use form actions with URLs that include query strings such as “/cgi-bin/add.py?category=1”. (Contributed by Alexandre Fiori and Nubis; bpo-1817.)

  The parse_qs() and parse_qsl() functions have been relocated from the cgi module to the urlparse module. The
versions still available in the *cgi* module will trigger `PendingDeprecationWarning` messages in 2.6 (*bpo-600362*).

- The *cmath* module underwent extensive revision, contributed by Mark Dickinson and Christian Heimes. Five new functions were added:
  - `polar()` converts a complex number to polar form, returning the modulus and argument of the complex number.
  - `rect()` does the opposite, turning a modulus, argument pair back into the corresponding complex number.
  - `phase()` returns the argument (also called the angle) of a complex number.
  - `isnan()` returns True if either the real or imaginary part of its argument is a NaN.
  - `isinf()` returns True if either the real or imaginary part of its argument is infinite.

The revisions also improved the numerical soundness of the *cmath* module. For all functions, the real and imaginary parts of the results are accurate to within a few units of least precision (ulps) whenever possible. See *bpo-1381* for the details. The branch cuts for `asinh()`, `atanh()`: and `atan()` have also been corrected.

The tests for the module have been greatly expanded; nearly 2000 new test cases exercise the algebraic functions.

On IEEE 754 platforms, the *cmath* module now handles IEEE 754 special values and floating-point exceptions in a manner consistent with Annex ‘G’ of the C99 standard.

- A new data type in the *collections* module:
namedtuple(typename, fieldnames) is a factory function that creates subclasses of the standard tuple whose fields are accessible by name as well as by index. For example:

```python
>>> var_type = collections.namedtuple('variable', ...
...   'id name type size')
>>> # Names are separated by spaces or commas.
>>> # 'id, name, type, size' would also work.
>>> var_type._fields
('id', 'name', 'type', 'size')

>>> var = var_type(1, 'frequency', 'int', 4)
>>> print var[0], var.id  # Equivalent
1 1
>>> print var[2], var.type # Equivalent
int int
>>> var._asdict()
{'size': 4, 'type': 'int', 'id': 1, 'name': 'frequency'}
>>> v2 = var._replace(name='amplitude')
>>> v2
variable(id=1, name='amplitude', type='int', size=4)
```

Several places in the standard library that returned tuples have been modified to return namedtuple instances. For example, the Decimal.as_tuple() method now returns a named tuple with sign, digits, and exponent fields.

(Contributed by Raymond Hettinger.)

- Another change to the collections module is that the deque type now supports an optional maxlen parameter; if supplied, the deque's size will be restricted to no more than maxlen items. Adding more items to a full deque causes old items to be discarded.
```python
>>> from collections import deque
dq=deque(maxlen=3)
dq
deque([], maxlen=3)
dq.append(1); dq.append(2); dq.append(3)
dq
deque([1, 2, 3], maxlen=3)
dq.append(4)
dq
deque([2, 3, 4], maxlen=3)
```

(Contributed by Raymond Hettinger.)

- The Cookie module’s Morsel objects now support an `httponly` attribute. In some browsers, cookies with this attribute set cannot be accessed or manipulated by JavaScript code. (Contributed by Arvin Schnell; bpo-1638033.)

- A new window method in the `curses` module, `chgat()`, changes the display attributes for a certain number of characters on a single line. (Contributed by Fabian Kreutz.)

```python
# Boldface text starting at y=0, x=21
# and affecting the rest of the line.
stdscr.chgat(0, 21, curses.A_BOLD)
```

The Textbox class in the `curses.textpad` module now supports editing in insert mode as well as overwrite mode. Insert mode is enabled by supplying a true value for the `insert_mode` parameter when creating the Textbox instance.

- The `datetime` module’s `strftime()` methods now support a `%f` format code that expands to the number of microseconds in the object, zero-padded on the left to six places. (Contributed by
The `decimal` module was updated to version 1.66 of the General Decimal Specification. New features include some methods for some basic mathematical functions such as `exp()` and `log10()`:

```python
>>> Decimal(1).exp()
Decimal("2.718281828459045235360287471")
>>> Decimal("2.7182818").ln()
Decimal("0.9999999895305022877376682436")
>>> Decimal(1000).log10()
Decimal("3")
```

The `as_tuple()` method of Decimal objects now returns a named tuple with sign, digits, and exponent fields.

(Implemented by Facundo Batista and Mark Dickinson. Named tuple support added by Raymond Hettinger.)

- The `difflib` module's `SequenceMatcher` class now returns named tuples representing matches, with a, b, and size attributes. (Contributed by Raymond Hettinger.)

- An optional `timeout` parameter, specifying a timeout measured in seconds, was added to the `ftplib.FTP` class constructor as well as the `connect()` method. (Added by Facundo Batista.) Also, the FTP class's `storbinary()` and `storlines()` now take an optional `callback` parameter that will be called with each block of data after the data has been sent. (Contributed by Phil Schwartz; `bpo-1221598`.)

- The `reduce()` built-in function is also available in the
**functools** module. In Python 3.0, the builtin has been dropped and `reduce()` is only available from **functools**; currently there are no plans to drop the builtin in the 2.x series. (Patched by Christian Heimes; bpo-1739906.)

- When possible, the **getpass** module will now use `/dev/tty` to print a prompt message and read the password, falling back to standard error and standard input. If the password may be echoed to the terminal, a warning is printed before the prompt is displayed. (Contributed by Gregory P. Smith.)

- The **glob.glob()** function can now return Unicode filenames if a Unicode path was used and Unicode filenames are matched within the directory. (bpo-1001604)

- A new function in the **heapq** module, `merge(iter1, iter2, ...)`, takes any number of iterables returning data in sorted order, and returns a new generator that returns the contents of all the iterators, also in sorted order. For example:

  ```python
  >>> list(heapq.merge([1, 3, 5, 9], [2, 8, 16]))
  [1, 2, 3, 5, 8, 9, 16]
  ```

  Another new function, `heappushpop(heap, item)`, pushes `item` onto `heap`, then pops off and returns the smallest item. This is more efficient than making a call to `heappush()` and then `heappop()`.

  **heapq** is now implemented to only use less-than comparison, instead of the less-than-or-equal comparison it previously used. This makes **heapq**'s usage of a type match the **list.sort()** method. (Contributed by Raymond Hettinger.)
• An optional *timeout* parameter, specifying a timeout measured in seconds, was added to the `httplib.HTTPConnection` and `HTTPSConnection` class constructors. (Added by Facundo Batista.)

• Most of the *inspect* module’s functions, such as `getmoduleinfo()` and `getargs()`, now return named tuples. In addition to behaving like tuples, the elements of the return value can also be accessed as attributes. (Contributed by Raymond Hettinger.)

Some new functions in the module include `isgenerator()`, `isgeneratorfunction()`, and `isabstract()`.

• The *itertools* module gained several new functions.

  `izip_longest(iter1, iter2, ...[, fillvalue])` makes tuples from each of the elements; if some of the iterables are shorter than others, the missing values are set to `fillvalue`. For example:

  ```python
  >>> tuple(itertools.izip_longest([1,2,3], [1,2,3,4,5], fillvalue=None))
  [(1, 1), (2, 2), (3, 3), (4, 4), (5, None)]
  ```

  `product(iter1, iter2, ...[, repeat=N])` returns the Cartesian product of the supplied iterables, a set of tuples containing every possible combination of the elements returned from each iterable.

  ```python
  >>> list(itertools.product([1,2,3], [4,5,6]))
  [(1, 4), (1, 5), (1, 6),
   (2, 4), (2, 5), (2, 6),
   (3, 4), (3, 5), (3, 6)]
  ```
The optional *repeat* keyword argument is used for taking the product of an iterable or a set of iterables with themselves, repeated $N$ times. With a single iterable argument, $N$-tuples are returned:

```python
>>> list(itertools.product([1,2], repeat=3))
[(1, 1, 1), (1, 1, 2), (1, 2, 1), (1, 2, 2),
 (2, 1, 1), (2, 1, 2), (2, 2, 1), (2, 2, 2)]
```

With two iterables, $2N$-tuples are returned.

```python
>>> list(itertools.product([1,2], [3,4], repeat=2))
[(1, 3, 1, 3), (1, 3, 1, 4), (1, 3, 2, 3), (1, 3,
 (1, 4, 1, 3), (1, 4, 1, 4), (1, 4, 2, 3), (1, 4,
 (2, 3, 1, 3), (2, 3, 1, 4), (2, 3, 2, 3), (2, 3,
 (2, 4, 1, 3), (2, 4, 1, 4), (2, 4, 2, 3), (2, 4,
```

*combinations(iterable, r)* returns sub-sequences of length $r$ from the elements of *iterable*.

```python
>>> list(itertools.combinations('123', 2))
[('1', '2'), ('1', '3'), ('2', '3')]
>>> list(itertools.combinations('123', 3))
[('1', '2', '3')]
>>> list(itertools.combinations('1234', 3))
[('1', '2', '3'), ('1', '2', '4'), ('1', '3', '4'), ('2', '3', '4')]
```

*permutations(iter[, r])* returns all the permutations of length $r$ of the iterable's elements. If $r$ is not specified, it will default to the number of elements produced by the iterable.

```python
>>> list(itertools.permutations([1,2,3,4], 2))
```
**itertools.chain(*iterables)** is an existing function in **itertools** that gained a new constructor in Python 2.6. **itertools.chain.from_iterable(iterable)** takes a single iterable that should return other iterables. chain() will then return all the elements of the first iterable, then all the elements of the second, and so on.

```python
>>> list(itertools.chain.from_iterable([[1,2,3], [1,2,3,4,5,6]]))
```

(All contributed by Raymond Hettinger.)

- The **logging** module's FileHandler class and its subclasses WatchedFileHandler, RotatingFileHandler, and TimedRotatingFileHandler now have an optional delay parameter to their constructors. If delay is true, opening of the log file is deferred until the first emit() call is made. (Contributed by Vinay Sajip.)

  TimedRotatingFileHandler also has a utc constructor parameter. If the argument is true, UTC time will be used in determining when midnight occurs and in generating filenames; otherwise local time will be used.

- Several new functions were added to the **math** module:
  - **isinf()** and **isnan()** determine whether a given float is a (positive or negative) infinity or a NaN (Not a Number),
respectively.
- `copysign()` copies the sign bit of an IEEE 754 number, returning the absolute value of \( x \) combined with the sign bit of \( y \). For example, `math.copysign(1, -0.0)` returns -1.0. (Contributed by Christian Heimes.)
- `factorial()` computes the factorial of a number. (Contributed by Raymond Hettinger; `bpo-2138`.)
- `fsum()` adds up the stream of numbers from an iterable, and is careful to avoid loss of precision through using partial sums. (Contributed by Jean Brouwers, Raymond Hettinger, and Mark Dickinson; `bpo-2819`.)
- `acosh()`, `asinh()` and `atanh()` compute the inverse hyperbolic functions.
- `log1p()` returns the natural logarithm of \( 1+x \) (base \( e \)).
- `trunc()` rounds a number toward zero, returning the closest Integral that's between the function's argument and zero. Added as part of the backport of PEP 3141's type hierarchy for numbers.

- The `math` module has been improved to give more consistent behaviour across platforms, especially with respect to handling of floating-point exceptions and IEEE 754 special values.

Whenever possible, the module follows the recommendations of the C99 standard about 754’s special values. For example, `sqrt(-1.)` should now give a `ValueError` across almost all platforms, while `sqrt(float('NaN'))` should return a NaN on all IEEE 754 platforms. Where Annex ‘F’ of the C99 standard recommends signaling ‘divide-by-zero’ or ‘invalid’, Python will raise `ValueError`. Where Annex ‘F’ of the C99 standard recommends signaling ‘overflow’, Python will raise `OverflowError`. (See `bpo-711019` and `bpo-1640`.)

(Contributed by Christian Heimes and Mark Dickinson.)
• **mmap** objects now have a `rfind()` method that searches for a substring beginning at the end of the string and searching backwards. The `find()` method also gained an `end` parameter giving an index at which to stop searching. (Contributed by John Lenton.)

• The **operator** module gained a `methodcaller()` function that takes a name and an optional set of arguments, returning a callable that will call the named function on any arguments passed to it. For example:

```python
>>> # Equivalent to lambda s: s.replace('old', 'new')
>>> replacer = operator.methodcaller('replace', 'old')
>>> replacer('old wine in old bottles')
'new wine in new bottles'
```

(Contributed by Georg Brandl, after a suggestion by Gregory Petrosyan.)

The `attrgetter()` function now accepts dotted names and performs the corresponding attribute lookups:

```python
>>> inst_name = operator.attrgetter('...__class__.__name__')
>>> inst_name()  
'str'
>>> inst_name(help)
'_Helper'
```

(Contributed by Georg Brandl, after a suggestion by Barry Warsaw.)

• The **os** module now wraps several new system calls.
fchmod(fd, mode) and fchown(fd, uid, gid) change the mode and ownership of an opened file, and lchmod(path, mode) changes the mode of a symlink. (Contributed by Georg Brandl and Christian Heimes.)

chflags() and lchflags() are wrappers for the corresponding system calls (where they're available), changing the flags set on a file. Constants for the flag values are defined in the stat module; some possible values include UF_IMMUTABLE to signal the file may not be changed and UF_APPEND to indicate that data can only be appended to the file. (Contributed by M. Levinson.)

os.closerange(low, high) efficiently closes all file descriptors from low to high, ignoring any errors and not including high itself. This function is now used by the subprocess module to make starting processes faster. (Contributed by Georg Brandl; bpo-1663329.)

- The os.environ object's clear() method will now unset the environment variables using os.unsetenv() in addition to clearing the object's keys. (Contributed by Martin Horcicka; bpo-1181.)

- The os.walk() function now has a followlinks parameter. If set to True, it will follow symlinks pointing to directories and visit the directory's contents. For backward compatibility, the parameter's default value is false. Note that the function can fall into an infinite recursion if there's a symlink that points to a parent directory. (bpo-1273829)

- In the os.path module, the splitext() function has been
changed to not split on leading period characters. This produces better results when operating on Unix’s dot-files. For example, `os.path.splitext('.ipython')` now returns `('.ipython', '')` instead of `('', '.ipython')`. (bpo-1115886)

A new function, `os.path.relpatherlpath(path, start='.'),` returns a relative path from the `start` path, if it’s supplied, or from the current working directory to the destination `path`. (Contributed by Richard Barran; bpo-1339796.)

On Windows, `os.path.expandvars()` will now expand environment variables given in the form “%var%”, and “~user” will be expanded into the user’s home directory path. (Contributed by Josiah Carlson; bpo-957650.)

- The Python debugger provided by the `pdb` module gained a new command: “run” restarts the Python program being debugged and can optionally take new command-line arguments for the program. (Contributed by Rocky Bernstein; bpo-1393667.)

- The `pdb.post_mortem()` function, used to begin debugging a traceback, will now use the traceback returned by `sys.exc_info()` if no traceback is supplied. (Contributed by Facundo Batista; bpo-1106316.)

- The `pickletools` module now has an `optimize()` function that takes a string containing a pickle and removes some unused opcodes, returning a shorter pickle that contains the same data structure. (Contributed by Raymond Hettinger.)

- A `get_data()` function was added to the `pkgutil` module that returns the contents of resource files included with an installed
Python package. For example:

```
>>> import pkgutil
>>> print(pkgutil.get_data('test', 'exception_hierarchy.txt'))
BaseException
   +- SystemExit
   +- KeyboardInterrupt
   +- GeneratorExit
   +- Exception
      +- StopIteration
      +- StandardError
...
```

(Contributed by Paul Moore; bpo-2439.)

- The pyexpat module's Parser objects now allow setting their `buffer_size` attribute to change the size of the buffer used to hold character data. (Contributed by Achim Gaedke; bpo-1137.)

- The Queue module now provides queue variants that retrieve entries in different orders. The `PriorityQueue` class stores queued items in a heap and retrieves them in priority order, and `LifoQueue` retrieves the most recently added entries first, meaning that it behaves like a stack. (Contributed by Raymond Hettinger.)

- The `random` module's Random objects can now be pickled on a 32-bit system and unpickled on a 64-bit system, and vice versa. Unfortunately, this change also means that Python 2.6's Random objects can't be unpickled correctly on earlier versions of Python. (Contributed by Shawn Ligocki; bpo-1727780.)

The new `triangular(low, high, mode)` function returns
random numbers following a triangular distribution. The returned values are between low and high, not including high itself, and with mode as the most frequently occurring value in the distribution. (Contributed by Wladmir van der Laan and Raymond Hettinger; bpo-1681432.)

- Long regular expression searches carried out by the re module will check for signals being delivered, so time-consuming searches can now be interrupted. (Contributed by Josh Hoyt and Ralf Schmitt; bpo-846388.)

The regular expression module is implemented by compiling bytecodes for a tiny regex-specific virtual machine. Untrusted code could create malicious strings of bytecode directly and cause crashes, so Python 2.6 includes a verifier for the regex bytecode. (Contributed by Guido van Rossum from work for Google App Engine; bpo-3487.)

- The rlcompleter module's Completer.complete() method will now ignore exceptions triggered while evaluating a name. (Fixed by Lorenz Quack; bpo-2250.)

- The sched module's scheduler instances now have a read-only queue attribute that returns the contents of the scheduler's queue, represented as a list of named tuples with the fields (time, priority, action, argument). (Contributed by Raymond Hettinger; bpo-1861.)

- The select module now has wrapper functions for the Linux epoll() and BSD kqueue() system calls. modify() method was added to the existing poll objects; pollobj.modify(fd, eventmask) takes a file descriptor or file object and an event
mask, modifying the recorded event mask for that file. (Contributed by Christian Heimes; bpo-1657.)

- The `shutil.copytree()` function now has an optional `ignore` argument that takes a callable object. This callable will receive each directory path and a list of the directory's contents, and returns a list of names that will be ignored, not copied.

  The `shutil` module also provides an `ignore_patterns()` function for use with this new parameter. `ignore_patterns()` takes an arbitrary number of glob-style patterns and returns a callable that will ignore any files and directories that match any of these patterns. The following example copies a directory tree, but skips both `.svn` directories and Emacs backup files, which have names ending with `~`:

  ```
  shutil.copytree('Doc/library', '/tmp/library',
                  ignore=shutil.ignore_patterns('*.~'))
  ```

  (Contributed by Tarek Ziadé; bpo-2663.)

- Integrating signal handling with GUI handling event loops like those used by Tkinter or GTK+ has long been a problem; most software ends up polling, waking up every fraction of a second to check if any GUI events have occurred. The `signal` module can now make this more efficient. Calling `signal.set_wakeup_fd(fd)` sets a file descriptor to be used; when a signal is received, a byte is written to that file descriptor. There's also a C-level function, `PySignal_SetWakeupFd()`, for setting the descriptor.

  Event loops will use this by opening a pipe to create two
descriptors, one for reading and one for writing. The writable descriptor will be passed to set_wakeup_fd(), and the readable descriptor will be added to the list of descriptors monitored by the event loop via select() or poll(). On receiving a signal, a byte will be written and the main event loop will be woken up, avoiding the need to poll.

(Contributed by Adam Olsen; bpo-1583.)

The siginterrupt() function is now available from Python code, and allows changing whether signals can interrupt system calls or not. (Contributed by Ralf Schmitt.)

The setitimer() and getitimer() functions have also been added (where they're available). setitimer() allows setting interval timers that will cause a signal to be delivered to the process after a specified time, measured in wall-clock time, consumed process time, or combined process+system time. (Contributed by Guilherme Polo; bpo-2240.)

- The smtplib module now supports SMTP over SSL thanks to the addition of the SMTP_SSL class. This class supports an interface identical to the existing SMTP class. (Contributed by Monty Taylor.) Both class constructors also have an optional timeout parameter that specifies a timeout for the initial connection attempt, measured in seconds. (Contributed by Facundo Batista.)

An implementation of the LMTP protocol (RFC 2033) was also added to the module. LMTP is used in place of SMTP when transferring e-mail between agents that don't manage a mail queue. (LMTP implemented by Leif Hedstrom; bpo-957003.)
SMTP.starttls() now complies with RFC 3207 and forgets any knowledge obtained from the server not obtained from the TLS negotiation itself. (Patch contributed by Bill Fenner; bpo-829951.)

- The socket module now supports TIPC (http://tipc.sourceforge.net/), a high-performance non-IP-based protocol designed for use in clustered environments. TIPC addresses are 4- or 5-tuples. (Contributed by Alberto Bertogli; bpo-1646.)

A new function, create_connection(), takes an address and connects to it using an optional timeout value, returning the connected socket object. This function also looks up the address's type and connects to it using IPv4 or IPv6 as appropriate. Changing your code to use create_connection() instead of socket(socket.AF_INET, ...) may be all that's required to make your code work with IPv6.

- The base classes in the SocketServer module now support calling a handle_timeout() method after a span of inactivity specified by the server's timeout attribute. (Contributed by Michael Pomraning.) The serve_forever() method now takes an optional poll interval measured in seconds, controlling how often the server will check for a shutdown request. (Contributed by Pedro Werneck and Jeffrey Yasskin; bpo-742598, bpo-1193577.)

- The sqlite3 module, maintained by Gerhard Häring, has been updated from version 2.3.2 in Python 2.5 to version 2.4.1.

- The struct module now supports the C99 _Bool type, using
the format character `'?'`. (Contributed by David Remahl.)

- The Popen objects provided by the `subprocess` module now have `terminate()`, `kill()`, and `send_signal()` methods. On Windows, `send_signal()` only supports the SIGTERM signal, and all these methods are aliases for the Win32 API function `TerminateProcess()`. (Contributed by Christian Heimes.)

- A new variable in the `sys` module, `float_info`, is an object containing information derived from the `float.h` file about the platform's floating-point support. Attributes of this object include `mant_dig` (number of digits in the mantissa), `epsilon` (smallest difference between 1.0 and the next largest value representable), and several others. (Contributed by Christian Heimes; bpo-1534.)

Another new variable, `dont_write_bytecode`, controls whether Python writes any `.pyc` or `.pyo` files on importing a module. If this variable is true, the compiled files are not written. The variable is initially set on start-up by supplying the `-B` switch to the Python interpreter, or by setting the `PYTHONDONTWRITEBYTECODE` environment variable before running the interpreter. Python code can subsequently change the value of this variable to control whether bytecode files are written or not. (Contributed by Neal Norwitz and Georg Brandl.)

Information about the command-line arguments supplied to the Python interpreter is available by reading attributes of a named tuple available as `sys.flags`. For example, the `verbose` attribute is true if Python was executed in verbose mode, `debug` is true in debugging mode, etc. These attributes are all read-only. (Contributed by Christian Heimes.)
A new function, `getsizeof()`, takes a Python object and returns the amount of memory used by the object, measured in bytes. Built-in objects return correct results; third-party extensions may not, but can define a `__sizeof__()` method to return the object's size. (Contributed by Robert Schuppenies; bpo-2898.)

It's now possible to determine the current profiler and tracer functions by calling `sys.getprofile()` and `sys.gettrace()`. (Contributed by Georg Brandl; bpo-1648.)

- The `tarfile` module now supports POSIX.1-2001 (pax) tarfiles in addition to the POSIX.1-1988 (ustar) and GNU tar formats that were already supported. The default format is GNU tar; specify the `format` parameter to open a file using a different format:

```python
tar = tarfile.open("output.tar", "w", format=tarfile.PAX_FORMAT)
```

The new `encoding` and `errors` parameters specify an encoding and an error handling scheme for character conversions. 'strict', 'ignore', and 'replace' are the three standard ways Python can handle errors; 'utf-8' is a special value that replaces bad characters with their UTF-8 representation. (Character conversions occur because the PAX format supports Unicode filenames, defaulting to UTF-8 encoding.)

The `TarFile.add()` method now accepts an `exclude` argument that's a function that can be used to exclude certain filenames from an archive. The function must take a filename and return true if the file should be excluded or false if it should be archived. The function is applied to both the name initially passed
to add() and to the names of files in recursively-added directories.

(All changes contributed by Lars Gustäbel).

- An optional timeout parameter was added to the telnetlib.Telnet class constructor, specifying a timeout measured in seconds. (Added by Facundo Batista.)

- The tempfile.NamedTemporaryFile class usually deletes the temporary file it created when the file is closed. This behaviour can now be changed by passing delete=False to the constructor. (Contributed by Damien Miller; bpo-1537850.)

A new class, SpooledTemporaryFile, behaves like a temporary file but stores its data in memory until a maximum size is exceeded. On reaching that limit, the contents will be written to an on-disk temporary file. (Contributed by Dustin J. Mitchell.)

The NamedTemporaryFile and SpooledTemporaryFile classes both work as context managers, so you can write with tempfile.NamedTemporaryFile() as tmp: .... (Contributed by Alexander Belopolsky; bpo-2021.)

- The test.test_support module gained a number of context managers useful for writing tests. EnvironmentVarGuard() is a context manager that temporarily changes environment variables and automatically restores them to their old values.

Another context manager, TransientResource, can surround calls to resources that may or may not be available; it will catch and ignore a specified list of exceptions. For example, a network test may ignore certain failures when connecting to an external
web site:

```python
with test_support.TransientResource(IOError,
    errno=errno.ETIMEDOUT)
    
f = urllib.urlopen('https://sf.net')
```

Finally, check_warnings() resets the warning module's warning filters and returns an object that will record all warning messages triggered (bpo-3781):

```python
with test_support.check_warnings() as wrec:
    warnings.simplefilter("always")
    # ... code that triggers a warning ...
    assert str(wrec.message) == "function is outdated"
    assert len(wrec.warnings) == 1, "Multiple warnings raised"
```

(Contributed by Brett Cannon.)

- The `textwrap` module can now preserve existing whitespace at the beginnings and ends of the newly-created lines by specifying `drop_whitespace=False` as an argument:

```python
>>> S = """This sentence has a bunch of ... extra whitespace."""
>>> print textwrap.fill(S, width=15)
This sentence has a bunch of extra whitespace.
```

```python
>>> print textwrap.fill(S, drop_whitespace=False)
This sentence has a bunch of extra whitespace.
```
The **threading** module API is being changed to use properties such as daemon instead of setDaemon() and isDaemon() methods, and some methods have been renamed to use underscores instead of camel-case; for example, the activeCount() method is renamed to active_count(). Both the 2.6 and 3.0 versions of the module support the same properties and renamed methods, but don't remove the old methods. No date has been set for the deprecation of the old APIs in Python 3.x; the old APIs won't be removed in any 2.x version. (Carried out by several people, most notably Benjamin Peterson.)

The **threading** module's Thread objects gained an ident property that returns the thread's identifier, a nonzero integer. (Contributed by Gregory P. Smith; bpo-2871.)

- The **timeit** module now accepts callables as well as strings for the statement being timed and for the setup code. Two convenience functions were added for creating Timer instances: `repeat(stmt, setup, time, repeat, number)` and `timeit(stmt, setup, time, number)` create an instance and call the corresponding method. (Contributed by Erik Demaine; bpo-1533909.)

- The Tkinter module now accepts lists and tuples for options, separating the elements by spaces before passing the resulting value to Tcl/Tk. (Contributed by Guilherme Polo; bpo-2906.)
The **turtle** module for turtle graphics was greatly enhanced by Gregor Lingl. New features in the module include:

- Better animation of turtle movement and rotation.
- Control over turtle movement using the new `delay()`, `tracer()`, and `speed()` methods.
- The ability to set new shapes for the turtle, and to define a new coordinate system.
- Turtles now have an `undo()` method that can roll back actions.
- Simple support for reacting to input events such as mouse and keyboard activity, making it possible to write simple games.
- A `turtle.cfg` file can be used to customize the starting appearance of the turtle's screen.
- The module's docstrings can be replaced by new docstrings that have been translated into another language.

(\textit{bpo-1513695})

- An optional `timeout` parameter was added to the `urllib.urlopen()` function and the `urllib.ftpwrapper` class constructor, as well as the `urllib2.urlopen()` function. The parameter specifies a timeout measured in seconds. For example:

```python
>>> u = urllib2.urlopen("http://slow.example.com", timeout=3)
Traceback (most recent call last):
  ... 
urllib2.URLError: <urlopen error timed out>
```

```bash```
```
The Unicode database provided by the unicodedata module has been updated to version 5.1.0. (Updated by Martin von Löwis; bpo-3811.)

The warnings module's formatwarning() and showwarning() gained an optional line argument that can be used to supply the line of source code. (Added as part of bpo-1631171, which re-implemented part of the warnings module in C code.)

A new function, catch_warnings(), is a context manager intended for testing purposes that lets you temporarily modify the warning filters and then restore their original values (bpo-3781).

The XML-RPC SimpleXMLRPCServer and DocXMLRPCServer classes can now be prevented from immediately opening and binding to their socket by passing True as the bind_and_activate constructor parameter. This can be used to modify the instance's allow_reuse_address attribute before calling the server_bind() and server_activate() methods to open the socket and begin listening for connections. (Contributed by Peter Parente; bpo-1599845.)

SimpleXMLRPCServer also has a _send_traceback_header attribute; if true, the exception and formatted traceback are returned as HTTP headers “X-Exception” and “X-Traceback”. This feature is for debugging purposes only and should not be used on production servers because the tracebacks might reveal passwords or other sensitive information. (Contributed by Alan McIntyre as part of his project for Google's
The xmlrpclib module no longer automatically converts \texttt{datetime.date} and \texttt{datetime.time} to the \texttt{xmlrpclib.DateTime} type; the conversion semantics were not necessarily correct for all applications. Code using xmlrpclib should convert date and \texttt{time} instances. (\texttt{bpo-1330538}) The code can also handle dates before 1900 (contributed by Ralf Schmitt; \texttt{bpo-2014}) and 64-bit integers represented by using \texttt{<i8>} in XML-RPC responses (contributed by Riku Lindblad; \texttt{bpo-2985}).

The \texttt{zipfile} module's \texttt{ZipFile} class now has \texttt{extract()} and \texttt{extractall()} methods that will unpack a single file or all the files in the archive to the current directory, or to a specified directory:

```
z = zipfile.ZipFile('python-251.zip')

# Unpack a single file, writing it relative
# to the /tmp directory.
z.extract('Python/sysmodule.c', '/tmp')

# Unpack all the files in the archive.
z.extractall()
```

(Contributed by Alan McIntyre; \texttt{bpo-467924}.)

The \texttt{open()}, \texttt{read()} and \texttt{extract()} methods can now take either a filename or a \texttt{ZipInfo} object. This is useful when an archive accidentally contains a duplicated filename. (Contributed by Graham Horler; \texttt{bpo-1775025}.)
Finally, `zipfile` now supports using Unicode filenames for archived files. (Contributed by Alexey Borzenkov; bpo-1734346.)

The **ast** module

The **ast** module provides an Abstract Syntax Tree representation of Python code, and Armin Ronacher contributed a set of helper functions that perform a variety of common tasks. These will be useful for HTML templating packages, code analyzers, and similar tools that process Python code.

The `parse()` function takes an expression and returns an AST. The `dump()` function outputs a representation of a tree, suitable for debugging:

```python
import ast

t = ast.parse('"

  d = {}

  for i in 'abcdefghijklm':
      d[i+i] = ord(i) - ord('a') + 1

print d
  ""

print ast.dump(t)
```

This outputs a deeply nested tree:

```plaintext
Module(body=[
    Assign(targets=[
        Name(id='d', ctx=Store())
    ], value=Dict(keys=[], values=[]))
    For(target=Name(id='i', ctx=Store()),
        iter=Str(s='abcdefghijklm'), body=[
            Assign(targets=[
```
Subscript(value=
    Name(id='d', ctx=Load()),
    slice=
    Index(value=
        BinOp(left=Name(id='i', ctx=Load()), op=
            right=Name(id='i', ctx=Load()))), ctx=Store),
value=
    BinOp(left=
        BinOp(left=
            Call(func=
                Name(id='ord', ctx=Load()), args=[
                    Name(id='i', ctx=Load())
                ], keywords=[], starargs=None, kwargs=None)
            op=Sub(), right=Call(func=
                Name(id='ord', ctx=Load()), args=[
                    Str(s='a')
                ], keywords=[], starargs=None, kwargs=None)
        ),
    ),
    orelse=[])
Print(dest=None, values=[
    Name(id='d', ctx=Load())
], n1=True)
]

The literal_eval() method takes a string or an AST representing a literal expression, parses and evaluates it, and returns the resulting value. A literal expression is a Python expression containing only strings, numbers, dictionaries, etc. but no statements or function calls. If you need to evaluate an expression but cannot accept the security risk of using an eval() call, literal_eval() will handle it safely:

```python
>>> literal = 'a', 'b', {2: 4, 3: 8, 1: 2})
>>> print ast.literal_eval(literal)
('a', 'b', {1: 2, 2: 4, 3: 8})
>>> print ast.literal_eval("a + b")
```
Traceback (most recent call last):
...
ValueError: malformed string

The module also includes NodeVisitor and NodeTransformer classes for traversing and modifying an AST, and functions for common transformations such as changing line numbers.

The future_builtins module

Python 3.0 makes many changes to the repertoire of built-in functions, and most of the changes can’t be introduced in the Python 2.x series because they would break compatibility. The future_builtins module provides versions of these built-in functions that can be imported when writing 3.0-compatible code.

The functions in this module currently include:

- `ascii(obj)`: equivalent to `repr()`. In Python 3.0, `repr()` will return a Unicode string, while `ascii()` will return a pure ASCII bytestring.
- `filter(predicate, iterable), map(func, iterable1, ...)`: the 3.0 versions return iterators, unlike the 2.x builtins which return lists.
- `hex(value), oct(value)`: instead of calling the `__hex__()` or `__oct__()` methods, these versions will call the `__index__()` method and convert the result to hexadecimal or octal. `oct()` will use the new 0o notation for its result.

The json module: JavaScript Object Notation

The new `json` module supports the encoding and decoding of Python
types in JSON (Javascript Object Notation). JSON is a lightweight interchange format often used in web applications. For more information about JSON, see http://www.json.org.

json comes with support for decoding and encoding most built-in Python types. The following example encodes and decodes a dictionary:

```
>>> import json
>>> data = {"spam": "foo", "parrot": 42}
>>> in_json = json.dumps(data) # Encode the data
>>> in_json
'{"parrot": 42, "spam": "foo"}"
>>> json.loads(in_json) # Decode into a Python object
{"spam": "foo", "parrot": 42}
```

It’s also possible to write your own decoders and encoders to support more types. Pretty-printing of the JSON strings is also supported.

json (originally called simplejson) was written by Bob Ippolito.

The **plistlib** module: A Property-List Parser

The .plist format is commonly used on Mac OS X to store basic data types (numbers, strings, lists, and dictionaries) by serializing them into an XML-based format. It resembles the XML-RPC serialization of data types.

Despite being primarily used on Mac OS X, the format has nothing Mac-specific about it and the Python implementation works on any platform that Python supports, so the plistlib module has been promoted to the standard library.
Using the module is simple:

```python
import sys
import plistlib
import datetime

# Create data structure
data_struct = dict(lastAccessed=datetime.datetime.now()
                   version=1,
                   categories=('Personal','Shared',)

# Create string containing XML.
plist_str = plistlib.writePlistToString(data_struct)
new_struct = plistlib.readPlistFromString(plist_str)
print data_struct
print new_struct

# Write data structure to a file and read it back.
plistlib.writePlist(data_struct, '/tmp/customizations.plist')
new_struct = plistlib.readPlist('/tmp/customizations.plist')

# read/writePlist accepts file-like objects as well
plistlib.writePlist(data_struct, sys.stdout)
```

ctypes Enhancements

Thomas Heller continued to maintain and enhance the `ctypes` module.

`ctypes` now supports a `c_bool` datatype that represents the C99 `bool` type. (Contributed by David Remahl; [bpo-1649190](https://bugs.python.org/issue1649190).)

The `ctypes` string, buffer and array types have improved support for extended slicing syntax, where various combinations of `(start,
stop, step) are supplied. (Implemented by Thomas Wouters.)

All ctypes data types now support from_buffer() and from_buffer_copy() methods that create a ctypes instance based on a provided buffer object. from_buffer_copy() copies the contents of the object, while from_buffer() will share the same memory area.

A new calling convention tells ctypes to clear the errno or Win32 LastError variables at the outset of each wrapped call. (Implemented by Thomas Heller; bpo-1798.)

You can now retrieve the Unix errno variable after a function call. When creating a wrapped function, you can supply use_errno=True as a keyword parameter to the DLL() function and then call the module-level methods set_errno() and get_errno() to set and retrieve the error value.

The Win32 LastError variable is similarly supported by the DLL(), OleDLL(), and WinDLL() functions. You supply use_last_error=True as a keyword parameter and then call the module-level methods set_last_error() and get_last_error().

The byref() function, used to retrieve a pointer to a ctypes instance, now has an optional offset parameter that is a byte count that will be added to the returned pointer.

**Improved SSL Support**

Bill Janssen made extensive improvements to Python 2.6’s support for the Secure Sockets Layer by adding a new module, ssl, that’s built
atop the OpenSSL library. This new module provides more control over the protocol negotiated, the X.509 certificates used, and has better support for writing SSL servers (as opposed to clients) in Python. The existing SSL support in the socket module hasn't been removed and continues to work, though it will be removed in Python 3.0.

To use the new module, you must first create a TCP connection in the usual way and then pass it to the ssl.wrap_socket() function. It's possible to specify whether a certificate is required, and to obtain certificate info by calling the getpeercert() method.

See also: The documentation for the ssl module.
Deprecations and Removals

- String exceptions have been removed. Attempting to use them raises a `TypeError`.

- Changes to the `Exception` interface as dictated by PEP 352 continue to be made. For 2.6, the message attribute is being deprecated in favor of the `args` attribute.

- (3.0-warning mode) Python 3.0 will feature a reorganized standard library that will drop many outdated modules and rename others. Python 2.6 running in 3.0-warning mode will warn about these modules when they are imported.

The list of deprecated modules is: audiodev, bgenlocations, buildtools, bundlebuilder, Canvas, compiler, dircache, dl, fpformat, gensuitemodule, ihooks, imageop, imgfile, linuxaudiodev, mhlib, mimetools, multifile, new, pure, statvfs, sunaudiodev, test.testall, and toaiff.

- The gopherlib module has been removed.

- The MimeWriter module and mimify module have been deprecated; use the `email` package instead.

- The md5 module has been deprecated; use the `hashlib` module instead.

- The posixfile module has been deprecated; `fcntl.lockf()` provides better locking.
- The popen2 module has been deprecated; use the subprocess module.

- The rgbimg module has been removed.

- The sets module has been deprecated; it’s better to use the built-in set and frozenset types.

- The sha module has been deprecated; use the hashlib module instead.
Build and C API Changes

Changes to Python’s build process and to the C API include:

- Python now must be compiled with C89 compilers (after 19 years!). This means that the Python source tree has dropped its own implementations of `memmove()` and `strerror()`, which are in the C89 standard library.

- Python 2.6 can be built with Microsoft Visual Studio 2008 (version 9.0), and this is the new default compiler. See the `PCbuild` directory for the build files. (Implemented by Christian Heimes.)

- On Mac OS X, Python 2.6 can be compiled as a 4-way universal build. The `configure` script can take a `--with-universal-archs=[32-bit|64-bit|all]` switch, controlling whether the binaries are built for 32-bit architectures (x86, PowerPC), 64-bit (x86-64 and PPC-64), or both. (Contributed by Ronald Oussoren.)

- The BerkeleyDB module now has a C API object, available as `bsddb.db.api`. This object can be used by other C extensions that wish to use the bsddb module for their own purposes. (Contributed by Duncan Grisby.)

- The new buffer interface, previously described in the PEP 3118 section, adds `PyObject_GetBuffer()` and `PyBuffer_Release()`, as well as a few other functions.

- Python’s use of the C stdio library is now thread-safe, or at least as thread-safe as the underlying library is. A long-standing potential bug occurred if one thread closed a file object while another thread was reading from or writing to the object. In 2.6 file
objects have a reference count, manipulated by the `PyFile_IncUseCount()` and `PyFile_DecUseCount()` functions. File objects can’t be closed unless the reference count is zero. `PyFile_IncUseCount()` should be called while the GIL is still held, before carrying out an I/O operation using the `FILE` pointer, and `PyFile_DecUseCount()` should be called immediately after the GIL is re-acquired. (Contributed by Antoine Pitrou and Gregory P. Smith.)

- Importing modules simultaneously in two different threads no longer deadlocks; it will now raise an `ImportError`. A new API function, `PyImport_ImportModuleNoBlock()`, will look for a module in `sys.modules` first, then try to import it after acquiring an import lock. If the import lock is held by another thread, an `ImportError` is raised. (Contributed by Christian Heimes.)

- Several functions return information about the platform’s floating-point support. `PyFloat_GetMax()` returns the maximum representable floating point value, and `PyFloat_GetMin()` returns the minimum positive value. `PyFloat_GetInfo()` returns an object containing more information from the `float.h` file, such as "mant_dig" (number of digits in the mantissa), "epsilon" (smallest difference between 1.0 and the next largest value representable), and several others. (Contributed by Christian Heimes; bpo-1534.)

- C functions and methods that use `PyComplex_AsCComplex()` will now accept arguments that have a `__complex__()` method. In particular, the functions in the `cmath` module will now accept objects with this method. This is a backport of a Python 3.0 change. (Contributed by Mark Dickinson; bpo-1675423.)
Python’s C API now includes two functions for case-insensitive string comparisons, `PyOS_stricmp(char*, char*)` and `PyOS_strnicmp(char*, char*, Py_ssize_t)`. (Contributed by Christian Heimes; bpo-1635.)

Many C extensions define their own little macro for adding integers and strings to the module’s dictionary in the `init*` function. Python 2.6 finally defines standard macros for adding values to a module, `PyModule_AddStringMacro` and `PyModule_AddIntMacro()`. (Contributed by Christian Heimes.)

Some macros were renamed in both 3.0 and 2.6 to make it clearer that they are macros, not functions. `Py_Size()` became `Py_SIZE()`, `Py_Type()` became `Py_TYPE()`, and `Py_Refcnt()` became `Py_REFCNT()`. The mixed-case macros are still available in Python 2.6 for backward compatibility. (bpo-1629)

Distutils now places C extensions it builds in a different directory when running on a debug version of Python. (Contributed by Collin Winter; bpo-1530959.)

Several basic data types, such as integers and strings, maintain internal free lists of objects that can be re-used. The data structures for these free lists now follow a naming convention: the variable is always named `free_list`, the counter is always named `numfree`, and a macro `Py<typename>_MAXFREELIST` is always defined.

A new Makefile target, “make patchcheck”, prepares the Python source tree for making a patch: it fixes trailing whitespace in all modified `.py` files, checks whether the documentation has been
changed, and reports whether the Misc/ACKS and Misc/NEWS files have been updated. (Contributed by Brett Cannon.)

Another new target, “make profile-opt”, compiles a Python binary using GCC’s profile-guided optimization. It compiles Python with profiling enabled, runs the test suite to obtain a set of profiling results, and then compiles using these results for optimization. (Contributed by Gregory P. Smith.)

Port-Specific Changes: Windows

- The support for Windows 95, 98, ME and NT4 has been dropped. Python 2.6 requires at least Windows 2000 SP4.

- The new default compiler on Windows is Visual Studio 2008 (version 9.0). The build directories for Visual Studio 2003 (version 7.1) and 2005 (version 8.0) were moved into the PC/ directory. The new PCbuild directory supports cross compilation for X64, debug builds and Profile Guided Optimization (PGO). PGO builds are roughly 10% faster than normal builds. (Contributed by Christian Heimes with help from Amaury Forgeot d’Arc and Martin von Löwis.)

- The msvcrt module now supports both the normal and wide char variants of the console I/O API. The getwch() function reads a keypress and returns a Unicode value, as does the getwche() function. The putwch() function takes a Unicode character and writes it to the console. (Contributed by Christian Heimes.)

- os.path.expandvars() will now expand environment variables in the form “%var%”, and “~user” will be expanded into the user’s home directory path. (Contributed by Josiah Carlson;
The `socket` module's socket objects now have an `ioctl()` method that provides a limited interface to the `WSAIoctl()` system interface.

The `_winreg` module now has a function, `ExpandEnvironmentStrings()`, that expands environment variable references such as `%NAME%` in an input string. The handle objects provided by this module now support the context protocol, so they can be used in `with` statements. (Contributed by Christian Heimes.)

 `_winreg` also has better support for x64 systems, exposing the `DisableReflectionKey()`, `EnableReflectionKey()`, and `QueryReflectionKey()` functions, which enable and disable registry reflection for 32-bit processes running on 64-bit systems. (bpo-1753245)

The `msilib` module's Record object gained `GetInteger()` and `GetString()` methods that return field values as an integer or a string. (Contributed by Floris Bruynooghe; bpo-2125.)

Port-Specific Changes: Mac OS X

When compiling a framework build of Python, you can now specify the framework name to be used by providing the `--with-framework-name=` option to the `configure` script.

The `macfs` module has been removed. This in turn required the `macostools.touched()` function to be removed because it depended on the `macfs` module. (bpo-1490190)

Many other Mac OS modules have been deprecated and will be
removed in Python 3.0: _builtinSuites, aepack, aetools, aetypes, applesingle, appletrawmain, appletrunner, argvemulator, Audio_mac, autoGIL, Carbon, cfmfile, CodeWarrior, ColorPicker, EasyDialogs, Explorer, Finder, FrameWork, findertools, ic, icglue, icopen, macerrors, MacOS, macfs, macostools, macresource, MiniAEFrame, Nav, Netscape, OSATerminology, pimp, PixMapWrapper, StdSuites, SystemEvents, Terminal, and terminalcommand.

Port-Specific Changes: IRIX

A number of old IRIX-specific modules were deprecated and will be removed in Python 3.0: a1 and AL, cd, cddb, cdplayer, CL and cl, DEVICE, ERRNO, FILE, FL and fl, flp, fm, GET, GLWS, GL and gl, IN, IOCTL, jpeg, panelparser, readcd, SV and sv, torgb, videoreader, and WAIT.
Porting to Python 2.6

This section lists previously described changes and other bugfixes that may require changes to your code:

- Classes that aren’t supposed to be hashable should set `__hash__ = None` in their definitions to indicate the fact.

- String exceptions have been removed. Attempting to use them raises a `TypeError`.

- The `__init__()` method of `collections.deque` now clears any existing contents of the deque before adding elements from the iterable. This change makes the behavior match `list.__init__()`. 

- `object.__init__()` previously accepted arbitrary arguments and keyword arguments, ignoring them. In Python 2.6, this is no longer allowed and will result in a `TypeError`. This will affect `__init__()` methods that end up calling the corresponding method on `object` (perhaps through using `super()`). See `bpo-1683368` for discussion.

- The Decimal constructor now accepts leading and trailing whitespace when passed a string. Previously it would raise an `InvalidOperation` exception. On the other hand, the `create_decimal()` method of `Context` objects now explicitly disallows extra whitespace, raising a `ConversionSyntax` exception.

- Due to an implementation accident, if you passed a file path to the built-in `__import__()` function, it would actually import the
specified file. This was never intended to work, however, and the implementation now explicitly checks for this case and raises an \texttt{ImportError}.

- C API: the \texttt{PyImport_Import() \ and} \texttt{PyImport_ImportModule()} functions now default to absolute imports, not relative imports. This will affect C extensions that import other modules.

- C API: extension data types that shouldn't be hashable should define their \texttt{tp_hash} slot to \texttt{PyObject_HashNotImplemented()}.

- The \texttt{socket} module exception \texttt{socket.error} now inherits from \texttt{IOError}. Previously it wasn't a subclass of \texttt{StandardError} but now it is, through \texttt{IOError}. (Implemented by Gregory P. Smith; \texttt{bpo-1706815}.)

- The \texttt{xmlrpclib} module no longer automatically converts \texttt{datetime.date} and \texttt{datetime.time} to the \texttt{xmlrpclib.DateTime} type; the conversion semantics were not necessarily correct for all applications. Code using \texttt{xmlrpclib} should convert date and \texttt{time} instances. (\texttt{bpo-1330538})

- (3.0-warning mode) The \texttt{Exception} class now warns when accessed using slicing or index access; having \texttt{Exception} behave like a tuple is being phased out.

- (3.0-warning mode) Inequality comparisons between two dictionaries or two objects that don't implement comparison methods are reported as warnings. \texttt{dict1 == dict2} still works, but \texttt{dict1 < dict2} is being phased out.
Comparisons between cells, which are an implementation detail of Python’s scoping rules, also cause warnings because such comparisons are forbidden entirely in 3.0.

What’s New in Python 2.5

Author: A.M. Kuchling

This article explains the new features in Python 2.5. The final release of Python 2.5 is scheduled for August 2006; PEP 356 describes the planned release schedule.

The changes in Python 2.5 are an interesting mix of language and library improvements. The library enhancements will be more important to Python’s user community, I think, because several widely-useful packages were added. New modules include ElementTree for XML processing (xml.etree), the SQLite database module (sqlite), and the ctypes module for calling C functions.

The language changes are of middling significance. Some pleasant new features were added, but most of them aren’t features that you'll use every day. Conditional expressions were finally added to the language using a novel syntax; see section PEP 308: Conditional Expressions. The new ‘with’ statement will make writing cleanup code easier (section PEP 343: The ‘with’ statement). Values can now be passed into generators (section PEP 342: New Generator Features). Imports are now visible as either absolute or relative (section PEP 328: Absolute and Relative Imports). Some corner cases of exception handling are handled better (section PEP 341: Unified try/except/finally). All these improvements are worthwhile, but they’re improvements to one specific language feature or another; none of them are broad modifications to Python’s semantics.

As well as the language and library additions, other improvements and bugfixes were made throughout the source tree. A search through the
SVN change logs finds there were 353 patches applied and 458 bugs fixed between Python 2.4 and 2.5. (Both figures are likely to be underestimates.)

This article doesn’t try to be a complete specification of the new features; instead changes are briefly introduced using helpful examples. For full details, you should always refer to the documentation for Python 2.5 at https://docs.python.org. If you want to understand the complete implementation and design rationale, refer to the PEP for a particular new feature.

Comments, suggestions, and error reports for this document are welcome; please e-mail them to the author or open a bug in the Python bug tracker.
PEP 308: Conditional Expressions

For a long time, people have been requesting a way to write conditional expressions, which are expressions that return value A or value B depending on whether a Boolean value is true or false. A conditional expression lets you write a single assignment statement that has the same effect as the following:

```python
if condition:
    x = true_value
else:
    x = false_value
```

There have been endless tedious discussions of syntax on both python-dev and comp.lang.python. A vote was even held that found the majority of voters wanted conditional expressions in some form, but there was no syntax that was preferred by a clear majority. Candidates included C's `cond ? true_v : false_v`, `if cond then true_v else false_v`, and 16 other variations.

Guido van Rossum eventually chose a surprising syntax:

```python
x = true_value if condition else false_value
```

Evaluation is still lazy as in existing Boolean expressions, so the order of evaluation jumps around a bit. The `condition` expression in the middle is evaluated first, and the `true_value` expression is evaluated only if the condition was true. Similarly, the `false_value` expression is only evaluated when the condition is false.

This syntax may seem strange and backwards; why does the condition go in the middle of the expression, and not in the front as in C's `c ? x`
The decision was checked by applying the new syntax to the modules in the standard library and seeing how the resulting code read. In many cases where a conditional expression is used, one value seems to be the ‘common case’ and one value is an ‘exceptional case’, used only on rarer occasions when the condition isn’t met. The conditional syntax makes this pattern a bit more obvious:

```python
contents = ((doc + '\n') if doc else '')
```

I read the above statement as meaning “here contents is usually assigned a value of doc+'\n'; sometimes doc is empty, in which special case an empty string is returned.” I doubt I will use conditional expressions very often where there isn’t a clear common and uncommon case.

There was some discussion of whether the language should require surrounding conditional expressions with parentheses. The decision was made to not require parentheses in the Python language’s grammar, but as a matter of style I think you should always use them. Consider these two statements:

```python
# First version -- no parens
level = 1 if logging else 0

# Second version -- with parens
level = (1 if logging else 0)
```

In the first version, I think a reader’s eye might group the statement into ‘level = 1’, ‘if logging’, ‘else 0’, and think that the condition decides whether the assignment to level is performed. The second version reads better, in my opinion, because it makes it clear that the assignment is always performed and the choice is being made between two values.
Another reason for including the brackets: a few odd combinations of list comprehensions and lambdas could look like incorrect conditional expressions. See PEP 308 for some examples. If you put parentheses around your conditional expressions, you won’t run into this case.

PEP 308 - Conditional Expressions
PEP written by Guido van Rossum and Raymond D. Hettinger; implemented by Thomas Wouters.
PEP 309: Partial Function Application

The `functools` module is intended to contain tools for functional-style programming.

One useful tool in this module is the `partial()` function. For programs written in a functional style, you'll sometimes want to construct variants of existing functions that have some of the parameters filled in. Consider a Python function `f(a, b, c);` you could create a new function `g(b, c)` that was equivalent to `f(1, b, c)`. This is called “partial function application”.

`partial()` takes the arguments `(function, arg1, arg2, ... kwarg1=value1, kwarg2=value2).` The resulting object is callable, so you can just call it to invoke `function` with the filled-in arguments.

Here's a small but realistic example:

```python
import functools

def log (message, subsystem):
    "Write the contents of 'message' to the specified subsystem.
    print '%s: %s' % (subsystem, message)
    ...

server_log = functools.partial(log, subsystem='server')
server_log('Unable to open socket')
```

Here's another example, from a program that uses PyGTK. Here a context-sensitive pop-up menu is being constructed dynamically. The callback provided for the menu option is a partially applied version of
the open_item() method, where the first argument has been provided.

```python
... class Application:
    def open_item(self, path):
        ...
    def init(self):
        open_func = functools.partial(self.open_item,
                                       popup_menu.append(("Open", open_func, 1))
```  

Another function in the `functools` module is the `update_wrapper(wrapper, wrapped)` function that helps you write well-behaved decorators. `update_wrapper()` copies the name, module, and docstring attribute to a wrapper function so that tracebacks inside the wrapped function are easier to understand. For example, you might write:

```python
def my_decorator(f):
    def wrapper(*args, **kwds):
        print 'Calling decorated function'
        return f(*args, **kwds)
    functools.update_wrapper(wrapper, f)
    return wrapper
```

wraps() is a decorator that can be used inside your own decorators to copy the wrapped function's information. An alternate version of the previous example would be:

```python
def my_decorator(f):
    @functools.wraps(f)
    def wrapper(*args, **kwds):
        print 'Calling decorated function'
        return f(*args, **kwds)
```
See also:

**PEP 309 - Partial Function Application**

PEP proposed and written by Peter Harris; implemented by Hye-Shik Chang and Nick Coghlan, with adaptations by Raymond Hettinger.
PEP 314: Metadata for Python Software Packages v1.1

Some simple dependency support was added to Distutils. The setup() function now has requires, provides, and obsoletes keyword parameters. When you build a source distribution using the sdist command, the dependency information will be recorded in the PKG-INFO file.

Another new keyword parameter is download_url, which should be set to a URL for the package's source code. This means it's now possible to look up an entry in the package index, determine the dependencies for a package, and download the required packages.

```python
VERSION = '1.0'
ssetup(name='PyPackage',
   version=VERSION,
   requires=['numarray', 'zlib (>=1.1.4)'],
   obsoletes=['OldPackage']
   download_url=('http://www.example.com/pypackage
% VERSION'),
)
```

Another new enhancement to the Python package index at https://pypi.python.org is storing source and binary archives for a package. The new upload Distutils command will upload a package to the repository.

Before a package can be uploaded, you must be able to build a distribution using the sdist Distutils command. Once that works, you can run python setup.py upload to add your package to the
PyPI archive. Optionally you can GPG-sign the package by supplying the --sign and --identity options.

Package uploading was implemented by Martin von Löwis and Richard Jones.

See also:

**PEP 314 - Metadata for Python Software Packages v1.1**
PEP proposed and written by A.M. Kuchling, Richard Jones, and Fred Drake; implemented by Richard Jones and Fred Drake.
PEP 328: Absolute and Relative Imports

The simpler part of PEP 328 was implemented in Python 2.4: parentheses could now be used to enclose the names imported from a module using the `from ... import ...` statement, making it easier to import many different names.

The more complicated part has been implemented in Python 2.5: importing a module can be specified to use absolute or package-relative imports. The plan is to move toward making absolute imports the default in future versions of Python.

Let's say you have a package directory like this:

```
pkg/
pkg/__init__.py
pkg/main.py
pkg/string.py
```

This defines a package named `pkg` containing the `pkg.main` and `pkg.string` submodules.

Consider the code in the `main.py` module. What happens if it executes the statement `import string`? In Python 2.4 and earlier, it will first look in the package's directory to perform a relative import, finds `pkg/string.py`, imports the contents of that file as the `pkg.string` module, and that module is bound to the name `string` in the `pkg.main` module's namespace.

That's fine if `pkg.string` was what you wanted. But what if you wanted Python's standard `string` module? There's no clean way to ignore `pkg.string` and look for the standard module; generally you
had to look at the contents of sys.modules, which is slightly unclean. Holger Krekel's py.std package provides a tidier way to perform imports from the standard library, import py; py.std.string.join(), but that package isn't available on all Python installations.

Reading code which relies on relative imports is also less clear, because a reader may be confused about which module, string or pkg.string, is intended to be used. Python users soon learned not to duplicate the names of standard library modules in the names of their packages' submodules, but you can't protect against having your submodule's name being used for a new module added in a future version of Python.

In Python 2.5, you can switch import's behaviour to absolute imports using a from __future__ import absolute_import directive. This absolute-import behaviour will become the default in a future version (probably Python 2.7). Once absolute imports are the default, import string will always find the standard library's version. It's suggested that users should begin using absolute imports as much as possible, so it's preferable to begin writing from pkg import string in your code.

Relative imports are still possible by adding a leading period to the module name when using the from ... import form:

```python
# Import names from pkg.string
from .string import name1, name2
# Import pkg.string
from . import string
```

This imports the string module relative to the current package, so in
pkg.main this will import name1 and name2 from pkg.string. Additional leading periods perform the relative import starting from the parent of the current package. For example, code in the A.B.C module can do:

```
from .. import D     # Imports A.B.D
from .. import E     # Imports A.E
from ..F import G    # Imports A.F.G
```

Leading periods cannot be used with the import modname form of the import statement, only the from ... import form.

**PEP 328 - Imports: Multi-Line and Absolute/Relative**

PEP written by Aahz; implemented by Thomas Wouters.

[https://pylib.readthedocs.org/](https://pylib.readthedocs.org/)

The py library by Holger Krekel, which contains the py.std package.
PEP 338: Executing Modules as Scripts

The `-m` switch added in Python 2.4 to execute a module as a script gained a few more abilities. Instead of being implemented in C code inside the Python interpreter, the switch now uses an implementation in a new module, `runpy`.

The `runpy` module implements a more sophisticated import mechanism so that it's now possible to run modules in a package such as `pychecker.checker`. The module also supports alternative import mechanisms such as the `zipimport` module. This means you can add a .zip archive's path to `sys.path` and then use the `-m` switch to execute code from the archive.

**PEP 338 - Executing modules as scripts**

PEP written and implemented by Nick Coghlan.
PEP 341: Unified try/except/finally

Until Python 2.5, the try statement came in two flavours. You could use a finally block to ensure that code is always executed, or one or more except blocks to catch specific exceptions. You couldn’t combine both except blocks and a finally block, because generating the right bytecode for the combined version was complicated and it wasn’t clear what the semantics of the combined statement should be.

Guido van Rossum spent some time working with Java, which does support the equivalent of combining except blocks and a finally block, and this clarified what the statement should mean. In Python 2.5, you can now write:

```
try:
    block-1 ...
except Exception1:
    handler-1 ...
except Exception2:
    handler-2 ...
else:
    else-block
finally:
    final-block
```

The code in block-1 is executed. If the code raises an exception, the various except blocks are tested: if the exception is of class Exception1, handler-1 is executed; otherwise if it’s of class Exception2, handler-2 is executed, and so forth. If no exception is raised, the else-block is executed.
No matter what happened previously, the *final-block* is executed once the code block is complete and any raised exceptions handled. Even if there’s an error in an exception handler or the *else-block* and a new exception is raised, the code in the *final-block* is still run.

**PEP 341 - Unifying try-except and try-finally**

PEP written by Georg Brandl; implementation by Thomas Lee.
PEP 342: New Generator Features

Python 2.5 adds a simple way to pass values into a generator. As introduced in Python 2.3, generators only produce output; once a generator's code was invoked to create an iterator, there was no way to pass any new information into the function when its execution is resumed. Sometimes the ability to pass in some information would be useful. Hackish solutions to this include making the generator’s code look at a global variable and then changing the global variable’s value, or passing in some mutable object that callers then modify.

To refresh your memory of basic generators, here’s a simple example:

```python
def counter (maximum):
    i = 0
    while i < maximum:
        yield i
        i += 1
```

When you call `counter(10)`, the result is an iterator that returns the values from 0 up to 9. On encountering the `yield` statement, the iterator returns the provided value and suspends the function's execution, preserving the local variables. Execution resumes on the following call to the iterator's `next()` method, picking up after the `yield` statement.

In Python 2.3, `yield` was a statement; it didn’t return any value. In 2.5, `yield` is now an expression, returning a value that can be assigned to a variable or otherwise operated on:

```python
val = (yield i)
```
I recommend that you always put parentheses around a `yield` expression when you’re doing something with the returned value, as in the above example. The parentheses aren’t always necessary, but it’s easier to always add them instead of having to remember when they’re needed.

(PEP 342 explains the exact rules, which are that a `yield`-expression must always be parenthesized except when it occurs at the top-level expression on the right-hand side of an assignment. This means you can write `val = yield i` but have to use parentheses when there’s an operation, as in `val = (yield i) + 12.`)

Values are sent into a generator by calling its `send(value)` method. The generator’s code is then resumed and the `yield` expression returns the specified `value`. If the regular `next()` method is called, the `yield` returns `None`.

Here’s the previous example, modified to allow changing the value of the internal counter.

```python
def counter(maximum):
    i = 0
    while i < maximum:
        val = (yield i)
        # If value provided, change counter
        if val is not None:
            i = val
        else:
            i += 1
```

And here’s an example of changing the counter:

```python
>>> it = counter(10)
>>> print it.next()
```
yield will usually return None, so you should always check for this case. Don’t just use its value in expressions unless you’re sure that the send() method will be the only method used to resume your generator function.

In addition to send(), there are two other new methods on generators:

- **throw(type, value=None, traceback=None)** is used to raise an exception inside the generator; the exception is raised by the yield expression where the generator’s execution is paused.

- close() raises a new GeneratorExit exception inside the generator to terminate the iteration. On receiving this exception, the generator’s code must either raise GeneratorExit or StopIteration. Catching the GeneratorExit exception and returning a value is illegal and will trigger a RuntimeError; if the function raises some other exception, that exception is propagated to the caller. close() will also be called by Python’s garbage collector when the generator is garbage-collected.
If you need to run cleanup code when a `GeneratorExit` occurs, I suggest using a `try: ... finally:` suite instead of catching `GeneratorExit`.

The cumulative effect of these changes is to turn generators from one-way producers of information into both producers and consumers.

Generators also become *coroutines*, a more generalized form of subroutines. Subroutines are entered at one point and exited at another point (the top of the function, and a `return` statement), but coroutines can be entered, exited, and resumed at many different points (the `yield` statements). We'll have to figure out patterns for using coroutines effectively in Python.

The addition of the `close()` method has one side effect that isn't obvious. `close()` is called when a generator is garbage-collected, so this means the generator's code gets one last chance to run before the generator is destroyed. This last chance means that `try...finally` statements in generators can now be guaranteed to work; the `finally` clause will now always get a chance to run. The syntactic restriction that you couldn't mix `yield` statements with a `try...finally` suite has therefore been removed. This seems like a minor bit of language trivia, but using generators and `try...finally` is actually necessary in order to implement the `with` statement described by PEP 343. I'll look at this new statement in the following section.

Another even more esoteric effect of this change: previously, the `gi_frame` attribute of a generator was always a frame object. It’s now possible for `gi_frame` to be `None` once the generator has been exhausted.

**PEP 342 - Coroutines via Enhanced Generators**

PEP written by Guido van Rossum and Phillip J. Eby; implemented by Phillip J. Eby. Includes examples of some fancier uses of generators as coroutines.

Earlier versions of these features were proposed in PEP 288 by Raymond Hettinger and PEP 325 by Samuele Pedroni.

The Wikipedia entry for coroutines.

http://www.sidhe.org/~dan/blog/archives/000178.html

An explanation of coroutines from a Perl point of view, written by Dan Sugalski.
PEP 343: The ‘with’ statement

The ‘with’ statement clarifies code that previously would use try...finally blocks to ensure that clean-up code is executed. In this section, I'll discuss the statement as it will commonly be used. In the next section, I'll examine the implementation details and show how to write objects for use with this statement.

The ‘with’ statement is a new control-flow structure whose basic structure is:

```
with expression [as variable]:
    with-block
```

The expression is evaluated, and it should result in an object that supports the context management protocol (that is, has __enter__() and __exit__() methods.

The object's __enter__() is called before with-block is executed and therefore can run set-up code. It also may return a value that is bound to the name variable, if given. (Note carefully that variable is not assigned the result of expression.)

After execution of the with-block is finished, the object's __exit__() method is called, even if the block raised an exception, and can therefore run clean-up code.

To enable the statement in Python 2.5, you need to add the following directive to your module:

```
from __future__ import with_statement
```
The statement will always be enabled in Python 2.6.

Some standard Python objects now support the context management protocol and can be used with the ‘with’ statement. File objects are one example:

```python
with open('/etc/passwd', 'r') as f:
    for line in f:
        print line
... more processing code ...
```

After this statement has executed, the file object in `f` will have been automatically closed, even if the `for` loop raised an exception part-way through the block.

**Note:** In this case, `f` is the same object created by `open()`, because `file.__enter__()` returns `self`.

The `threading` module’s locks and condition variables also support the ‘with’ statement:

```python
lock = threading.Lock()
with lock:
    # Critical section of code
    ...
```

The lock is acquired before the block is executed and always released once the block is complete.

The new `localcontext()` function in the `decimal` module makes it easy to save and restore the current decimal context, which encapsulates the desired precision and rounding characteristics for computations:
```python
from decimal import Decimal, Context, localcontext

# Displays with default precision of 28 digits
v = Decimal('578')
print v.sqrt()

with localcontext(Context(prec=16)):
    # All code in this block uses a precision of 16
    # The original context is restored on exiting the block.
    print v.sqrt()
```

## Writing Context Managers

Under the hood, the `with` statement is fairly complicated. Most people will only use `with` in company with existing objects and don’t need to know these details, so you can skip the rest of this section if you like. Authors of new objects will need to understand the details of the underlying implementation and should keep reading.

A high-level explanation of the context management protocol is:

- The expression is evaluated and should result in an object called a “context manager”. The context manager must have `__enter__()` and `__exit__()` methods.
- The context manager’s `__enter__()` method is called. The value returned is assigned to `VAR`. If no `as VAR` clause is present, the value is simply discarded.
- The code in `BLOCK` is executed.
- If `BLOCK` raises an exception, the `__exit__(type, value, traceback)` is called with the exception details, the same values returned by `sys.exc_info()`. The method’s return value controls whether the exception is re-raised: any false value re-raises the exception, and `True` will result in suppressing it. You'll
only rarely want to suppress the exception, because if you do the author of the code containing the `with` statement will never realize anything went wrong.

- If `BLOCK` didn't raise an exception, the `__exit__()` method is still called, but `type`, `value`, and `traceback` are all `None`.

Let's think through an example. I won't present detailed code but will only sketch the methods necessary for a database that supports transactions.

(For people unfamiliar with database terminology: a set of changes to the database are grouped into a transaction. Transactions can be either committed, meaning that all the changes are written into the database, or rolled back, meaning that the changes are all discarded and the database is unchanged. See any database textbook for more information.)

Let's assume there's an object representing a database connection. Our goal will be to let the user write code like this:

```python
db_connection = DatabaseConnection()
with db_connection as cursor:
    cursor.execute('insert into ...')
    cursor.execute('delete from ...')
# ... more operations ...
```

The transaction should be committed if the code in the block runs flawlessly or rolled back if there's an exception. Here's the basic interface for `DatabaseConnection` that I'll assume:

```python
class DatabaseConnection:
    # Database interface
    def cursor (self):
        """Returns a cursor object and starts a new tr""
```
```python
def commit (self):  
    "Commits current transaction"
def rollback (self):  
    "Rolls back current transaction"
```

The `__enter__()` method is pretty easy, having only to start a new transaction. For this application the resulting cursor object would be a useful result, so the method will return it. The user can then add `as cursor` to their `with` statement to bind the cursor to a variable name.

```python
class DatabaseConnection:
...
    def __enter__ (self):
        # Code to start a new transaction
        cursor = self.cursor()
        return cursor
```

The `__exit__()` method is the most complicated because it’s where most of the work has to be done. The method has to check if an exception occurred. If there was no exception, the transaction is committed. The transaction is rolled back if there was an exception.

In the code below, execution will just fall off the end of the function, returning the default value of `None`. `None` is false, so the exception will be re-raised automatically. If you wished, you could be more explicit and add a `return` statement at the marked location.

```python
class DatabaseConnection:
...
    def __exit__ (self, type, value, tb):
        if tb is None:
            # No exception, so commit
            self.commit()
```
else:
    # Exception occurred, so rollback.
    self.rollback()
    # return False

The contextlib module

The new contextlib module provides some functions and a decorator that are useful for writing objects for use with the ‘with’ statement.

The decorator is called contextmanager(), and lets you write a single generator function instead of defining a new class. The generator should yield exactly one value. The code up to the yield will be executed as the __enter__() method, and the value yielded will be the method’s return value that will get bound to the variable in the ‘with’ statement’s as clause, if any. The code after the yield will be executed in the __exit__() method. Any exception raised in the block will be raised by the yield statement.

Our database example from the previous section could be written using this decorator as:

```python
from contextlib import contextmanager

@contextmanager
def db_transaction (connection):
    cursor = connection.cursor()
    try:
        yield cursor
    except:
        connection.rollback()
        raise
```
else:
    connection.commit()

db = DatabaseConnection()
with db_transaction(db) as cursor:
    ...

The `contextlib` module also has a `nested(mgr1, mgr2, ...)` function that combines a number of context managers so you don't need to write nested `with` statements. In this example, the single `with` statement both starts a database transaction and acquires a thread lock:

```
lock = threading.Lock()
with nested (db_transaction(db), lock) as (cursor, l):
    ...
```

Finally, the `closing(object)` function returns `object` so that it can be bound to a variable, and calls `object.close` at the end of the block.

```
import urllib, sys
from contextlib import closing

with closing(urllib.urlopen('http://www.yahoo.com'))
    for line in f:
        sys.stdout.write(line)
```

**PEP 343 - The “with” statement**

PEP written by Guido van Rossum and Nick Coghlan; implemented by Mike Bland, Guido van Rossum, and Neal
Norwitz. The PEP shows the code generated for a `with` statement, which can be helpful in learning how the statement works.

The documentation for the `contextlib` module.
PEP 352: Exceptions as New-Style Classes

Exception classes can now be new-style classes, not just classic classes, and the built-in `Exception` class and all the standard built-in exceptions (`NameError`, `ValueError`, etc.) are now new-style classes.

The inheritance hierarchy for exceptions has been rearranged a bit. In 2.5, the inheritance relationships are:

```
BaseException       # New in Python 2.5
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
</tbody>
</table>
 |      KeyboardInterrupt
 |                  |
 |      SystemExit
 |      Exception
 |      (all other current built-in exceptions)
```

This rearrangement was done because people often want to catch all exceptions that indicate program errors. `KeyboardInterrupt` and `SystemExit` aren’t errors, though, and usually represent an explicit action such as the user hitting `Control-C` or code calling `sys.exit()`. A bare `except:` will catch all exceptions, so you commonly need to list `KeyboardInterrupt` and `SystemExit` in order to re-raise them. The usual pattern is:

```
try:
    ...
except (KeyboardInterrupt, SystemExit):
    raise
except:
    # Log error...
    # Continue running program...
```
In Python 2.5, you can now write `except Exception` to achieve the same result, catching all the exceptions that usually indicate errors but leaving `KeyboardInterrupt` and `SystemExit` alone. As in previous versions, a bare `except:` still catches all exceptions.

The goal for Python 3.0 is to require any class raised as an exception to derive from `BaseException` or some descendant of `BaseException`, and future releases in the Python 2.x series may begin to enforce this constraint. Therefore, I suggest you begin making all your exception classes derive from `Exception` now. It’s been suggested that the bare `except:` form should be removed in Python 3.0, but Guido van Rossum hasn’t decided whether to do this or not.

Raising of strings as exceptions, as in the statement `raise "Error occurred"`, is deprecated in Python 2.5 and will trigger a warning. The aim is to be able to remove the string-exception feature in a few releases.

**See also:**

**PEP 352 - Required Superclass for Exceptions**

PEP written by Brett Cannon and Guido van Rossum; implemented by Brett Cannon.
PEP 353: Using ssize_t as the index type

A wide-ranging change to Python’s C API, using a new `Py_ssize_t` type definition instead of `int`, will permit the interpreter to handle more data on 64-bit platforms. This change doesn’t affect Python’s capacity on 32-bit platforms.

Various pieces of the Python interpreter used C’s `int` type to store sizes or counts; for example, the number of items in a list or tuple were stored in an `int`. The C compilers for most 64-bit platforms still define `int` as a 32-bit type, so that meant that lists could only hold up to $2^{31} - 1 = 2147483647$ items. (There are actually a few different programming models that 64-bit C compilers can use – see http://www.unix.org/version2/whatsnew/lp64_wp.html for a discussion – but the most commonly available model leaves `int` as 32 bits.)

A limit of 2147483647 items doesn’t really matter on a 32-bit platform because you’ll run out of memory before hitting the length limit. Each list item requires space for a pointer, which is 4 bytes, plus space for a `PyObject` representing the item. 2147483647*4 is already more bytes than a 32-bit address space can contain.

It’s possible to address that much memory on a 64-bit platform, however. The pointers for a list that size would only require 16 GiB of space, so it’s not unreasonable that Python programmers might construct lists that large. Therefore, the Python interpreter had to be changed to use some type other than `int`, and this will be a 64-bit type on 64-bit platforms. The change will cause incompatibilities on 64-bit machines, so it was deemed worth making the transition now, while the number of 64-bit users is still relatively small. (In 5 or 10 years, we may all be on 64-bit machines, and the transition would be
more painful then.)

This change most strongly affects authors of C extension modules. Python strings and container types such as lists and tuples now use Py_ssize_t to store their size. Functions such as `PyList_Size()` now return Py_ssize_t. Code in extension modules may therefore need to have some variables changed to Py_ssize_t.

The `PyArg_ParseTuple()` and `Py_BuildValue()` functions have a new conversion code, \texttt{n}, for Py_ssize_t. `PyArg_ParseTuple()`'s \texttt{s#} and \texttt{t#} still output \texttt{int} by default, but you can define the macro \texttt{PY_SSIZE_T_CLEAN} before including \texttt{Python.h} to make them return Py_ssize_t.

\textbf{PEP 353} has a section on conversion guidelines that extension authors should read to learn about supporting 64-bit platforms.

\textbf{See also:}

\textbf{PEP 353 - Using ssize_t as the index type}

PEP written and implemented by Martin von Löwis.
PEP 357: The ‘__index__’ method

The NumPy developers had a problem that could only be solved by adding a new special method, __index__(). When using slice notation, as in [start:stop:step], the values of the start, stop, and step indexes must all be either integers or long integers. NumPy defines a variety of specialized integer types corresponding to unsigned and signed integers of 8, 16, 32, and 64 bits, but there was no way to signal that these types could be used as slice indexes.

Slicing can’t just use the existing __int__() method because that method is also used to implement coercion to integers. If slicing used __int__(), floating-point numbers would also become legal slice indexes and that’s clearly an undesirable behaviour.

Instead, a new special method called __index__() was added. It takes no arguments and returns an integer giving the slice index to use. For example:

```python
class C:
    def __index__(self):
        return self.value
```

The return value must be either a Python integer or long integer. The interpreter will check that the type returned is correct, and raises a TypeError if this requirement isn’t met.

A corresponding nb_index slot was added to the C-level PyNumberMethods structure to let C extensions implement this protocol. PyNumber_Index(obj) can be used in extension code to call the __index__() function and retrieve its result.
See also:

**PEP 357 - Allowing Any Object to be Used for Slicing**

PEP written and implemented by Travis Oliphant.
Other Language Changes

Here are all of the changes that Python 2.5 makes to the core Python language.

- The `dict` type has a new hook for letting subclasses provide a default value when a key isn’t contained in the dictionary. When a key isn’t found, the dictionary’s `__missing__(key)` method will be called. This hook is used to implement the new `defaultdict` class in the `collections` module. The following example defines a dictionary that returns zero for any missing key:

```python
class zerodict (dict):
    def __missing__ (self, key):
        return 0

d = zerodict({1:1, 2:2})
print d[1], d[2]  # Prints 1, 2
print d[3], d[4]  # Prints 0, 0
```

- Both 8-bit and Unicode strings have new `partition(sep)` and `rpartition(sep)` methods that simplify a common use case.

  The `find(S)` method is often used to get an index which is then used to slice the string and obtain the pieces that are before and after the separator. `partition(sep)` condenses this pattern into a single method call that returns a 3-tuple containing the substring before the separator, the separator itself, and the substring after the separator. If the separator isn’t found, the first element of the tuple is the entire string and the other two elements are empty. `rpartition(sep)` also returns a 3-tuple but starts searching from the end of the string; the `r` stands for ‘reverse’.
Some examples:

```python
>>> ('http://www.python.org').partition('://')
('http', '://', 'www.python.org')
>>> ('file:/usr/share/doc/index.html').partition('://')
('file://', '', 'www.python.org')
>>> (u'Subject: a quick question').partition(':')
(u'Subject', ':', 'a quick question')
>>> 'www.python.org'.rpartition('.')
('www.python', '.', 'org')
>>> 'www.python.org'.rpartition(':')
('', '', 'www.python.org')
```

(Implemented by Fredrik Lundh following a suggestion by Raymond Hettinger.)

- The `startswith()` and `endswith()` methods of string types now accept tuples of strings to check for.

```python
def is_image_file (filename):
    return filename.endswith(('gif', 'jpg', 'tiff'))
```

(Implemented by Georg Brandl following a suggestion by Tom Lynn.)

- The `min()` and `max()` built-in functions gained a `key` keyword parameter analogous to the `key` argument for `sort()`. This parameter supplies a function that takes a single argument and is called for every value in the list; `min()`/`max()` will return the element with the smallest/largest return value from this function. For example, to find the longest string in a list, you can do:

```python
L = ['medium', 'longest', 'short']
```
Two new built-in functions, `any()` and `all()`, evaluate whether an iterator contains any true or false values. `any()` returns `True` if any value returned by the iterator is true; otherwise it will return `False`. `all()` returns `True` only if all of the values returned by the iterator evaluate as true. (Suggested by Guido van Rossum, and implemented by Raymond Hettinger.)

The result of a class's `__hash__()` method can now be either a long integer or a regular integer. If a long integer is returned, the hash of that value is taken. In earlier versions the hash value was required to be a regular integer, but in 2.5 the `id()` built-in was changed to always return non-negative numbers, and users often seem to use `id(self)` in `__hash__()` methods (though this is discouraged).

ASCII is now the default encoding for modules. It's now a syntax error if a module contains string literals with 8-bit characters but doesn't have an encoding declaration. In Python 2.4 this triggered a warning, not a syntax error. See PEP 263 for how to declare a module's encoding; for example, you might add a line like this near the top of the source file:

```python
# -*- coding: latin1 -*-
```

A new warning, `UnicodeWarning`, is triggered when you attempt
to compare a Unicode string and an 8-bit string that can’t be converted to Unicode using the default ASCII encoding. The result of the comparison is false:

```python
>>> chr(128) == unichr(128)  # Can't convert chr(128) to Unicode
__main__:1: UnicodeWarning: Unicode equal comparison failed to convert both arguments to Unicode - interpreting them as being unequal
False
>>> chr(127) == unichr(127)  # chr(127) can be converted
True
```

Previously this would raise a `UnicodeDecodeError` exception, but in 2.5 this could result in puzzling problems when accessing a dictionary. If you looked up `unichr(128)` and `chr(128)` was being used as a key, you’d get a `UnicodeDecodeError` exception. Other changes in 2.5 resulted in this exception being raised instead of suppressed by the code in `dictobject.c` that implements dictionaries.

Raising an exception for such a comparison is strictly correct, but the change might have broken code, so instead `UnicodeWarning` was introduced.

(Implemented by Marc-André Lemburg.)

- One error that Python programmers sometimes make is forgetting to include an `__init__.py` module in a package directory. Debugging this mistake can be confusing, and usually requires running Python with the `-v` switch to log all the paths searched. In Python 2.5, a new `ImportWarning` warning is triggered when an import would have picked up a directory as a package but no
__init__.py was found. This warning is silently ignored by default; provide the -Wd option when running the Python executable to display the warning message. (Implemented by Thomas Wouters.)

- The list of base classes in a class definition can now be empty. As an example, this is now legal:

```python
class C():
    pass
```

(Implemented by Brett Cannon.)

Interactive Interpreter Changes

In the interactive interpreter, `quit` and `exit` have long been strings so that new users get a somewhat helpful message when they try to `quit`:

```python
>>> quit
'Use Ctrl-D (i.e. EOF) to exit.'
```

In Python 2.5, `quit` and `exit` are now objects that still produce string representations of themselves, but are also callable. Newbies who try `quit()` or `exit()` will now exit the interpreter as they expect. (Implemented by Georg Brandl.)

The Python executable now accepts the standard long options `--help` and `--version`; on Windows, it also accepts the `/?` option for displaying a help message. (Implemented by Georg Brandl.)

Optimizations
Several of the optimizations were developed at the NeedForSpeed sprint, an event held in Reykjavik, Iceland, from May 21–28 2006. The sprint focused on speed enhancements to the CPython implementation and was funded by EWT LLC with local support from CCP Games. Those optimizations added at this sprint are specially marked in the following list.

- When they were introduced in Python 2.4, the built-in `set` and `frozenset` types were built on top of Python's dictionary type. In 2.5 the internal data structure has been customized for implementing sets, and as a result sets will use a third less memory and are somewhat faster. (Implemented by Raymond Hettinger.)
- The speed of some Unicode operations, such as finding substrings, string splitting, and character map encoding and decoding, has been improved. (Substring search and splitting improvements were added by Fredrik Lundh and Andrew Dalke at the NeedForSpeed sprint. Character maps were improved by Walter Dörwald and Martin von Löwis.)
- The `long(str, base)` function is now faster on long digit strings because fewer intermediate results are calculated. The peak is for strings of around 800–1000 digits where the function is 6 times faster. (Contributed by Alan McIntyre and committed at the NeedForSpeed sprint.)
- It's now illegal to mix iterating over a file with `for line in file` and calling the file object's `read()`/`readline()`/`readlines()` methods. Iteration uses an internal buffer and the read*() methods don't use that buffer. Instead they would return the data following the buffer, causing the data to appear out of order. Mixing iteration and these methods will now trigger a ValueError from the read*() method. (Implemented by Thomas Wouters.)
- The `struct` module now compiles structure format strings into
an internal representation and caches this representation, yielding a 20% speedup. (Contributed by Bob Ippolito at the NeedForSpeed sprint.)

- The `re` module got a 1 or 2% speedup by switching to Python's allocator functions instead of the system's `malloc()` and `free()`. (Contributed by Jack Diederich at the NeedForSpeed sprint.)
- The code generator’s peephole optimizer now performs simple constant folding in expressions. If you write something like `a = 2+3`, the code generator will do the arithmetic and produce code corresponding to `a = 5`. (Proposed and implemented by Raymond Hettinger.)
- Function calls are now faster because code objects now keep the most recently finished frame (a “zombie frame”) in an internal field of the code object, reusing it the next time the code object is invoked. (Original patch by Michael Hudson, modified by Armin Rigo and Richard Jones; committed at the NeedForSpeed sprint.) Frame objects are also slightly smaller, which may improve cache locality and reduce memory usage a bit. (Contributed by Neal Norwitz.)
- Python’s built-in exceptions are now new-style classes, a change that speeds up instantiation considerably. Exception handling in Python 2.5 is therefore about 30% faster than in 2.4. (Contributed by Richard Jones, Georg Brandl and Sean Reifschneider at the NeedForSpeed sprint.)
- Importing now caches the paths tried, recording whether they exist or not so that the interpreter makes fewer `open()` and `stat()` calls on startup. (Contributed by Martin von Löwis and Georg Brandl.)
New, Improved, and Removed Modules

The standard library received many enhancements and bug fixes in Python 2.5. Here’s a partial list of the most notable changes, sorted alphabetically by module name. Consult the Misc/NEWS file in the source tree for a more complete list of changes, or look through the SVN logs for all the details.

- The `audioop` module now supports the a-LAW encoding, and the code for u-LAW encoding has been improved. (Contributed by Lars Immisch.)

- The `codecs` module gained support for incremental codecs. The `codec.lookup()` function now returns a `CodecInfo` instance instead of a tuple. `CodecInfo` instances behave like a 4-tuple to preserve backward compatibility but also have the attributes `encode`, `decode`, `incrementalencoder`, `incrementaldecoder`, `streamwriter`, and `streamreader`. Incremental codecs can receive input and produce output in multiple chunks; the output is the same as if the entire input was fed to the non-incremental codec. See the `codecs` module documentation for details. (Designed and implemented by Walter Dörwald.)

- The `collections` module gained a new type, `defaultdict`, that subclasses the standard `dict` type. The new type mostly behaves like a dictionary but constructs a default value when a key isn’t present, automatically adding it to the dictionary for the requested key value.

  The first argument to `defaultdict`’s constructor is a factory
function that gets called whenever a key is requested but not found. This factory function receives no arguments, so you can use built-in type constructors such as \texttt{list()} or \texttt{int()}. For example, you can make an index of words based on their initial letter like this:

```python
words = """Nel mezzo del cammin di nostra vita mi ritrovai per una selva oscura che la diritta via era smarrita""".lower().split()
index = defaultdict(list)
for w in words:
    init_letter = w[0]
    index[init_letter].append(w)
```  

Printing \texttt{index} results in the following output:

```
defaultdict(<type 'list'>, {'c': ['cammin', 'che', 'd': ['del', 'di', 'diritta'], 'm': ['mezz', 'l': ['la'], 'o': ['oscura'], 'n': ['nel', 'p': ['per'], 's': ['selva', 'smarrita'], 'r': ['ritrovai'], 'u': ['una'], 'v': ['vita']})
```

(Contributed by Guido van Rossum.)

- The \texttt{deque} double-ended queue type supplied by the \texttt{collections} module now has a \texttt{remove(value)} method that removes the first occurrence of \texttt{value} in the queue, raising \texttt{ValueError} if the value isn't found. (Contributed by Raymond Hettinger.)

- New module: The \texttt{contextlib} module contains helper functions
for use with the new 'with' statement. See section The contextlib module for more about this module.

- New module: The cProfile module is a C implementation of the existing profile module that has much lower overhead. The module's interface is the same as profile: you run cProfile.run('main()') to profile a function, can save profile data to a file, etc. It's not yet known if the Hotshot profiler, which is also written in C but doesn't match the profile module's interface, will continue to be maintained in future versions of Python. (Contributed by Armin Rigo.)

Also, the pstats module for analyzing the data measured by the profiler now supports directing the output to any file object by supplying a stream argument to the Stats constructor. (Contributed by Skip Montanaro.)

- The csv module, which parses files in comma-separated value format, received several enhancements and a number of bugfixes. You can now set the maximum size in bytes of a field by calling the csv.field_size_limit(new_limit) function; omitting the new_limit argument will return the currently-set limit. The reader class now has a line_num attribute that counts the number of physical lines read from the source; records can span multiple physical lines, so line_num is not the same as the number of records read.

The CSV parser is now stricter about multi-line quoted fields. Previously, if a line ended within a quoted field without a terminating newline character, a newline would be inserted into the returned field. This behavior caused problems when reading files that contained carriage return characters within fields, so the
code was changed to return the field without inserting newlines. As a consequence, if newlines embedded within fields are important, the input should be split into lines in a manner that preserves the newline characters.

(Contributed by Skip Montanaro and Andrew McNamara.)

- The `datetime` class in the `datetime` module now has a `strptime(string, format)` method for parsing date strings, contributed by Josh Spoerri. It uses the same format characters as `time.strptime()` and `time.strftime()`:

```
from datetime import datetime

ts = datetime.strptime('10:13:15 2006-03-07', '%H:%M:%S %Y-%m-%d')
```

- The `SequenceMatcher.get_matching_blocks()` method in the `difflib` module now guarantees to return a minimal list of blocks describing matching subsequences. Previously, the algorithm would occasionally break a block of matching elements into two list entries. (Enhancement by Tim Peters.)

- The `doctest` module gained a `SKIP` option that keeps an example from being executed at all. This is intended for code snippets that are usage examples intended for the reader and aren’t actually test cases.

  An `encoding` parameter was added to the `testfile()` function and the `DocFileSuite` class to specify the file's encoding. This makes it easier to use non-ASCII characters in tests contained within a docstring. (Contributed by Bjorn Tillenius.)
• The **email** package has been updated to version 4.0. (Contributed by Barry Warsaw.)

• The **fileinput** module was made more flexible. Unicode filenames are now supported, and a *mode* parameter that defaults to "r" was added to the `input()` function to allow opening files in binary or universal newlines mode. Another new parameter, `openhook`, lets you use a function other than `open()` to open the input files. Once you're iterating over the set of files, the `FileInput` object's new `fileno()` returns the file descriptor for the currently opened file. (Contributed by Georg Brandl.)

• In the **gc** module, the new `get_count()` function returns a 3-tuple containing the current collection counts for the three GC generations. This is accounting information for the garbage collector; when these counts reach a specified threshold, a garbage collection sweep will be made. The existing `gc.collect()` function now takes an optional *generation* argument of 0, 1, or 2 to specify which generation to collect. (Contributed by Barry Warsaw.)

• The `nsmallest()` and `nlargest()` functions in the **heapq** module now support a `key` keyword parameter similar to the one provided by the `min()`/`max()` functions and the `sort()` methods. For example:

```python
>>> import heapq
>>> L = ['short', 'medium', 'longest', 'longer still']
>>> heapq.nsmallest(2, L)  # Return two lowest elements
['longer still', 'longest']
>>> heapq.nsmallest(2, L, key=len)  # Return two shortest elements
['short', 'medium']
```
The `itertools.islice()` function now accepts `None` for the start and step arguments. This makes it more compatible with the attributes of slice objects, so that you can now write the following:

```python
s = slice(5)  # Create slice object
itertools.islice(iterable, s.start, s.stop, s.step)
```

The `format()` function in the `locale` module has been modified and two new functions were added, `format_string()` and `currency()`.

The `format()` function’s `val` parameter could previously be a string as long as no more than one `%char` specifier appeared; now the parameter must be exactly one `%char` specifier with no surrounding text. An optional `monetary` parameter was also added which, if `True`, will use the locale’s rules for formatting currency in placing a separator between groups of three digits.

To format strings with multiple `%char` specifiers, use the new `format_string()` function that works like `format()` but also supports mixing `%char` specifiers with arbitrary text.

A new `currency()` function was also added that formats a number according to the current locale’s settings.

The `mailbox` module underwent a massive rewrite to add the capability to modify mailboxes in addition to reading them. A new
set of classes that include mbox, MH, and Maildir are used to read mailboxes, and have an `add(message)` method to add messages, `remove(key)` to remove messages, and `lock()/unlock()` to lock/unlock the mailbox. The following example converts a maildir-format mailbox into an mbox-format one:

```python
import mailbox

# 'factory=None' uses email.Message.Message as the class representing individual messages.
src = mailbox.Maildir('maildir', factory=None)
dest = mailbox.mbox('/tmp/mbox')

for msg in src:
    dest.add(msg)
```

(Contributed by Gregory K. Johnson. Funding was provided by Google's 2005 Summer of Code.)

- New module: the `msilib` module allows creating Microsoft Installer `.msi` files and CAB files. Some support for reading the `.msi` database is also included. (Contributed by Martin von Löwis.)

- The `nis` module now supports accessing domains other than the system default domain by supplying a `domain` argument to the `nis.match()` and `nis.maps()` functions. (Contributed by Ben Bell.)

- The `operator` module's `itemgetter()` and `attrgetter()` functions now support multiple fields. A call such as `operator.attrgetter('a', 'b')` will return a function that
retrieves the a and b attributes. Combining this new feature with the sort() method’s key parameter lets you easily sort lists using multiple fields. (Contributed by Raymond Hettinger.)

- The optparse module was updated to version 1.5.1 of the Optik library. The OptionParser class gained an epilog attribute, a string that will be printed after the help message, and a destroy() method to break reference cycles created by the object. (Contributed by Greg Ward.)

- The os module underwent several changes. The stat_float_times variable now defaults to true, meaning that os.stat() will now return time values as floats. (This doesn’t necessarily mean that os.stat() will return times that are precise to fractions of a second; not all systems support such precision.)

  Constants named os.SEEK_SET, os.SEEK_CUR, and os.SEEK_END have been added; these are the parameters to the os.lseek() function. Two new constants for locking are os.O_SHLOCK and os.O_EXLOCK.

  Two new functions, wait3() and wait4(), were added. They’re similar the waitpid() function which waits for a child process to exit and returns a tuple of the process ID and its exit status, but wait3() and wait4() return additional information. wait3() doesn’t take a process ID as input, so it waits for any child process to exit and returns a 3-tuple of process-id, exit-status, resource-usage as returned from the resource.getrusage() function. wait4(pid) does take a process ID. (Contributed by Chad J. Schroeder.)
On FreeBSD, the `os.stat()` function now returns times with nanosecond resolution, and the returned object now has `st_gen` and `st_birthtime`. The `st_flags` attribute is also available, if the platform supports it. (Contributed by Antti Louko and Diego Pettenò.)

- The Python debugger provided by the `pdb` module can now store lists of commands to execute when a breakpoint is reached and execution stops. Once breakpoint #1 has been created, enter `commands 1` and enter a series of commands to be executed, finishing the list with `end`. The command list can include commands that resume execution, such as `continue` or `next`. (Contributed by Grégoire Dooms.)

- The `pickle` and cPickle modules no longer accept a return value of `None` from the `__reduce__()` method; the method must return a tuple of arguments instead. The ability to return `None` was deprecated in Python 2.4, so this completes the removal of the feature.

- The `pkgutil` module, containing various utility functions for finding packages, was enhanced to support PEP 302’s import hooks and now also works for packages stored in ZIP-format archives. (Contributed by Phillip J. Eby.)

- The pybench benchmark suite by Marc-André Lemburg is now included in the Tools/pybench directory. The pybench suite is an improvement on the commonly used `pystone.py` program because pybench provides a more detailed measurement of the interpreter’s speed. It times particular operations such as function calls, tuple slicing, method lookups, and numeric operations, instead of performing many different operations and reducing the
result to a single number as pystone.py does.

- The pyexpat module now uses version 2.0 of the Expat parser. (Contributed by Trent Mick.)

- The Queue class provided by the Queue module gained two new methods. join() blocks until all items in the queue have been retrieved and all processing work on the items have been completed. Worker threads call the other new method, task_done(), to signal that processing for an item has been completed. (Contributed by Raymond Hettinger.)

- The old regex and regsub modules, which have been deprecated ever since Python 2.0, have finally been deleted. Other deleted modules: statcache, tzparse, whrandom.

- Also deleted: the lib-old directory, which includes ancient modules such as dircmp and ni, was removed. lib-old wasn't on the default sys.path, so unless your programs explicitly added the directory to sys.path, this removal shouldn't affect your code.

- The rlcompleter module is no longer dependent on importing the readline module and therefore now works on non-Unix platforms. (Patch from Robert Kiendl.)

- The SimpleXMLRPCServer and DocXMLRPCServer classes now have a rpc_paths attribute that constrains XML-RPC operations to a limited set of URL paths; the default is to allow only '/\ and '/RPC2'. Setting rpc_paths to None or an empty tuple disables this path checking.
The `socket` module now supports AF_NETLINK sockets on Linux, thanks to a patch from Philippe Biondi. Netlink sockets are a Linux-specific mechanism for communications between a user-space process and kernel code; an introductory article about them is at https://www.linuxjournal.com/article/7356. In Python code, netlink addresses are represented as a tuple of 2 integers, `(pid, group_mask)`. Two new methods on socket objects, `recv_into(buffer)` and `recvfrom_into(buffer)`, store the received data in an object that supports the buffer protocol instead of returning the data as a string. This means you can put the data directly into an array or a memory-mapped file.

Socket objects also gained `getfamily()`, `gettype()`, and `getproto()` accessor methods to retrieve the family, type, and protocol values for the socket.

New module: the `spwd` module provides functions for accessing the shadow password database on systems that support shadow passwords.

The `struct` is now faster because it compiles format strings into Struct objects with `pack()` and `unpack()` methods. This is similar to how the `re` module lets you create compiled regular expression objects. You can still use the module-level `pack()` and `unpack()` functions; they'll create Struct objects and cache them. Or you can use Struct instances directly:

```python
s = struct.Struct('ih3s')
data = s.pack(1972, 187, 'abc')
```
year, number, name = s.unpack(data)

You can also pack and unpack data to and from buffer objects directly using the `pack_into(buffer, offset, v1, v2, ...)` and `unpack_from(buffer, offset)` methods. This lets you store data directly into an array or a memory-mapped file.

(Struct objects were implemented by Bob Ippolito at the NeedForSpeed sprint. Support for buffer objects was added by Martin Blais, also at the NeedForSpeed sprint.)

- The Python developers switched from CVS to Subversion during the 2.5 development process. Information about the exact build version is available as the `sys.subversion` variable, a 3-tuple of `(interpreter-name, branch-name, revision-range)`. For example, at the time of writing my copy of 2.5 was reporting ('CPython', 'trunk', '45313:45315').

  This information is also available to C extensions via the `Py_GetBuildInfo()` function that returns a string of build information like this: "trunk:45355:45356M, Apr 13 2006, 07:42:19". (Contributed by Barry Warsaw.)

- Another new function, `sys._current_frames()`, returns the current stack frames for all running threads as a dictionary mapping thread identifiers to the topmost stack frame currently active in that thread at the time the function is called. (Contributed by Tim Peters.)

- The TarFile class in the `tarfile` module now has an `extractall()` method that extracts all members from the archive into the current working directory. It's also possible to set
a different directory as the extraction target, and to unpack only a subset of the archive's members.

The compression used for a tarfile opened in stream mode can now be autodetected using the mode `'r*'

(Contributed by Lars Gustäbel.)

- The `threading` module now lets you set the stack size used when new threads are created. The `stack_size([*size*])` function returns the currently configured stack size, and supplying the optional `size` parameter sets a new value. Not all platforms support changing the stack size, but Windows, POSIX threading, and OS/2 all do. (Contributed by Andrew MacIntyre.)

- The `unicodedata` module has been updated to use version 4.1.0 of the Unicode character database. Version 3.2.0 is required by some specifications, so it's still available as `unicodedata.ucd_3_2_0`.

- New module: the `uuid` module generates universally unique identifiers (UUIDs) according to RFC 4122. The RFC defines several different UUID versions that are generated from a starting string, from system properties, or purely randomly. This module contains a UUID class and functions named `uuid1()`, `uuid3()`, `uuid4()`, and `uuid5()` to generate different versions of UUID. (Version 2 UUIDs are not specified in RFC 4122 and are not supported by this module.)

```python
>>> import uuid
>>> # make a UUID based on the host ID and current time
>>> uuid.uuid1()
UUID('a8098c1a-f86e-11da-bd1a-00112444be1e')
```
The `weakref` module's `WeakKeyDictionary` and `WeakValueDictionary` types gained new methods for iterating over the weak references contained in the dictionary. `iterkeyrefs()` and `keyrefs()` methods were added to `WeakKeyDictionary`, and `itervaluerefs()` and `valuerefs()` were added to `WeakValueDictionary`. (Contributed by Fred L. Drake, Jr.)

The `webbrowser` module received a number of enhancements. It's now usable as a script with `python -m webbrowser`, taking a URL as the argument; there are a number of switches to control the behaviour (-n for a new browser window, -t for a new tab). New module-level functions, `open_new()` and `open_new_tab()`, were added to support this. The module's `open()` function supports an additional feature, an `autoraise` parameter that signals whether to raise the open window when possible. A number of additional browsers were added to the supported list such as Firefox, Opera, Konqueror, and elinks. (Contributed by Oleg Broytmann and Georg Brandl.)
• The xmlrpcclib module now supports returning datetime objects for the XML-RPC date type. Supply use_datetime=True to the loads() function or the Unmarshaller class to enable this feature. (Contributed by Skip Montanaro.)

• The zipfile module now supports the ZIP64 version of the format, meaning that a .zip archive can now be larger than 4 GiB and can contain individual files larger than 4 GiB. (Contributed by Ronald Oussoren.)

• The zlib module's Compress and Decompress objects now support a copy() method that makes a copy of the object's internal state and returns a new Compress or Decompress object. (Contributed by Chris AtLee.)

The ctypes package

The ctypes package, written by Thomas Heller, has been added to the standard library. ctypes lets you call arbitrary functions in shared libraries or DLLs. Long-time users may remember the dl module, which provides functions for loading shared libraries and calling functions in them. The ctypes package is much fancier.

To load a shared library or DLL, you must create an instance of the CDLL class and provide the name or path of the shared library or DLL. Once that's done, you can call arbitrary functions by accessing them as attributes of the CDLL object.

```python
import ctypes
```
```python
libc = ctypes.CDLL('libc.so.6')
result = libc.printf("Line of output\n")
```

Type constructors for the various C types are provided: `c_int()`, `c_float()`, `c_double()`, `c_char_p()` (equivalent to `char *`), and so forth. Unlike Python's types, the C versions are all mutable; you can assign to their `value` attribute to change the wrapped value. Python integers and strings will be automatically converted to the corresponding C types, but for other types you must call the correct type constructor. (And I mean *must*; getting it wrong will often result in the interpreter crashing with a segmentation fault.)

You shouldn't use `c_char_p()` with a Python string when the C function will be modifying the memory area, because Python strings are supposed to be immutable; breaking this rule will cause puzzling bugs. When you need a modifiable memory area, use `create_string_buffer()`:

```python
s = "this is a string"
buf = ctypes.create_string_buffer(s)
libc.strfry(buf)
```

C functions are assumed to return integers, but you can set the `restype` attribute of the function object to change this:

```python
>>> libc.atof('2.71828')
-1783957616
>>> libc.atof.restype = ctypes.c_double
>>> libc.atof('2.71828')
2.71828
```

c\textit{ctypes} also provides a wrapper for Python's C API as the `ctypes.pythonapi` object. This object does \textit{not} release the global
interpreter lock before calling a function, because the lock must be held when calling into the interpreter's code. There's a `py_object()` type constructor that will create a `PyObject *` pointer. A simple usage:

```python
import ctypes

d = {}
ctypes.pythonapi.PyObject_SetItem(ctypes.py_object(d),
    ctypes.py_object("abc"),
    # d is now {'abc', 1}.
```

Don't forget to use `py_object()`; if it's omitted you end up with a segmentation fault.

`ctypes` has been around for a while, but people still write and distribution hand-coded extension modules because you can't rely on `ctypes` being present. Perhaps developers will begin to write Python wrappers atop a library accessed through `ctypes` instead of extension modules, now that `ctypes` is included with core Python.

The ctypes web page, with a tutorial, reference, and FAQ.

The documentation for the `ctypes` module.

**The ElementTree package**

A subset of Fredrik Lundh's ElementTree library for processing XML has been added to the standard library as `xml.etree`. The available
modules are ElementTree, ElementPath, and ElementInclude from ElementTree 1.2.6. The cElementTree accelerator module is also included.

The rest of this section will provide a brief overview of using ElementTree. Full documentation for ElementTree is available at http://effbot.org/zone/element-index.htm.

ElementTree represents an XML document as a tree of element nodes. The text content of the document is stored as the text and tail attributes of (This is one of the major differences between ElementTree and the Document Object Model; in the DOM there are many different types of node, includingTextNode.)

The most commonly used parsing function is parse(), that takes either a string (assumed to contain a filename) or a file-like object and returns an ElementTree instance:

```python
from xml.etree import ElementTree as ET

tree = ET.parse('ex-1.xml')

feed = urllib.urlopen(
    'http://planet.python.org/rss10.xml')
tree = ET.parse(feed)
```

Once you have an ElementTree instance, you can call its getroot() method to get the root Element node.

There's also an XML() function that takes a string literal and returns an Element node (not an ElementTree). This function provides a tidy way to incorporate XML fragments, approaching the convenience of an XML literal:
Each XML element supports some dictionary-like and some list-like access methods. Dictionary-like operations are used to access attribute values, and list-like operations are used to access child nodes.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>elem[n]</td>
<td>Returns n'th child element.</td>
</tr>
<tr>
<td>elem[m:n]</td>
<td>Returns list of m'th through n'th child elements.</td>
</tr>
<tr>
<td>len(elem)</td>
<td>Returns number of child elements.</td>
</tr>
<tr>
<td>list(elem)</td>
<td>Returns list of child elements.</td>
</tr>
<tr>
<td>elem.append(elem2)</td>
<td>Adds elem2 as a child.</td>
</tr>
<tr>
<td>elem.insert(index, elem2)</td>
<td>Inserts elem2 at the specified location.</td>
</tr>
<tr>
<td>del elem[n]</td>
<td>Deletes n'th child element.</td>
</tr>
<tr>
<td>elem.keys()</td>
<td>Returns list of attribute names.</td>
</tr>
<tr>
<td>elem.get(name)</td>
<td>Returns value of attribute name.</td>
</tr>
<tr>
<td>elem.set(name, value)</td>
<td>Sets new value for attribute name.</td>
</tr>
<tr>
<td>elem.attrib</td>
<td>Retrieves the dictionary containing attributes.</td>
</tr>
<tr>
<td>del elem.attrib[name]</td>
<td>Deletes attribute name.</td>
</tr>
</tbody>
</table>

Comments and processing instructions are also represented as
Element nodes. To check if a node is a comment or processing instructions:

```python
if elem.tag is ET.Comment:
    ...
elif elem.tag is ET.ProcessingInstruction:
    ...
```

To generate XML output, you should call the ElementTree.write() method. Like parse(), it can take either a string or a file-like object:

```python
# Encoding is US-ASCII
tree.write('output.xml')

# Encoding is UTF-8
f = open('output.xml', 'w')
tree.write(f, encoding='utf-8')
```

(Caution: the default encoding used for output is ASCII. For general XML work, where an element’s name may contain arbitrary Unicode characters, ASCII isn’t a very useful encoding because it will raise an exception if an element’s name contains any characters with values greater than 127. Therefore, it’s best to specify a different encoding such as UTF-8 that can handle any Unicode character.)

This section is only a partial description of the ElementTree interfaces. Please read the package’s official documentation for more details.

Official documentation for ElementTree.
The hashlib package

A new `hashlib` module, written by Gregory P. Smith, has been added to replace the md5 and sha modules. `hashlib` adds support for additional secure hashes (SHA-224, SHA-256, SHA-384, and SHA-512). When available, the module uses OpenSSL for fast platform optimized implementations of algorithms.

The old md5 and sha modules still exist as wrappers around hashlib to preserve backwards compatibility. The new module’s interface is very close to that of the old modules, but not identical. The most significant difference is that the constructor functions for creating new hashing objects are named differently.

```
# Old versions
h = md5.md5()
h = md5.new()

# New version
h = hashlib.md5()

# Old versions
h = sha.sha()
h = sha.new()

# New version
h = hashlib.sha1()

# Hash that weren't previously available
h = hashlib.sha224()
h = hashlib.sha256()
h = hashlib.sha384()
h = hashlib.sha512()
```
Once a hash object has been created, its methods are the same as before: `update(string)` hashes the specified string into the current digest state, `digest()` and `hexdigest()` return the digest value as a binary string or a string of hex digits, and `copy()` returns a new hashing object with the same digest state.

**See also:** The documentation for the `hashlib` module.

### The `sqlite3` package

The `pysqlite` module ([http://www.pysqlite.org](http://www.pysqlite.org)), a wrapper for the SQLite embedded database, has been added to the standard library under the package name `sqlite3`.

SQLite is a C library that provides a lightweight disk-based database that doesn’t require a separate server process and allows accessing the database using a nonstandard variant of the SQL query language. Some applications can use SQLite for internal data storage. It’s also possible to prototype an application using SQLite and then port the code to a larger database such as PostgreSQL or Oracle.

`pysqlite` was written by Gerhard Häring and provides a SQL interface compliant with the DB-API 2.0 specification described by [PEP 249](https://www.python.org/dev/peps/pep-0249/).

If you’re compiling the Python source yourself, note that the source tree doesn’t include the SQLite code, only the wrapper module. You’ll need to have the SQLite libraries and headers installed before compiling Python, and the build process will compile the module when the necessary headers are available.
To use the module, you must first create a Connection object that represents the database. Here the data will be stored in the /tmp/example file:

```python
conn = sqlite3.connect('/tmp/example')
```

You can also supply the special name :memory: to create a database in RAM.

Once you have a Connection, you can create a Cursor object and call its `execute()` method to perform SQL commands:

```python
c = conn.cursor()

# Create table
c.execute('create table stocks
(date text, trans text, symbol text,
  qty real, price real)')

# Insert a row of data
c.execute("insert into stocks
values ('2006-01-05','BUY','RHAT',100,35.14)"")
```

Usually your SQL operations will need to use values from Python variables. You shouldn’t assemble your query using Python’s string operations because doing so is insecure; it makes your program vulnerable to an SQL injection attack.

Instead, use the DB-API’s parameter substitution. Put ? as a placeholder wherever you want to use a value, and then provide a tuple of values as the second argument to the cursor’s `execute()` method. (Other database modules may use a different placeholder, such as %s or :1.) For example:
# Never do this -- insecure!
symbol = 'IBM'
c.execute("... where symbol = '%s'" % symbol)

# Do this instead
t = (symbol,)
c.execute('select * from stocks where symbol=?', t)

# Larger example
for t in [('2006-03-28', 'BUY', 'IBM', 1000, 45.00),
          ('2006-04-05', 'BUY', 'MSOFT', 1000, 72.00),
          ('2006-04-06', 'SELL', 'IBM', 500, 53.00),
          ]:
c.execute('insert into stocks values (?, ?, ?, ?, ?)

To retrieve data after executing a SELECT statement, you can either treat the cursor as an iterator, call the cursor's fetchone() method to retrieve a single matching row, or call fetchall() to get a list of the matching rows.

This example uses the iterator form:

```python
>>> c = conn.cursor()
>>> c.execute('select * from stocks order by price')
>>> for row in c:
...     print row
...
(u'2006-01-05', u'BUY', u'RHAT', 100, 35.140000000000001)
(u'2006-03-28', u'BUY', u'IBM', 1000, 45.0)
(u'2006-04-06', u'SELL', u'IBM', 500, 53.0)
(u'2006-04-05', u'BUY', u'MSOFT', 1000, 72.0)
```

The wsgiref package

The Web Server Gateway Interface (WSGI) v1.0 defines a standard interface between web servers and Python web applications and is described in PEP 333. The wsgiref package is a reference implementation of the WSGI specification.

The package includes a basic HTTP server that will run a WSGI application; this server is useful for debugging but isn't intended for production use. Setting up a server takes only a few lines of code:

```python
from wsgiref import simple_server

wsgi_app = ...

host = ''
port = 8000
httpd = simple_server.make_server(host, port, wsgi_app)
httpd.serve_forever()
```

PEP 333 - Python Web Server Gateway Interface v1.0
   PEP written by Phillip J. Eby.
Build and C API Changes

Changes to Python’s build process and to the C API include:

- The Python source tree was converted from CVS to Subversion, in a complex migration procedure that was supervised and flawlessly carried out by Martin von Löwis. The procedure was developed as PEP 347.

- Coverity, a company that markets a source code analysis tool called Prevent, provided the results of their examination of the Python source code. The analysis found about 60 bugs that were quickly fixed. Many of the bugs were refcounting problems, often occurring in error-handling code. See https://scan.coverity.com for the statistics.

- The largest change to the C API came from PEP 353, which modifies the interpreter to use a Py_ssize_t type definition instead of int. See the earlier section PEP 353: Using ssize_t as the index type for a discussion of this change.

- The design of the bytecode compiler has changed a great deal, no longer generating bytecode by traversing the parse tree. Instead the parse tree is converted to an abstract syntax tree (or AST), and it is the abstract syntax tree that’s traversed to produce the bytecode.

It’s possible for Python code to obtain AST objects by using the `compile()` built-in and specifying `_ast.PyCF_ONLY_AST` as the value of the `flags` parameter:

```python
from _ast import PyCF_ONLY_AST
```
No official documentation has been written for the AST code yet, but PEP 339 discusses the design. To start learning about the code, read the definition of the various AST nodes in Parser/Python.asdl. A Python script reads this file and generates a set of C structure definitions in Include/Python-ast.h. The PyParser_ASTFromString() and PyParser_ASTFromFile(), defined in Include/pythonrun.h, take Python source as input and return the root of an AST representing the contents. This AST can then be turned into a code object by PyAST_Compile(). For more information, read the source code, and then ask questions on python-dev.

The AST code was developed under Jeremy Hylton's management, and implemented by (in alphabetical order) Brett Cannon, Nick Coghlan, Grant Edwards, John Ehresman, Kurt Kaiser, Neal Norwitz, Tim Peters, Armin Rigo, and Neil Schemenauer, plus the participants in a number of AST sprints at conferences such as PyCon.

- Evan Jones's patch to obmalloc, first described in a talk at PyCon DC 2005, was applied. Python 2.4 allocated small objects in 256K-sized arenas, but never freed arenas. With this patch, Python will free arenas when they're empty. The net effect is that on some platforms, when you allocate many objects, Python's
memory usage may actually drop when you delete them and the memory may be returned to the operating system. (Implemented by Evan Jones, and reworked by Tim Peters.)

Note that this change means extension modules must be more careful when allocating memory. Python’s API has many different functions for allocating memory that are grouped into families. For example, `PyMem_Malloc()`, `PyMem_Realloc()`, and `PyMem_Free()` are one family that allocates raw memory, while `PyObject_Malloc()`, `PyObject_Realloc()`, and `PyObject_Free()` are another family that's supposed to be used for creating Python objects.

Previously these different families all reduced to the platform's `malloc()` and `free()` functions. This meant it didn't matter if you got things wrong and allocated memory with the `PyMem()` function but freed it with the `PyObject()` function. With 2.5's changes to obmalloc, these families now do different things and mismatches will probably result in a segfault. You should carefully test your C extension modules with Python 2.5.

- The built-in set types now have an official C API. Call `PySet_New()` and `PyFrozenSet_New()` to create a new set, `PySet_Add()` and `PySet_Discard()` to add and remove elements, and `PySet_Contains()` and `PySet_Size()` to examine the set's state. (Contributed by Raymond Hettinger.)

- C code can now obtain information about the exact revision of the Python interpreter by calling the `Py_GetBuildInfo()` function that returns a string of build information like this: "trunk:45355:45356M, Apr 13 2006, 07:42:19". (Contributed by Barry Warsaw.)
Two new macros can be used to indicate C functions that are local to the current file so that a faster calling convention can be used. `Py_LOCAL(type)` declares the function as returning a value of the specified type and uses a fast-calling qualifier. `Py_LOCAL_INLINE(type)` does the same thing and also requests the function be inlined. If `PY_LOCAL_AGGRESSIVE()` is defined before `python.h` is included, a set of more aggressive optimizations are enabled for the module; you should benchmark the results to find out if these optimizations actually make the code faster. (Contributed by Fredrik Lundh at the NeedForSpeed sprint.)

`PyErr_NewException(name, base, dict)` can now accept a tuple of base classes as its base argument. (Contributed by Georg Brandl.)

The `PyErr_Warn()` function for issuing warnings is now deprecated in favour of `PyErr_WarnEx(category, message, stacklevel)` which lets you specify the number of stack frames separating this function and the caller. A `stacklevel` of 1 is the function calling `PyErr_WarnEx()`, 2 is the function above that, and so forth. (Added by Neal Norwitz.)

The CPython interpreter is still written in C, but the code can now be compiled with a C++ compiler without errors. (Implemented by Anthony Baxter, Martin von Löwis, Skip Montanaro.)

The `PyRange_New()` function was removed. It was never documented, never used in the core code, and had dangerously lax error checking. In the unlikely case that your extensions were using it, you can replace it by something like the following:
Port-Specific Changes

- MacOS X (10.3 and higher): dynamic loading of modules now uses the dlopen() function instead of MacOS-specific functions.
- MacOS X: an --enable-universalsdk switch was added to the configure script that compiles the interpreter as a universal binary able to run on both PowerPC and Intel processors. (Contributed by Ronald Oussoren; bpo-2573.)
- Windows: .dll is no longer supported as a filename extension for extension modules. .pyd is now the only filename extension that will be searched for.
Porting to Python 2.5

This section lists previously described changes that may require changes to your code:

- ASCII is now the default encoding for modules. It’s now a syntax error if a module contains string literals with 8-bit characters but doesn’t have an encoding declaration. In Python 2.4 this triggered a warning, not a syntax error.
- Previously, the gi_frame attribute of a generator was always a frame object. Because of the PEP 342 changes described in section PEP 342: New Generator Features, it’s now possible for gi_frame to be None.
- A new warning, UnicodeWarning, is triggered when you attempt to compare a Unicode string and an 8-bit string that can’t be converted to Unicode using the default ASCII encoding. Previously such comparisons would raise a UnicodeDecodeError exception.
- Library: the csv module is now stricter about multi-line quoted fields. If your files contain newlines embedded within fields, the input should be split into lines in a manner which preserves the newline characters.
- Library: the locale module’s format() function’s would previously accept any string as long as no more than one %char specifier appeared. In Python 2.5, the argument must be exactly one %char specifier with no surrounding text.
- Library: The pickle and cPickle modules no longer accept a return value of None from the __reduce__() method; the method must return a tuple of arguments instead. The modules also no longer accept the deprecated bin keyword parameter.
- Library: The SimpleXMLRPCServer and DocXMLRPCServer classes now have a rpc_paths attribute that constrains XML-
RPC operations to a limited set of URL paths; the default is to allow only '/\' and '/RPC2'. Setting rpc_paths to None or an empty tuple disables this path checking.

- C API: Many functions now use Py_ssize_t instead of int to allow processing more data on 64-bit machines. Extension code may need to make the same change to avoid warnings and to support 64-bit machines. See the earlier section PEP 353: Using ssize_t as the index type for a discussion of this change.

- C API: The obmalloc changes mean that you must be careful to not mix usage of the PyMem_*() and PyObject_*() families of functions. Memory allocated with one family's *_Malloc() must be freed with the corresponding family's *_Free() function.

What’s New in Python 2.4

Author: A.M. Kuchling

This article explains the new features in Python 2.4.1, released on March 30, 2005.

Python 2.4 is a medium-sized release. It doesn’t introduce as many changes as the radical Python 2.2, but introduces more features than the conservative 2.3 release. The most significant new language features are function decorators and generator expressions; most other changes are to the standard library.

According to the CVS change logs, there were 481 patches applied and 502 bugs fixed between Python 2.3 and 2.4. Both figures are likely to be underestimates.

This article doesn’t attempt to provide a complete specification of every single new feature, but instead provides a brief introduction to each feature. For full details, you should refer to the documentation for Python 2.4, such as the Python Library Reference and the Python Reference Manual. Often you will be referred to the PEP for a particular new feature for explanations of the implementation and design rationale.
PEP 218: Built-In Set Objects

Python 2.3 introduced the sets module. C implementations of set data types have now been added to the Python core as two new built-in types, `set(iterable)` and `frozenset(iterable)`. They provide high speed operations for membership testing, for eliminating duplicates from sequences, and for mathematical operations like unions, intersections, differences, and symmetric differences.

```python
>>> a = set('abracadabra')  # form a set
>>> 'z' in a               # fast membership test
False
>>> a                      # unique letters
set(['a', 'r', 'b', 'c', 'd'])
>>> ''.join(a)             # convert back into string
'arbcd'

>>> b = set('alacazam')    # form a second set
>>> a - b                  # letters in a but not in b
set(['r', 'd', 'b'])
>>> a | b                   # letters in either a or b
set(['a', 'c', 'r', 'd', 'b', 'm', 'z', 'l'])
>>> a & b                  # letters in both a and b
set(['a', 'c'])
>>> a ^ b                  # letters in a or b but not both
set(['r', 'd', 'b', 'm', 'z', 'l'])

>>> a.add('z')             # add a new element
>>> a                      # add a new element
set(['a', 'c', 'b', 'd', 'r', 'w', 'y', 'x', 'z'])
>>> a.remove('x')          # take one element out
>>> a                      # take one element out
set(['a', 'c', 'b', 'd', 'r', 'w', 'y', 'z'])
```
The `frozenset()` type is an immutable version of `set()`. Since it is immutable and hashable, it may be used as a dictionary key or as a member of another set.

The `sets` module remains in the standard library, and may be useful if you wish to subclass the `Set` or `ImmutableSet` classes. There are currently no plans to deprecate the module.

Originally proposed by Greg Wilson and ultimately implemented by Raymond Hettinger.
PEP 237: Unifying Long Integers and Integers

The lengthy transition process for this PEP, begun in Python 2.2, takes another step forward in Python 2.4. In 2.3, certain integer operations that would behave differently after int/long unification triggered `FutureWarning` warnings and returned values limited to 32 or 64 bits (depending on your platform). In 2.4, these expressions no longer produce a warning and instead produce a different result that's usually a long integer.

The problematic expressions are primarily left shifts and lengthy hexadecimal and octal constants. For example, \(2 << 32\) results in a warning in 2.3, evaluating to 0 on 32-bit platforms. In Python 2.4, this expression now returns the correct answer, 8589934592.

**PEP 237 - Unifying Long Integers and Integers**
Original PEP written by Moshe Zadka and GvR. The changes for 2.4 were implemented by Kalle Svensson.
PEP 289: Generator Expressions

The iterator feature introduced in Python 2.2 and the `itertools` module make it easier to write programs that loop through large data sets without having the entire data set in memory at one time. List comprehensions don’t fit into this picture very well because they produce a Python list object containing all of the items. This unavoidably pulls all of the objects into memory, which can be a problem if your data set is very large. When trying to write a functionally-styled program, it would be natural to write something like:

```python
links = [link for link in get_all_links() if not link for link in links:
    ...
```

instead of

```python
for link in get_all_links():
    if link.followed:
        continue
    ...
```

The first form is more concise and perhaps more readable, but if you’re dealing with a large number of link objects you’d have to write the second form to avoid having all link objects in memory at the same time.

Generator expressions work similarly to list comprehensions but don’t materialize the entire list; instead they create a generator that will return elements one by one. The above example could be written as:

```python
links = (link for link in get_all_links() if not link for link in links:
    ...
```
Generator expressions always have to be written inside parentheses, as in the above example. The parentheses signalling a function call also count, so if you want to create an iterator that will be immediately passed to a function you could write:

```python
print sum(obj.count for obj in list_all_objects())
```

Generator expressions differ from list comprehensions in various small ways. Most notably, the loop variable (``obj`` in the above example) is not accessible outside of the generator expression. List comprehensions leave the variable assigned to its last value; future versions of Python will change this, making list comprehensions match generator expressions in this respect.

See also:

**PEP 289 - Generator Expressions**

Proposed by Raymond Hettinger and implemented by Jiwon Seo with early efforts steered by Hye-Shik Chang.
PEP 292: Simpler String Substitutions

Some new classes in the standard library provide an alternative mechanism for substituting variables into strings; this style of substitution may be better for applications where untrained users need to edit templates.

The usual way of substituting variables by name is the % operator:

```python
>>> '%(page)i: %(title)s' % {'page': 2, 'title': 'The Best of Times'}
2: The Best of Times
```

When writing the template string, it can be easy to forget the `i` or `s` after the closing parenthesis. This isn’t a big problem if the template is in a Python module, because you run the code, get an “Unsupported format character” `ValueError`, and fix the problem. However, consider an application such as Mailman where template strings or translations are being edited by users who aren’t aware of the Python language. The format string’s syntax is complicated to explain to such users, and if they make a mistake, it’s difficult to provide helpful feedback to them.

PEP 292 adds a `Template` class to the `string` module that uses $ to indicate a substitution:

```python
>>> import string
>>> t = string.Template('$page: $title')
>>> t.substitute({'page': 2, 'title': 'The Best of Times'}
2: The Best of Times
```

If a key is missing from the dictionary, the `substitute()` method will
raise a **KeyError**. There's also a `safe_substitute()` method that ignores missing keys:

```python
>>> t = string.Template('${page: $title}')
>>> t.safe_substitute({'page':3})
'3: $title'
```

See also:

**PEP 292 - Simpler String Substitutions**

Written and implemented by Barry Warsaw.
PEP 318: Decorators for Functions and Methods

Python 2.2 extended Python’s object model by adding static methods and class methods, but it didn’t extend Python’s syntax to provide any new way of defining static or class methods. Instead, you had to write a `def` statement in the usual way, and pass the resulting method to a `staticmethod()` or `classmethod()` function that would wrap up the function as a method of the new type. Your code would look like this:

```python
class C:
    def meth (cls):
        ...

    meth = classmethod(meth)  # Rebind name to wrapped-up class method
```

If the method was very long, it would be easy to miss or forget the `classmethod()` invocation after the function body.

The intention was always to add some syntax to make such definitions more readable, but at the time of 2.2’s release a good syntax was not obvious. Today a good syntax still isn’t obvious but users are asking for easier access to the feature; a new syntactic feature has been added to meet this need.

The new feature is called “function decorators”. The name comes from the idea that `classmethod()`, `staticmethod()`, and friends are storing additional information on a function object; they’re *decorating* functions with more details.
The notation borrows from Java and uses the '@' character as an indicator. Using the new syntax, the example above would be written:

```python
class C:
    @classmethod
def meth(cls):
    ...
```

The `@classmethod` is shorthand for the `meth=classmethod(meth)` assignment. More generally, if you have the following:

```python
@A
@B
@C
def f():
    ...
```

It's equivalent to the following pre-decorator code:

```python
def f(): ...
f = A(B(C(f)))
```

Decorators must come on the line before a function definition, one decorator per line, and can't be on the same line as the def statement, meaning that `@A def f(): ...` is illegal. You can only decorate function definitions, either at the module level or inside a class; you can't decorate class definitions.

A decorator is just a function that takes the function to be decorated as an argument and returns either the same function or some new object. The return value of the decorator need not be callable (though it typically is), unless further decorators will be applied to the result. It's
easy to write your own decorators. The following simple example just sets an attribute on the function object:

```python
>>> def deco(func):
...     func.attr = 'decorated'
...     return func
...
>>> @deco
... def f(): pass
...
>>> f
<function f at 0x402ef0d4>
>>> f.attr
'decorated'
```

As a slightly more realistic example, the following decorator checks that the supplied argument is an integer:

```python
def require_int (func):
    def wrapper (arg):
        assert isinstance(arg, int)
        return func(arg)

    return wrapper

@require_int
def p1 (arg):
    print arg

@require_int
def p2(arg):
    print arg*2
```

An example in PEP 318 contains a fancier version of this idea that lets you both specify the required type and check the returned type.
Decorator functions can take arguments. If arguments are supplied, your decorator function is called with only those arguments and must return a new decorator function; this function must take a single function and return a function, as previously described. In other words, \@A \@B \@C(args) becomes:

```python
def f(): ...
    _deco = C(args)
    f = A(B(_deco(f)))
```

Getting this right can be slightly brain-bending, but it’s not too difficult.

A small related change makes the \texttt{func\_name} attribute of functions writable. This attribute is used to display function names in tracebacks, so decorators should change the name of any new function that’s constructed and returned.

\textbf{See also:}

\textbf{PEP 318 - Decorators for Functions, Methods and Classes}

Written by Kevin D. Smith, Jim Jewett, and Skip Montanaro. Several people wrote patches implementing function decorators, but the one that was actually checked in was patch \#979728, written by Mark Russell.

\textbf{https://wiki.python.org/moin/PythonDecoratorLibrary}

This Wiki page contains several examples of decorators.
PEP 322: Reverse Iteration

A new built-in function, `reversed(seq)`, takes a sequence and returns an iterator that loops over the elements of the sequence in reverse order.

```python
>>> for i in reversed(xrange(1,4)):
    ...   print i
... 3
... 2
... 1
```

Compared to extended slicing, such as `range(1,4)[::-1]`, `reversed()` is easier to read, runs faster, and uses substantially less memory.

Note that `reversed()` only accepts sequences, not arbitrary iterators. If you want to reverse an iterator, first convert it to a list with `list()`.

```python
>>> input = open('/etc/passwd', 'r')
>>> for line in reversed(list(input)):
    ...   print line
... root:*:0:0:System Administrator:/var/root:/bin/tcsh
...
```

See also:

PEP 322 - Reverse Iteration
Written and implemented by Raymond Hettinger.
PEP 324: New subprocess Module

The standard library provides a number of ways to execute a subprocess, offering different features and different levels of complexity. `os.system(command)` is easy to use, but slow (it runs a shell process which executes the command) and dangerous (you have to be careful about escaping the shell’s metacharacters). The popen2 module offers classes that can capture standard output and standard error from the subprocess, but the naming is confusing. The `subprocess` module cleans this up, providing a unified interface that offers all the features you might need.

Instead of popen2’s collection of classes, `subprocess` contains a single class called Popen whose constructor supports a number of different keyword arguments.

```python
class Popen(args, bufsize=0, executable=None, stdin=None, stdout=None, stderr=None, preexec_fn=None, close_fds=False, shell=False, cwd=None, env=None, universal_newlines=False, startupinfo=None, creationflags=0):
```

`args` is commonly a sequence of strings that will be the arguments to the program executed as the subprocess. (If the `shell` argument is true, `args` can be a string which will then be passed on to the shell for interpretation, just as `os.system()` does.)

`stdin`, `stdout`, and `stderr` specify what the subprocess’s input, output, and error streams will be. You can provide a file object or a file descriptor, or you can use the constant `subprocess.PIPE` to create a pipe between the subprocess and the parent.
The constructor has a number of handy options:

- `close_fds` requests that all file descriptors be closed before running the subprocess.
- `cwd` specifies the working directory in which the subprocess will be executed (defaulting to whatever the parent's working directory is).
- `env` is a dictionary specifying environment variables.
- `preexec_fn` is a function that gets called before the child is started.
- `universal_newlines` opens the child's input and output using Python's `universal newlines` feature.

Once you've created the `Popen` instance, you can call its `wait()` method to pause until the subprocess has exited, `poll()` to check if it's exited without pausing, or `communicate(data)` to send the string `data` to the subprocess's standard input. `communicate(data)` then reads any data that the subprocess has sent to its standard output or standard error, returning a tuple `(stdout_data, stderr_data)`.

call() is a shortcut that passes its arguments along to the Popen constructor, waits for the command to complete, and returns the status code of the subprocess. It can serve as a safer analog to `os.system()`:

```python
call = subprocess.call(['dpkg', '-i', '/tmp/new-package.deb'])
if call == 0:
    # Success
...
else:
    # dpkg returned an error
...
```
The command is invoked without use of the shell. If you really do want to use the shell, you can add `shell=True` as a keyword argument and provide a string instead of a sequence:

```python
sts = subprocess.call('dpkg -i /tmp/new-package.deb'
```

The PEP takes various examples of shell and Python code and shows how they'd be translated into Python code that uses `subprocess`. Reading this section of the PEP is highly recommended.

**PEP 324 - subprocess - New process module**

Written and implemented by Peter Åstrand, with assistance from Fredrik Lundh and others.
PEP 327: Decimal Data Type

Python has always supported floating-point (FP) numbers, based on the underlying C `double` type, as a data type. However, while most programming languages provide a floating-point type, many people (even programmers) are unaware that floating-point numbers don’t represent certain decimal fractions accurately. The new `Decimal` type can represent these fractions accurately, up to a user-specified precision limit.

Why is Decimal needed?

The limitations arise from the representation used for floating-point numbers. FP numbers are made up of three components:

- The sign, which is positive or negative.
- The mantissa, which is a single-digit binary number followed by a fractional part. For example, \(1.01\) in base-2 notation is \(1 + \frac{0}{2} + \frac{1}{4}\), or \(1.25\) in decimal notation.
- The exponent, which tells where the decimal point is located in the number represented.

For example, the number 1.25 has positive sign, a mantissa value of 1.01 (in binary), and an exponent of 0 (the decimal point doesn’t need to be shifted). The number 5 has the same sign and mantissa, but the exponent is 2 because the mantissa is multiplied by 4 (2 to the power of the exponent 2); \(1.25 \times 4\) equals 5.

Modern systems usually provide floating-point support that conforms to a standard called IEEE 754. C’s `double` type is usually implemented as a 64-bit IEEE 754 number, which uses 52 bits of space for the mantissa. This means that numbers can only be
specified to 52 bits of precision. If you’re trying to represent numbers whose expansion repeats endlessly, the expansion is cut off after 52 bits. Unfortunately, most software needs to produce output in base 10, and common fractions in base 10 are often repeating decimals in binary. For example, 1.1 decimal is binary 1.0001100110011...; .1 = 1/16 + 1/32 + 1/256 plus an infinite number of additional terms. IEEE 754 has to chop off that infinitely repeated decimal after 52 digits, so the representation is slightly inaccurate.

Sometimes you can see this inaccuracy when the number is printed:

```python
>>> 1.1
1.1000000000000001
```

The inaccuracy isn’t always visible when you print the number because the FP-to-decimal-string conversion is provided by the C library, and most C libraries try to produce sensible output. Even if it’s not displayed, however, the inaccuracy is still there and subsequent operations can magnify the error.

For many applications this doesn’t matter. If I’m plotting points and displaying them on my monitor, the difference between 1.1 and 1.1000000000000001 is too small to be visible. Reports often limit output to a certain number of decimal places, and if you round the number to two or three or even eight decimal places, the error is never apparent. However, for applications where it does matter, it’s a lot of work to implement your own custom arithmetic routines.

Hence, the Decimal type was created.

The Decimal type
A new module, `decimal`, was added to Python’s standard library. It contains two classes, `Decimal` and `Context`. `Decimal` instances represent numbers, and `Context` instances are used to wrap up various settings such as the precision and default rounding mode.

Decimal instances are immutable, like regular Python integers and FP numbers; once it’s been created, you can’t change the value an instance represents. `Decimal` instances can be created from integers or strings:

```python
>>> import decimal
>>> decimal.Decimal(1972)
Decimal('1972')
>>> decimal.Decimal('1.1')
Decimal('1.1')
```

You can also provide tuples containing the sign, the mantissa represented as a tuple of decimal digits, and the exponent:

```python
>>> decimal.Decimal((1, (1, 4, 7, 5), -2))
Decimal('-14.75')
```

Cautionary note: the sign bit is a Boolean value, so 0 is positive and 1 is negative.

Converting from floating-point numbers poses a bit of a problem: should the FP number representing 1.1 turn into the decimal number for exactly 1.1, or for 1.1 plus whatever inaccuracies are introduced? The decision was to dodge the issue and leave such a conversion out of the API. Instead, you should convert the floating-point number into a string using the desired precision and pass the string to the `Decimal` constructor:
Once you have Decimal instances, you can perform the usual mathematical operations on them. One limitation: exponentiation requires an integer exponent:

```python
>>> a = decimal.Decimal('35.72')
>>> b = decimal.Decimal('1.73')
>>> a+b
Decimal("37.45")
>>> a-b
Decimal("33.99")
>>> a*b
Decimal("61.7956")
>>> a/b
Decimal("20.64739884393063583815028902")
>>> a ** 2
Decimal("1275.9184")
>>> a**b
Traceback (most recent call last):
  ...
  decimal.InvalidOperation: x ** (non-integer)
```

You can combine Decimal instances with integers, but not with floating-point numbers:

```python
>>> a + 4
Decimal("39.72")
>>> a + 4.5
Traceback (most recent call last):
  ...
```
TypeError: You can interact Decimal only with int, long or Decimal data types.

>>> Decimal numbers can be used with the math and cmath modules, but note that they'll be immediately converted to floating-point numbers before the operation is performed, resulting in a possible loss of precision and accuracy. You'll also get back a regular floating-point number and not a Decimal.

>>> import math, cmath
>>> d = decimal.Decimal('123456789012.345')
>>> math.sqrt(d)
351364.18288201344
>>> cmath.sqrt(-d)
351364.18288201344j

Decimal instances have a sqrt() method that returns a Decimal, but if you need other things such as trigonometric functions you'll have to implement them.

>>> d.sqrt()
Decimal("351364.1828820134592177245001")

The Context type

Instances of the Context class encapsulate several settings for decimal operations:

- prec is the precision, the number of decimal places.
- rounding specifies the rounding mode. The decimal module has constants for the various possibilities: ROUND_DOWN, ROUND_CEILING, ROUND_HALF_EVEN, and various others.
traps is a dictionary specifying what happens on encountering certain error conditions: either an exception is raised or a value is returned. Some examples of error conditions are division by zero, loss of precision, and overflow.

There's a thread-local default context available by calling `getcontext()`; you can change the properties of this context to alter the default precision, rounding, or trap handling. The following example shows the effect of changing the precision of the default context:

```python
>>> decimal.getcontext().prec
28
>>> decimal.Decimal(1) / decimal.Decimal(7)
Decimal("0.1428571428571428571428571429")
>>> decimal.getcontext().prec = 9
>>> decimal.Decimal(1) / decimal.Decimal(7)
Decimal("0.142857143")
```

The default action for error conditions is selectable; the module can either return a special value such as infinity or not-a-number, or exceptions can be raised:

```python
>>> decimal.Decimal(1) / decimal.Decimal(0)
Traceback (most recent call last):
 ... 
decimal.DivisionByZero: x / 0
>>> decimal.getcontext().traps[decimal.DivisionByZero] = True
>>> decimal.Decimal(1) / decimal.Decimal(0)
Decimal("Infinity")
```

The Context instance also has various methods for formatting numbers such as `to_eng_string()` and `to_sci_string()`.
For more information, see the documentation for the decimal module, which includes a quick-start tutorial and a reference.

**PEP 327 - Decimal Data Type**
Written by Facundo Batista and implemented by Facundo Batista, Eric Price, Raymond Hettinger, Aahz, and Tim Peters.

[http://www.lahey.com/float.htm](http://www.lahey.com/float.htm)
The article uses Fortran code to illustrate many of the problems that floating-point inaccuracy can cause.

A description of a decimal-based representation. This representation is being proposed as a standard, and underlies the new Python decimal type. Much of this material was written by Mike Cowlishaw, designer of the Rexx language.
One language change is a small syntactic tweak aimed at making it easier to import many names from a module. In a `from module import names` statement, `names` is a sequence of names separated by commas. If the sequence is very long, you can either write multiple imports from the same module, or you can use backslashes to escape the line endings like this:

```python
from SimpleXMLRPCServer import SimpleXMLRPCServer,
    SimpleXMLRPCRequestHandler,
    CGIXMLRPCRequestHandler,
    resolve_dotted_attribute
```

The syntactic change in Python 2.4 simply allows putting the names within parentheses. Python ignores newlines within a parenthesized expression, so the backslashes are no longer needed:

```python
from SimpleXMLRPCServer import (SimpleXMLRPCServer,
    SimpleXMLRPCRequestHandler,
    CGIXMLRPCRequestHandler,
    resolve_dotted_attribute)
```

The PEP also proposes that all `import` statements be absolute imports, with a leading `.` character to indicate a relative import. This part of the PEP was not implemented for Python 2.4, but was completed for Python 2.5.

See also:

**PEP 328 - Imports: Multi-Line and Absolute/Relative**

Written by Aahz. Multi-line imports were implemented by Dima
Dorfman.
PEP 331: Locale-Independent Float/String Conversions

The `locale` modules lets Python software select various conversions and display conventions that are localized to a particular country or language. However, the module was careful to not change the numeric locale because various functions in Python's implementation required that the numeric locale remain set to the 'C' locale. Often this was because the code was using the C library's `atof()` function.

Not setting the numeric locale caused trouble for extensions that used third-party C libraries, however, because they wouldn't have the correct locale set. The motivating example was GTK+, whose user interface widgets weren't displaying numbers in the current locale.

The solution described in the PEP is to add three new functions to the Python API that perform ASCII-only conversions, ignoring the locale setting:

- `PyOS_ascii_strtod(str, ptr)` and `PyOS_ascii_atof(str, ptr)` both convert a string to a C double.
- `PyOS_ascii_formatd(buffer, buf_len, format, d)` converts a double to an ASCII string.

The code for these functions came from the GLib library (https://developer.gnome.org/glib/stable/), whose developers kindly relicensed the relevant functions and donated them to the Python Software Foundation. The `locale` module can now change the numeric locale, letting extensions such as GTK+ produce the correct results.
See also:

**PEP 331** - Locale-Independent Float/String Conversions

Written by Christian R. Reis, and implemented by Gustavo Carneiro.
Other Language Changes

Here are all of the changes that Python 2.4 makes to the core Python language.

- Decorators for functions and methods were added (PEP 318).
- Built-in set() and frozenset() types were added (PEP 218). Other new built-ins include the reversed(seq) function (PEP 322).
- Generator expressions were added (PEP 289).
- Certain numeric expressions no longer return values restricted to 32 or 64 bits (PEP 237).
- You can now put parentheses around the list of names in a from module import names statement (PEP 328).
- The dict.update() method now accepts the same argument forms as the dict constructor. This includes any mapping, any iterable of key/value pairs, and keyword arguments. (Contributed by Raymond Hettinger.)
- The string methods ljust(), rjust(), and center() now take an optional argument for specifying a fill character other than a space. (Contributed by Raymond Hettinger.)
- Strings also gained an rsplit() method that works like the split() method but splits from the end of the string. (Contributed by Sean Reifschneider.)

```python
>>> 'www.python.org'.split('.', 1)
```
Three keyword parameters, `cmp`, `key`, and `reverse`, were added to the `sort()` method of lists. These parameters make some common usages of `sort()` simpler. All of these parameters are optional.

For the `cmp` parameter, the value should be a comparison function that takes two parameters and returns -1, 0, or +1 depending on how the parameters compare. This function will then be used to sort the list. Previously this was the only parameter that could be provided to `sort()`.

`key` should be a single-parameter function that takes a list element and returns a comparison key for the element. The list is then sorted using the comparison keys. The following example sorts a list case-insensitively:

```python
>>> L = ['A', 'b', 'c', 'D']
>>> L.sort()                           # Case-sensitive sort
>>> L
['A', 'D', 'b', 'c']

>>> # Using 'key' parameter to sort list
>>> L.sort(key=lambda x: x.lower())   # Old-fashioned way
>>> L
['A', 'b', 'c', 'D']
```

The last example, which uses the `cmp` parameter, is the old way
to perform a case-insensitive sort. It works but is slower than using a *key* parameter. Using *key* calls *lower()* method once for each element in the list while using *cmp* will call it twice for each comparison, so using *key* saves on invocations of the *lower()* method.

For simple key functions and comparison functions, it is often possible to avoid a *lambda* expression by using an unbound method instead. For example, the above case-insensitive sort is best written as:

```
>>> L.sort(key=str.lower)
>>> L
['A', 'b', 'c', 'D']
```

Finally, the *reverse* parameter takes a Boolean value. If the value is true, the list will be sorted into reverse order. Instead of `L.sort(); L.reverse()`, you can now write `L.sort(reverse=True)`.

The results of sorting are now guaranteed to be stable. This means that two entries with equal keys will be returned in the same order as they were input. For example, you can sort a list of people by name, and then sort the list by age, resulting in a list sorted by age where people with the same age are in name-sorted order.

(All changes to *sort()* contributed by Raymond Hettinger.)

- There is a new built-in function *sorted(iterable)* that works like the in-place *list.sort()* method but can be used in expressions. The differences are:
• the input may be any iterable;

• a newly formed copy is sorted, leaving the original intact; and

• the expression returns the new sorted copy

```python
>>> L = [9, 7, 8, 3, 2, 4, 1, 6, 5]
>>> [10+i for i in sorted(L)]       # usable in a list comprehension
[11, 12, 13, 14, 15, 16, 17, 18, 19]
>>> L                               # original is left unchanged
[9, 7, 8, 3, 2, 4, 1, 6, 5]
>>> sorted('Monty Python')          # any iterable may be an input
[' ', 'M', 'P', 'h', 'n', 'o', 'o', 't', 'y']
```

```bash
>>> # List the contents of a dict sorted by key values
>>> colormap = dict(red=1, blue=2, green=3, black=4)
>>> for k, v in sorted(colormap.items()):
...     print k, v
...
black 4
blue 2
green 3
red 1
yellow 5
```

(Contributed by Raymond Hettinger.)

• Integer operations will no longer trigger an OverflowWarning. The OverflowWarning warning will disappear in Python 2.5.

• The interpreter gained a new switch, `-m`, that takes a name, searches for the corresponding module on `sys.path`, and runs the module as a script. For example, you can now run the Python profiler with `python -m profile`. (Contributed by Nick Coghlan.)
- The `eval(expr, globals, locals)` and `execfile(filename, globals, locals)` functions and the `exec` statement now accept any mapping type for the `locals` parameter. Previously this had to be a regular Python dictionary. (Contributed by Raymond Hettinger.)

- The `zip()` built-in function and `itertools.izip()` now return an empty list if called with no arguments. Previously they raised a `TypeError` exception. This makes them more suitable for use with variable length argument lists:

```python
def transpose(array):
    ... return zip(*array)
...
>>> transpose(((1,2,3), (4,5,6)))
[(1, 4), (2, 5), (3, 6)]
>>> transpose([])
[]
```

(Contributed by Raymond Hettinger.)

- Encountering a failure while importing a module no longer leaves a partially-initialized module object in `sys.modules`. The incomplete module object left behind would fool further imports of the same module into succeeding, leading to confusing errors. (Fixed by Tim Peters.)

- `None` is now a constant; code that binds a new value to the name `None` is now a syntax error. (Contributed by Raymond Hettinger.)

Optimizations

- The inner loops for list and tuple slicing were optimized and now
run about one-third faster. The inner loops for dictionaries were also optimized, resulting in performance boosts for keys(), values(), items(), iterkeys(), itervalues(), and iteritems. (Contributed by Raymond Hettinger.)

- The machinery for growing and shrinking lists was optimized for speed and for space efficiency. Appending and popping from lists now runs faster due to more efficient code paths and less frequent use of the underlying system realloc(). List comprehensions also benefit. list.extend() was also optimized and no longer converts its argument into a temporary list before extending the base list. (Contributed by Raymond Hettinger.)

- list(), tuple(), map(), filter(), and zip() now run several times faster with non-sequence arguments that supply a __len__() method. (Contributed by Raymond Hettinger.)

- The methods list.__getitem__, dict.__getitem__, and dict.__contains__ are now implemented as method_descriptor objects rather than wrapper_descriptor objects. This form of access doubles their performance and makes them more suitable for use as arguments to functionals: map(mydict.__getitem__, keylist). (Contributed by Raymond Hettinger.)

- Added a new opcode, LIST_APPEND, that simplifies the generated bytecode for list comprehensions and speeds them up by about a third. (Contributed by Raymond Hettinger.)

- The peephole bytecode optimizer has been improved to produce shorter, faster bytecode; remarkably, the resulting bytecode is more readable. (Enhanced by Raymond Hettinger.)

- String concatenations in statements of the form \( s = s + "abc" \) and \( s += "abc" \) are now performed more efficiently in certain circumstances. This optimization won't be present in other Python implementations such as Jython, so you shouldn't rely on it; using the join() method of strings is still recommended when you want to efficiently glue a large number of strings together.
The net result of the 2.4 optimizations is that Python 2.4 runs the pystone benchmark around 5% faster than Python 2.3 and 35% faster than Python 2.2. (pystone is not a particularly good benchmark, but it's the most commonly used measurement of Python's performance. Your own applications may show greater or smaller benefits from Python 2.4.)
New, Improved, and Deprecated Modules

As usual, Python's standard library received a number of enhancements and bug fixes. Here's a partial list of the most notable changes, sorted alphabetically by module name. Consult the Misc/NEWS file in the source tree for a more complete list of changes, or look through the CVS logs for all the details.

- The asyncore module's loop() function now has a count parameter that lets you perform a limited number of passes through the polling loop. The default is still to loop forever.

- The base64 module now has more complete RFC 3548 support for Base64, Base32, and Base16 encoding and decoding, including optional case folding and optional alternative alphabets. (Contributed by Barry Warsaw.)

- The bisect module now has an underlying C implementation for improved performance. (Contributed by Dmitry Vasiliev.)

- The CJKCodecs collections of East Asian codecs, maintained by Hye-Shik Chang, was integrated into 2.4. The new encodings are:
  
  - Chinese (PRC): gb2312, gbk, gb18030, big5hkscs, hz
  - Chinese (ROC): big5, cp950
• Some other new encodings were added: HP Roman8, ISO_8859-11, ISO_8859-16, PCTP-154, and TIS-620.

• The UTF-8 and UTF-16 codecs now cope better with receiving partial input. Previously the StreamReader class would try to read more data, making it impossible to resume decoding from the stream. The read() method will now return as much data as it can and future calls will resume decoding where previous ones left off. (Implemented by Walter Dörwald.)

• There is a new collections module for various specialized collection datatypes. Currently it contains just one type, deque, a double-ended queue that supports efficiently adding and removing elements from either end:

```python
>>> from collections import deque
>>> d = deque('ghi')  # make a new deque with three items
>>> d.append('j')  # add a new entry to the right side
>>> d.appendleft('f')  # add a new entry to the left side
>>> d  # show the representation of the deque
deque(['f', 'g', 'h', 'i', 'j'])
>>> d.pop()  # return and remove the rightmost item
'j'
>>> d.popleft()  # return and remove the leftmost item
'f'
>>> list(d)  # list the contents of the deque
['g', 'h', 'i']
>>> 'h' in d  # search the deque
True
```

Several modules, such as the Queue and threading modules, now take advantage of collections.deque for improved performance. (Contributed by Raymond Hettinger.)
- The ConfigParser classes have been enhanced slightly. The read() method now returns a list of the files that were successfully parsed, and the set() method raises TypeError if passed a value argument that isn’t a string. (Contributed by John Belmonte and David Goodger.)

- The curses module now supports the ncurses extension use_default_colors(). On platforms where the terminal supports transparency, this makes it possible to use a transparent background. (Contributed by Jörg Lehmann.)

- The difflib module now includes an HtmlDiff class that creates an HTML table showing a side by side comparison of two versions of a text. (Contributed by Dan Gass.)

- The email package was updated to version 3.0, which dropped various deprecated APIs and removes support for Python versions earlier than 2.3. The 3.0 version of the package uses a new incremental parser for MIME messages, available in the email.FeedParser module. The new parser doesn’t require reading the entire message into memory, and doesn’t raise exceptions if a message is malformed; instead it records any problems in the defect attribute of the message. (Developed by Anthony Baxter, Barry Warsaw, Thomas Wouters, and others.)

- The heapq module has been converted to C. The resulting tenfold improvement in speed makes the module suitable for handling high volumes of data. In addition, the module has two new functions nlargest() and nsmallest() that use heaps to find the N largest or smallest values in a dataset without the expense of a full sort. (Contributed by Raymond Hettinger.)
The `httplib` module now contains constants for HTTP status codes defined in various HTTP-related RFC documents. Constants have names such as `OK`, `CREATED`, `CONTINUE`, and `MOVED_PERMANENTLY`; use `pydoc` to get a full list. (Contributed by Andrew Eland.)

The `imaplib` module now supports IMAP's THREAD command (contributed by Yves Dionne) and new `deleteacl()` and `myrights()` methods (contributed by Arnaud Mazin).

The `itertools` module gained a `groupby(iterable[, *func*])` function. `iterable` is something that can be iterated over to return a stream of elements, and the optional `func` parameter is a function that takes an element and returns a key value; if omitted, the key is simply the element itself. `groupby()` then groups the elements into subsequences which have matching values of the key, and returns a series of 2-tuples containing the key value and an iterator over the subsequence.

Here's an example to make this clearer. The `key` function simply returns whether a number is even or odd, so the result of `groupby()` is to return consecutive runs of odd or even numbers.

```python
>>> import itertools
>>> L = [2, 4, 6, 7, 8, 9, 11, 12, 14]
>>> for key_val, it in itertools.groupby(L, lambda x: x % 2)
...     print key_val, list(it)
0 [2, 4, 6]
1 [7]
0 [8]
1 [9, 11]
```
groupby() is typically used with sorted input. The logic for groupby() is similar to the Unix uniq filter which makes it handy for eliminating, counting, or identifying duplicate elements:

```python
>>> word = 'abracadabra'
>>> letters = sorted(word)  # Turn string into a list of letters
['a', 'a', 'a', 'a', 'b', 'b', 'c', 'd', 'r']
>>> for k, g in itertools.groupby(letters):
...     print(k, list(g))
...  a ['a', 'a', 'a', 'a', 'a']
  b ['b', 'b']
  c ['c']
  d ['d']
  r ['r', 'r']
>>> # List unique letters
>>> [k for k, g in groupby(letters)]
['a', 'b', 'c', 'd', 'r']
>>> # Count letter occurrences
>>> [(k, len(list(g))) for k, g in groupby(letters)]
[('a', 5), ('b', 2), ('c', 1), ('d', 1), ('r', 2)]
```

(Contributed by Hye-Shik Chang.)

- `itertools` also gained a function named `tee(iterator, N)` that returns $N$ independent iterators that replicate `iterator`. If $N$ is omitted, the default is 2.

```python
>>> L = [1, 2, 3]
>>> i1, i2 = itertools.tee(L)
```
>>> i1, i2
(<itertools.tee object at 0x402c2080>, <itertools.tee object at 0x402c2090>),

>>> list(i1)  # Run the first iterator
[1, 2, 3]

>>> list(i2)  # Run the second iterator
[1, 2, 3]

Note that tee() has to keep copies of the values returned by the iterator; in the worst case, it may need to keep all of them. This should therefore be used carefully if the leading iterator can run far ahead of the trailing iterator in a long stream of inputs. If the separation is large, then you might as well use list() instead. When the iterators track closely with one another, tee() is ideal. Possible applications include bookmarking, windowing, or lookahead iterators. (Contributed by Raymond Hettinger.)

- A number of functions were added to the locale module, such as bind_textdomain_codeset() to specify a particular encoding and a family of lgettext() functions that return messages in the chosen encoding. (Contributed by Gustavo Niemeyer.)

- Some keyword arguments were added to the logging package's basicConfig() function to simplify log configuration. The default behavior is to log messages to standard error, but various keyword arguments can be specified to log to a particular file, change the logging format, or set the logging level. For example:

  ```python
  import logging
  logging.basicConfig(filename='/var/log/application.log',
                      level=0,  # Log all messages
                      format='%(levelname):%(process):%(thread):%(message)'
  ```
Other additions to the `logging` package include a `log(level, msg)` convenience method, as well as a `TimedRotatingFileHandler` class that rotates its log files at a timed interval. The module already had `RotatingFileHandler`, which rotated logs once the file exceeded a certain size. Both classes derive from a new `BaseRotatingHandler` class that can be used to implement other rotating handlers.

(Changes implemented by Vinay Sajip.)

- The `marshal` module now shares interned strings on unpacking a data structure. This may shrink the size of certain pickle strings, but the primary effect is to make `.pyc` files significantly smaller. (Contributed by Martin von Löwis.)

- The `nntplib` module's NNTP class gained `description()` and `descriptions()` methods to retrieve newsgroup descriptions for a single group or for a range of groups. (Contributed by Jürgen A. Erhard.)

- Two new functions were added to the `operator` module, `attrgetter(attr)` and `itemgetter(index)`. Both functions return callables that take a single argument and return the corresponding attribute or item; these callables make excellent data extractors when used with `map()` or `sorted()`. For example:

```python
>>> L = [('c', 2), ('d', 1), ('a', 4), ('b', 3)]
>>> map(operator.itemgetter(0), L)
['c', 'd', 'a', 'b']
>>> map(operator.itemgetter(1), L)
[2, 1, 4, 3]
```
The `optparse` module was updated in various ways. The module now passes its messages through `gettext.gettext()`, making it possible to internationalize Optik’s help and error messages. Help messages for options can now include the string `%default`, which will be replaced by the option’s default value. (Contributed by Greg Ward.)

The long-term plan is to deprecate the `rfc822` module in some future Python release in favor of the `email` package. To this end, the `email.Utils.formatdate()` function has been changed to make it usable as a replacement for `rfc822.formatdate()`. You may want to write new e-mail processing code with this in mind. (Change implemented by Anthony Baxter.)

A new `urandom(n)` function was added to the `os` module, returning a string containing `n` bytes of random data. This function provides access to platform-specific sources of randomness such as `/dev/urandom` on Linux or the Windows CryptoAPI. (Contributed by Trevor Perrin.)

Another new function: `os.path.lexists(path)` returns true if the file specified by `path` exists, whether or not it’s a symbolic link. This differs from the existing `os.path.exists(path)` function, which returns false if `path` is a symlink that points to a destination that doesn’t exist. (Contributed by Beni Cherniavsky.)

A new `getsid()` function was added to the `posix` module that

```
>>> sorted(L, key=operator.itemgetter(1))  # Sort
[('d', 1), ('c', 2), ('b', 3), ('a', 4)]

(Contributed by Raymond Hettinger.)
```
underlies the os module. (Contributed by J. Raynor.)

- The poplib module now supports POP over SSL. (Contributed by Hector Urtubia.)

- The profile module can now profile C extension functions. (Contributed by Nick Bastin.)

- The random module has a new method called getrandbits(N) that returns a long integer N bits in length. The existing randrange() method now uses getrandbits() where appropriate, making generation of arbitrarily large random numbers more efficient. (Contributed by Raymond Hettinger.)

- The regular expression language accepted by the re module was extended with simple conditional expressions, written as (? (group)A|B). group is either a numeric group ID or a group name defined with (?P<group>...) earlier in the expression. If the specified group matched, the regular expression pattern A will be tested against the string; if the group didn’t match, the pattern B will be used instead. (Contributed by Gustavo Niemeyer.)

- The re module is also no longer recursive, thanks to a massive amount of work by Gustavo Niemeyer. In a recursive regular expression engine, certain patterns result in a large amount of C stack space being consumed, and it was possible to overflow the stack. For example, if you matched a 30000-byte string of a characters against the expression (a|b)+, one stack frame was consumed per character. Python 2.3 tried to check for stack overflow and raise a RuntimeError exception, but certain patterns could sidestep the checking and if you were unlucky Python could segfault. Python 2.4’s regular expression engine can
match this pattern without problems.

- The `signal` module now performs tighter error-checking on the parameters to the `signal.signal()` function. For example, you can’t set a handler on the SIGKILL signal; previous versions of Python would quietly accept this, but 2.4 will raise a `RuntimeError` exception.

- Two new functions were added to the `socket` module. `socketpair()` returns a pair of connected sockets and `getservbyport(port)` looks up the service name for a given port number. (Contributed by Dave Cole and Barry Warsaw.)

- The `sys.exitfunc()` function has been deprecated. Code should be using the existing `atexit` module, which correctly handles calling multiple exit functions. Eventually `sys.exitfunc()` will become a purely internal interface, accessed only by `atexit`.

- The `tarfile` module now generates GNU-format tar files by default. (Contributed by Lars Gustäbel.)

- The `threading` module now has an elegantly simple way to support thread-local data. The module contains a `local` class whose attribute values are local to different threads.

```python
import threading

data = threading.local()
data.number = 42
data.url = ('www.python.org', 80)
```

Other threads can assign and retrieve their own values for the
number and url attributes. You can subclass local to initialize attributes or to add methods. (Contributed by Jim Fulton.)

- The timeit module now automatically disables periodic garbage collection during the timing loop. This change makes consecutive timings more comparable. (Contributed by Raymond Hettinger.)

- The weakref module now supports a wider variety of objects including Python functions, class instances, sets, frozensets, deques, arrays, files, sockets, and regular expression pattern objects. (Contributed by Raymond Hettinger.)

- The xmlrpclib module now supports a multi-call extension for transmitting multiple XML-RPC calls in a single HTTP operation. (Contributed by Brian Quinlan.)

- The mpz, rotor, and xreadlines modules have been removed.

**cookielib**

The cookielib library supports client-side handling for HTTP cookies, mirroring the Cookie module's server-side cookie support. Cookies are stored in cookie jars; the library transparently stores cookies offered by the web server in the cookie jar, and fetches the cookie from the jar when connecting to the server. As in web browsers, policy objects control whether cookies are accepted or not.

In order to store cookies across sessions, two implementations of cookie jars are provided: one that stores cookies in the Netscape format so applications can use the Mozilla or Lynx cookie files, and one that stores cookies in the same format as the Perl libwww library.
urllib2 has been changed to interact with cookielib: HTTPCookieProcessor manages a cookie jar that is used when accessing URLs.

This module was contributed by John J. Lee.

**doctest**

The *doctest* module underwent considerable refactoring thanks to Edward Loper and Tim Peters. Testing can still be as simple as running `doctest.testmod()`, but the refactorings allow customizing the module’s operation in various ways.

The new DocTestFinder class extracts the tests from a given object’s docstrings:

```python
def f(x, y):
    """>>> f(2,2)
    4
    >>> f(3,2)
    6
    ""
    return x*y

finder = doctest.DocTestFinder()

# Get list of DocTest instances
tests = finder.find(f)
```

The new DocTestRunner class then runs individual tests and can produce a summary of the results:

```python
runner = doctest.DocTestRunner()
for t in tests:
```
tried, failed = runner.run(t)

runner.summarize(verbos=1)

The above example produces the following output:

```
1 items passed all tests:
  2 tests in f
2 tests in 1 items.
2 passed and 0 failed.
Test passed.
```

DocTestRunner uses an instance of the OutputChecker class to compare the expected output with the actual output. This class takes a number of different flags that customize its behaviour; ambitious users can also write a completely new subclass of OutputChecker.

The default output checker provides a number of handy features. For example, with the doctest.ELLIPSIS option flag, an ellipsis (…) in the expected output matches any substring, making it easier to accommodate outputs that vary in minor ways:

```
def o(n):
    """>>> o(1)
<__main__.C instance at 0x...>
>>>
""
```

Another special string, <BLANKLINE>, matches a blank line:

```
def p(n):
    """>>> p(1)
<BLANKLINE>
>>>
""
```
Another new capability is producing a diff-style display of the output by specifying the `doctest.REPORT_UDIFF` (unified diffs), `doctest.REPORT_CDIFF` (context diffs), or `doctest.REPORT_NDIFF` (delta-style) option flags. For example:

```python
def g(n):
    """>>> g(4)
here
is
a
lengthy

>>>"
    L = 'here is a rather lengthy list of words'.split
    for word in L[:n]:
        print word
```

Running the above function’s tests with `doctest.REPORT_UDIFF` specified, you get the following output:

```
**********************************************************************
File "t.py", line 15, in g
Failed example:
g(4)
Differences (unified diff with -expected +actual):
@@ -2,3 +2,3 @@
is
+a
-lengthy
+rather
**********************************************************************
```
Build and C API Changes

Some of the changes to Python’s build process and to the C API are:

- Three new convenience macros were added for common return values from extension functions: `Py_RETURN_NONE`, `Py_RETURN_TRUE`, and `Py_RETURN_FALSE`. (Contributed by Brett Cannon.)
- Another new macro, `Py_CLEAR(obj)`, decreases the reference count of `obj` and sets `obj` to the null pointer. (Contributed by Jim Fulton.)
- A new function, `PyTuple_Pack(N, obj1, obj2, ..., objN)`, constructs tuples from a variable length argument list of Python objects. (Contributed by Raymond Hettinger.)
- A new function, `PyDict_Contains(d, k)`, implements fast dictionary lookups without masking exceptions raised during the look-up process. (Contributed by Raymond Hettinger.)
- The `Py_IS_NAN(X)` macro returns 1 if its float or double argument `X` is a NaN. (Contributed by Tim Peters.)
- C code can avoid unnecessary locking by using the new `PyEval_ThreadsInitialized()` function to tell if any thread operations have been performed. If this function returns false, no lock operations are needed. (Contributed by Nick Coghlan.)
- A new function, `PyArg_VaParseTupleAndKeywords()`, is the same as `PyArg_ParseTupleAndKeywords()` but takes a `va_list` instead of a number of arguments. (Contributed by Greg Chapman.)
- A new method flag, `METH_COEXIST`, allows a function defined in slots to co-exist with a `PyCFunction` having the same name. This can halve the access time for a method such as `set.__contains__()`. (Contributed by Raymond Hettinger.)
- Python can now be built with additional profiling for the interpreter
itself, intended as an aid to people developing the Python core. Providing `--enable-profiling` to the `configure` script will let you profile the interpreter with `gprof`, and providing the `--with-tsc` switch enables profiling using the Pentium’s Time-Stamp-Counter register. Note that the `--with-tsc` switch is slightly misnamed, because the profiling feature also works on the PowerPC platform, though that processor architecture doesn’t call that register “the TSC register”. (Contributed by Jeremy Hylton.)

- The `tracebackobject` type has been renamed to `PyTracebackObject`.

**Port-Specific Changes**

- The Windows port now builds under MSVC++ 7.1 as well as version 6. (Contributed by Martin von Löwis.)
Porting to Python 2.4

This section lists previously described changes that may require changes to your code:

- Left shifts and hexadecimal/octal constants that are too large no longer trigger a `FutureWarning` and return a value limited to 32 or 64 bits; instead they return a long integer.
- Integer operations will no longer trigger an `OverflowWarning`. The `OverflowWarning` warning will disappear in Python 2.5.
- The `zip()` built-in function and `itertools.izip()` now return an empty list instead of raising a `TypeError` exception if called with no arguments.
- You can no longer compare the date and `datetime` instances provided by the `datetime` module. Two instances of different classes will now always be unequal, and relative comparisons (<, >) will raise a `TypeError`.
- `dircache.listdir()` now passes exceptions to the caller instead of returning empty lists.
- `LexicalHandler.startDTD()` used to receive the public and system IDs in the wrong order. This has been corrected; applications relying on the wrong order need to be fixed.
- `fcntl.ioctl()` now warns if the `mutate` argument is omitted and relevant.
- The `tarfile` module now generates GNU-format tar files by default.
- Encountering a failure while importing a module no longer leaves a partially-initialized module object in `sys.modules`.
- `None` is now a constant; code that binds a new value to the name `None` is now a syntax error.
- The `signals.signal()` function now raises a `RuntimeError` exception for certain illegal values; previously these errors would
pass silently. For example, you can no longer set a handler on the SIGKILL signal.
Acknowledgements

The author would like to thank the following people for offering suggestions, corrections and assistance with various drafts of this article: Koray Can, Hye-Shik Chang, Michael Dyck, Raymond Hettinger, Brian Hurt, Hamish Lawson, Fredrik Lundh, Sean Reifschneider, Sadruddin Rejeb.
What’s New in Python 2.3

Author: A.M. Kuchling

This article explains the new features in Python 2.3. Python 2.3 was released on July 29, 2003.

The main themes for Python 2.3 are polishing some of the features added in 2.2, adding various small but useful enhancements to the core language, and expanding the standard library. The new object model introduced in the previous version has benefited from 18 months of bugfixes and from optimization efforts that have improved the performance of new-style classes. A few new built-in functions have been added such as `sum()` and `enumerate()`. The `in` operator can now be used for substring searches (e.g. "ab" in "abc" returns `True`).

Some of the many new library features include Boolean, set, heap, and date/time data types, the ability to import modules from ZIP-format archives, metadata support for the long-awaited Python catalog, an updated version of IDLE, and modules for logging messages, wrapping text, parsing CSV files, processing command-line options, using BerkeleyDB databases… the list of new and enhanced modules is lengthy.

This article doesn’t attempt to provide a complete specification of the new features, but instead provides a convenient overview. For full details, you should refer to the documentation for Python 2.3, such as the Python Library Reference and the Python Reference Manual. If you want to understand the complete implementation and design rationale, refer to the PEP for a particular new feature.
PEP 218: A Standard Set Datatype

The new sets module contains an implementation of a set datatype. The Set class is for mutable sets, sets that can have members added and removed. The ImmutableSet class is for sets that can't be modified, and instances of ImmutableSet can therefore be used as dictionary keys. Sets are built on top of dictionaries, so the elements within a set must be hashable.

Here's a simple example:

```python
>>> import sets
>>> S = sets.Set([1, 2, 3])
>>> S
Set([1, 2, 3])
>>> 1 in S
True
>>> 0 in S
False
>>> S.add(5)
>>> S.remove(3)
>>> S
Set([1, 2, 5])
```

The union and intersection of sets can be computed with the union() and intersection() methods; an alternative notation uses the bitwise operators \& and |. Mutable sets also have in-place versions of these methods, union_update() and intersection_update().

```python
>>> S1 = sets.Set([1, 2, 3])
>>> S2 = sets.Set([4, 5, 6])
>>> S1.union(S2)
Set([1, 2, 3, 4, 5, 6])
```
It's also possible to take the symmetric difference of two sets. This is the set of all elements in the union that aren't in the intersection. Another way of putting it is that the symmetric difference contains all elements that are in exactly one set. Again, there's an alternative notation (^), and an in-place version with the ungainly name symmetric_difference_update().

```python
>>> S1 = sets.Set([1, 2, 3, 4])
>>> S2 = sets.Set([3, 4, 5, 6])
>>> S1.symmetric_difference(S2)
Set([1, 2, 5, 6])
>>> S1 ^ S2
Set([1, 2, 5, 6])
```
False

>>> S1.issuperset(S2)
True

**PEP 218 - Adding a Built-In Set Object Type**

PEP written by Greg V. Wilson. Implemented by Greg V. Wilson, Alex Martelli, and GvR.
PEP 255: Simple Generators

In Python 2.2, generators were added as an optional feature, to be enabled by a `from __future__ import generators` directive. In 2.3 generators no longer need to be specially enabled, and are now always present; this means that `yield` is now always a keyword. The rest of this section is a copy of the description of generators from the “What’s New in Python 2.2” document; if you read it back when Python 2.2 came out, you can skip the rest of this section.

You're doubtless familiar with how function calls work in Python or C. When you call a function, it gets a private namespace where its local variables are created. When the function reaches a `return` statement, the local variables are destroyed and the resulting value is returned to the caller. A later call to the same function will get a fresh new set of local variables. But, what if the local variables weren't thrown away on exiting a function? What if you could later resume the function where it left off? This is what generators provide; they can be thought of as resumable functions.

Here’s the simplest example of a generator function:

```python
def generate_ints(N):
    for i in range(N):
        yield i
```

A new keyword, `yield`, was introduced for generators. Any function containing a `yield` statement is a generator function; this is detected by Python's bytecode compiler which compiles the function specially as a result.

When you call a generator function, it doesn't return a single value;
instead it returns a generator object that supports the iterator protocol. On executing the `yield` statement, the generator outputs the value of `i`, similar to a `return` statement. The big difference between `yield` and a `return` statement is that on reaching a `yield` the generator’s state of execution is suspended and local variables are preserved. On the next call to the generator’s `.next()` method, the function will resume executing immediately after the `yield` statement. (For complicated reasons, the `yield` statement isn’t allowed inside the `try` block of a `try...finally` statement; read PEP 255 for a full explanation of the interaction between `yield` and exceptions.)

Here’s a sample usage of the `generate_ints()` generator:

```python
>>> gen = generate_ints(3)
>>> gen
<generator object at 0x8117f90>
>>> gen.next()
0
>>> gen.next()
1
>>> gen.next()
2
>>> gen.next()
Traceback (most recent call last):
  File "stdin", line 1, in ?
  File "stdin", line 2, in generate_ints
StopIteration
```

You could equally write `for i in generate_ints(5)`, or `a, b, c = generate_ints(3)`.

Inside a generator function, the `return` statement can only be used without a value, and signals the end of the procession of values;
afterwards the generator cannot return any further values. return with a value, such as return 5, is a syntax error inside a generator function. The end of the generator’s results can also be indicated by raising StopIteration manually, or by just letting the flow of execution fall off the bottom of the function.

You could achieve the effect of generators manually by writing your own class and storing all the local variables of the generator as instance variables. For example, returning a list of integers could be done by setting self.count to 0, and having the next() method increment self.count and return it. However, for a moderately complicated generator, writing a corresponding class would be much messier. Lib/test/test_generators.py contains a number of more interesting examples. The simplest one implements an in-order traversal of a tree using generators recursively.

```python
# A recursive generator that generates Tree leaves in order.
def inorder(t):
    if t:
        for x in inorder(t.left):
            yield x
        yield t.label
        for x in inorder(t.right):
            yield x
```

Two other examples in Lib/test/test_generators.py produce solutions for the N-Queens problem (placing $N$ queens on an $N \times N$ chess board so that no queen threatens another) and the Knight’s Tour (a route that takes a knight to every square of an $N \times N$ chessboard without visiting any square twice).

The idea of generators comes from other programming languages,
especially Icon ([https://www.cs.arizona.edu/icon/](https://www.cs.arizona.edu/icon/)), where the idea of generators is central. In Icon, every expression and function call behaves like a generator. One example from “An Overview of the Icon Programming Language” at [https://www.cs.arizona.edu/icon/docs/ipd266.htm](https://www.cs.arizona.edu/icon/docs/ipd266.htm) gives an idea of what this looks like:

```plaintext
class := "Store it in the neighboring harbor"
if (i := find("or", sentence)) > 5 then write(i)
```

In Icon the `find()` function returns the indexes at which the substring “or” is found: 3, 23, 33. In the `if` statement, `i` is first assigned a value of 3, but 3 is less than 5, so the comparison fails, and Icon retries it with the second value of 23. 23 is greater than 5, so the comparison now succeeds, and the code prints the value 23 to the screen.

Python doesn’t go nearly as far as Icon in adopting generators as a central concept. Generators are considered part of the core Python language, but learning or using them isn’t compulsory; if they don’t solve any problems that you have, feel free to ignore them. One novel feature of Python’s interface as compared to Icon’s is that a generator’s state is represented as a concrete object (the iterator) that can be passed around to other functions or stored in a data structure.

**PEP 255 - Simple Generators**

Written by Neil Schemenauer, Tim Peters, Magnus Lie Hetland. Implemented mostly by Neil Schemenauer and Tim Peters, with other fixes from the Python Labs crew.
Python source files can now be declared as being in different character set encodings. Encodings are declared by including a specially formatted comment in the first or second line of the source file. For example, a UTF-8 file can be declared with:

```bash
#!/usr/bin/env python
# -*- coding: UTF-8 -*-
```

Without such an encoding declaration, the default encoding used is 7-bit ASCII. Executing or importing modules that contain string literals with 8-bit characters and have no encoding declaration will result in a `DeprecationWarning` being signalled by Python 2.3; in 2.4 this will be a syntax error.

The encoding declaration only affects Unicode string literals, which will be converted to Unicode using the specified encoding. Note that Python identifiers are still restricted to ASCII characters, so you can't have variable names that use characters outside of the usual alphanumerics.

See also:

**PEP 263 - Defining Python Source Code Encodings**

Written by Marc-André Lemburg and Martin von Löwis; implemented by Suzuki Hisao and Martin von Löwis.
PEP 273: Importing Modules from ZIP Archives

The new `zipimport` module adds support for importing modules from a ZIP-format archive. You don’t need to import the module explicitly; it will be automatically imported if a ZIP archive’s filename is added to `sys.path`. For example:

```
unzip -l /tmp/example.zip
Archive: /tmp/example.zip
Length Date Time Name
-------- ---- ---- ----
  8467 11-26-02 22:30 jwzthreading.py
-------- ---- ---- ----
  8467 1 file
```  

```
./python
Python 2.3 (#1, Aug 1 2003, 19:54:32)
>>> import sys
>>> sys.path.insert(0, '/tmp/example.zip')  # Add .zip file to front of path
>>> import jwzthreading
>>> jwzthreading.__file__
'/tmp/example.zip/jwzthreading.py'
```  

An entry in `sys.path` can now be the filename of a ZIP archive. The ZIP archive can contain any kind of files, but only files named `*.py`, `*.pyc`, or `*.pyo` can be imported. If an archive only contains `*.py` files, Python will not attempt to modify the archive by adding the corresponding `*.pyc` file, meaning that if a ZIP archive doesn’t contain `*.pyc` files, importing may be rather slow.

A path within the archive can also be specified to only import from a
subdirectory; for example, the path `/tmp/example.zip/lib/` would only import from the `lib/` subdirectory within the archive.

See also:

**PEP 273 - Import Modules from Zip Archives**

Written by James C. Ahlstrom, who also provided an implementation. Python 2.3 follows the specification in PEP 273, but uses an implementation written by Just van Rossum that uses the import hooks described in PEP 302. See section PEP 302: New Import Hooks for a description of the new import hooks.
PEP 277: Unicode file name support for Windows NT

On Windows NT, 2000, and XP, the system stores file names as Unicode strings. Traditionally, Python has represented file names as byte strings, which is inadequate because it renders some file names inaccessible.

Python now allows using arbitrary Unicode strings (within the limitations of the file system) for all functions that expect file names, most notably the `open()` built-in function. If a Unicode string is passed to `os.listdir()`, Python now returns a list of Unicode strings. A new function, `os.getcwdu()`, returns the current directory as a Unicode string.

Byte strings still work as file names, and on Windows Python will transparently convert them to Unicode using the `mbcs` encoding.

Other systems also allow Unicode strings as file names but convert them to byte strings before passing them to the system, which can cause a `UnicodeError` to be raised. Applications can test whether arbitrary Unicode strings are supported as file names by checking `os.path.supports_unicode_filenames`, a Boolean value.

Under MacOS, `os.listdir()` may now return Unicode filenames.

See also:

**PEP 277 - Unicode file name support for Windows NT**

Written by Neil Hodgson; implemented by Neil Hodgson, Martin von Löwis, and Mark Hammond.
PEP 278: Universal Newline Support

The three major operating systems used today are Microsoft Windows, Apple's Macintosh OS, and the various Unix derivatives. A minor irritation of cross-platform work is that these three platforms all use different characters to mark the ends of lines in text files. Unix uses the linefeed (ASCII character 10), MacOS uses the carriage return (ASCII character 13), and Windows uses a two-character sequence of a carriage return plus a newline.

Python's file objects can now support end of line conventions other than the one followed by the platform on which Python is running. Opening a file with the mode `'U'` or `'rU'` will open a file for reading in universal newlines mode. All three line ending conventions will be translated to a '
' in the strings returned by the various file methods such as `read()` and `readline()`.

Universal newline support is also used when importing modules and when executing a file with the `execfile()` function. This means that Python modules can be shared between all three operating systems without needing to convert the line-endings.

This feature can be disabled when compiling Python by specifying the `--without-universal-newlines` switch when running Python's `configure` script.

See also:

**PEP 278 - Universal Newline Support**
Written and implemented by Jack Jansen.
PEP 279: enumerate()

A new built-in function, `enumerate()`, will make certain loops a bit clearer. `enumerate(thing)`, where `thing` is either an iterator or a sequence, returns an iterator that will return `(0, thing[0]), (1, thing[1]), (2, thing[2])`, and so forth.

A common idiom to change every element of a list looks like this:

```python
for i in range(len(L)):
    item = L[i]
    # ... compute some result based on item ...
    L[i] = result
```

This can be rewritten using `enumerate()` as:

```python
for i, item in enumerate(L):
    # ... compute some result based on item ...
    L[i] = result
```

See also:

**PEP 279 - The enumerate() built-in function**

Written and implemented by Raymond D. Hettinger.
PEP 282: The logging Package

A standard package for writing logs, `logging`, has been added to Python 2.3. It provides a powerful and flexible mechanism for generating logging output which can then be filtered and processed in various ways. A configuration file written in a standard format can be used to control the logging behavior of a program. Python includes handlers that will write log records to standard error or to a file or socket, send them to the system log, or even e-mail them to a particular address; of course, it’s also possible to write your own handler classes.

The Logger class is the primary class. Most application code will deal with one or more Logger objects, each one used by a particular subsystem of the application. Each Logger is identified by a name, and names are organized into a hierarchy using `.` as the component separator. For example, you might have Logger instances named `server`, `server.auth` and `server.network`. The latter two instances are below `server` in the hierarchy. This means that if you turn up the verbosity for `server` or direct `server` messages to a different handler, the changes will also apply to records logged to `server.auth` and `server.network`. There’s also a root Logger that’s the parent of all other loggers.

For simple uses, the `logging` package contains some convenience functions that always use the root log:

```python
import logging

logging.debug('Debugging information')
logging.info('Informational message')
```
logging.warning('Warning:config file %s not found'),
logging.error('Error occurred')
logging.critical('Critical error -- shutting down')

This produces the following output:

WARNING:root:Warning:config file server.conf not found
ERROR:root:Error occurred
CRITICAL:root:Critical error -- shutting down

In the default configuration, informational and debugging messages are suppressed and the output is sent to standard error. You can enable the display of informational and debugging messages by calling the setLevel() method on the root logger.

Notice the warning() call's use of string formatting operators; all of the functions for logging messages take the arguments \( \text{msg, arg1, arg2, ...} \) and log the string resulting from \( \text{msg \% (arg1, arg2, ...)} \).

There's also an exception() function that records the most recent traceback. Any of the other functions will also record the traceback if you specify a true value for the keyword argument \text{exc_info}.

```python
def f():
    try: 1/0
    except: logging.exception('Problem recorded')
f()
```

This produces the following output:

ERROR:root:Problem recorded
Traceback (most recent call last):
  File "t.py", line 6, in f
  1/0
ZeroDivisionError: integer division or modulo by zero

Slightly more advanced programs will use a logger other than the root logger. The `getLogger(name)` function is used to get a particular log, creating it if it doesn’t exist yet. `getLogger(None)` returns the root logger.

```python
log = logging.getLogger('server')
...
log.info('Listening on port %i', port)
...
log.critical('Disk full')
...
```

Log records are usually propagated up the hierarchy, so a message logged to `server.auth` is also seen by `server` and `root`, but a Logger can prevent this by setting its `propagate` attribute to `False`.

There are more classes provided by the `logging` package that can be customized. When a Logger instance is told to log a message, it creates a LogRecord instance that is sent to any number of different Handler instances. Loggers and handlers can also have an attached list of filters, and each filter can cause the LogRecord to be ignored or can modify the record before passing it along. When they’re finally output, LogRecord instances are converted to text by a Formatter class. All of these classes can be replaced by your own specially-written classes.

With all of these features the `logging` package should provide enough flexibility for even the most complicated applications. This is
only an incomplete overview of its features, so please see the package’s reference documentation for all of the details. Reading PEP 282 will also be helpful.

See also:

PEP 282 - A Logging System
Written by Vinay Sajip and Trent Mick; implemented by Vinay Sajip.
PEP 285: A Boolean Type

A Boolean type was added to Python 2.3. Two new constants were added to the __builtin__ module, True and False. (True and False constants were added to the built-ins in Python 2.2.1, but the 2.2.1 versions are simply set to integer values of 1 and 0 and aren’t a different type.)

The type object for this new type is named bool; the constructor for it takes any Python value and converts it to True or False.

```python
>>> bool(1)
True
>>> bool(0)
False
>>> bool([])
False
>>> bool((1,))
True
```

Most of the standard library modules and built-in functions have been changed to return Booleans.

```python
>>> obj = []
>>> hasattr(obj, 'append')
True
>>> isinstance(obj, list)
True
>>> isinstance(obj, tuple)
False
```

Python’s Booleans were added with the primary goal of making code clearer. For example, if you’re reading a function and encounter the
statement `return 1`, you might wonder whether the `1` represents a Boolean truth value, an index, or a coefficient that multiplies some other quantity. If the statement is `return True`, however, the meaning of the return value is quite clear.

Python’s Booleans were not added for the sake of strict type-checking. A very strict language such as Pascal would also prevent you performing arithmetic with Booleans, and would require that the expression in an `if` statement always evaluate to a Boolean result. Python is not this strict and never will be, as PEP 285 explicitly says. This means you can still use any expression in an `if` statement, even ones that evaluate to a list or tuple or some random object. The Boolean type is a subclass of the `int` class so that arithmetic using a Boolean still works.

```
>>> True + 1
2
>>> False + 1
1
>>> False * 75
0
>>> True * 75
75
```

To sum up `True` and `False` in a sentence: they’re alternative ways to spell the integer values 1 and 0, with the single difference that `str()` and `repr()` return the strings 'True' and 'False' instead of '1' and '0'.

**PEP 285 - Adding a bool type**

Written and implemented by GvR.
PEP 293: Codec Error Handling Callbacks

When encoding a Unicode string into a byte string, unencodable characters may be encountered. So far, Python has allowed specifying the error processing as either “strict” (raising `UnicodeError`), “ignore” (skipping the character), or “replace” (using a question mark in the output string), with “strict” being the default behavior. It may be desirable to specify alternative processing of such errors, such as inserting an XML character reference or HTML entity reference into the converted string.

Python now has a flexible framework to add different processing strategies. New error handlers can be added with `codecs.register_error()`, and codecs then can access the error handler with `codecs.lookup_error()`. An equivalent C API has been added for codecs written in C. The error handler gets the necessary state information such as the string being converted, the position in the string where the error was detected, and the target encoding. The handler can then either raise an exception or return a replacement string.

Two additional error handlers have been implemented using this framework: “backslashreplace” uses Python backslash quoting to represent unencodable characters and “xmlcharrefreplace” emits XML character references.

**PEP 293 - Codec Error Handling Callbacks**

Written and implemented by Walter Dörwald.
PEP 301: Package Index and Metadata for Distutils

Support for the long-requested Python catalog makes its first appearance in 2.3.

The heart of the catalog is the new Distutils `register` command. Running `python setup.py register` will collect the metadata describing a package, such as its name, version, maintainer, description, &c., and send it to a central catalog server. The resulting catalog is available from https://pypi.python.org/pypi.

To make the catalog a bit more useful, a new optional `classifiers` keyword argument has been added to the Distutils `setup()` function. A list of Trove-style strings can be supplied to help classify the software.

Here's an example `setup.py` with classifiers, written to be compatible with older versions of the Distutils:

```python
from distutils import core
kw = {
    'name': 'Quixote',
    'version': '0.5.1',
    'description': 'A highly Pythonic Web application
    # ...'
}

if (hasattr(core, 'setup_keywords') and
    'classifiers' in core.setup_keywords):
    kw['classifiers'] = [
        'Topic :: Internet :: WWW/HTTP :: Dynamic Content',
        'Environment :: No Input/Output (Daemon)',
        'Intended Audience :: Developers']
```
core.setup(**kw)

The full list of classifiers can be obtained by running `python setup.py register --list-classifiers`.

**PEP 301** - Package Index and Metadata for Distutils

Written and implemented by Richard Jones.
PEP 302: New Import Hooks

While it’s been possible to write custom import hooks ever since the ihooks module was introduced in Python 1.3, no one has ever been really happy with it because writing new import hooks is difficult and messy. There have been various proposed alternatives such as the imputil and iu modules, but none of them has ever gained much acceptance, and none of them were easily usable from C code.

PEP 302 borrows ideas from its predecessors, especially from Gordon McMillan’s iu module. Three new items are added to the sys module:

- **sys.path_hooks** is a list of callable objects; most often they’ll be classes. Each callable takes a string containing a path and either returns an importer object that will handle imports from this path or raises an `ImportError` exception if it can’t handle this path.
- **sys.path_importer_cache** caches importer objects for each path, so `sys.path_hooks` will only need to be traversed once for each path.
- **sys.meta_path** is a list of importer objects that will be traversed before `sys.path` is checked. This list is initially empty, but user code can add objects to it. Additional built-in and frozen modules can be imported by an object added to this list.

Importer objects must have a single method, `find_module(fullname, path=None)`. `fullname` will be a module or package name, e.g. `string` or `distutils.core`. `find_module()` must return a loader object that has a single method, `load_module(fullname)`, that creates and returns the corresponding module object.
Pseudo-code for Python’s new import logic, therefore, looks something like this (simplified a bit; see PEP 302 for the full details):

```python
for mp in sys.meta_path:
    loader = mp(fullname)
    if loader is not None:
        <module> = loader.load_module(fullname)

for path in sys.path:
    for hook in sys.path_hooks:
        try:
            importer = hook(path)
        except ImportError:
            # ImportError, so try the other path hooks
            pass
        else:
            loader = importer.find_module(fullname)
            <module> = loader.load_module(fullname)

# Not found!
raise ImportError
```

**PEP 302 - New Import Hooks**

Written by Just van Rossum and Paul Moore. Implemented by Just van Rossum.
PEP 305: Comma-separated Files

Comma-separated files are a format frequently used for exporting data from databases and spreadsheets. Python 2.3 adds a parser for comma-separated files.

Comma-separated format is deceptively simple at first glance:

```
Costs,150,200,3.95
```

Read a line and call `line.split(',')`: what could be simpler? But toss in string data that can contain commas, and things get more complicated:

```
"Costs",150,200,3.95,"Includes taxes, shipping, and 
```

A big ugly regular expression can parse this, but using the new `csv` package is much simpler:

```
import csv

input = open('datafile', 'rb')
reader = csv.reader(input)
for line in reader:
    print line
```

The `reader()` function takes a number of different options. The field separator isn’t limited to the comma and can be changed to any character, and so can the quoting and line-ending characters.

Different dialects of comma-separated files can be defined and registered; currently there are two dialects, both used by Microsoft
Excel. A separate `csv.writer` class will generate comma-separated files from a succession of tuples or lists, quoting strings that contain the delimiter.

**See also:**

**PEP 305 - CSV File API**

Written and implemented by Kevin Altis, Dave Cole, Andrew McNamara, Skip Montanaro, Cliff Wells.
PEP 307: Pickle Enhancements

The pickle and cPickle modules received some attention during the 2.3 development cycle. In 2.2, new-style classes could be pickled without difficulty, but they weren’t pickled very compactly; PEP 307 quotes a trivial example where a new-style class results in a pickled string three times longer than that for a classic class.

The solution was to invent a new pickle protocol. The pickle.dumps() function has supported a text-or-binary flag for a long time. In 2.3, this flag is redefined from a Boolean to an integer: 0 is the old text-mode pickle format, 1 is the old binary format, and now 2 is a new 2.3-specific format. A new constant, pickle.HIGHEST_PROTOCOL, can be used to select the fanciest protocol available.

Unpickling is no longer considered a safe operation. 2.2’s pickle provided hooks for trying to prevent unsafe classes from being unpickled (specifically, a __safe_for_unpickling__ attribute), but none of this code was ever audited and therefore it’s all been ripped out in 2.3. You should not unpickle untrusted data in any version of Python.

To reduce the pickling overhead for new-style classes, a new interface for customizing pickling was added using three special methods: __getstate__(), __setstate__() , and __getnewargs__(). Consult PEP 307 for the full semantics of these methods.

As a way to compress pickles yet further, it’s now possible to use integer codes instead of long strings to identify pickled classes. The Python Software Foundation will maintain a list of standardized codes; there’s also a range of codes for private use. Currently no codes have
been specified.

**PEP 307 - Extensions to the pickle protocol**

Written and implemented by Guido van Rossum and Tim Peters.
Extended Slices

Ever since Python 1.4, the slicing syntax has supported an optional third “step” or “stride” argument. For example, these are all legal Python syntax: L[1:10:2], L[:1:1], L[::1]. This was added to Python at the request of the developers of Numerical Python, which uses the third argument extensively. However, Python’s built-in list, tuple, and string sequence types have never supported this feature, raising a `TypeError` if you tried it. Michael Hudson contributed a patch to fix this shortcoming.

For example, you can now easily extract the elements of a list that have even indexes:

```python
>>> L = range(10)
>>> L[::2]
[0, 2, 4, 6, 8]
```

Negative values also work to make a copy of the same list in reverse order:

```python
>>> L[::-1]
[9, 8, 7, 6, 5, 4, 3, 2, 1, 0]
```

This also works for tuples, arrays, and strings:

```python
>>> s='abcd'
>>> s[::2]
'ac'
>>> s[::1]
'dcba'
```

If you have a mutable sequence such as a list or an array you can
assign to or delete an extended slice, but there are some differences between assignment to extended and regular slices. Assignment to a regular slice can be used to change the length of the sequence:

```python
>>> a = range(3)
>>> a
[0, 1, 2]
>>> a[1:3] = [4, 5, 6]
>>> a
[0, 4, 5, 6]
```

Extended slices aren't this flexible. When assigning to an extended slice, the list on the right hand side of the statement must contain the same number of items as the slice it is replacing:

```python
>>> a = range(4)
>>> a
[0, 1, 2, 3]
>>> a[::2]
[0, 2]
>>> a[::2] = [0, -1]
>>> a
[0, 1, -1, 3]
>>> a[::2] = [0, 1, 2]
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
ValueError: attempt to assign sequence of size 3 to extended slice of size 2
```

Deletion is more straightforward:

```python
>>> a = range(4)
>>> a
[0, 1, 2, 3]
>>> a[::2]
[0, 2]
```
One can also now pass slice objects to the `__getitem__()` methods of the built-in sequences:

```python
>>> range(10).__getitem__(slice(0, 5, 2))
[0, 2, 4]
```

Or use slice objects directly in subscripts:

```python
>>> range(10)[slice(0, 5, 2)]
[0, 2, 4]
```

To simplify implementing sequences that support extended slicing, slice objects now have a method `indices(length)` which, given the length of a sequence, returns a `(start, stop, step)` tuple that can be passed directly to `range().indices()` handles omitted and out-of-bounds indices in a manner consistent with regular slices (and this innocuous phrase hides a welter of confusing details!). The method is intended to be used like this:

```python
class FakeSeq:
    ...
    def calc_item(self, i):
        ...
    def __getitem__(self, item):
        if isinstance(item, slice):
            indices = item.indices(len(self))
            return FakeSeq([self.calc_item(i) for i in indices])
        else:
            return self.calc_item(i)
```
From this example you can also see that the built-in `slice` object is now the type object for the slice type, and is no longer a function. This is consistent with Python 2.2, where `int`, `str`, etc., underwent the same change.
Other Language Changes

Here are all of the changes that Python 2.3 makes to the core Python language.

- The \texttt{yield} statement is now always a keyword, as described in section \texttt{PEP 255: Simple Generators} of this document.

- A new built-in function \texttt{enumerate()} was added, as described in section \texttt{PEP 279: enumerate()} of this document.

- Two new constants, \texttt{True} and \texttt{False} were added along with the built-in \texttt{bool} type, as described in section \texttt{PEP 285: A Boolean Type} of this document.

- The \texttt{int()} type constructor will now return a long integer instead of raising an \texttt{OverflowError} when a string or floating-point number is too large to fit into an integer. This can lead to the paradoxical result that \texttt{isinstance(int(expression), int)} is false, but that seems unlikely to cause problems in practice.

- Built-in types now support the extended slicing syntax, as described in section \texttt{Extended Slices} of this document.

- A new built-in function, \texttt{sum(iterable, start=0)}, adds up the numeric items in the iterable object and returns their sum. \texttt{sum()} only accepts numbers, meaning that you can't use it to concatenate a bunch of strings. (Contributed by Alex Martelli.)

- \texttt{list.insert(pos, value)} used to insert \texttt{value} at the front of the list when \texttt{pos} was negative. The behaviour has now been
changed to be consistent with slice indexing, so when \textit{pos} is -1
the value will be inserted before the last element, and so forth.

- \texttt{list.index(value)}, which searches for \textit{value} within the list
  and returns its index, now takes optional \texttt{start} and \texttt{stop} arguments
to limit the search to only part of the list.

- Dictionaries have a new method, \texttt{pop(key[, \texttt{*default}*])},
  that returns the value corresponding to \textit{key} and removes that
  key/value pair from the dictionary. If the requested key isn’t
  present in the dictionary, \texttt{default} is returned if it’s specified and
  \texttt{KeyError} raised if it isn’t.

```python
>>> d = {1: 2}
>>> d
{1: 2}
>>> d.pop(4)
Traceback (most recent call last):
  File "stdin", line 1, in ?
KeyError: 4
>>> d.pop(1)
2
>>> d.pop(1)
Traceback (most recent call last):
  File "stdin", line 1, in ?
KeyError: 'pop(): dictionary is empty'
>>> d
{}
>>> 
```

There’s also a new class method, \texttt{dict.fromkeys(iterable, value)},
that creates a dictionary with keys taken from the
supplied iterator \textit{iterable} and all values set to \textit{value}, defaulting to
\texttt{None}. 
(Patches contributed by Raymond Hettinger.)

Also, the `dict()` constructor now accepts keyword arguments to simplify creating small dictionaries:

```python
>>> dict(red=1, blue=2, green=3, black=4)
{'blue': 2, 'black': 4, 'green': 3, 'red': 1}
```

(Contributed by Just van Rossum.)

- The `assert` statement no longer checks the `__debug__` flag, so you can no longer disable assertions by assigning to `__debug__`. Running Python with the `-O` switch will still generate code that doesn't execute any assertions.

- Most type objects are now callable, so you can use them to create new objects such as functions, classes, and modules. (This means that the new module can be deprecated in a future Python version, because you can now use the type objects available in the `types` module.) For example, you can create a new module object with the following code:

```python
>>> import types
>>> m = types.ModuleType('abc','docstring')
>>> m
<module 'abc' (built-in)>
>>> m.__doc__
'docstring'
```

- A new warning, `PendingDeprecationWarning` was added to indicate features which are in the process of being deprecated. The warning will not be printed by default. To check for use of features that will be deprecated in the future, supply `-
The process of deprecating string-based exceptions, as in `raise "Error occurred"`, has begun. Raising a string will now trigger `PendingDeprecationWarning`.

Using `None` as a variable name will now result in a `SyntaxWarning` warning. In a future version of Python, `None` may finally become a keyword.

The `xreadlines()` method of file objects, introduced in Python 2.1, is no longer necessary because files now behave as their own iterator. `xreadlines()` was originally introduced as a faster way to loop over all the lines in a file, but now you can simply write `for line in file_obj`. File objects also have a new read-only encoding attribute that gives the encoding used by the file; Unicode strings written to the file will be automatically converted to bytes using the given encoding.

The method resolution order used by new-style classes has changed, though you'll only notice the difference if you have a really complicated inheritance hierarchy. Classic classes are unaffected by this change. Python 2.2 originally used a topological sort of a class's ancestors, but 2.3 now uses the C3 algorithm as described in the paper "A Monotonic Superclass Linearization for Dylan". To understand the motivation for this change, read Michele Simionato's article "Python 2.3 Method Resolution Order", or read the thread on python-dev starting with the message at https://mail.python.org/pipermail/python-dev/2002-October/029035.html. Samuele Pedroni first pointed out the problem and also implemented the fix by coding the C3 algorithm.
• Python runs multithreaded programs by switching between threads after executing N bytecodes. The default value for N has been increased from 10 to 100 bytecodes, speeding up single-threaded applications by reducing the switching overhead. Some multithreaded applications may suffer slower response time, but that's easily fixed by setting the limit back to a lower number using `sys.setcheckinterval(N)`. The limit can be retrieved with the new `sys.getcheckinterval()` function.

• One minor but far-reaching change is that the names of extension types defined by the modules included with Python now contain the module and a ' . ' in front of the type name. For example, in Python 2.2, if you created a socket and printed its `__class__`, you’d get this output:

```python
>>> s = socket.socket()
>>> s.__class__
<type 'socket'>
```

In 2.3, you get this:

```python
>>> s.__class__
<type '_socket.socket'>
```

• One of the noted incompatibilities between old- and new-style classes has been removed: you can now assign to the `__name__` and `__bases__` attributes of new-style classes. There are some restrictions on what can be assigned to `__bases__` along the lines of those relating to assigning to an instance's `__class__` attribute.

### String Changes
The *in* operator now works differently for strings. Previously, when evaluating $X \text{ in } Y$ where $X$ and $Y$ are strings, $X$ could only be a single character. That's now changed; $X$ can be a string of any length, and $X \text{ in } Y$ will return *True* if $X$ is a substring of $Y$. If $X$ is the empty string, the result is always *True*.

```
>>> 'ab' in 'abcd'
True
>>> 'ad' in 'abcd'
False
>>> '' in 'abcd'
True
```

Note that this doesn't tell you where the substring starts; if you need that information, use the `find()` string method.

The `strip()`, `lstrip()`, and `rstrip()` string methods now have an optional argument for specifying the characters to strip. The default is still to remove all whitespace characters:

```
>>> '   abc '.strip()
'abc'
>>> '><><abc><><><'.strip('<>')
'abc'
>>> '><><abc><><><
'.strip('<>')
'abc'><><><

>>> u'\u4000\u4001abc\u4000'.strip(u'\u4000')
u'\u4001abc'
```

(Suggested by Simon Brunning and implemented by Walter Dörwald.)

The `startswith()` and `endswith()` string methods now
accept negative numbers for the \textit{start} and \textit{end} parameters.

- Another new string method is \texttt{zfill()}, originally a function in the \texttt{string} module. \texttt{zfill()} pads a numeric string with zeros on the left until it's the specified width. Note that the \% operator is still more flexible and powerful than \texttt{zfill()}.

\begin{verbatim}
>>> '45'.zfill(4)
'0045'
>>> '12345'.zfill(4)
'12345'
>>> 'goofy'.zfill(6)
'0goofy'
\end{verbatim}

(Contributed by Walter Dörwald.)

- A new type object, \texttt{basestring}, has been added. Both 8-bit strings and Unicode strings inherit from this type, so \texttt{isinstance(obj, basestring)} will return \texttt{True} for either kind of string. It’s a completely abstract type, so you can’t create \texttt{basestring} instances.

- Interned strings are no longer immortal and will now be garbage-collected in the usual way when the only reference to them is from the internal dictionary of interned strings. (Implemented by Oren Tirosh.)

\section*{Optimizations}

- The creation of new-style class instances has been made much faster; they're now faster than classic classes!
- The \texttt{sort()} method of list objects has been extensively rewritten by Tim Peters, and the implementation is significantly faster.
Multiplication of large long integers is now much faster thanks to an implementation of Karatsuba multiplication, an algorithm that scales better than the $O(n^2)$ required for the grade-school multiplication algorithm. (Original patch by Christopher A. Craig, and significantly reworked by Tim Peters.)

The `SET_LINE_NO` opcode is now gone. This may provide a small speed increase, depending on your compiler’s idiosyncrasies. See section Other Changes and Fixes for a longer explanation. (Removed by Michael Hudson.)

`xrange()` objects now have their own iterator, making `for i in xrange(n)` slightly faster than `for i in range(n)`. (Patch by Raymond Hettinger.)

A number of small rearrangements have been made in various hotspots to improve performance, such as inlining a function or removing some code. (Implemented mostly by GvR, but lots of people have contributed single changes.)

The net result of the 2.3 optimizations is that Python 2.3 runs the pystone benchmark around 25% faster than Python 2.2.
New, Improved, and Deprecated Modules

As usual, Python’s standard library received a number of enhancements and bug fixes. Here’s a partial list of the most notable changes, sorted alphabetically by module name. Consult the Misc/NEWS file in the source tree for a more complete list of changes, or look through the CVS logs for all the details.

- The `array` module now supports arrays of Unicode characters using the 'u' format character. Arrays also now support using the `+=` assignment operator to add another array’s contents, and the `*=` assignment operator to repeat an array. (Contributed by Jason Orendorff.)

- The `bsddb` module has been replaced by version 4.1.6 of the PyBSDDDB package, providing a more complete interface to the transactional features of the BerkeleyDB library.

The old version of the module has been renamed to `bsdddb185` and is no longer built automatically; you’ll have to edit `Modules/Setup` to enable it. Note that the new bsddb package is intended to be compatible with the old module, so be sure to file bugs if you discover any incompatibilities. When upgrading to Python 2.3, if the new interpreter is compiled with a new version of the underlying BerkeleyDB library, you will almost certainly have to convert your database files to the new version. You can do this fairly easily with the new scripts `db2pickle.py` and `pickle2db.py` which you will find in the distribution’s `Tools/scripts` directory. If you’ve already been using the PyBSDDDB package and importing it as `bsddb3`, you will have to change your import statements to import it as `bsddb`. 
• The new **bz2** module is an interface to the bz2 data compression library. bz2-compressed data is usually smaller than corresponding **zlib**-compressed data. (Contributed by Gustavo Niemeyer.)

• A set of standard date/time types has been added in the new **datetime** module. See the following section for more details.

• The Distutils Extension class now supports an extra constructor argument named `depends` for listing additional source files that an extension depends on. This lets Distutils recompile the module if any of the dependency files are modified. For example, if `sampmodule.c` includes the header file `sample.h`, you would create the Extension object like this:

```python
ext = Extension("samp",
    sources=["sampmodule.c"],
    depends=["sample.h"]
)
```

Modifying `sample.h` would then cause the module to be recompiled. (Contributed by Jeremy Hylton.)

• Other minor changes to Distutils: it now checks for the `CC`, `CFLAGS`, `CPP`, `LDFLAGS`, and `CPPFLAGS` environment variables, using them to override the settings in Python’s configuration (contributed by Robert Weber).

• Previously the **doctest** module would only search the docstrings of public methods and functions for test cases, but it now also examines private ones as well. The `DocTestSuite()` function creates a `unittest.TestSuite` object from a set of **doctest** tests.
• The new `gc.get_referents(object)` function returns a list of all the objects referenced by `object`.

• The `getopt` module gained a new function, `gnu_getopt()`, that supports the same arguments as the existing `getopt()` function but uses GNU-style scanning mode. The existing `getopt()` stops processing options as soon as a non-option argument is encountered, but in GNU-style mode processing continues, meaning that options and arguments can be mixed. For example:

```python
>>> getopt.getopt(['-f', 'filename', 'output', ''], (['-f', 'filename']), ['output', '-v'])
>>> getopt.gnu_getopt(['-f', 'filename', 'output', (['-f', 'filename'), ('-v', '')], ['output'])
```

(Contributed by Peter Åstrand.)

• The `grp`, `pwd`, and `resource` modules now return enhanced tuples:

```python
>>> import grp
>>> g = grp.getgrnam('amk')
>>> g.gr_name, g.gr_gid
('amk', 500)
```

• The `gzip` module can now handle files exceeding 2 GiB.

• The new `heapq` module contains an implementation of a heap queue algorithm. A heap is an array-like data structure that keeps items in a partially sorted order such that, for every index `k`, `heap[k] <= heap[2*k+1]` and `heap[k] <= heap[2*k+2]`. This makes it quick to remove the smallest item, and inserting a
new item while maintaining the heap property is $O(\log n)$. (See
https://xlinux.nist.gov/dads//HTML/priorityque.html for more
information about the priority queue data structure.)

The `heapq` module provides `heappush()` and `heappop()`
functions for adding and removing items while maintaining the
heap property on top of some other mutable Python sequence
type. Here's an example that uses a Python list:

```python
>>> import heapq
>>> heap = []
>>> for item in [3, 7, 5, 11, 1]:
...    heapq.heappush(heap, item)
...    print(heap)
[1]
[1, 3]
[1, 3, 5]
[1, 3, 5, 7]
[1, 3, 5, 11]
>>> heapq.heappop(heap)
1
>>> heapq.heappop(heap)
3
>>> heap
[5, 7, 11]
```

(Contributed by Kevin O'Connor.)

- The IDLE integrated development environment has been updated
  using the code from the IDLEfork project
  (http://idlefork.sourceforge.net). The most notable feature is that
  the code being developed is now executed in a subprocess,
  meaning that there's no longer any need for manual `reload()`
  operations. IDLE's core code has been incorporated into the
  standard library as the `idlelib` package.

- The `imaplib` module now supports IMAP over SSL. (Contributed
The `itertools` contains a number of useful functions for use with iterators, inspired by various functions provided by the ML and Haskell languages. For example, `itertools.ifilter(predicate, iterator)` returns all elements in the iterator for which the function `predicate()` returns `True`, and `itertools.repeat(obj, N)` returns `obj` `N` times. There are a number of other functions in the module; see the package’s reference documentation for details. (Contributed by Raymond Hettinger.)

Two new functions in the `math` module, `degrees(rads)` and `radians(degs)`, convert between radians and degrees. Other functions in the `math` module such as `math.sin()` and `math.cos()` have always required input values measured in radians. Also, an optional `base` argument was added to `math.log()` to make it easier to compute logarithms for bases other than `e` and `10`. (Contributed by Raymond Hettinger.)

Several new POSIX functions (`getpgid()`, `killpg()`, `lchown()`, `loadavg()`, `major()`, `makedev()`, `minor()`, and `mknod()`) were added to the `posix` module that underlies the `os` module. (Contributed by Gustavo Niemeyer, Geert Jansen, and Denis S. Otkidach.)

In the `os` module, the `*stat()` family of functions can now report fractions of a second in a timestamp. Such time stamps are represented as floats, similar to the value returned by `time.time()`.

During testing, it was found that some applications will break if
time stamps are floats. For compatibility, when using the tuple interface of the stat_result time stamps will be represented as integers. When using named fields (a feature first introduced in Python 2.2), time stamps are still represented as integers, unless `os.stat_float_times()` is invoked to enable float return values:

```python
>>> os.stat("/tmp").st_mtime
1034791200
>>> os.stat_float_times(True)
>>> os.stat("/tmp").st_mtime
1034791200.6335014
```

In Python 2.4, the default will change to always returning floats.

Application developers should enable this feature only if all their libraries work properly when confronted with floating point time stamps, or if they use the tuple API. If used, the feature should be activated on an application level instead of trying to enable it on a per-use basis.

- The `optparse` module contains a new parser for command-line arguments that can convert option values to a particular Python type and will automatically generate a usage message. See the following section for more details.

- The old and never DOCUMENTED `linuxaudiodev` module has been deprecated, and a new version named `ossaudiodev` has been added. The module was renamed because the OSS sound drivers can be used on platforms other than Linux, and the interface has also been tidied and brought up to date in various ways. (Contributed by Greg Ward and Nicholas FitzRoy-Dale.)
The new **platform** module contains a number of functions that try to determine various properties of the platform you're running on. There are functions for getting the architecture, CPU type, the Windows OS version, and even the Linux distribution version. (Contributed by Marc-André Lemburg.)

The parser objects provided by the pyexpat module can now optionally buffer character data, resulting in fewer calls to your character data handler and therefore faster performance. Setting the parser object's buffer_text attribute to **True** will enable buffering.

The **sample(population, k)** function was added to the **random** module. **population** is a sequence or **xrange** object containing the elements of a population, and **sample()** chooses **k** elements from the population without replacing chosen elements. **k** can be any value up to **len(population)**. For example:

```python
days = ['Mo', 'Tu', 'We', 'Th', 'Fr', 'St', 'Sn']
>>> random.sample(days, 3)       # Choose 3 elements
['St', 'Sn', 'Th']
>>> random.sample(days, 7)       # Choose 7 elements
['Tu', 'Th', 'Mo', 'We', 'St', 'Fr', 'Sn']
>>> random.sample(days, 7)       # Choose 7 again
['We', 'Mo', 'Sn', 'Fr', 'Tu', 'St', 'Th']
>>> random.sample(days, 8)       # Can't choose 8
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
    File "random.py", line 414, in sample
      raise ValueError, "sample larger than population"
ValueError: sample larger than population
```
The `random` module now uses a new algorithm, the Mersenne Twister, implemented in C. It's faster and more extensively studied than the previous algorithm.

(All changes contributed by Raymond Hettinger.)

- The `readline` module also gained a number of new functions: `get_history_item()`, `get_current_history_length()`, and `redisplay()`.

- The `reexec` and `Bastion` modules have been declared dead, and attempts to import them will fail with a `RuntimeError`. New-style classes provide new ways to break out of the restricted execution environment provided by `reexec`, and no one has interest in fixing them or time to do so. If you have applications using `reexec`, rewrite them to use something else.

  (Sticking with Python 2.2 or 2.1 will not make your applications any safer because there are known bugs in the `reexec` module in those versions. To repeat: if you're using `reexec`, stop using it immediately.)

- The `rotor` module has been deprecated because the algorithm it uses for encryption is not believed to be secure. If you need encryption, use one of the several AES Python modules that are available separately.

- The `shutil` module gained a `move(src, dest)` function that recursively moves a file or directory to a new location.

- Support for more advanced POSIX signal handling was added to the `signal` but then removed again as it proved impossible to
make it work reliably across platforms.

- The **socket** module now supports timeouts. You can call the `settimeout(t)` method on a socket object to set a timeout of $t$ seconds. Subsequent socket operations that take longer than $t$ seconds to complete will abort and raise a `socket.timeout` exception.

The original timeout implementation was by Tim O’Malley. Michael Gilfix integrated it into the Python `socket` module and shepherded it through a lengthy review. After the code was checked in, Guido van Rossum rewrote parts of it. (This is a good example of a collaborative development process in action.)

- On Windows, the **socket** module now ships with Secure Sockets Layer (SSL) support.

- The value of the C `PYTHON_API_VERSION` macro is now exposed at the Python level as `sys.api_version`. The current exception can be cleared by calling the new `sys.exc_clear()` function.

- The new **tarfile** module allows reading from and writing to `tar`-format archive files. (Contributed by Lars Gustäbel.)

- The new **textwrap** module contains functions for wrapping strings containing paragraphs of text. The `wrap(text, width)` function takes a string and returns a list containing the text split into lines of no more than the chosen width. The `fill(text, width)` function returns a single string, reformatted to fit into lines no longer than the chosen width. (As you can guess, `fill()` is built on top of `wrap()`. For example:
The module also contains a TextWrapper class that actually implements the text wrapping strategy. Both the TextWrapper class and the wrap() and fill() functions support a number of additional keyword arguments for fine-tuning the formatting; consult the module's documentation for details. (Contributed by Greg Ward.)

- The thread and threading modules now have companion modules, dummy_thread and dummy_threading, that provide a do-nothing implementation of the thread module's interface for platforms where threads are not supported. The intention is to simplify thread-aware modules (ones that don't rely on threads to run) by putting the following code at the top:

```python
try:
    import threading as _threading
except ImportError:
    import dummy_threading as _threading
```
In this example, _threading is used as the module name to make it clear that the module being used is not necessarily the actual threading module. Code can call functions and use classes in _threading whether or not threads are supported, avoiding an if statement and making the code slightly clearer. This module will not magically make multithreaded code run without threads; code that waits for another thread to return or to do something will simply hang forever.

- The time module's strftime() function has long been an annoyance because it uses the platform C library's strftime() implementation, and different platforms sometimes have odd bugs. Brett Cannon contributed a portable implementation that's written in pure Python and should behave identically on all platforms.

- The new timeit module helps measure how long snippets of Python code take to execute. The timeit.py file can be run directly from the command line, or the module's Timer class can be imported and used directly. Here's a short example that figures out whether it's faster to convert an 8-bit string to Unicode by appending an empty Unicode string to it or by using the unicode() function:

```python
import timeit

timer1 = timeit.Timer('unicode("abc")')
timer2 = timeit.Timer('"abc" + u""')

# Run three trials
print timer1.repeat(repeat=3, number=100000)
print timer2.repeat(repeat=3, number=100000)
```
• The Tix module has received various bug fixes and updates for the current version of the Tix package.

• The Tkinter module now works with a thread-enabled version of Tcl. Tcl's threading model requires that widgets only be accessed from the thread in which they're created; accesses from another thread can cause Tcl to panic. For certain Tcl interfaces, Tkinter will now automatically avoid this when a widget is accessed from a different thread by marshalling a command, passing it to the correct thread, and waiting for the results. Other interfaces can't be handled automatically but Tkinter will now raise an exception on such an access so that you can at least find out about the problem. See https://mail.python.org/pipermail/python-dev/2002-December/031107.html for a more detailed explanation of this change. (Implemented by Martin von Löwis.)

• Calling Tcl methods through _tkinter no longer returns only strings. Instead, if Tcl returns other objects those objects are converted to their Python equivalent, if one exists, or wrapped with a _tkinter.Tcl_Obj object if no Python equivalent exists. This behavior can be controlled through the wantobjects() method of tkapp objects.

When using _tkinter through the Tkinter module (as most Tkinter applications will), this feature is always activated. It should not cause compatibility problems, since Tkinter would always convert string results to Python types where possible.
If any incompatibilities are found, the old behavior can be restored by setting the wantobjects variable in the Tkinter module to false before creating the first tkapp object.

```python
import Tkinter
Tkinter.wantobjects = 0
```

Any breakage caused by this change should be reported as a bug.

- The UserDict module has a new DictMixin class which defines all dictionary methods for classes that already have a minimum mapping interface. This greatly simplifies writing classes that need to be substitutable for dictionaries, such as the classes in the shelve module.

Adding the mix-in as a superclass provides the full dictionary interface whenever the class defines `__getitem__()`, `__setitem__()`, `__delitem__()`, and keys(). For example:

```python
>>> import UserDict
>>> class SeqDict(UserDict.DictMixin):
...     """Dictionary lookalike implemented with lists."
...     def __init__(self):
...         self.keylist = []
...         self.valuelist = []
...     def __getitem__(self, key):
...         try:
...             i = self.keylist.index(key)
...         except ValueError:
...             raise KeyError
...         return self.valuelist[i]
...     def __setitem__(self, key, value):
...         try:
```
The DOM implementation in `xml.dom.minidom` can now generate XML output in a particular encoding by providing an optional encoding argument to the `toxml()` and `toprettyxml()` methods of DOM nodes.

The `xmlrpclib` module now supports an XML-RPC extension for handling nil data values such as Python's `None`. Nil values are always supported on unmarshalling an XML-RPC response. To generate requests containing `None`, you must supply a true value.
for the *allow_none* parameter when creating a Marshaller instance.

- The new DocXMLRPCServer module allows writing self-documenting XML-RPC servers. Run it in demo mode (as a program) to see it in action. Pointing the Web browser to the RPC server produces pydoc-style documentation; pointing xmlrpclib to the server allows invoking the actual methods. (Contributed by Brian Quinlan.)

- Support for internationalized domain names (RFCs 3454, 3490, 3491, and 3492) has been added. The “idna” encoding can be used to convert between a Unicode domain name and the ASCII-compatible encoding (ACE) of that name.

```python
>{u}>
```

The *socket* module has also been extended to transparently convert Unicode hostnames to the ACE version before passing them to the C library. Modules that deal with hostnames such as *httpplib* and *ftplib*) also support Unicode host names; *httpplib* also sends HTTP Host headers using the ACE version of the domain name. *urllib* supports Unicode URLs with non-ASCII host names as long as the path part of the URL is ASCII only.

To implement this change, the *stringprep* module, the *mkstringprep* tool and the *punycode* encoding have been added.

**Date/Time Type**
Date and time types suitable for expressing timestamps were added as the `datetime` module. The types don’t support different calendars or many fancy features, and just stick to the basics of representing time.

The three primary types are: `date`, representing a day, month, and year; `time`, consisting of hour, minute, and second; and `datetime`, which contains all the attributes of both `date` and `time`. There’s also a `timedelta` class representing differences between two points in time, and time zone logic is implemented by classes inheriting from the abstract `tzinfo` class.

You can create instances of `date` and `time` by either supplying keyword arguments to the appropriate constructor, e.g. `datetime.date(year=1972, month=10, day=15)`, or by using one of a number of class methods. For example, the `date.today()` class method returns the current local date.

Once created, instances of the date/time classes are all immutable. There are a number of methods for producing formatted strings from objects:

```python
>>> import datetime
>>> now = datetime.datetime.now()
>>> now.isoformat()
'2002-12-30T21:27:03.994956'
>>> now.ctime()  # Only available on date, datetime
'Mon Dec 30 21:27:03 2002'
>>> now.strftime('%Y %d %b')
'2002 30 Dec'
```

The `replace()` method allows modifying one or more fields of a
date or datetime instance, returning a new instance:

```python
>>> d = datetime.datetime.now()
>>> d
datetime.datetime(2002, 12, 30, 22, 15, 38, 827738)
>>> d.replace(year=2001, hour = 12)
datetime.datetime(2001, 12, 30, 12, 15, 38, 827738)
```

Instances can be compared, hashed, and converted to strings (the result is the same as that of isoformat()). date and datetime instances can be subtracted from each other, and added to timedelta instances. The largest missing feature is that there's no standard library support for parsing strings and getting back a date or datetime.

For more information, refer to the module’s reference documentation. (Contributed by Tim Peters.)

The optparse Module

The getopt module provides simple parsing of command-line arguments. The new optparse module (originally named Optik) provides more elaborate command-line parsing that follows the Unix conventions, automatically creates the output for --help, and can perform different actions for different options.

You start by creating an instance of OptionParser and telling it what your program’s options are.

```python
import sys
from optparse import OptionParser
```
op = OptionParser()
op.add_option('-i', '--input',
               action='store', type='string', dest='input',
               help='set input filename')
op.add_option('-l', '--length',
               action='store', type='int', dest='length',
               help='set maximum length of output')

Parsing a command line is then done by calling the parse_args() method.

options, args = op.parse_args(sys.argv[1:])
print options
print args

This returns an object containing all of the option values, and a list of strings containing the remaining arguments.

Invoking the script with the various arguments now works as you’d expect it to. Note that the length argument is automatically converted to an integer.

$ ./python opt.py -i data arg1
<Values at 0x400cad4c: {'input': 'data', 'length': None, ['arg1']
$ ./python opt.py --input=data --length=4
<Values at 0x400cad2c: {'input': 'data', 'length': 4}

The help message is automatically generated for you:

$ ./python opt.py --help
usage: opt.py [options]
options:
- `-h`, `--help`  
  show this help message and exit
- `-i INPUT`, `--input=INPUT`  
  set input filename
- `-l LENGTH`, `--length=LENGTH`  
  set maximum length of output

See the module's documentation for more details.

Optik was written by Greg Ward, with suggestions from the readers of the Getopt SIG.
Pymalloc: A Specialized Object Allocator

Pymalloc, a specialized object allocator written by Vladimir Marangozov, was a feature added to Python 2.1. Pymalloc is intended to be faster than the system malloc() and to have less memory overhead for allocation patterns typical of Python programs. The allocator uses C’s malloc() function to get large pools of memory and then fulfills smaller memory requests from these pools.

In 2.1 and 2.2, pymalloc was an experimental feature and wasn’t enabled by default; you had to explicitly enable it when compiling Python by providing the --with-pymalloc option to the configure script. In 2.3, pymalloc has had further enhancements and is now enabled by default; you’ll have to supply --without-pymalloc to disable it.

This change is transparent to code written in Python; however, pymalloc may expose bugs in C extensions. Authors of C extension modules should test their code with pymalloc enabled, because some incorrect code may cause core dumps at runtime.

There's one particularly common error that causes problems. There are a number of memory allocation functions in Python's C API that have previously just been aliases for the C library's malloc() and free(), meaning that if you accidentally called mismatched functions the error wouldn't be noticeable. When the object allocator is enabled, these functions aren't aliases of malloc() and free() any more, and calling the wrong function to free memory may get you a core dump. For example, if memory was allocated using PyObject_Malloc(), it has to be freed using PyObject_Free(), not free(). A few modules included with Python fell afoul of this and
had to be fixed; doubtless there are more third-party modules that will have the same problem.

As part of this change, the confusing multiple interfaces for allocating memory have been consolidated down into two API families. Memory allocated with one family must not be manipulated with functions from the other family. There is one family for allocating chunks of memory and another family of functions specifically for allocating Python objects.

- To allocate and free an undistinguished chunk of memory use the “raw memory” family: `PyMem_Malloc()`, `PyMem_Realloc()`, and `PyMem_Free()`.
- The “object memory” family is the interface to the pymalloc facility described above and is biased towards a large number of “small” allocations: `PyObject_Malloc()`, `PyObject_Realloc()`, and `PyObject_Free()`.
- To allocate and free Python objects, use the “object” family `PyObject_New()`, `PyObject_NewVar()`, and `PyObject_Del()`.

Thanks to lots of work by Tim Peters, pymalloc in 2.3 also provides debugging features to catch memory overwrites and doubled frees in both extension modules and in the interpreter itself. To enable this support, compile a debugging version of the Python interpreter by running `configure` with `--with-pydebug`.

To aid extension writers, a header file `Misc/pymemcompat.h` is distributed with the source to Python 2.3 that allows Python extensions to use the 2.3 interfaces to memory allocation while compiling against any version of Python since 1.5.2. You would copy the file from Python’s source distribution and bundle it with the source of your extension.
See also:

https://hg.python.org/cpython/file/default/Objects/obmalloc.c

For the full details of the pymalloc implementation, see the comments at the top of the file `Objects/obmalloc.c` in the Python source code. The above link points to the file within the python.org SVN browser.
Build and C API Changes

Changes to Python’s build process and to the C API include:

- The cycle detection implementation used by the garbage collection has proven to be stable, so it’s now been made mandatory. You can no longer compile Python without it, and the --with-cycle-gc switch to configure has been removed.
- Python can now optionally be built as a shared library (libpython2.3.so) by supplying --enable-shared when running Python’s configure script. (Contributed by Ondrej Palkovsky.)
- The DL_EXPORT and DL_IMPORT macros are now deprecated. Initialization functions for Python extension modules should now be declared using the new macro PyMODINIT_FUNC, while the Python core will generally use the PyAPI_FUNC and PyAPI_DATA macros.
- The interpreter can be compiled without any docstrings for the built-in functions and modules by supplying --without-docstrings to the configure script. This makes the Python executable about 10% smaller, but will also mean that you can’t get help for Python’s built-ins. (Contributed by Gustavo Niemeyer.)
- The PyArg_NoArgs() macro is now deprecated, and code that uses it should be changed. For Python 2.2 and later, the method definition table can specify the METH_NOARGS flag, signalling that there are no arguments, and the argument checking can then be removed. If compatibility with pre-2.2 versions of Python is important, the code could use PyArg_ParseTuple(args, "") instead, but this will be slower than using METH_NOARGS.
- PyArg_ParseTuple() accepts new format characters for various sizes of unsigned integers: B for unsigned char, H for unsigned short int, I for unsigned int, and K for
unsigned long long.

- A new function, PyObject_DelItemString(mapping, char *key) was added as shorthand for PyObject_DelItem(mapping, PyString_New(key)).
- File objects now manage their internal string buffer differently, increasing it exponentially when needed. This results in the benchmark tests in Lib/test/test_bufio.py speeding up considerably (from 57 seconds to 1.7 seconds, according to one measurement).
- It's now possible to define class and static methods for a C extension type by setting either the METH_CLASS or METH_STATIC flags in a method's PyMethodDef structure.
- Python now includes a copy of the Expat XML parser's source code, removing any dependence on a system version or local installation of Expat.
- If you dynamically allocate type objects in your extension, you should be aware of a change in the rules relating to the __module__ and __name__ attributes. In summary, you will want to ensure the type's dictionary contains a '__module__' key; making the module name the part of the type name leading up to the final period will no longer have the desired effect. For more detail, read the API reference documentation or the source.

Port-Specific Changes

Support for a port to IBM's OS/2 using the EMX runtime environment was merged into the main Python source tree. EMX is a POSIX emulation layer over the OS/2 system APIs. The Python port for EMX tries to support all the POSIX-like capability exposed by the EMX runtime, and mostly succeeds; fork() and fcntl() are restricted by the limitations of the underlying emulation layer. The standard OS/2 port, which uses IBM's Visual Age compiler, also gained support for
case-sensitive import semantics as part of the integration of the EMX port into CVS. (Contributed by Andrew MacIntyre.)

On MacOS, most toolbox modules have been weaklinked to improve backward compatibility. This means that modules will no longer fail to load if a single routine is missing on the current OS version. Instead calling the missing routine will raise an exception. (Contributed by Jack Jansen.)

The RPM spec files, found in the Misc/RPM/ directory in the Python source distribution, were updated for 2.3. (Contributed by Sean Reifschneider.)

Other new platforms now supported by Python include AtheOS (http://atheos.cx/), GNU/Hurd, and OpenVMS.
Other Changes and Fixes

As usual, there were a bunch of other improvements and bugfixes scattered throughout the source tree. A search through the CVS change logs finds there were 523 patches applied and 514 bugs fixed between Python 2.2 and 2.3. Both figures are likely to be underestimates.

Some of the more notable changes are:

- If the `PYTHONINSPECT` environment variable is set, the Python interpreter will enter the interactive prompt after running a Python program, as if Python had been invoked with the `-i` option. The environment variable can be set before running the Python interpreter, or it can be set by the Python program as part of its execution.

- The `regrtest.py` script now provides a way to allow “all resources except foo.” A resource name passed to the `-u` option can now be prefixed with a hyphen (`'-'`) to mean “remove this resource.” For example, the option `'-uall,-bsddb'` could be used to enable the use of all resources except bsddb.

- The tools used to build the documentation now work under Cygwin as well as Unix.

- The `SET_LINENO` opcode has been removed. Back in the mists of time, this opcode was needed to produce line numbers in tracebacks and support trace functions (for, e.g., `pdb`). Since Python 1.5, the line numbers in tracebacks have been computed using a different mechanism that works with “python -O”. For Python 2.3 Michael Hudson implemented a similar scheme to
determine when to call the trace function, removing the need for
\texttt{SET\_LINENO} entirely.

It would be difficult to detect any resulting difference from Python
code, apart from a slight speed up when Python is run without \texttt{-O}.

C extensions that access the \texttt{f\_lineno} field of frame objects
should instead call \texttt{PyCode\_Addr2Line(f->f\_code, f->f\_lasti)}. This will have the added effect of making the code
work as desired under "python -O" in earlier versions of Python.

A nifty new feature is that trace functions can now assign to the
\texttt{f\_lineno} attribute of frame objects, changing the line that will be
executed next. A \texttt{jump} command has been added to the \texttt{pdb}
debugger taking advantage of this new feature. (Implemented by
Richie Hindle.)
Porting to Python 2.3

This section lists previously described changes that may require changes to your code:

- **yield** is now always a keyword; if it’s used as a variable name in your code, a different name must be chosen.

- For strings $X$ and $Y$, $X$ in $Y$ now works if $X$ is more than one character long.

- The `int()` type constructor will now return a long integer instead of raising a `OverflowError` when a string or floating-point number is too large to fit into an integer.

- If you have Unicode strings that contain 8-bit characters, you must declare the file’s encoding (UTF-8, Latin-1, or whatever) by adding a comment to the top of the file. See section [PEP 263: Source Code Encodings](https://www.python.org/dev/peps/pep-0263/) for more information.

- Calling Tcl methods through `_tkinter` no longer returns only strings. Instead, if Tcl returns other objects those objects are converted to their Python equivalent, if one exists, or wrapped with a `_tkinter.Tcl_Obj` object if no Python equivalent exists.

- Large octal and hex literals such as `0xffffffff` now trigger a `FutureWarning`. Currently they’re stored as 32-bit numbers and result in a negative value, but in Python 2.4 they’ll become positive long integers.

There are a few ways to fix this warning. If you really need a positive number, just add an `L` to the end of the literal. If you’re
trying to get a 32-bit integer with low bits set and have previously used an expression such as \( \sim (1 << 31) \), it's probably clearest to start with all bits set and clear the desired upper bits. For example, to clear just the top bit (bit 31), you could write \( 0xffffffffL \land \sim (1L<<31) \).

- You can no longer disable assertions by assigning to `__debug__`.

- The Distutils `setup()` function has gained various new keyword arguments such as `depends`. Old versions of the Distutils will abort if passed unknown keywords. A solution is to check for the presence of the new `get_distutil_options()` function in your `setup.py` and only uses the new keywords with a version of the Distutils that supports them:

```python
from distutils import core

kw = {'sources': 'foo.c', ...}
if hasattr(core, 'get_distutil_options'):
    kw['depends'] = ['foo.h']
ext = Extension(**kw)
```

- Using `None` as a variable name will now result in a `SyntaxWarning` warning.

- Names of extension types defined by the modules included with Python now contain the module and a `'.'` in front of the type name.

What’s New in Python 2.2

Author: A.M. Kuchling
Introduction

This article explains the new features in Python 2.2.2, released on October 14, 2002. Python 2.2.2 is a bugfix release of Python 2.2, originally released on December 21, 2001.

Python 2.2 can be thought of as the “cleanup release”. There are some features such as generators and iterators that are completely new, but most of the changes, significant and far-reaching though they may be, are aimed at cleaning up irregularities and dark corners of the language design.

This article doesn’t attempt to provide a complete specification of the new features, but instead provides a convenient overview. For full details, you should refer to the documentation for Python 2.2, such as the Python Library Reference and the Python Reference Manual. If you want to understand the complete implementation and design rationale for a change, refer to the PEP for a particular new feature.
PEPs 252 and 253: Type and Class Changes

The largest and most far-reaching changes in Python 2.2 are to Python's model of objects and classes. The changes should be backward compatible, so it's likely that your code will continue to run unchanged, but the changes provide some amazing new capabilities. Before beginning this, the longest and most complicated section of this article, I'll provide an overview of the changes and offer some comments.

A long time ago I wrote a Web page listing flaws in Python's design. One of the most significant flaws was that it's impossible to subclass Python types implemented in C. In particular, it's not possible to subclass built-in types, so you can't just subclass, say, lists in order to add a single useful method to them. The UserList module provides a class that supports all of the methods of lists and that can be subclassed further, but there's lots of C code that expects a regular Python list and won't accept a UserList instance.

Python 2.2 fixes this, and in the process adds some exciting new capabilities. A brief summary:

- You can subclass built-in types such as lists and even integers, and your subclasses should work in every place that requires the original type.
- It's now possible to define static and class methods, in addition to the instance methods available in previous versions of Python.
- It's also possible to automatically call methods on accessing or setting an instance attribute by using a new mechanism called properties. Many uses of __getattr__() can be rewritten to use properties instead, making the resulting code simpler and
faster. As a small side benefit, attributes can now have docstrings, too.

- The list of legal attributes for an instance can be limited to a particular set using *slots*, making it possible to safeguard against typos and perhaps make more optimizations possible in future versions of Python.

Some users have voiced concern about all these changes. Sure, they say, the new features are neat and lend themselves to all sorts of tricks that weren’t possible in previous versions of Python, but they also make the language more complicated. Some people have said that they’ve always recommended Python for its simplicity, and feel that its simplicity is being lost.

Personally, I think there’s no need to worry. Many of the new features are quite esoteric, and you can write a lot of Python code without ever needed to be aware of them. Writing a simple class is no more difficult than it ever was, so you don’t need to bother learning or teaching them unless they’re actually needed. Some very complicated tasks that were previously only possible from C will now be possible in pure Python, and to my mind that’s all for the better.

I’m not going to attempt to cover every single corner case and small change that were required to make the new features work. Instead this section will paint only the broad strokes. See section *Related Links*, “Related Links”, for further sources of information about Python 2.2’s new object model.

**Old and New Classes**

First, you should know that Python 2.2 really has two kinds of classes: classic or old-style classes, and new-style classes. The old-style class model is exactly the same as the class model in earlier versions of
Python. All the new features described in this section apply only to new-style classes. This divergence isn’t intended to last forever; eventually old-style classes will be dropped, possibly in Python 3.0.

So how do you define a new-style class? You do it by subclassing an existing new-style class. Most of Python’s built-in types, such as integers, lists, dictionaries, and even files, are new-style classes now. A new-style class named `object`, the base class for all built-in types, has also been added so if no built-in type is suitable, you can just subclass `object`:

```python

class C(object):
    def __init__(self):
        ...
```

This means that `class` statements that don’t have any base classes are always classic classes in Python 2.2. (Actually you can also change this by setting a module-level variable named `__metaclass__` — see PEP 253 for the details — but it’s easier to just subclass `object`.)

The type objects for the built-in types are available as built-ins, named using a clever trick. Python has always had built-in functions named `int()`, `float()`, and `str()`. In 2.2, they aren’t functions any more, but type objects that behave as factories when called.

```python
>>> int
<type 'int'>
>>> int('123')
123
```

To make the set of types complete, new type objects such as `dict()`
and file() have been added. Here's a more interesting example, adding a lock() method to file objects:

```python
class LockableFile(file):
    def lock(self, operation, length=0, start=0, whence=0):
        import fcntl
        return fcntl.lockf(self.fileno(), operation, length, start, whence)
```

The now-obsolete posixfile module contained a class that emulated all of a file object's methods and also added a lock() method, but this class couldn’t be passed to internal functions that expected a built-in file, something which is possible with our new LockableFile.

### Descriptors

In previous versions of Python, there was no consistent way to discover what attributes and methods were supported by an object. There were some informal conventions, such as defining __members__ and __methods__ attributes that were lists of names, but often the author of an extension type or a class wouldn’t bother to define them. You could fall back on inspecting the __dict__ of an object, but when class inheritance or an arbitrary __getattr__() hook were in use this could still be inaccurate.

The one big idea underlying the new class model is that an API for describing the attributes of an object using descriptors has been formalized. Descriptors specify the value of an attribute, stating whether it’s a method or a field. With the descriptor API, static methods and class methods become possible, as well as more exotic
constructs.

Attribute descriptors are objects that live inside class objects, and have a few attributes of their own:

- `__name__` is the attribute's name.
- `__doc__` is the attribute's docstring.
- `__get__(object)` is a method that retrieves the attribute value from `object`.
- `__set__(object, value)` sets the attribute on `object` to `value`.
- `__delete__(object, value)` deletes the `value` attribute of `object`.

For example, when you write `obj.x`, the steps that Python actually performs are:

```python
descriptor = obj.__class__.x
descriptor.__get__(obj)
```

For methods, `descriptor.__get__()` returns a temporary object that's callable, and wraps up the instance and the method to be called on it. This is also why static methods and class methods are now possible; they have descriptors that wrap up just the method, or the method and the class. As a brief explanation of these new kinds of methods, static methods aren't passed the instance, and therefore resemble regular functions. Class methods are passed the class of the object, but not the object itself. Static and class methods are defined like this:

```python
class C(object):
    def f(arg1, arg2):
        ...
    f = staticmethod(f)
```
The `staticmethod()` function takes the function `f()` and returns it wrapped up in a descriptor so it can be stored in the class object. You might expect there to be special syntax for creating such methods (`def static f`, `defstatic f()`, or something like that) but no such syntax has been defined yet; that’s been left for future versions of Python.

More new features, such as slots and properties, are also implemented as new kinds of descriptors, and it’s not difficult to write a descriptor class that does something novel. For example, it would be possible to write a descriptor class that made it possible to write Eiffel-style preconditions and postconditions for a method. A class that used this feature might be defined like this:

```python
from eiffel import eiffelmethod

class C(object):
    def f(self, arg1, arg2):
        # The actual function
        ...
    def pre_f(self):
        # Check preconditions
        ...
    def post_f(self):
        # Check postconditions
        ...

    f = eiffelmethod(f, pre_f, post_f)
```

Note that a person using the new `eiffelmethod()` doesn’t have to
understand anything about descriptors. This is why I think the new features don’t increase the basic complexity of the language. There will be a few wizards who need to know about it in order to write `eiffelmethod()` or the ZODB or whatever, but most users will just write code on top of the resulting libraries and ignore the implementation details.

**Multiple Inheritance: The Diamond Rule**

Multiple inheritance has also been made more useful through changing the rules under which names are resolved. Consider this set of classes (diagram taken from [PEP 253](https://www.python.org/dev/peps/pep-0253/) by Guido van Rossum):

```python
class A:
    def save(self): ...

class B
class C:
    def save(self): ...

class D
```

The lookup rule for classic classes is simple but not very smart; the base classes are searched depth-first, going from left to right. A reference to `D.save()` will search the classes `D, B, and then A`, where `save()` would be found and returned. `C.save()` would never be found at all. This is bad, because if C’s `save()` method is saving some internal state specific to C, not calling it will result in that state
never getting saved.

New-style classes follow a different algorithm that’s a bit more complicated to explain, but does the right thing in this situation. (Note that Python 2.3 changes this algorithm to one that produces the same results in most cases, but produces more useful results for really complicated inheritance graphs.)

1. List all the base classes, following the classic lookup rule and include a class multiple times if it’s visited repeatedly. In the above example, the list of visited classes is [D, B, A, C, A].
2. Scan the list for duplicated classes. If any are found, remove all but one occurrence, leaving the last one in the list. In the above example, the list becomes [D, B, C, A] after dropping duplicates.

Following this rule, referring to D.save() will return C.save(), which is the behaviour we’re after. This lookup rule is the same as the one followed by Common Lisp. A new built-in function, super(), provides a way to get at a class’s superclasses without having to reimplement Python’s algorithm. The most commonly used form will be super(class, obj), which returns a bound superclass object (not the actual class object). This form will be used in methods to call a method in the superclass; for example, D’s save() method would look like this:

```python
class D (B,C):
    def save (self):
        # Call superclass .save()
        super(D, self).save()
        # Save D's private information here
        ...
```

super() can also return unbound superclass objects when called as
super(class) or super(class1, class2), but this probably won’t often be useful.

Attribute Access

A fair number of sophisticated Python classes define hooks for attribute access using \_getattr\_(); most commonly this is done for convenience, to make code more readable by automatically mapping an attribute access such as obj.parent into a method call such as obj.get_parent. Python 2.2 adds some new ways of controlling attribute access.

First, \_getattr\_(attr\_name) is still supported by new-style classes, and nothing about it has changed. As before, it will be called when an attempt is made to access obj.foo and no attribute named foo is found in the instance’s dictionary.

New-style classes also support a new method, \_getattribute\_(attr\_name). The difference between the two methods is that \_getattribute\_() is always called whenever any attribute is accessed, while the old \_getattr\_() is only called if foo isn’t found in the instance’s dictionary.

However, Python 2.2’s support for properties will often be a simpler way to trap attribute references. Writing a \_getattr\_() method is complicated because to avoid recursion you can’t use regular attribute accesses inside them, and instead have to mess around with the contents of \_dict\_. \_getattribute\_() methods also end up being called by Python when it checks for other methods such as \_repr\_() or \_coerce\_(), and so have to be written with this in mind. Finally, calling a function on every attribute access results in a
sizable performance loss.

`property` is a new built-in type that packages up three functions that get, set, or delete an attribute, and a docstring. For example, if you want to define a size attribute that's computed, but also settable, you could write:

```python
class C(object):
    def get_size (self):
        result = ... computation ...
        return result
    def set_size (self, size):
        ... compute something based on the size and set internal state appropriately ...

    # Define a property. The 'delete this attribute' method is defined as None, so the attribute can't be deleted.
    size = property(get_size, set_size, None,
                    "Storage size of this instance")
```

That is certainly clearer and easier to write than a pair of `__getattr__()`/`__setattr__()` methods that check for the size attribute and handle it specially while retrieving all other attributes from the instance's `__dict__`. Accesses to size are also the only ones which have to perform the work of calling a function, so references to other attributes run at their usual speed.

Finally, it's possible to constrain the list of attributes that can be referenced on an object using the new `__slots__` class attribute. Python objects are usually very dynamic; at any time it's possible to define a new attribute on an instance by just doing `obj.new_attr=1.`
A new-style class can define a class attribute named `__slots__` to limit the legal attributes to a particular set of names. An example will make this clear:

```python
class C(object):
    ...  __slots__ = ('template', 'name')
    ...
>>> obj = C()
>>> print obj.template
None
>>> obj.template = 'Test'
>>> print obj.template
Test
>>> obj.newattr = None
AttributeError: 'C' object has no attribute 'newattr'
```

Note how you get an `AttributeError` on the attempt to assign to an attribute not listed in `__slots__`.

**Related Links**

This section has just been a quick overview of the new features, giving enough of an explanation to start you programming, but many details have been simplified or ignored. Where should you go to get a more complete picture?

[https://docs.python.org/dev/howto/descriptor.html](https://docs.python.org/dev/howto/descriptor.html) is a lengthy tutorial introduction to the descriptor features, written by Guido van Rossum. If my description has whetted your appetite, go read this tutorial next, because it goes into much more detail about the new features while still remaining quite easy to read.
Next, there are two relevant PEPs, **PEP 252** and **PEP 253**. PEP 252 is titled “Making Types Look More Like Classes”, and covers the descriptor API. PEP 253 is titled “Subtyping Built-in Types”, and describes the changes to type objects that make it possible to subtype built-in objects. PEP 253 is the more complicated PEP of the two, and at a few points the necessary explanations of types and meta-types may cause your head to explode. Both PEPs were written and implemented by Guido van Rossum, with substantial assistance from the rest of the Zope Corp. team.

Finally, there’s the ultimate authority: the source code. Most of the machinery for the type handling is in `Objects/typeobject.c`, but you should only resort to it after all other avenues have been exhausted, including posting a question to python-list or python-dev.
PEP 234: Iterators

Another significant addition to 2.2 is an iteration interface at both the C and Python levels. Objects can define how they can be looped over by callers.

In Python versions up to 2.1, the usual way to make for item in obj work is to define a `__getitem__()` method that looks something like this:

```python
def __getitem__(self, index):
    return <next item>
```

`__getitem__()` is more properly used to define an indexing operation on an object so that you can write `obj[5]` to retrieve the sixth element. It’s a bit misleading when you’re using this only to support `for` loops. Consider some file-like object that wants to be looped over; the `index` parameter is essentially meaningless, as the class probably assumes that a series of `__getitem__()` calls will be made with `index` incrementing by one each time. In other words, the presence of the `__getitem__()` method doesn’t mean that using `file[5]` to randomly access the sixth element will work, though it really should.

In Python 2.2, iteration can be implemented separately, and `__getitem__()` methods can be limited to classes that really do support random access. The basic idea of iterators is simple. A new built-in function, `iter(obj)` or `iter(C, sentinel)`, is used to get an iterator. `iter(obj)` returns an iterator for the object `obj`, while `iter(C, sentinel)` returns an iterator that will invoke the callable object `C` until it returns `sentinel` to signal that the iterator is done.
Python classes can define an `__iter__()` method, which should create and return a new iterator for the object; if the object is its own iterator, this method can just return `self`. In particular, iterators will usually be their own iterators. Extension types implemented in C can implement a `tp_iter` function in order to return an iterator, and extension types that want to behave as iterators can define a `tp_iternext` function.

So, after all this, what do iterators actually do? They have one required method, `next()`, which takes no arguments and returns the next value. When there are no more values to be returned, calling `next()` should raise the `StopIteration` exception.

```python
>>> L = [1, 2, 3]
>>> i = iter(L)
>>> print i
<iterator object at 0x8116870>
>>> i.next()
1
>>> i.next()
2
>>> i.next()
3
>>> i.next()
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
StopIteration
```

In 2.2, Python’s `for` statement no longer expects a sequence; it expects something for which `iter()` will return an iterator. For backward compatibility and convenience, an iterator is automatically constructed for sequences that don’t implement `__iter__()` or a
tp_iter slot, so for i in [1,2,3] will still work. Wherever the Python interpreter loops over a sequence, it's been changed to use the iterator protocol. This means you can do things like this:

```python
>>> L = [1,2,3]
>>> i = iter(L)
>>> a,b,c = i
>>> a,b,c
(1, 2, 3)
```

Iterator support has been added to some of Python’s basic types. Calling `iter()` on a dictionary will return an iterator which loops over its keys:

```python
>>> m = {'Jan': 1, 'Feb': 2, 'Mar': 3, 'Apr': 4, 'May': 5, 'Jun': 6, 'Jul': 7, 'Aug': 8, 'Sep': 9, 'Oct': 10, 'Nov': 11, 'Dec': 12}
>>> for key in m: print key, m[key]
... Mar 3
Feb 2
Aug 8
Sep 9
May 5
Jun 6
Jul 7
Jan 1
Apr 4
Nov 11
Dec 12
Oct 10
```

That’s just the default behaviour. If you want to iterate over keys, values, or key/value pairs, you can explicitly call the `iterkeys()`, `itervalues()`, or `iteritems()` methods to get an appropriate
iterator. In a minor related change, the in operator now works on
dictionaries, so key in dict is now equivalent to
dict.has_key(key).

Files also provide an iterator, which calls the readline() method
until there are no more lines in the file. This means you can now read
each line of a file using code like this:

```python
for line in file:
    # do something for each line
    ...
```

Note that you can only go forward in an iterator; there's no way to get
the previous element, reset the iterator, or make a copy of it. An
iterator object could provide such additional capabilities, but the
iterator protocol only requires a next() method.

**See also:**

**PEP 234 - Iterators**

Written by Ka-Ping Yee and GvR; implemented by the Python
Labs crew, mostly by GvR and Tim Peters.
Generators are another new feature, one that interacts with the introduction of iterators.

You’re doubtless familiar with how function calls work in Python or C. When you call a function, it gets a private namespace where its local variables are created. When the function reaches a `return` statement, the local variables are destroyed and the resulting value is returned to the caller. A later call to the same function will get a fresh new set of local variables. But, what if the local variables weren’t thrown away on exiting a function? What if you could later resume the function where it left off? This is what generators provide; they can be thought of as resumable functions.

Here’s the simplest example of a generator function:

```python
def generate_ints(N):
    for i in range(N):
        yield i
```

A new keyword, `yield`, was introduced for generators. Any function containing a `yield` statement is a generator function; this is detected by Python’s bytecode compiler which compiles the function specially as a result. Because a new keyword was introduced, generators must be explicitly enabled in a module by including a `from __future__ import generators` statement near the top of the module’s source code. In Python 2.3 this statement will become unnecessary.

When you call a generator function, it doesn’t return a single value; instead it returns a generator object that supports the iterator protocol. On executing the `yield` statement, the generator outputs the value of
i, similar to a return statement. The big difference between yield and a return statement is that on reaching a yield the generator's state of execution is suspended and local variables are preserved. On the next call to the generator's next() method, the function will resume executing immediately after the yield statement. (For complicated reasons, the yield statement isn't allowed inside the try block of a try...finally statement; read PEP 255 for a full explanation of the interaction between yield and exceptions.)

Here's a sample usage of the generate_ints() generator:

```python
>>> gen = generate_ints(3)
>>> gen
<generator object at 0x8117f90>
>>> gen.next()
0
>>> gen.next()
1
>>> gen.next()
2
>>> gen.next()
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
  File "<stdin>", line 2, in generate_ints
StopIteration
```

You could equally write for i in generate_ints(5), or a, b, c = generate_ints(3).

Inside a generator function, the return statement can only be used without a value, and signals the end of the procession of values; afterwards the generator cannot return any further values. return with a value, such as return 5, is a syntax error inside a generator function.
function. The end of the generator’s results can also be indicated by raising `StopIteration` manually, or by just letting the flow of execution fall off the bottom of the function.

You could achieve the effect of generators manually by writing your own class and storing all the local variables of the generator as instance variables. For example, returning a list of integers could be done by setting `self.count` to 0, and having the `next()` method increment `self.count` and return it. However, for a moderately complicated generator, writing a corresponding class would be much messier. `Lib/test/test_generators.py` contains a number of more interesting examples. The simplest one implements an in-order traversal of a tree using generators recursively.

```python
# A recursive generator that generates Tree leaves in order.
def inorder(t):
    if t:
        for x in inorder(t.left):
            yield x
        yield t.label
        for x in inorder(t.right):
            yield x
```

Two other examples in `Lib/test/test_generators.py` produce solutions for the N-Queens problem (placing $N$ queens on an $N\times N$ chess board so that no queen threatens another) and the Knight’s Tour (a route that takes a knight to every square of an $N\times N$ chessboard without visiting any square twice).

The idea of generators comes from other programming languages, especially Icon ([https://www.cs.arizona.edu/icon/](https://www.cs.arizona.edu/icon/)), where the idea of generators is central. In Icon, every expression and function call behaves like a generator. One example from “An Overview of the Icon
Programming Language at https://www.cs.arizona.edu/icon/docs/ipd266.htm gives an idea of what this looks like:

```plaintext
sentence := "Store it in the neighboring harbor"
if (i := find("or", sentence)) > 5 then write(i)
```

In Icon the find() function returns the indexes at which the substring “or” is found: 3, 23, 33. In the if statement, i is first assigned a value of 3, but 3 is less than 5, so the comparison fails, and Icon retries it with the second value of 23. 23 is greater than 5, so the comparison now succeeds, and the code prints the value 23 to the screen.

Python doesn’t go nearly as far as Icon in adopting generators as a central concept. Generators are considered a new part of the core Python language, but learning or using them isn’t compulsory; if they don’t solve any problems that you have, feel free to ignore them. One novel feature of Python’s interface as compared to Icon’s is that a generator’s state is represented as a concrete object (the iterator) that can be passed around to other functions or stored in a data structure.

**PEP 255 - Simple Generators**
Written by Neil Schemenauer, Tim Peters, Magnus Lie Hetland. Implemented mostly by Neil Schemenauer and Tim Peters, with other fixes from the Python Labs crew.
PEP 237: Unifying Long Integers and Integers

In recent versions, the distinction between regular integers, which are 32-bit values on most machines, and long integers, which can be of arbitrary size, was becoming an annoyance. For example, on platforms that support files larger than \(2^{*32}\) bytes, the `tell()` method of file objects has to return a long integer. However, there were various bits of Python that expected plain integers and would raise an error if a long integer was provided instead. For example, in Python 1.5, only regular integers could be used as a slice index, and \('abc'[1L:]\) would raise a `TypeError` exception with the message ‘slice index must be int’.

Python 2.2 will shift values from short to long integers as required. The ‘L’ suffix is no longer needed to indicate a long integer literal, as now the compiler will choose the appropriate type. (Using the ‘L’ suffix will be discouraged in future 2.x versions of Python, triggering a warning in Python 2.4, and probably dropped in Python 3.0.) Many operations that used to raise an `OverflowError` will now return a long integer as their result. For example:

```
>>> 1234567890123
1234567890123L
>>> 2 ** 64
18446744073709551616L
```

In most cases, integers and long integers will now be treated identically. You can still distinguish them with the `type()` built-in function, but that's rarely needed.

**PEP 237 - Unifying Long Integers and Integers**
Written by Moshe Zadka and Guido van Rossum. Implemented mostly by Guido van Rossum.
PEP 238: Changing the Division Operator

The most controversial change in Python 2.2 heralds the start of an effort to fix an old design flaw that’s been in Python from the beginning. Currently Python’s division operator, `/`, behaves like C’s division operator when presented with two integer arguments: it returns an integer result that’s truncated down when there would be a fractional part. For example, `3/2` is 1, not 1.5, and `(-1)/2` is -1, not -0.5. This means that the results of division can vary unexpectedly depending on the type of the two operands and because Python is dynamically typed, it can be difficult to determine the possible types of the operands.

(The controversy is over whether this is really a design flaw, and whether it’s worth breaking existing code to fix this. It’s caused endless discussions on python-dev, and in July 2001 erupted into a storm of acidly sarcastic postings on comp.lang.python. I won’t argue for either side here and will stick to describing what’s implemented in 2.2. Read PEP 238 for a summary of arguments and counter-arguments.)

Because this change might break code, it’s being introduced very gradually. Python 2.2 begins the transition, but the switch won’t be complete until Python 3.0.

First, I’ll borrow some terminology from PEP 238. “True division” is the division that most non-programmers are familiar with: `3/2` is 1.5, `1/4` is 0.25, and so forth. “Floor division” is what Python’s `/` operator currently does when given integer operands; the result is the floor of the value returned by true division. “Classic division” is the current mixed behaviour of `/`; it returns the result of floor division when the operands are integers, and returns the result of true division when one
of the operands is a floating-point number.

Here are the changes 2.2 introduces:

- A new operator, `//`, is the floor division operator. (Yes, we know it looks like C++'s comment symbol.) `//` always performs floor division no matter what the types of its operands are, so `1 // 2` is 0 and `1.0 // 2.0` is also 0.0.

  `//` is always available in Python 2.2; you don't need to enable it using a `__future__` statement.

- By including a `from __future__ import division` in a module, the `/` operator will be changed to return the result of true division, so `1/2` is 0.5. Without the `__future__` statement, `/` still means classic division. The default meaning of `/` will not change until Python 3.0.

- Classes can define methods called `__truediv__( )` and `__floordiv__( )` to overload the two division operators. At the C level, there are also slots in the `PyNumberMethods` structure so extension types can define the two operators.

- Python 2.2 supports some command-line arguments for testing whether code will work with the changed division semantics. Running python with `-Q warn` will cause a warning to be issued whenever division is applied to two integers. You can use this to find code that's affected by the change and fix it. By default, Python 2.2 will simply perform classic division without a warning; the warning will be turned on by default in Python 2.3.

See also:
PEP 238 - Changing the Division Operator
Written by Moshe Zadka and Guido van Rossum. Implemented by Guido van Rossum.
Unicode Changes

Python’s Unicode support has been enhanced a bit in 2.2. Unicode strings are usually stored as UCS-2, as 16-bit unsigned integers. Python 2.2 can also be compiled to use UCS-4, 32-bit unsigned integers, as its internal encoding by supplying `--enable-unicode=ucs4` to the configure script. (It’s also possible to specify `-disable-unicode` to completely disable Unicode support.)

When built to use UCS-4 (a “wide Python”), the interpreter can natively handle Unicode characters from U+000000 to U+110000, so the range of legal values for the `unichr()` function is expanded accordingly. Using an interpreter compiled to use UCS-2 (a “narrow Python”), values greater than 65535 will still cause `unichr()` to raise a `ValueError` exception. This is all described in PEP 261, “Support for ‘wide’ Unicode characters”; consult it for further details.

Another change is simpler to explain. Since their introduction, Unicode strings have supported an `encode()` method to convert the string to a selected encoding such as UTF-8 or Latin-1. A symmetric `decode([*encoding*])` method has been added to 8-bit strings (though not to Unicode strings) in 2.2. `decode()` assumes that the string is in the specified encoding and decodes it, returning whatever is returned by the codec.

Using this new feature, codecs have been added for tasks not directly related to Unicode. For example, codecs have been added for uu-encoding, MIME’s base64 encoding, and compression with the `zlib` module:

```python
>>> s = """Here is a lengthy piece of redundant, over"""
```
and repetitive text.

>>> data = s.encode('zlib')

>>> data
'x\x9c\r\xc9 xc1\r \x80 \x10\x04\xc0?U1...

>>> data.decode('zlib')
'Here is a lengthy piece of redundant, overly verbose, and repetitive text.'

>>> print s.encode('uu')
begin 666 <data>
M2&5R92!I<R!A(&QE;F=T:'D@<&EE8V4@;V8@<F5D=6YD86YT+"!
>=F5R8F]S92P*86YD(')E<&5T:71I=F4@=&5X="X*
end

>>> "sheesh".encode('rot-13')
'furrfu'

To convert a class instance to Unicode, a \_\_unicode\_() method can be defined by a class, analogous to \_\_str\_().

encode(), decode(), and \_\_unicode\_() were implemented by Marc-André Lemburg. The changes to support using UCS-4 internally were implemented by Fredrik Lundh and Martin von Löwis.

**PEP 261 - Support for ‘wide’ Unicode characters**

Written by Paul Prescod.
PEP 227: Nested Scopes

In Python 2.1, statically nested scopes were added as an optional feature, to be enabled by a `from __future__ import nested_scopes` directive. In 2.2 nested scopes no longer need to be specially enabled, and are now always present. The rest of this section is a copy of the description of nested scopes from my “What’s New in Python 2.1” document; if you read it when 2.1 came out, you can skip the rest of this section.

The largest change introduced in Python 2.1, and made complete in 2.2, is to Python’s scoping rules. In Python 2.0, at any given time there are at most three namespaces used to look up variable names: local, module-level, and the built-in namespace. This often surprised people because it didn’t match their intuitive expectations. For example, a nested recursive function definition doesn’t work:

```python
def f():
    ...
    def g(value):
        ...
        return g(value - 1) + 1
    ...
```

The function `g()` will always raise a `NameError` exception, because the binding of the name `g` isn’t in either its local namespace or in the module-level namespace. This isn’t much of a problem in practice (how often do you recursively define interior functions like this?), but this also made using the `lambda` statement clumsier, and this was a problem in practice. In code which uses `lambda` you can often find local variables being copied by passing them as the default values of arguments.
The readability of Python code written in a strongly functional style suffers greatly as a result.

The most significant change to Python 2.2 is that static scoping has been added to the language to fix this problem. As a first effect, the name=name default argument is now unnecessary in the above example. Put simply, when a given variable name is not assigned a value within a function (by an assignment, or the def, class, or import statements), references to the variable will be looked up in the local namespace of the enclosing scope. A more detailed explanation of the rules, and a dissection of the implementation, can be found in the PEP.

This change may cause some compatibility problems for code where the same variable name is used both at the module level and as a local variable within a function that contains further function definitions. This seems rather unlikely though, since such code would have been pretty confusing to read in the first place.

One side effect of the change is that the from module import * and exec statements have been made illegal inside a function scope under certain conditions. The Python reference manual has said all along that from module import * is only legal at the top level of a module, but the CPython interpreter has never enforced this before. As part of the implementation of nested scopes, the compiler which turns Python source into bytecodes has to generate different code to access variables in a containing scope. from module import *
and `exec` make it impossible for the compiler to figure this out, because they add names to the local namespace that are unknowable at compile time. Therefore, if a function contains function definitions or `lambda` expressions with free variables, the compiler will flag this by raising a `SyntaxError` exception.

To make the preceding explanation a bit clearer, here's an example:

```python
x = 1
def f():
    # The next line is a syntax error
    exec 'x=2'
def g():
    return x
```

Line 4 containing the `exec` statement is a syntax error, since `exec` would define a new local variable named `x` whose value should be accessed by `g()`.

This shouldn't be much of a limitation, since `exec` is rarely used in most Python code (and when it is used, it's often a sign of a poor design anyway).

**PEP 227 - Statically Nested Scopes**

Written and implemented by Jeremy Hylton.
New and Improved Modules

- The xmlrpclib module was contributed to the standard library by Fredrik Lundh, providing support for writing XML-RPC clients. XML-RPC is a simple remote procedure call protocol built on top of HTTP and XML. For example, the following snippet retrieves a list of RSS channels from the O’Reilly Network, and then lists the recent headlines for one channel:

```python
import xmlrpclib
channels = s.meerkat.getChannels()
# channels is a list of dictionaries, like this:
# [{'id': 4, 'title': 'Freshmeat Daily News'},
#  {'id': 190, 'title': '32Bits Online'},
#  {'id': 4549, 'title': '3DGamers'}, ...
#
# Get the items for one channel
items = s.meerkat.getItems( {'channel': 4} )
# 'items' is another list of dictionaries, like this:
# [{'link': 'http://freshmeat.net/releases/52719/',
#  'description': 'A utility which converts HTML to XSL FO.',
#  'title': 'html2fo 0.3 (Default)'}, ...
```

The SimpleXMLRPCServer module makes it easy to create straightforward XML-RPC servers. See http://www.xmlrpc.com/ for more information about XML-RPC.

- The new hmac module implements the HMAC algorithm described by RFC 2104. (Contributed by Gerhard Häring.)
Several functions that originally returned lengthy tuples now return pseudo-sequences that still behave like tuples but also have mnemonic attributes such as memberst_mtime or tm_year. The enhanced functions include `stat()`, `fstat()`, `statvfs()`, and `fstatvfs()` in the `os` module, and `localtime()`, `gmtime()`, and `strptime()` in the `time` module.

For example, to obtain a file’s size using the old tuples, you’d end up writing something like `file_size = os.stat(filename)[stat.ST_SIZE]`, but now this can be written more clearly as `file_size = os.stat(filename).st_size`.

The original patch for this feature was contributed by Nick Mathewson.

The Python profiler has been extensively reworked and various errors in its output have been corrected. (Contributed by Fred L. Drake, Jr. and Tim Peters.)

The `socket` module can be compiled to support IPv6; specify the `--enable-ipv6` option to Python’s configure script. (Contributed by Jun-ichiro “itojun” Hagino.)

Two new format characters were added to the `struct` module for 64-bit integers on platforms that support the C `long long` type. `q` is for a signed 64-bit integer, and `Q` is for an unsigned one. The value is returned in Python’s long integer type. (Contributed by Tim Peters.)

In the interpreter’s interactive mode, there’s a new built-in function `help()` that uses the `pydoc` module introduced in Python 2.1 to provide interactive help. `help(object)` displays any available
help text about object. help() with no argument puts you in an online help utility, where you can enter the names of functions, classes, or modules to read their help text. (Contributed by Guido van Rossum, using Ka-Ping Yee’s pydoc module.)

- Various bugfixes and performance improvements have been made to the SRE engine underlying the re module. For example, the re.sub() and re.split() functions have been rewritten in C. Another contributed patch speeds up certain Unicode character ranges by a factor of two, and a new finditer() method that returns an iterator over all the non-overlapping matches in a given string. (SRE is maintained by Fredrik Lundh. The BIGCHARSET patch was contributed by Martin von Löwis.)

- The smtplib module now supports RFC 2487, “Secure SMTP over TLS”, so it's now possible to encrypt the SMTP traffic between a Python program and the mail transport agent being handed a message. smtplib also supports SMTP authentication. (Contributed by Gerhard Häring.)

- The imaplib module, maintained by Piers Lauder, has support for several new extensions: the NAMESPACE extension defined in RFC 2342, SORT, GETACL and SETACL. (Contributed by Anthony Baxter and Michel Pelletier.)

- The rfc822 module's parsing of email addresses is now compliant with RFC 2822, an update to RFC 822. (The module's name is not going to be changed to rfc2822.) A new package, email, has also been added for parsing and generating e-mail messages. (Contributed by Barry Warsaw, and arising out of his work on Mailman.)
• The **difflib** module now contains a new Differ class for producing human-readable lists of changes (a “delta”) between two sequences of lines of text. There are also two generator functions, ndiff() and restore(), which respectively return a delta from two sequences, or one of the original sequences from a delta. (Grunt work contributed by David Goodger, from ndiff.py code by Tim Peters who then did the generatorization.)

• New constants `ascii_letters`, `ascii_lowercase`, and `ascii_uppercase` were added to the **string** module. There were several modules in the standard library that used `string.letters` to mean the ranges A-Za-z, but that assumption is incorrect when locales are in use, because `string.letters` varies depending on the set of legal characters defined by the current locale. The buggy modules have all been fixed to use `ascii_letters` instead. (Reported by an unknown person; fixed by Fred L. Drake, Jr.)

• The **mimetypes** module now makes it easier to use alternative MIME-type databases by the addition of a MimeTypes class, which takes a list of filenames to be parsed. (Contributed by Fred L. Drake, Jr.)

• A **Timer** class was added to the **threading** module that allows scheduling an activity to happen at some future time. (Contributed by Itamar Shtull-Trauring.)
Interpreter Changes and Fixes

Some of the changes only affect people who deal with the Python interpreter at the C level because they're writing Python extension modules, embedding the interpreter, or just hacking on the interpreter itself. If you only write Python code, none of the changes described here will affect you very much.

- Profiling and tracing functions can now be implemented in C, which can operate at much higher speeds than Python-based functions and should reduce the overhead of profiling and tracing. This will be of interest to authors of development environments for Python. Two new C functions were added to Python’s API, `PyEval_SetProfile()` and `PyEval_SetTrace()`. The existing `sys.setprofile()` and `sys.settrace()` functions still exist, and have simply been changed to use the new C-level interface. (Contributed by Fred L. Drake, Jr.)

- Another low-level API, primarily of interest to implementors of Python debuggers and development tools, was added. `PyInterpreterState_Head()` and `PyInterpreterState_Next()` let a caller walk through all the existing interpreter objects; `PyInterpreterState_ThreadHead()` and `PyThreadState_Next()` allow looping over all the thread states for a given interpreter. (Contributed by David Beazley.)

- The C-level interface to the garbage collector has been changed to make it easier to write extension types that support garbage collection and to debug misuses of the functions. Various functions have slightly different semantics, so a bunch of functions
had to be renamed. Extensions that use the old API will still compile but will not participate in garbage collection, so updating them for 2.2 should be considered fairly high priority.

To upgrade an extension module to the new API, perform the following steps:

- Rename `Py_TPFLAGS_GC()` to `PyTPFLAGS_HAVE_GC()`.

- Use `PyObject_GC_New()` or `PyObject_GC_NewVar()` to allocate objects, and `PyObject_GC_Del()` to deallocate them.

- Rename `PyObject_GC_Init()` to `PyObject_GC_Track()` and `PyObject_GC_Fini()` to `PyObject_GC_UnTrack()`.

- Remove `PyGC_HEAD_SIZE()` from object size calculations.

- Remove calls to `PyObject_AS_GC()` and `PyObject_FROM_GC()`.

- A new `et` format sequence was added to `PyArg_ParseTuple()`; `et` takes both a parameter and an encoding name, and converts the parameter to the given encoding if the parameter turns out to be a Unicode string, or leaves it alone if it's an 8-bit string, assuming it to already be in the desired encoding. This differs from the `es` format character, which assumes that 8-bit strings are in Python's default ASCII encoding and converts them to the specified new encoding. (Contributed by M.-A. Lemburg, and used for the MBCS support on Windows described in the following section.)
• A different argument parsing function, `PyArg_UnpackTuple()`, has been added that’s simpler and presumably faster. Instead of specifying a format string, the caller simply gives the minimum and maximum number of arguments expected, and a set of pointers to `PyObject*` variables that will be filled in with argument values.

• Two new flags `METH_NOARGS` and `METH_O` are available in method definition tables to simplify implementation of methods with no arguments or a single untyped argument. Calling such methods is more efficient than calling a corresponding method that uses `METH_VARARGS`. Also, the old `METH_OLDARGS` style of writing C methods is now officially deprecated.

• Two new wrapper functions, `PyOS_snprintf()` and `PyOS_vsnprintf()` were added to provide cross-platform implementations for the relatively new `snprintf()` and `vsnprintf()` C lib APIs. In contrast to the standard `sprintf()` and `vssprintf()` functions, the Python versions check the bounds of the buffer used to protect against buffer overruns. (Contributed by M.-A. Lemburg.)

• The `_PyTuple_Resize()` function has lost an unused parameter, so now it takes 2 parameters instead of 3. The third argument was never used, and can simply be discarded when porting code from earlier versions to Python 2.2.
Other Changes and Fixes

As usual there were a bunch of other improvements and bugfixes scattered throughout the source tree. A search through the CVS change logs finds there were 527 patches applied and 683 bugs fixed between Python 2.1 and 2.2; 2.2.1 applied 139 patches and fixed 143 bugs; 2.2.2 applied 106 patches and fixed 82 bugs. These figures are likely to be underestimates.

Some of the more notable changes are:

- The code for the MacOS port for Python, maintained by Jack Jansen, is now kept in the main Python CVS tree, and many changes have been made to support MacOS X.

  The most significant change is the ability to build Python as a framework, enabled by supplying the --enable-framework option to the configure script when compiling Python. According to Jack Jansen, “This installs a self-contained Python installation plus the OS X framework “glue” into /Library/Frameworks/Python.framework (or another location of choice). For now there is little immediate added benefit to this (actually, there is the disadvantage that you have to change your PATH to be able to find Python), but it is the basis for creating a full-blown Python application, porting the MacPython IDE, possibly using Python as a standard OSA scripting language and much more.”

  Most of the MacPython toolbox modules, which interface to MacOS APIs such as windowing, QuickTime, scripting, etc. have been ported to OS X, but they’ve been left commented out in setup.py. People who want to experiment with these modules
can uncomment them manually.

- Keyword arguments passed to built-in functions that don’t take them now cause a `TypeError` exception to be raised, with the message “*function* takes no keyword arguments”.

- Weak references, added in Python 2.1 as an extension module, are now part of the core because they’re used in the implementation of new-style classes. The `ReferenceError` exception has therefore moved from the `weakref` module to become a built-in exception.

- A new script, `Tools/scripts/cleanfuture.py` by Tim Peters, automatically removes obsolete `__future__` statements from Python source code.

- An additional `flags` argument has been added to the built-in function `compile()`, so the behaviour of `__future__` statements can now be correctly observed in simulated shells, such as those presented by IDLE and other development environments. This is described in PEP 264. (Contributed by Michael Hudson.)

- The new license introduced with Python 1.6 wasn’t GPL-compatible. This is fixed by some minor textual changes to the 2.2 license, so it’s now legal to embed Python inside a GPLed program again. Note that Python itself is not GPLed, but instead is under a license that’s essentially equivalent to the BSD license, same as it always was. The license changes were also applied to the Python 2.0.1 and 2.1.1 releases.

- When presented with a Unicode filename on Windows, Python will now convert it to an MBCS encoded string, as used by the
Microsoft file APIs. As MBCS is explicitly used by the file APIs, Python’s choice of ASCII as the default encoding turns out to be an annoyance. On Unix, the locale’s character set is used if \texttt{locale.nl\_langinfo(CODESET)} is available. (Windows support was contributed by Mark Hammond with assistance from Marc-André Lemburg. Unix support was added by Martin von Löwis.)

- Large file support is now enabled on Windows. (Contributed by Tim Peters.)

- The \texttt{Tools/scripts/ftpmirror.py} script now parses a \texttt{.netrc} file, if you have one. (Contributed by Mike Romberg.)

- Some features of the object returned by the \texttt{xrange()} function are now deprecated, and trigger warnings when they’re accessed; they’ll disappear in Python 2.3. \texttt{xrange} objects tried to pretend they were full sequence types by supporting slicing, sequence multiplication, and the \texttt{in} operator, but these features were rarely used and therefore buggy. The \texttt{tolist()} method and the \texttt{start}, \texttt{stop}, and \texttt{step} attributes are also being deprecated. At the C level, the fourth argument to the \texttt{PyRange\_New()} function, \texttt{repeat}, has also been deprecated.

- There were a bunch of patches to the dictionary implementation, mostly to fix potential core dumps if a dictionary contains objects that sneakily changed their hash value, or mutated the dictionary they were contained in. For a while python-dev fell into a gentle rhythm of Michael Hudson finding a case that dumped core, Tim Peters fixing the bug, Michael finding another case, and round and round it went.
• On Windows, Python can now be compiled with Borland C thanks to a number of patches contributed by Stephen Hansen, though the result isn't fully functional yet. (But this is progress...)

• Another Windows enhancement: Wise Solutions generously offered PythonLabs use of their InstallerMaster 8.1 system. Earlier PythonLabs Windows installers used Wise 5.0a, which was beginning to show its age. (Packaged up by Tim Peters.)

• Files ending in .pyw can now be imported on Windows. .pyw is a Windows-only thing, used to indicate that a script needs to be run using PYTHONW.EXE instead of PYTHON.EXE in order to prevent a DOS console from popping up to display the output. This patch makes it possible to import such scripts, in case they’re also usable as modules. (Implemented by David Bolen.)

• On platforms where Python uses the C dlopen() function to load extension modules, it’s now possible to set the flags used by dlopen() using the sys.getdlopenflags() and sys.setdlopenflags() functions. (Contributed by Bram Stolk.)

• The pow() built-in function no longer supports 3 arguments when floating-point numbers are supplied. pow(x, y, z) returns (x**y) % z, but this is never useful for floating point numbers, and the final result varies unpredictably depending on the platform. A call such as pow(2.0, 8.0, 7.0) will now raise a TypeError exception.

What’s New in Python 2.1

Author: A.M. Kuchling
Introduction

This article explains the new features in Python 2.1. While there aren’t as many changes in 2.1 as there were in Python 2.0, there are still some pleasant surprises in store. 2.1 is the first release to be steered through the use of Python Enhancement Proposals, or PEPs, so most of the sizable changes have accompanying PEPs that provide more complete documentation and a design rationale for the change. This article doesn’t attempt to document the new features completely, but simply provides an overview of the new features for Python programmers. Refer to the Python 2.1 documentation, or to the specific PEP, for more details about any new feature that particularly interests you.

One recent goal of the Python development team has been to accelerate the pace of new releases, with a new release coming every 6 to 9 months. 2.1 is the first release to come out at this faster pace, with the first alpha appearing in January, 3 months after the final version of 2.0 was released.

The final release of Python 2.1 was made on April 17, 2001.
PEP 227: Nested Scopes

The largest change in Python 2.1 is to Python’s scoping rules. In Python 2.0, at any given time there are at most three namespaces used to look up variable names: local, module-level, and the built-in namespace. This often surprised people because it didn’t match their intuitive expectations. For example, a nested recursive function definition doesn’t work:

```python
def f():
    ...
    def g(value):
        ...
        return g(value-1) + 1
    ...
```

The function `g()` will always raise a `NameError` exception, because the binding of the name `g` isn’t in either its local namespace or in the module-level namespace. This isn’t much of a problem in practice (how often do you recursively define interior functions like this?), but this also made using the `lambda` statement clumsier, and this was a problem in practice. In code which uses `lambda` you can often find local variables being copied by passing them as the default values of arguments.

```python
def find(self, name):
    "Return list of any entries equal to 'name'"
    L = filter(lambda x, name=name: x == name, self.list_attribute)
    return L
```

The readability of Python code written in a strongly functional style
suffers greatly as a result.

The most significant change to Python 2.1 is that static scoping has been added to the language to fix this problem. As a first effect, the name=name default argument is now unnecessary in the above example. Put simply, when a given variable name is not assigned a value within a function (by an assignment, or the def, class, or import statements), references to the variable will be looked up in the local namespace of the enclosing scope. A more detailed explanation of the rules, and a dissection of the implementation, can be found in the PEP.

This change may cause some compatibility problems for code where the same variable name is used both at the module level and as a local variable within a function that contains further function definitions. This seems rather unlikely though, since such code would have been pretty confusing to read in the first place.

One side effect of the change is that the from module import * and exec statements have been made illegal inside a function scope under certain conditions. The Python reference manual has said all along that from module import * is only legal at the top level of a module, but the CPython interpreter has never enforced this before. As part of the implementation of nested scopes, the compiler which turns Python source into bytecodes has to generate different code to access variables in a containing scope. from module import * and exec make it impossible for the compiler to figure this out, because they add names to the local namespace that are unknowable at compile time. Therefore, if a function contains function definitions or lambda expressions with free variables, the compiler will flag this by raising a SyntaxError exception.
To make the preceding explanation a bit clearer, here’s an example:

```python
x = 1
def f():
    # The next line is a syntax error
    exec 'x=2'
def g():
    return x
```

Line 4 containing the `exec` statement is a syntax error, since `exec` would define a new local variable named `x` whose value should be accessed by `g()`.

This shouldn’t be much of a limitation, since `exec` is rarely used in most Python code (and when it is used, it's often a sign of a poor design anyway).

Compatibility concerns have led to nested scopes being introduced gradually; in Python 2.1, they aren’t enabled by default, but can be turned on within a module by using a future statement as described in PEP 236. (See the following section for further discussion of PEP 236.) In Python 2.2, nested scopes will become the default and there will be no way to turn them off, but users will have had all of 2.1’s lifetime to fix any breakage resulting from their introduction.

See also:

**PEP 227 - Statically Nested Scopes**

Written and implemented by Jeremy Hylton.
PEP 236: __future__ Directives

The reaction to nested scopes was widespread concern about the dangers of breaking code with the 2.1 release, and it was strong enough to make the Pythoneers take a more conservative approach. This approach consists of introducing a convention for enabling optional functionality in release N that will become compulsory in release N+1.

The syntax uses a `from __future__ import` statement using the reserved module name `__future__`. Nested scopes can be enabled by the following statement:

```
from __future__ import nested_scopes
```

While it looks like a normal `import` statement, it’s not; there are strict rules on where such a future statement can be put. They can only be at the top of a module, and must precede any Python code or regular `import` statements. This is because such statements can affect how the Python bytecode compiler parses code and generates bytecode, so they must precede any statement that will result in bytecodes being produced.

See also:

PEP 236 - Back to the __future__

Written by Tim Peters, and primarily implemented by Jeremy Hylton.
PEP 207: Rich Comparisons

In earlier versions, Python’s support for implementing comparisons on user-defined classes and extension types was quite simple. Classes could implement a `__cmp__()` method that was given two instances of a class, and could only return 0 if they were equal or +1 or -1 if they weren’t; the method couldn’t raise an exception or return anything other than a Boolean value. Users of Numeric Python often found this model too weak and restrictive, because in the number-crunching programs that numeric Python is used for, it would be more useful to be able to perform elementwise comparisons of two matrices, returning a matrix containing the results of a given comparison for each element. If the two matrices are of different sizes, then the compare has to be able to raise an exception to signal the error.

In Python 2.1, rich comparisons were added in order to support this need. Python classes can now individually overload each of the `<`, `<=`, `>`, `>=`, `==`, and `!=` operations. The new magic method names are:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Method name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;</code></td>
<td><code>__lt__()</code></td>
</tr>
<tr>
<td><code>&lt;=</code></td>
<td><code>__le__()</code></td>
</tr>
<tr>
<td><code>&gt;</code></td>
<td><code>__gt__()</code></td>
</tr>
<tr>
<td><code>&gt;=</code></td>
<td><code>__ge__()</code></td>
</tr>
<tr>
<td><code>==</code></td>
<td><code>__eq__()</code></td>
</tr>
<tr>
<td><code>!=</code></td>
<td><code>__ne__()</code></td>
</tr>
</tbody>
</table>

(The magic methods are named after the corresponding Fortran operators `.LT.` `.LE.`, &c. Numeric programmers are almost certainly
quite familiar with these names and will find them easy to remember.)

Each of these magic methods is of the form `method(self, other)`, where `self` will be the object on the left-hand side of the operator, while `other` will be the object on the right-hand side. For example, the expression `A < B` will cause `A.__lt__(B)` to be called.

Each of these magic methods can return anything at all: a Boolean, a matrix, a list, or any other Python object. Alternatively they can raise an exception if the comparison is impossible, inconsistent, or otherwise meaningless.

The built-in `cmp(A, B)` function can use the rich comparison machinery, and now accepts an optional argument specifying which comparison operation to use; this is given as one of the strings "<", "<=", ">", ">=", "==", or "!='. If called without the optional third argument, `cmp()` will only return -1, 0, or +1 as in previous versions of Python; otherwise it will call the appropriate method and can return any Python object.

There are also corresponding changes of interest to C programmers; there's a new slot `tp_richcmp` in type objects and an API for performing a given rich comparison. I won't cover the C API here, but will refer you to PEP 207, or to 2.1’s C API documentation, for the full list of related functions.

See also:

**PEP 207 - Rich Comparisons**

Written by Guido van Rossum, heavily based on earlier work by David Ascher, and implemented by Guido van Rossum.
PEP 230: Warning Framework

Over its 10 years of existence, Python has accumulated a certain number of obsolete modules and features along the way. It’s difficult to know when a feature is safe to remove, since there’s no way of knowing how much code uses it — perhaps no programs depend on the feature, or perhaps many do. To enable removing old features in a more structured way, a warning framework was added. When the Python developers want to get rid of a feature, it will first trigger a warning in the next version of Python. The following Python version can then drop the feature, and users will have had a full release cycle to remove uses of the old feature.

Python 2.1 adds the warning framework to be used in this scheme. It adds a warnings module that provide functions to issue warnings, and to filter out warnings that you don’t want to be displayed. Third-party modules can also use this framework to deprecate old features that they no longer wish to support.

For example, in Python 2.1 the regex module is deprecated, so importing it causes a warning to be printed:

```python
>>> import regex
__main__:1: DeprecationWarning: the regex module is deprecated; please use the re module
```

Warnings can be issued by calling the `warnings.warn()` function:

```python
warnings.warn("feature X no longer supported")
```

The first parameter is the warning message; an additional optional
parameters can be used to specify a particular warning category.

Filters can be added to disable certain warnings; a regular expression pattern can be applied to the message or to the module name in order to suppress a warning. For example, you may have a program that uses the regex module and not want to spare the time to convert it to use the \texttt{re} module right now. The warning can be suppressed by calling

```python
import warnings
warnings.filterwarnings(action = 'ignore',
message='.*regex module is deprecated',
category=DeprecationWarning,
module = '__main__')
```

This adds a filter that will apply only to warnings of the class \texttt{DeprecationWarning} triggered in the \texttt{__main__} module, and applies a regular expression to only match the message about the regex module being deprecated, and will cause such warnings to be ignored. Warnings can also be printed only once, printed every time the offending code is executed, or turned into exceptions that will cause the program to stop (unless the exceptions are caught in the usual way, of course).

Functions were also added to Python's C API for issuing warnings; refer to PEP 230 or to Python's API documentation for the details.

\textbf{PEP 5 - Guidelines for Language Evolution}

Written by Paul Prescod, to specify procedures to be followed when removing old features from Python. The policy described in this PEP hasn't been officially adopted, but the eventual policy
probably won’t be too different from Prescod’s proposal.

**PEP 230 - Warning Framework**
Written and implemented by Guido van Rossum.
PEP 229: New Build System

When compiling Python, the user had to go in and edit the ` Modules/Setup ` file in order to enable various additional modules; the default set is relatively small and limited to modules that compile on most Unix platforms. This means that on Unix platforms with many more features, most notably Linux, Python installations often don’t contain all useful modules they could.

Python 2.0 added the Distutils, a set of modules for distributing and installing extensions. In Python 2.1, the Distutils are used to compile much of the standard library of extension modules, autodetecting which ones are supported on the current machine. It’s hoped that this will make Python installations easier and more featureful.

Instead of having to edit the ` Modules/Setup ` file in order to enable modules, a ` setup.py ` script in the top directory of the Python source distribution is run at build time, and attempts to discover which modules can be enabled by examining the modules and header files on the system. If a module is configured in ` Modules/Setup `, the ` setup.py ` script won’t attempt to compile that module and will defer to the ` Modules/Setup ` file’s contents. This provides a way to specific any strange command-line flags or libraries that are required for a specific platform.

In another far-reaching change to the build mechanism, Neil Schemenauer restructured things so Python now uses a single makefile that isn’t recursive, instead of makefiles in the top directory and in each of the ` Python/ `, ` Parser/ `, ` Objects/ `, and ` Modules/ ` subdirectories. This makes building Python faster and also makes hacking the Makefiles clearer and simpler.

**PEP 229 - Using Distutils to Build Python**

Written and implemented by A.M. Kuchling.
Weak references, available through the `weakref` module, are a minor but useful new data type in the Python programmer’s toolbox.

Storing a reference to an object (say, in a dictionary or a list) has the side effect of keeping that object alive forever. There are a few specific cases where this behaviour is undesirable, object caches being the most common one, and another being circular references in data structures such as trees.

For example, consider a memoizing function that caches the results of another function $f(x)$ by storing the function's argument and its result in a dictionary:

```python
_cache = {}
def memoize(x):
    if _cache.has_key(x):
        return _cache[x]
    retval = f(x)
    # Cache the returned object
    _cache[x] = retval
    return retval
```

This version works for simple things such as integers, but it has a side effect; the `_cache` dictionary holds a reference to the return values, so they'll never be deallocated until the Python process exits and cleans up. This isn't very noticeable for integers, but if $f()$ returns an object, or a data structure that takes up a lot of memory, this can be a problem.
Weak references provide a way to implement a cache that won’t keep objects alive beyond their time. If an object is only accessible through weak references, the object will be deallocated and the weak references will now indicate that the object it referred to no longer exists. A weak reference to an object \( \textit{obj} \) is created by calling \( \textit{wr} = \text{weakref.ref(\textit{obj})} \). The object being referred to is returned by calling the weak reference as if it were a function: \( \textit{wr}() \). It will return the referenced object, or \texttt{None} if the object no longer exists.

This makes it possible to write a \texttt{memoize()} function whose cache doesn’t keep objects alive, by storing weak references in the cache.

```python
_cache = {}
def memoize(x):
    if _cache.has_key(x):
        obj = _cache[x]()
        # If weak reference object still exists,
        # return it
        if obj is not None: return obj

    retval = f(x)

    # Cache a weak reference
    _cache[x] = weakref.ref(retval)

    return retval
```

The \texttt{weakref} module also allows creating proxy objects which behave like weak references — an object referenced only by proxy objects is deallocated — but instead of requiring an explicit call to retrieve the object, the proxy transparently forwards all operations to the object as long as the object still exists. If the object is deallocated, attempting to use a proxy will cause a \texttt{weakref.ReferenceError} exception to be raised.
proxy = weakref.proxy(obj)
proxy.attr  # Equivalent to obj.attr
proxy.meth()  # Equivalent to obj.meth()
    del  obj
proxy.attr  # raises weakref.ReferenceError

**PEP 205 - Weak References**
Written and implemented by Fred L. Drake, Jr.
PEP 232: Function Attributes

In Python 2.1, functions can now have arbitrary information attached to them. People were often using docstrings to hold information about functions and methods, because the \_doc\_ attribute was the only way of attaching any information to a function. For example, in the Zope Web application server, functions are marked as safe for public access by having a docstring, and in John Aycock's SPARK parsing framework, docstrings hold parts of the BNF grammar to be parsed. This overloading is unfortunate, since docstrings are really intended to hold a function's documentation; for example, it means you can't properly document functions intended for private use in Zope.

Arbitrary attributes can now be set and retrieved on functions using the regular Python syntax:

```python
def f(): pass
f.publish = 1
f.secure = 1
f.grammar = "A ::= B (C D)*"
```

The dictionary containing attributes can be accessed as the function's \_dict\_. Unlike the \_dict\_ attribute of class instances, in functions you can actually assign a new dictionary to \_dict\_, though the new value is restricted to a regular Python dictionary; you can't be tricky and set it to a UserDict instance, or any other random object that behaves like a mapping.

See also:

PEP 232 - Function Attributes
Written and implemented by Barry Warsaw.
PEP 235: Importing Modules on Case-Insensitive Platforms

Some operating systems have filesystems that are case-insensitive, MacOS and Windows being the primary examples; on these systems, it's impossible to distinguish the filenames FILE.PY and file.py, even though they do store the file's name in its original case (they're case-preserving, too).

In Python 2.1, the import statement will work to simulate case-sensitivity on case-insensitive platforms. Python will now search for the first case-sensitive match by default, raising an ImportError if no such file is found, so import file will not import a module named FILE.PY. Case-insensitive matching can be requested by setting the PYTHONCASEOK environment variable before starting the Python interpreter.
### PEP 217: Interactive Display Hook

When using the Python interpreter interactively, the output of commands is displayed using the built-in `repr()` function. In Python 2.1, the variable `sys.displayhook()` can be set to a callable object which will be called instead of `repr()`. For example, you can set it to a special pretty-printing function:

```python
>>> # Create a recursive data structure
... L = [1, 2, 3]
>>> L.append(L)
>>> L # Show Python's default output
[1, 2, 3, [...]]
>>> # Use pprint.pprint() as the display function
... import sys, pprint
>>> sys.displayhook = pprint.pprint
>>> L
[1, 2, 3, <Recursion on list with id=135143996>]
``` 

See also:

**PEP 217 - Display Hook for Interactive Use**

Written and implemented by Moshe Zadka.
PEP 208: New Coercion Model

How numeric coercion is done at the C level was significantly modified. This will only affect the authors of C extensions to Python, allowing them more flexibility in writing extension types that support numeric operations.

Extension types can now set the type flag Py_TPFLAGS_CHECKTYPES in their PyTypeObject structure to indicate that they support the new coercion model. In such extension types, the numeric slot functions can no longer assume that they’ll be passed two arguments of the same type; instead they may be passed two arguments of differing types, and can then perform their own internal coercion. If the slot function is passed a type it can’t handle, it can indicate the failure by returning a reference to the Py_NotImplemented singleton value. The numeric functions of the other type will then be tried, and perhaps they can handle the operation; if the other type also returns Py_NotImplemented, then a TypeError will be raised. Numeric methods written in Python can also return Py_NotImplemented, causing the interpreter to act as if the method did not exist (perhaps raising a TypeError, perhaps trying another object’s numeric methods).

See also:

PEP 208 - Reworking the Coercion Model
Written and implemented by Neil Schemenauer, heavily based upon earlier work by Marc-André Lemburg. Read this to understand the fine points of how numeric operations will now be processed at the C level.
PEP 241: Metadata in Python Packages

A common complaint from Python users is that there's no single catalog of all the Python modules in existence. T. Middleton's Vaults of Parnassus at http://www.vex.net/parnassus/ are the largest catalog of Python modules, but registering software at the Vaults is optional, and many people don't bother.

As a first small step toward fixing the problem, Python software packaged using the Distutils sdist command will include a file named PKG-INFO containing information about the package such as its name, version, and author (metadata, in cataloguing terminology). PEP 241 contains the full list of fields that can be present in the PKG-INFO file. As people began to package their software using Python 2.1, more and more packages will include metadata, making it possible to build automated cataloguing systems and experiment with them. With the result experience, perhaps it'll be possible to design a really good catalog and then build support for it into Python 2.2. For example, the Distutils sdist and bdist_* commands could support an upload option that would automatically upload your package to a catalog server.

You can start creating packages containing PKG-INFO even if you're not using Python 2.1, since a new release of the Distutils will be made for users of earlier Python versions. Version 1.0.2 of the Distutils includes the changes described in PEP 241, as well as various bugfixes and enhancements. It will be available from the Distutils SIG at https://www.python.org/community/sigs/current/distutils-sig/.

PEP 241 - Metadata for Python Software Packages
Written and implemented by A.M. Kuchling.

**PEP 243 - Module Repository Upload Mechanism**

Written by Sean Reifschneider, this draft PEP describes a proposed mechanism for uploading Python packages to a central server.
New and Improved Modules

- Ka-Ping Yee contributed two new modules: `inspect.py`, a module for getting information about live Python code, and `pydoc.py`, a module for interactively converting docstrings to HTML or text. As a bonus, `Tools/scripts/pydoc`, which is now automatically installed, uses `pydoc.py` to display documentation given a Python module, package, or class name. For example, `pydoc xml.dom` displays the following:

```
NAME
  xml.dom - W3C Document Object Model implementation

FILE
  /usr/local/lib/python2.1/xml/dom/__init__.pyc

DESCRIPTION
  The Python mapping of the Document Object Model
  Python Library Reference in the section on the

  This package contains the following modules:
  ...
```

`pydoc` also includes a Tk-based interactive help browser. `pydoc` quickly becomes addictive; try it out!

- Two different modules for unit testing were added to the standard library. The `doctest` module, contributed by Tim Peters, provides a testing framework based on running embedded examples in docstrings and comparing the results against the expected output.
PyUnit, contributed by Steve Purcell, is a unit testing framework inspired by JUnit, which was in turn an adaptation of Kent Beck's Smalltalk testing framework. See http://pyunit.sourceforge.net/ for more information about PyUnit.

- The **difflib** module contains a class, SequenceMatcher, which compares two sequences and computes the changes required to transform one sequence into the other. For example, this module can be used to write a tool similar to the Unix **diff** program, and in fact the sample program Tools/scripts/ndiff.py demonstrates how to write such a script.

- **curses.panel**, a wrapper for the panel library, part of ncurses and of SYSV curses, was contributed by Thomas Gellekum. The panel library provides windows with the additional feature of depth. Windows can be moved higher or lower in the depth ordering, and the panel library figures out where panels overlap and which sections are visible.

- The PyXML package has gone through a few releases since Python 2.0, and Python 2.1 includes an updated version of the xml package. Some of the noteworthy changes include support for Expat 1.2 and later versions, the ability for Expat parsers to handle files in any encoding supported by Python, and various bugfixes for SAX, DOM, and the minidom module.

- Ping also contributed another hook for handling uncaught exceptions. **sys.excepthook()** can be set to a callable object. When an exception isn't caught by any **try...except** blocks, the exception will be passed to **sys.excepthook()**, which can then do whatever it likes. At the Ninth Python Conference, Ping
demonstrated an application for this hook: printing an extended traceback that not only lists the stack frames, but also lists the function arguments and the local variables for each frame.

- Various functions in the `time` module, such as `asctime()` and `localtime()`, require a floating point argument containing the time in seconds since the epoch. The most common use of these functions is to work with the current time, so the floating point argument has been made optional; when a value isn't provided, the current time will be used. For example, log file entries usually need a string containing the current time; in Python 2.1, `time.asctime()` can be used, instead of the lengthier `time.asctime(time.localtime(time.time()))` that was previously required.

  This change was proposed and implemented by Thomas Wouters.

- The `ftplib` module now defaults to retrieving files in passive mode, because passive mode is more likely to work from behind a firewall. This request came from the Debian bug tracking system, since other Debian packages use `ftplib` to retrieve files and then don't work from behind a firewall. It's deemed unlikely that this will cause problems for anyone, because Netscape defaults to passive mode and few people complain, but if passive mode is unsuitable for your application or network setup, call `set_pasv(0)` on FTP objects to disable passive mode.

- Support for raw socket access has been added to the `socket` module, contributed by Grant Edwards.

- The `pstats` module now contains a simple interactive statistics
browser for displaying timing profiles for Python programs, invoked when the module is run as a script. Contributed by Eric S. Raymond.

- A new implementation-dependent function, `sys._getframe([depth])`, has been added to return a given frame object from the current call stack. `sys._getframe()` returns the frame at the top of the call stack; if the optional integer argument `depth` is supplied, the function returns the frame that is `depth` calls below the top of the stack. For example, `sys._getframe(1)` returns the caller’s frame object.

This function is only present in CPython, not in Jython or the .NET implementation. Use it for debugging, and resist the temptation to put it into production code.
Other Changes and Fixes

There were relatively few smaller changes made in Python 2.1 due to the shorter release cycle. A search through the CVS change logs turns up 117 patches applied, and 136 bugs fixed; both figures are likely to be underestimates. Some of the more notable changes are:

- A specialized object allocator is now optionally available, that should be faster than the system `malloc()` and have less memory overhead. The allocator uses C’s `malloc()` function to get large pools of memory, and then fulfills smaller memory requests from these pools. It can be enabled by providing the `--with-pymalloc` option to the `configure` script; see `Objects/obmalloc.c` for the implementation details.

Authors of C extension modules should test their code with the object allocator enabled, because some incorrect code may break, causing core dumps at runtime. There are a bunch of memory allocation functions in Python’s C API that have previously been just aliases for the C library’s `malloc()` and `free()`, meaning that if you accidentally called mismatched functions, the error wouldn’t be noticeable. When the object allocator is enabled, these functions aren’t aliases of `malloc()` and `free()` any more, and calling the wrong function to free memory will get you a core dump. For example, if memory was allocated using `PyMem_New()`, it has to be freed using `PyMem_Del()`, not `free()`. A few modules included with Python fell afoul of this and had to be fixed; doubtless there are more third-party modules that will have the same problem.

The object allocator was contributed by Vladimir Marangozov.
- The speed of line-oriented file I/O has been improved because people often complain about its lack of speed, and because it's often been used as a naïve benchmark. The `readline()` method of file objects has therefore been rewritten to be much faster. The exact amount of the speedup will vary from platform to platform depending on how slow the C library's `getc()` was, but is around 66%, and potentially much faster on some particular operating systems. Tim Peters did much of the benchmarking and coding for this change, motivated by a discussion in comp.lang.python.

A new module and method for file objects was also added, contributed by Jeff Epler. The new method, `xreadlines()`, is similar to the existing `xrange()` built-in. `xreadlines()` returns an opaque sequence object that only supports being iterated over, reading a line on every iteration but not reading the entire file into memory as the existing `readlines()` method does. You'd use it like this:

```python
for line in sys.stdin.xreadlines():
    # ... do something for each line ... 
```

For a fuller discussion of the line I/O changes, see the python-dev summary for January 1–15, 2001 at https://mail.python.org/pipermail/python-dev/2001-January/.

- A new method, `popitem()`, was added to dictionaries to enable destructively iterating through the contents of a dictionary; this can be faster for large dictionaries because there's no need to construct a list containing all the keys or values. `D.popitem()` removes a random `(key, value)` pair from the dictionary `D` and
returns it as a 2-tuple. This was implemented mostly by Tim Peters and Guido van Rossum, after a suggestion and preliminary patch by Moshe Zadka.

- Modules can now control which names are imported when `from module import *` is used, by defining an `__all__` attribute containing a list of names that will be imported. One common complaint is that if the module imports other modules such as `sys` or `string`, `from module import *` will add them to the importing module's namespace. To fix this, simply list the public names in `__all__`:

  ```python
  # List public names
  __all__ = ['Database', 'open']
  ```

A stricter version of this patch was first suggested and implemented by Ben Wolfson, but after some python-dev discussion, a weaker final version was checked in.

- Applying `repr()` to strings previously used octal escapes for non-printable characters; for example, a newline was `'\012'`. This was a vestigial trace of Python’s C ancestry, but today octal is of very little practical use. Ka-Ping Yee suggested using hex escapes instead of octal ones, and using the `\n`, `\t`, `\r` escapes for the appropriate characters, and implemented this new formatting.

- Syntax errors detected at compile-time can now raise exceptions containing the filename and line number of the error, a pleasant side effect of the compiler reorganization done by Jeremy Hylton.

- C extensions which import other modules have been changed to use `PyImport_ImportModule()`, which means that they will
use any import hooks that have been installed. This is also encouraged for third-party extensions that need to import some other module from C code.

- The size of the Unicode character database was shrunk by another 340K thanks to Fredrik Lundh.

- Some new ports were contributed: MacOS X (by Steven Majewski), Cygwin (by Jason Tishler); RISCOS (by Dietmar Schwertberger); Unixware 7 (by Billy G. Allie).

And there’s the usual list of minor bugfixes, minor memory leaks, docstring edits, and other tweaks, too lengthy to be worth itemizing; see the CVS logs for the full details if you want them.

What’s New in Python 2.0

**Author:** A.M. Kuchling and Moshe Zadka
Introduction

A new release of Python, version 2.0, was released on October 16, 2000. This article covers the exciting new features in 2.0, highlights some other useful changes, and points out a few incompatible changes that may require rewriting code.

Python’s development never completely stops between releases, and a steady flow of bug fixes and improvements are always being submitted. A host of minor fixes, a few optimizations, additional docstrings, and better error messages went into 2.0; to list them all would be impossible, but they’re certainly significant. Consult the publicly-available CVS logs if you want to see the full list. This progress is due to the five developers working for PythonLabs are now getting paid to spend their days fixing bugs, and also due to the improved communication resulting from moving to SourceForge.
What About Python 1.6?

Python 1.6 can be thought of as the Contractual Obligations Python release. After the core development team left CNRI in May 2000, CNRI requested that a 1.6 release be created, containing all the work on Python that had been performed at CNRI. Python 1.6 therefore represents the state of the CVS tree as of May 2000, with the most significant new feature being Unicode support. Development continued after May, of course, so the 1.6 tree received a few fixes to ensure that it’s forward-compatible with Python 2.0. 1.6 is therefore part of Python’s evolution, and not a side branch.

So, should you take much interest in Python 1.6? Probably not. The 1.6final and 2.0beta1 releases were made on the same day (September 5, 2000), the plan being to finalize Python 2.0 within a month or so. If you have applications to maintain, there seems little point in breaking things by moving to 1.6, fixing them, and then having another round of breakage within a month by moving to 2.0; you’re better off just going straight to 2.0. Most of the really interesting features described in this document are only in 2.0, because a lot of work was done between May and September.
New Development Process

The most important change in Python 2.0 may not be to the code at all, but to how Python is developed: in May 2000 the Python developers began using the tools made available by SourceForge for storing source code, tracking bug reports, and managing the queue of patch submissions. To report bugs or submit patches for Python 2.0, use the bug tracking and patch manager tools available from Python's project page, located at https://sourceforge.net/projects/python/.

The most important of the services now hosted at SourceForge is the Python CVS tree, the version-controlled repository containing the source code for Python. Previously, there were roughly 7 or so people who had write access to the CVS tree, and all patches had to be inspected and checked in by one of the people on this short list. Obviously, this wasn’t very scalable. By moving the CVS tree to SourceForge, it became possible to grant write access to more people; as of September 2000 there were 27 people able to check in changes, a fourfold increase. This makes possible large-scale changes that wouldn’t be attempted if they’d have to be filtered through the small group of core developers. For example, one day Peter Schneider-Kamp took it into his head to drop K&R C compatibility and convert the C source for Python to ANSI C. After getting approval on the python-dev mailing list, he launched into a flurry of checkins that lasted about a week, other developers joined in to help, and the job was done. If there were only 5 people with write access, probably that task would have been viewed as “nice, but not worth the time and effort needed” and it would never have gotten done.

The shift to using SourceForge’s services has resulted in a remarkable increase in the speed of development. Patches now get submitted,
commented on, revised by people other than the original submitter, and bounced back and forth between people until the patch is deemed worth checking in. Bugs are tracked in one central location and can be assigned to a specific person for fixing, and we can count the number of open bugs to measure progress. This didn’t come without a cost: developers now have more e-mail to deal with, more mailing lists to follow, and special tools had to be written for the new environment. For example, SourceForge sends default patch and bug notification e-mail messages that are completely unhelpful, so Ka-Ping Yee wrote an HTML screen-scraper that sends more useful messages.

The ease of adding code caused a few initial growing pains, such as code was checked in before it was ready or without getting clear agreement from the developer group. The approval process that has emerged is somewhat similar to that used by the Apache group. Developers can vote +1, +0, -0, or -1 on a patch; +1 and -1 denote acceptance or rejection, while +0 and -0 mean the developer is mostly indifferent to the change, though with a slight positive or negative slant. The most significant change from the Apache model is that the voting is essentially advisory, letting Guido van Rossum, who has Benevolent Dictator For Life status, know what the general opinion is. He can still ignore the result of a vote, and approve or reject a change even if the community disagrees with him.

Producing an actual patch is the last step in adding a new feature, and is usually easy compared to the earlier task of coming up with a good design. Discussions of new features can often explode into lengthy mailing list threads, making the discussion hard to follow, and no one can read every posting to python-dev. Therefore, a relatively formal process has been set up to write Python Enhancement Proposals (PEPs), modelled on the Internet RFC process. PEPs are draft documents that describe a proposed new feature, and are continually
revised until the community reaches a consensus, either accepting or rejecting the proposal. Quoting from the introduction to PEP 1, “PEP Purpose and Guidelines”:

PEP stands for Python Enhancement Proposal. A PEP is a design document providing information to the Python community, or describing a new feature for Python. The PEP should provide a concise technical specification of the feature and a rationale for the feature.

We intend PEPs to be the primary mechanisms for proposing new features, for collecting community input on an issue, and for documenting the design decisions that have gone into Python. The PEP author is responsible for building consensus within the community and documenting dissenting opinions.

Read the rest of PEP 1 for the details of the PEP editorial process, style, and format. PEPs are kept in the Python CVS tree on SourceForge, though they’re not part of the Python 2.0 distribution, and are also available in HTML form from https://www.python.org/dev/peps/. As of September 2000, there are 25 PEPs, ranging from PEP 201, “Lockstep Iteration”, to PEP 225, “Elementwise/Objectwise Operators”.
Unicode

The largest new feature in Python 2.0 is a new fundamental data type: Unicode strings. Unicode uses 16-bit numbers to represent characters instead of the 8-bit number used by ASCII, meaning that 65,536 distinct characters can be supported.

The final interface for Unicode support was arrived at through countless often-stormy discussions on the python-dev mailing list, and mostly implemented by Marc-André Lemburg, based on a Unicode string type implementation by Fredrik Lundh. A detailed explanation of the interface was written up as PEP 100, “Python Unicode Integration”. This article will simply cover the most significant points about the Unicode interfaces.

In Python source code, Unicode strings are written as u"string". Arbitrary Unicode characters can be written using a new escape sequence, \uHHHH, where HHHH is a 4-digit hexadecimal number from 0000 to FFFF. The existing \xHHHH escape sequence can also be used, and octal escapes can be used for characters up to U+01FF, which is represented by \777.

Unicode strings, just like regular strings, are an immutable sequence type. They can be indexed and sliced, but not modified in place. Unicode strings have an encode([encoding]) method that returns an 8-bit string in the desired encoding. Encodings are named by strings, such as 'ascii', 'utf-8', 'iso-8859-1', or whatever. A codec API is defined for implementing and registering new encodings that are then available throughout a Python program. If an encoding isn’t specified, the default encoding is usually 7-bit ASCII, though it can be changed for your Python installation by calling the
sys.setdefaultencoding(encoding) function in a customized version of site.py.

Combining 8-bit and Unicode strings always coerces to Unicode, using the default ASCII encoding; the result of 'a' + u'bc' is u'abc'.

New built-in functions have been added, and existing built-ins modified to support Unicode:

- `unichr(ch)` returns a Unicode string 1 character long, containing the character `ch`.
- `ord(u)`, where `u` is a 1-character regular or Unicode string, returns the number of the character as an integer.
- `unicode(string [, encoding] [, errors] )` creates a Unicode string from an 8-bit string. `encoding` is a string naming the encoding to use. The `errors` parameter specifies the treatment of characters that are invalid for the current encoding; passing 'strict' as the value causes an exception to be raised on any encoding error, while 'ignore' causes errors to be silently ignored and 'replace' uses U+FFFD, the official replacement character, in case of any problems.
- The `exec` statement, and various built-ins such as `eval()`, `getattr()`, and `setattr()` will also accept Unicode strings as well as regular strings. (It's possible that the process of fixing this missed some built-ins; if you find a built-in function that accepts strings but doesn't accept Unicode strings at all, please report it as a bug.)

A new module, `unicodedata`, provides an interface to Unicode character properties. For example, `unicodedata.category(u'A')` returns the 2-character string ‘Lu’, the ‘L’ denoting it’s a letter, and ‘u’ meaning that it’s uppercase. `unicodedata.bidirectional(u'\u0660')` returns ‘AN',
meaning that U+0660 is an Arabic number.

The codecs module contains functions to look up existing encodings and register new ones. Unless you want to implement a new encoding, you'll most often use the codecs.lookup(encoding) function, which returns a 4-element tuple: (encode_func, decode_func, stream_reader, stream_writer).

- encode_func is a function that takes a Unicode string, and returns a 2-tuple (string, length). string is an 8-bit string containing a portion (perhaps all) of the Unicode string converted into the given encoding, and length tells you how much of the Unicode string was converted.
- decode_func is the opposite of encode_func, taking an 8-bit string and returning a 2-tuple (ustring, length), consisting of the resulting Unicode string ustring and the integer length telling how much of the 8-bit string was consumed.
- stream_reader is a class that supports decoding input from a stream. stream_reader(file_obj) returns an object that supports the read(), readline(), and readlines() methods. These methods will all translate from the given encoding and return Unicode strings.
- stream_writer, similarly, is a class that supports encoding output to a stream. stream_writer(file_obj) returns an object that supports the write() and writelines() methods. These methods expect Unicode strings, translating them to the given encoding on output.

For example, the following code writes a Unicode string into a file, encoding it as UTF-8:

```python
import codecs
unistr = u'\u0660\u2000ab ...'
```
The following code would then read UTF-8 input from the file:

```python
input = UTF8_streamreader( open( '/tmp/output', 'rb' ) )
print repr(input.read())
input.close()
```

Unicode-aware regular expressions are available through the `re` module, which has a new underlying implementation called SRE written by Fredrik Lundh of Secret Labs AB.

A `-U` command line option was added which causes the Python compiler to interpret all string literals as Unicode string literals. This is intended to be used in testing and future-proofing your Python code, since some future version of Python may drop support for 8-bit strings and provide only Unicode strings.
List Comprehensions

Lists are a workhorse data type in Python, and many programs manipulate a list at some point. Two common operations on lists are to loop over them, and either pick out the elements that meet a certain criterion, or apply some function to each element. For example, given a list of strings, you might want to pull out all the strings containing a given substring, or strip off trailing whitespace from each line.

The existing `map()` and `filter()` functions can be used for this purpose, but they require a function as one of their arguments. This is fine if there's an existing built-in function that can be passed directly, but if there isn't, you have to create a little function to do the required work, and Python's scoping rules make the result ugly if the little function needs additional information. Take the first example in the previous paragraph, finding all the strings in the list containing a given substring. You could write the following to do it:

```python
# Given the list L, make a list of all strings
# containing the substring S.
sublist = filter( lambda s, substring=S:
    string.find(s, substring) != -1
L)
```

Because of Python's scoping rules, a default argument is used so that the anonymous function created by the `lambda` statement knows what substring is being searched for. List comprehensions make this cleaner:

```python
sublist = [ s for s in L if string.find(s, S) != -1
```
List comprehensions have the form:

```
[ expression for expr in sequence1
  for expr2 in sequence2 ...
  for exprN in sequenceN
  if condition ]
```

The `for ... in` clauses contain the sequences to be iterated over. The sequences do not have to be the same length, because they are *not* iterated over in parallel, but from left to right; this is explained more clearly in the following paragraphs. The elements of the generated list will be the successive values of `expression`. The final `if` clause is optional; if present, `expression` is only evaluated and added to the result if `condition` is true.

To make the semantics very clear, a list comprehension is equivalent to the following Python code:

```
for expr1 in sequence1:
    for expr2 in sequence2:
        ...
    for exprN in sequenceN:
        if (condition):
            # Append the value of
            # the expression to the
            # resulting list.
```

This means that when there are multiple `for ... in` clauses, the resulting list will be equal to the product of the lengths of all the sequences. If you have two lists of length 3, the output list is 9 elements long:

```python
seq1 = 'abc'
seq2 = (1,2,3)
```
To avoid introducing an ambiguity into Python’s grammar, if expression is creating a tuple, it must be surrounded with parentheses. The first list comprehension below is a syntax error, while the second one is correct:

```python
# Syntax error
[ x, y for x in seq1 for y in seq2]
# Correct
[ (x, y) for x in seq1 for y in seq2]
```

The idea of list comprehensions originally comes from the functional programming language Haskell (https://www.haskell.org). Greg Ewing argued most effectively for adding them to Python and wrote the initial list comprehension patch, which was then discussed for a seemingly endless time on the python-dev mailing list and kept up-to-date by Skip Montanaro.
Augmented Assignment

Augmented assignment operators, another long-requested feature, have been added to Python 2.0. Augmented assignment operators include `+=`, `-=`, `*=` and so forth. For example, the statement `a += 2` increments the value of the variable `a` by 2, equivalent to the slightly lengthier `a = a + 2`.

The full list of supported assignment operators is `+=`, `-=` , `*=` , `/=` , `%=` , `**=` , `&=` , `|=` , `^=` , `>>=` , `<<=` . Python classes can override the augmented assignment operators by defining methods named `_iadd__()` , `_isub__()` , etc. For example, the following `Number` class stores a number and supports using `+=` to create a new instance with an incremented value.

```python
class Number:
    def __init__(self, value):
        self.value = value
    def __iadd__(self, increment):
        return Number(self.value + increment)

n = Number(5)
n += 3
print n.value
```

The `_iadd__()` special method is called with the value of the increment, and should return a new instance with an appropriately modified value; this return value is bound as the new value of the variable on the left-hand side.

Augmented assignment operators were first introduced in the C programming language, and most C-derived languages, such as `awk`,
C++, Java, Perl, and PHP also support them. The augmented assignment patch was implemented by Thomas Wouters.
String Methods

Until now string-manipulation functionality was in the `string` module, which was usually a front-end for the `strop` module written in C. The addition of Unicode posed a difficulty for the `strop` module, because the functions would all need to be rewritten in order to accept either 8-bit or Unicode strings. For functions such as `string.replace()`, which takes 3 string arguments, that means eight possible permutations, and correspondingly complicated code.

Instead, Python 2.0 pushes the problem onto the string type, making string manipulation functionality available through methods on both 8-bit strings and Unicode strings.

```python
>>> 'andrew'.capitalize()
'Andrew'
>>> 'hostname'.replace('os', 'linux')
'hlinuxtname'
>>> 'moshe'.find('sh')
2
```

One thing that hasn't changed, a noteworthy April Fools' joke notwithstanding, is that Python strings are immutable. Thus, the string methods return new strings, and do not modify the string on which they operate.

The old `string` module is still around for backwards compatibility, but it mostly acts as a front-end to the new string methods.

Two methods which have no parallel in pre-2.0 versions, although they did exist in JPython for quite some time, are `startswith()` and `endswith()`. `s.startswith(t)` is equivalent to `s[:len(t)] ==`
t, while `s.endswith(t)` is equivalent to `s[-len(t):] == t`.

One other method which deserves special mention is `join()`. The `join()` method of a string receives one parameter, a sequence of strings, and is equivalent to the `string.join()` function from the old `string` module, with the arguments reversed. In other words, `s.join(seq)` is equivalent to the old `string.join(seq, s)`. 
Garbage Collection of Cycles

The C implementation of Python uses reference counting to implement garbage collection. Every Python object maintains a count of the number of references pointing to itself, and adjusts the count as references are created or destroyed. Once the reference count reaches zero, the object is no longer accessible, since you need to have a reference to an object to access it, and if the count is zero, no references exist any longer.

Reference counting has some pleasant properties: it's easy to understand and implement, and the resulting implementation is portable, fairly fast, and reacts well with other libraries that implement their own memory handling schemes. The major problem with reference counting is that it sometimes doesn't realise that objects are no longer accessible, resulting in a memory leak. This happens when there are cycles of references.

Consider the simplest possible cycle, a class instance which has a reference to itself:

```python
instance = SomeClass()
instance.myself = instance
```

After the above two lines of code have been executed, the reference count of `instance` is 2; one reference is from the variable named 'instance', and the other is from the `myself` attribute of the instance.

If the next line of code is `del instance`, what happens? The reference count of `instance` is decreased by 1, so it has a reference count of 1; the reference in the `myself` attribute still exists. Yet the
instance is no longer accessible through Python code, and it could be deleted. Several objects can participate in a cycle if they have references to each other, causing all of the objects to be leaked.

Python 2.0 fixes this problem by periodically executing a cycle detection algorithm which looks for inaccessible cycles and deletes the objects involved. A new gc module provides functions to perform a garbage collection, obtain debugging statistics, and tuning the collector’s parameters.

Running the cycle detection algorithm takes some time, and therefore will result in some additional overhead. It is hoped that after we’ve gotten experience with the cycle collection from using 2.0, Python 2.1 will be able to minimize the overhead with careful tuning. It’s not yet obvious how much performance is lost, because benchmarking this is tricky and depends crucially on how often the program creates and destroys objects. The detection of cycles can be disabled when Python is compiled, if you can’t afford even a tiny speed penalty or suspect that the cycle collection is buggy, by specifying the --without-cycle-gc switch when running the configure script.

Several people tackled this problem and contributed to a solution. An early implementation of the cycle detection approach was written by Toby Kelsey. The current algorithm was suggested by Eric Tiedemann during a visit to CNRI, and Guido van Rossum and Neil Schemenauer wrote two different implementations, which were later integrated by Neil. Lots of other people offered suggestions along the way; the March 2000 archives of the python-dev mailing list contain most of the relevant discussion, especially in the threads titled “Reference cycle collection for Python” and “Finalization again”.
Other Core Changes

Various minor changes have been made to Python’s syntax and built-in functions. None of the changes are very far-reaching, but they’re handy conveniences.

Minor Language Changes

A new syntax makes it more convenient to call a given function with a tuple of arguments and/or a dictionary of keyword arguments. In Python 1.5 and earlier, you’d use the apply() built-in function: apply(f, args, kw) calls the function f() with the argument tuple args and the keyword arguments in the dictionary kw. apply() is the same in 2.0, but thanks to a patch from Greg Ewing, f(*args, **kw) is a shorter and clearer way to achieve the same effect. This syntax is symmetrical with the syntax for defining functions:

```python
def f(*args, **kw):
    # args is a tuple of positional args,
    # kw is a dictionary of keyword args
    ...
```

The print statement can now have its output directed to a file-like object by following the print with >> file, similar to the redirection operator in Unix shells. Previously you’d either have to use the write() method of the file-like object, which lacks the convenience and simplicity of print, or you could assign a new value to sys.stdout and then restore the old value. For sending output to standard error, it’s much easier to write this:

```python
print >> sys.stderr, "Warning: action field not supp"
Modules can now be renamed on importing them, using the syntax `import module as name` or `from module import name as othername`. The patch was submitted by Thomas Wouters.

A new format style is available when using the `%` operator; `‘%r’` will insert the `repr()` of its argument. This was also added from symmetry considerations, this time for symmetry with the existing `‘%s’` format style, which inserts the `str()` of its argument. For example, `‘%r %s’ % (‘abc’, ‘abc’)` returns a string containing `‘abc’ abc`.

Previously there was no way to implement a class that overrode Python's built-in `in` operator and implemented a custom version. `obj in seq` returns true if `obj` is present in the sequence `seq`; Python computes this by simply trying every index of the sequence until either `obj` is found or an `IndexError` is encountered. Moshe Zadka contributed a patch which adds a `__contains__()` magic method for providing a custom implementation for `in`. Additionally, new built-in objects written in C can define what `in` means for them via a new slot in the sequence protocol.

Earlier versions of Python used a recursive algorithm for deleting objects. Deeply nested data structures could cause the interpreter to fill up the C stack and crash; Christian Tismer rewrote the deletion logic to fix this problem. On a related note, comparing recursive objects recursed infinitely and crashed; Jeremy Hylton rewrote the code to no longer crash, producing a useful result instead. For example, after this code:

```python
a = []
b = []
```
The comparison `a==b` returns true, because the two recursive data structures are isomorphic. See the thread “trashcan and PR#7” in the April 2000 archives of the python-dev mailing list for the discussion leading up to this implementation, and some useful relevant links. Note that comparisons can now also raise exceptions. In earlier versions of Python, a comparison operation such as `cmp(a, b)` would always produce an answer, even if a user-defined `__cmp__()` method encountered an error, since the resulting exception would simply be silently swallowed.

Work has been done on porting Python to 64-bit Windows on the Itanium processor, mostly by Trent Mick of ActiveState. (Confusingly, `sys.platform` is still 'win32' on Win64 because it seems that for ease of porting, MS Visual C++ treats code as 32 bit on Itanium.) PythonWin also supports Windows CE; see the Python CE page at [http://pythonce.sourceforge.net/](http://pythonce.sourceforge.net/) for more information.

Another new platform is Darwin/MacOS X; initial support for it is in Python 2.0. Dynamic loading works, if you specify “configure –with-dyld –with-suffix=.x”. Consult the README in the Python source distribution for more instructions.

An attempt has been made to alleviate one of Python’s warts, the often-confusing `NameError` exception when code refers to a local variable before the variable has been assigned a value. For example, the following code raises an exception on the `print` statement in both 1.5.2 and 2.0; in 1.5.2 a `NameError` exception is raised, while 2.0 raises a new `UnboundLocalError` exception. `UnboundLocalError` is a subclass of `NameError`, so any existing
code that expects **NameError** to be raised should still work.

```python
def f():
    print "i=", i
    i = i + 1
f()
```

Two new exceptions, **TabError** and **IndentationError**, have been introduced. They're both subclasses of **SyntaxError**, and are raised when Python code is found to be improperly indented.

## Changes to Built-in Functions

A new built-in, `zip(seq1, seq2, ...)`, has been added. `zip()` returns a list of tuples where each tuple contains the i-th element from each of the argument sequences. The difference between `zip()` and `map(None, seq1, seq2)` is that `map()` pads the sequences with `None` if the sequences aren't all of the same length, while `zip()` truncates the returned list to the length of the shortest argument sequence.

The `int()` and `long()` functions now accept an optional “base” parameter when the first argument is a string. `int('123', 10)` returns 123, while `int('123', 16)` returns 291. `int(123, 16)` raises a **TypeError** exception with the message “can’t convert non-string with explicit base”.

A new variable holding more detailed version information has been added to the `sys` module. `sys.version_info` is a tuple (major, minor, micro, level, serial) For example, in a hypothetical 2.0.1beta1, `sys.version_info` would be (2, 0, 1, 'beta', 1). `level` is a string such as "alpha", "beta", or "final" for a
final release.

Dictionaries have an odd new method, `setdefault(key, default)`, which behaves similarly to the existing `get()` method. However, if the key is missing, `setdefault()` both returns the value of `default` as `get()` would do, and also inserts it into the dictionary as the value for `key`. Thus, the following lines of code:

```python
if dict.has_key(key): return dict[key]
else:
    dict[key] = []
return dict[key]
```

can be reduced to a single `return dict.setdefault(key, [])` statement.

The interpreter sets a maximum recursion depth in order to catch runaway recursion before filling the C stack and causing a core dump or GPF. Previously this limit was fixed when you compiled Python, but in 2.0 the maximum recursion depth can be read and modified using `sys.getrecursionlimit()` and `sys.setrecursionlimit()`. The default value is 1000, and a rough maximum value for a given platform can be found by running a new script, `Misc/find_recursionlimit.py`. 
Porting to 2.0

New Python releases try hard to be compatible with previous releases, and the record has been pretty good. However, some changes are considered useful enough, usually because they fix initial design decisions that turned out to be actively mistaken, that breaking backward compatibility can’t always be avoided. This section lists the changes in Python 2.0 that may cause old Python code to break.

The change which will probably break the most code is tightening up the arguments accepted by some methods. Some methods would take multiple arguments and treat them as a tuple, particularly various list methods such as append() and insert(). In earlier versions of Python, if L is a list, L.append( 1,2 ) appends the tuple (1,2) to the list. In Python 2.0 this causes a TypeError exception to be raised, with the message: ‘append requires exactly 1 argument; 2 given’. The fix is to simply add an extra set of parentheses to pass both values as a tuple: L.append( (1,2) ).

The earlier versions of these methods were more forgiving because they used an old function in Python’s C interface to parse their arguments; 2.0 modernizes them to use PyArg_ParseTuple(), the current argument parsing function, which provides more helpful error messages and treats multi-argument calls as errors. If you absolutely must use 2.0 but can’t fix your code, you can edit Objects/listobject.c and define the preprocessor symbol NO_STRICT_LIST_APPEND to preserve the old behaviour; this isn’t recommended.

Some of the functions in the socket module are still forgiving in this way. For example, socket.connect( ('hostname', 25) )() is
the correct form, passing a tuple representing an IP address, but
socket.connect( 'hostname', 25 )() also works.
socket.connect_ex() and socket.bind() are similarly easy-going. 2.0alpha1 tightened these functions up, but because the
documentation actually used the erroneous multiple argument form,
many people wrote code which would break with the stricter argument checking.
GvR backed out the changes in the face of public reaction, so for the
socket module, the documentation was fixed and the multiple
argument form is simply marked as deprecated; it will be tightened up
again in a future Python version.

The \x escape in string literals now takes exactly 2 hex digits.
Previously it would consume all the hex digits following the 'x' and take
the lowest 8 bits of the result, so \x123456 was equivalent to \x56.

The AttributeError and NameError exceptions have a more
friendly error message, whose text will be something like 'Spam'
instance has no attribute 'eggs' or name 'eggs' is not defined. Previously the error message was just the missing
attribute name eggs, and code written to take advantage of this fact
will break in 2.0.

Some work has been done to make integers and long integers a bit
more interchangeable. In 1.5.2, large-file support was added for
Solaris, to allow reading files larger than 2 GiB; this made the tell() method of file objects return a long integer instead of a regular integer.
Some code would subtract two file offsets and attempt to use the result
to multiply a sequence or slice a string, but this raised a TypeError.
In 2.0, long integers can be used to multiply or slice a sequence, and
it'll behave as you'd intuitively expect it to; 3L * 'abc' produces 'abcabcabc', and (0,1,2,3)[2L:4L] produces (2,3). Long integers
can also be used in various contexts where previously only integers
were accepted, such as in the seek() method of file objects, and in
the formats supported by the % operator (%d, %i, %x, etc.). For
example, "%d" % 2L**64 will produce the string 18446744073709551616.

The subtlest long integer change of all is that the str() of a long
integer no longer has a trailing ‘L’ character, though repr() still
includes it. The ‘L’ annoyed many people who wanted to print long
integers that looked just like regular integers, since they had to go out
of their way to chop off the character. This is no longer a problem in
2.0, but code which does str(longval)[:-1] and assumes the ‘L’
is there, will now lose the final digit.

Taking the repr() of a float now uses a different formatting precision
than str(). repr() uses %.17g format string for C’s sprintf(),
while str() uses %.12g as before. The effect is that repr() may
occasionally show more decimal places than str(), for certain
numbers. For example, the number 8.1 can’t be represented exactly in
binary, so repr(8.1) is '8.0999999999999996', while str(8.1) is
'8.1'.

The -X command-line option, which turned all standard exceptions
into strings instead of classes, has been removed; the standard
exceptions will now always be classes. The exceptions module
containing the standard exceptions was translated from Python to a
built-in C module, written by Barry Warsaw and Fredrik Lundh.
Extending/Embedding Changes

Some of the changes are under the covers, and will only be apparent to people writing C extension modules or embedding a Python interpreter in a larger application. If you aren’t dealing with Python’s C API, you can safely skip this section.

The version number of the Python C API was incremented, so C extensions compiled for 1.5.2 must be recompiled in order to work with 2.0. On Windows, it’s not possible for Python 2.0 to import a third party extension built for Python 1.5.x due to how Windows DLLs work, so Python will raise an exception and the import will fail.

Users of Jim Fulton’s ExtensionClass module will be pleased to find out that hooks have been added so that ExtensionClasses are now supported by `isinstance()` and `issubclass()`. This means you no longer have to remember to write code such as `if type(obj) == myExtensionClass`, but can use the more natural `if isinstance(obj, myExtensionClass)`.

The Python/importdl.c file, which was a mass of `#ifdefs` to support dynamic loading on many different platforms, was cleaned up and reorganised by Greg Stein. `importdl.c` is now quite small, and platform-specific code has been moved into a bunch of `Python/dynload_* .c` files. Another cleanup: there were also a number of `my*.h` files in the `Include/` directory that held various portability hacks; they’ve been merged into a single file, `Include/pyport.h`.

Vladimir Marangozov’s long-awaited malloc restructuring was completed, to make it easy to have the Python interpreter use a
custom allocator instead of C’s standard malloc(). For documentation, read the comments in Include/pymem.h and Include/objimpl.h. For the lengthy discussions during which the interface was hammered out, see the Web archives of the ‘patches’ and ‘python-dev’ lists at python.org.

Recent versions of the GUSI development environment for MacOS support POSIX threads. Therefore, Python's POSIX threading support now works on the Macintosh. Threading support using the user-space GNU pth library was also contributed.

Threading support on Windows was enhanced, too. Windows supports thread locks that use kernel objects only in case of contention; in the common case when there's no contention, they use simpler functions which are an order of magnitude faster. A threaded version of Python 1.5.2 on NT is twice as slow as an unthreaded version; with the 2.0 changes, the difference is only 10%. These improvements were contributed by Yakov Markovitch.

Python 2.0's source now uses only ANSI C prototypes, so compiling Python now requires an ANSI C compiler, and can no longer be done using a compiler that only supports K&R C.

Previously the Python virtual machine used 16-bit numbers in its bytecode, limiting the size of source files. In particular, this affected the maximum size of literal lists and dictionaries in Python source; occasionally people who are generating Python code would run into this limit. A patch by Charles G. Waldman raises the limit from $2^{16}$ to $2^{32}$.

Three new convenience functions intended for adding constants to a module's dictionary at module initialization time were added: PyModule_AddObject(), PyModule_AddIntConstant(), and
PyModule_AddStringConstant(). Each of these functions takes a module object, a null-terminated C string containing the name to be added, and a third argument for the value to be assigned to the name. This third argument is, respectively, a Python object, a C long, or a C string.

A wrapper API was added for Unix-style signal handlers. PyOS_getsig() gets a signal handler and PyOS_setsig() will set a new handler.
Distutils: Making Modules Easy to Install

Before Python 2.0, installing modules was a tedious affair – there was no way to figure out automatically where Python is installed, or what compiler options to use for extension modules. Software authors had to go through an arduous ritual of editing Makefiles and configuration files, which only really work on Unix and leave Windows and MacOS unsupported. Python users faced wildly differing installation instructions which varied between different extension packages, which made administering a Python installation something of a chore.

The SIG for distribution utilities, shepherded by Greg Ward, has created the Distutils, a system to make package installation much easier. They form the distutils package, a new part of Python's standard library. In the best case, installing a Python module from source will require the same steps: first you simply mean unpack the tarball or zip archive, and the run “python setup.py install”. The platform will be automatically detected, the compiler will be recognized, C extension modules will be compiled, and the distribution installed into the proper directory. Optional command-line arguments provide more control over the installation process, the distutils package offers many places to override defaults – separating the build from the install, building or installing in non-default directories, and more.

In order to use the Distutils, you need to write a setup.py script. For the simple case, when the software contains only .py files, a minimal setup.py can be just a few lines long:

```python
from distutils.core import setup
setup (name = "foo", version = "1.0",
       py_modules = ["module1", "module2"])
```
The `setup.py` file isn't much more complicated if the software consists of a few packages:

```python
from distutils.core import setup
setup (
    name = "foo", version = "1.0",
    packages = ["package", "package.subpackage"]
)
```

A C extension can be the most complicated case; here's an example taken from the PyXML package:

```python
from distutils.core import setup, Extension

expat_extension = Extension('xml.parsers.pyexpat',
    define_macros = [(
        'XML_NS', None)
    ],
    include_dirs = [ 'extensions/expat/xmltok',
        'extensions/expat/xmlparse' ],
    sources = [ 'extensions/pyexpat.c',
        'extensions/expat/xmltok/xmltok.c',
        'extensions/expat/xmltok/xmlrole.c'
    )

setup (name = "PyXML", version = "0.5.4",
    ext_modules = [ expat_extension ]
    )
```

The Distutils can also take care of creating source and binary distributions. The “sdist” command, run by “python setup.py sdist”, builds a source distribution such as `foo-1.0.tar.gz`. Adding new commands isn’t difficult, “bdist_rpm” and “bdist_wininst” commands have already been contributed to create an RPM distribution and a Windows installer for the software, respectively. Commands to create other distribution formats such as Debian packages and Solaris .pkg files are in various stages of development.
All this is documented in a new manual, *Distributing Python Modules*, that joins the basic set of Python documentation.
XML Modules

Python 1.5.2 included a simple XML parser in the form of the xmllib module, contributed by Sjoerd Mullender. Since 1.5.2’s release, two different interfaces for processing XML have become common: SAX2 (version 2 of the Simple API for XML) provides an event-driven interface with some similarities to xmllib, and the DOM (Document Object Model) provides a tree-based interface, transforming an XML document into a tree of nodes that can be traversed and modified. Python 2.0 includes a SAX2 interface and a stripped-down DOM interface as part of the xml package. Here we will give a brief overview of these new interfaces; consult the Python documentation or the source code for complete details. The Python XML SIG is also working on improved documentation.

SAX2 Support

SAX defines an event-driven interface for parsing XML. To use SAX, you must write a SAX handler class. Handler classes inherit from various classes provided by SAX, and override various methods that will then be called by the XML parser. For example, the startElement() and endElement() methods are called for every starting and end tag encountered by the parser, the characters() method is called for every chunk of character data, and so forth.

The advantage of the event-driven approach is that the whole document doesn't have to be resident in memory at any one time, which matters if you are processing really huge documents. However, writing the SAX handler class can get very complicated if you're trying to modify the document structure in some elaborate way.
For example, this little example program defines a handler that prints a message for every starting and ending tag, and then parses the file `hamlet.xml` using it:

```python
from xml import sax

class SimpleHandler(sax.ContentHandler):
    def startElement(self, name, attrs):
        print 'Start of element:', name, attrs.keys()

    def endElement(self, name):
        print 'End of element:', name

# Create a parser object
parser = sax.make_parser()

# Tell it what handler to use
handler = SimpleHandler()
parses.setContentHandler( handler )

# Parse a file!
parses.parse( 'hamlet.xml' )
```

For more information, consult the Python documentation, or the XML HOWTO at [http://pyxml.sourceforge.net/topics/howto/xml-howto.html](http://pyxml.sourceforge.net/topics/howto/xml-howto.html).

**DOM Support**

The Document Object Model is a tree-based representation for an XML document. A top-level `Document` instance is the root of the tree, and has a single child which is the top-level `Element` instance. This `Element` has children nodes representing character data and any sub-elements, which may have further children of their own, and so
forth. Using the DOM you can traverse the resulting tree any way you like, access element and attribute values, insert and delete nodes, and convert the tree back into XML.

The DOM is useful for modifying XML documents, because you can create a DOM tree, modify it by adding new nodes or rearranging subtrees, and then produce a new XML document as output. You can also construct a DOM tree manually and convert it to XML, which can be a more flexible way of producing XML output than simply writing `<tag1>...</tag1>` to a file.

The DOM implementation included with Python lives in the `xml.dom.minidom` module. It's a lightweight implementation of the Level 1 DOM with support for XML namespaces. The `parse()` and `parseString()` convenience functions are provided for generating a DOM tree:

```python
from xml.dom import minidom
doc = minidom.parse('hamlet.xml')
```

doc is a Document instance. Document, like all the other DOM classes such as Element and Text, is a subclass of the Node base class. All the nodes in a DOM tree therefore support certain common methods, such as `toxml()` which returns a string containing the XML representation of the node and its children. Each class also has special methods of its own; for example, Element and Document instances have a method to find all child elements with a given tag name. Continuing from the previous 2-line example:

```python
perslist = doc.getElementsByTagName('PERSONA')
print perslist[0].toxml()
print perslist[1].toxml()
```
For the *Hamlet* XML file, the above few lines output:

```xml
<PERSONA>CLAUDIUS, king of Denmark. </PERSONA>
<PERSONA>HAMLET, son to the late, and nephew to the
```

The root element of the document is available as `doc.documentElement`, and its children can be easily modified by deleting, adding, or removing nodes:

```python
root = doc.documentElement

# Remove the first child
root.removeChild( root.childNodes[0] )

# Move the new first child to the end
root.appendChild( root.childNodes[0] )

# Insert the new first child (originally, the third child) before the 20th child.
root.insertBefore( root.childNodes[0], root.childNodes[20] )
```

Again, I will refer you to the Python documentation for a complete listing of the different Node classes and their various methods.

**Relationship to PyXML**

The XML Special Interest Group has been working on XML-related Python code for a while. Its code distribution, called PyXML, is available from the SIG's Web pages at [https://www.python.org/community/sigs/current/xml-sig](https://www.python.org/community/sigs/current/xml-sig). The PyXML distribution also used the package name `xml`. If you’ve written programs that used PyXML, you’re probably wondering about its
compatibility with the 2.0 xml package.

The answer is that Python 2.0's xml package isn't compatible with PyXML, but can be made compatible by installing a recent version PyXML. Many applications can get by with the XML support that is included with Python 2.0, but more complicated applications will require that the full PyXML package will be installed. When installed, PyXML versions 0.6.0 or greater will replace the xml package shipped with Python, and will be a strict superset of the standard package, adding a bunch of additional features. Some of the additional features in PyXML include:

- 4DOM, a full DOM implementation from FourThought, Inc.
- The xmlproc validating parser, written by Lars Marius Garshol.
- The sgm1op parser accelerator module, written by Fredrik Lundh.
Module changes

Lots of improvements and bugfixes were made to Python’s extensive standard library; some of the affected modules include readline, ConfigParser, cgi, calendar, posix, readline, xmllib, aifc, chunk, wave, random, shelve, and nntplib. Consult the CVS logs for the exact patch-by-patch details.

Brian Gallew contributed OpenSSL support for the socket module. OpenSSL is an implementation of the Secure Socket Layer, which encrypts the data being sent over a socket. When compiling Python, you can edit Modules/Setup to include SSL support, which adds an additional function to the socket module: socket.ssl(socket, keyfile, certfile), which takes a socket object and returns an SSL socket. The httpplib and urllib modules were also changed to support https:// URLs, though no one has implemented FTP or SMTP over SSL.

The httpplib module has been rewritten by Greg Stein to support HTTP/1.1. Backward compatibility with the 1.5 version of httpplib is provided, though using HTTP/1.1 features such as pipelining will require rewriting code to use a different set of interfaces.

The Tkinter module now supports Tcl/Tk version 8.1, 8.2, or 8.3, and support for the older 7.x versions has been dropped. The Tkinter module now supports displaying Unicode strings in Tk widgets. Also, Fredrik Lundh contributed an optimization which makes operations like create_line and create_polygon much faster, especially when using lots of coordinates.

The curses module has been greatly extended, starting from Oliver
Andrich’s enhanced version, to provide many additional functions from ncurses and SYSV curses, such as colour, alternative character set support, pads, and mouse support. This means the module is no longer compatible with operating systems that only have BSD curses, but there don’t seem to be any currently maintained OSes that fall into this category.

As mentioned in the earlier discussion of 2.0’s Unicode support, the underlying implementation of the regular expressions provided by the `re` module has been changed. SRE, a new regular expression engine written by Fredrik Lundh and partially funded by Hewlett Packard, supports matching against both 8-bit strings and Unicode strings.
New modules

A number of new modules were added. We'll simply list them with brief descriptions; consult the 2.0 documentation for the details of a particular module.

- **atexit**: For registering functions to be called before the Python interpreter exits. Code that currently sets `sys.exitfunc` directly should be changed to use the `atexit` module instead, importing `atexit` and calling `atexit.register()` with the function to be called on exit. (Contributed by Skip Montanaro.)
- **codecs, encodings, unicodedata**: Added as part of the new Unicode support.
- **filecmp**: Supersedes the old cmp, cmpcache and dircmp modules, which have now become deprecated. (Contributed by Gordon MacMillan and Moshe Zadka.)
- **gettext**: This module provides internationalization (I18N) and localization (L10N) support for Python programs by providing an interface to the GNU gettext message catalog library. (Integrated by Barry Warsaw, from separate contributions by Martin von Löwis, Peter Funk, and James Henstridge.)
- **linuxaudiodev**: Support for the `/dev/audio` device on Linux, a twin to the existing sunaudiodev module. (Contributed by Peter Bosch, with fixes by Jeremy Hylton.)
- **mmap**: An interface to memory-mapped files on both Windows and Unix. A file's contents can be mapped directly into memory, at which point it behaves like a mutable string, so its contents can be read and modified. They can even be passed to functions that expect ordinary strings, such as the `re` module. (Contributed by Sam Rushing, with some extensions by A.M. Kuchling.)
- **pyexpat**: An interface to the Expat XML parser. (Contributed by Paul Prescod.)
robotparser: Parse a robots.txt file, which is used for writing Web spiders that politely avoid certain areas of a Web site. The parser accepts the contents of a robots.txt file, builds a set of rules from it, and can then answer questions about the fetchability of a given URL. (Contributed by Skip Montanaro.)

tabnanny: A module/script to check Python source code for ambiguous indentation. (Contributed by Tim Peters.)

UserString: A base class useful for deriving objects that behave like strings.

webbrowser: A module that provides a platform independent way to launch a web browser on a specific URL. For each platform, various browsers are tried in a specific order. The user can alter which browser is launched by setting the BROWSER environment variable. (Originally inspired by Eric S. Raymond's patch to urllib which added similar functionality, but the final module comes from code originally implemented by Fred Drake as Tools/idle/BrowserControl.py, and adapted for the standard library by Fred.)

_winreg: An interface to the Windows registry. _winreg is an adaptation of functions that have been part of PythonWin since 1995, but has now been added to the core distribution, and enhanced to support Unicode. _winreg was written by Bill Tutt and Mark Hammond.

zipfile: A module for reading and writing ZIP-format archives. These are archives produced by PKZIP on DOS/Windows or zip on Unix, not to be confused with gzip-format files (which are supported by the gzip module) (Contributed by James C. Ahlstrom.)

imputil: A module that provides a simpler way for writing customized import hooks, in comparison to the existing ihooks module. (Implemented by Greg Stein, with much discussion on python-dev along the way.)
IDLE Improvements

IDLE is the official Python cross-platform IDE, written using Tkinter. Python 2.0 includes IDLE 0.6, which adds a number of new features and improvements. A partial list:

- UI improvements and optimizations, especially in the area of syntax highlighting and auto-indentation.
- The class browser now shows more information, such as the top level functions in a module.
- Tab width is now a user settable option. When opening an existing Python file, IDLE automatically detects the indentation conventions, and adapts.
- There is now support for calling browsers on various platforms, used to open the Python documentation in a browser.
- IDLE now has a command line, which is largely similar to the vanilla Python interpreter.
- Call tips were added in many places.
- IDLE can now be installed as a package.
- In the editor window, there is now a line/column bar at the bottom.
- Three new keystroke commands: Check module (Alt-F5), Import module (F5) and Run script (Ctrl-F5).
Deleted and Deprecated Modules

A few modules have been dropped because they're obsolete, or because there are now better ways to do the same thing. The stdwin module is gone; it was for a platform-independent windowing toolkit that's no longer developed.

A number of modules have been moved to the lib-old subdirectory: cmp, cmpcache, dircmp, dump, find, grep, packmail, poly, util, whatsound, zmod. If you have code which relies on a module that's been moved to lib-old, you can simply add that directory to sys.path to get them back, but you're encouraged to update any code that uses these modules.
Acknowledgements

The authors would like to thank the following people for offering suggestions on various drafts of this article: David Bolen, Mark Hammond, Gregg Hauser, Jeremy Hylton, Fredrik Lundh, Detlef Lannert, Aahz Maruch, Skip Montanaro, Vladimir Marangozov, Tobias Polzin, Guido van Rossum, Neil Schemenauer, and Russ Schmidt.
Changelog
Python 3.6.3 final?

Release date: 2017-10-03

Library

- **bpo-31641**: Re-allow arbitrary iterables in `concurrent.futures.as_completed()`. Fixes regression in 3.6.3rc1.

Build

- **bpo-31423**: Fix building the PDF documentation with newer versions of Sphinx.
Python 3.6.3 release candidate 1?

Release date: 2017-09-18

Security

- **bpo-29781**: SSLObj.version() now correctly returns None when handshake over BIO has not been performed yet.
- **bpo-30947**: Upgrade libexpat embedded copy from version 2.2.1 to 2.2.3 to get security fixes.

Core and Builtins

- **bpo-31471**: Fix an assertion failure in subprocess.Popen() on Windows, in case the env argument has a bad keys() method. Patch by Oren Milman.
- **bpo-31418**: Fix an assertion failure in PyErr_WriteUnraisable() in case of an exception with a bad __module__ attribute. Patch by Oren Milman.
- **bpo-31416**: Fix assertion failures in case of a bad warnings.filters or warnings.defaultaction. Patch by Oren Milman.
- **bpo-31411**: Raise a TypeError instead of SystemError in case warnings.onceregistry is not a dictionary. Patch by Oren Milman.
- **bpo-31373**: Fix several possible instances of undefined behavior due to floating-point demotions.
- **bpo-30465**: Location information (lineno and col_offset) in f-strings is now (mostly) correct. This fixes tools like flake8 from
showing warnings on the wrong line (typically the first line of the file).

- **bpo-31343**: Include `sys/sysmacros.h` for `major()`, `minor()`, and `makedev()`. GNU C library plans to remove the functions from `sys/types.h`.

- **bpo-31291**: Fix an assertion failure in `zipimport.zipimporter.get_data` on Windows, when the return value of `pathname.replace('/','\\')` isn't a string. Patch by Oren Milman.

- **bpo-31271**: Fix an assertion failure in the `write()` method of `io.TextIOWrapper`, when the encoder doesn’t return a bytes object. Patch by Oren Milman.

- **bpo-31243**: Fix a crash in some methods of `io.TextIOWrapper`, when the decoder’s state is invalid. Patch by Oren Milman.

- **bpo-30721**: `print` now shows correct usage hint for using Python 2 redirection syntax. Patch by Sanyam Khurana.

- **bpo-31070**: Fix a race condition in `importlib._get_module_lock()`.

- **bpo-31095**: Fix potential crash during GC caused by `tp_dealloc` which doesn’t call `PyObject_GC_UnTrack()`.

- **bpo-31071**: Avoid masking original `TypeError` in call with `*` unpacking when other arguments are passed.

- **bpo-30978**: `str.format_map()` now passes key lookup exceptions through. Previously any exception was replaced with a `KeyError` exception.
- **bpo-30808**: Use _Py_atomic API for concurrency-sensitive signal state.

- **bpo-30876**: Relative import from unloaded package now reimports the package instead of failing with SystemError. Relative import from non-package now fails with ImportError rather than SystemError.

- **bpo-30703**: Improve signal delivery.
  
  Avoid using Py_AddPendingCall from signal handler, to avoid calling signal- unsafe functions. The tests I’m adding here fail without the rest of the patch, on Linux and OS X. This means our signal delivery logic had defects (some signals could be lost).

- **bpo-30765**: Avoid blocking in pthread_mutex_lock() when PyThread_acquire_lock() is asked not to block.

- **bpo-31161**: Make sure the ‘Missing parentheses’ syntax error message is only applied to SyntaxError, not to subclasses. Patch by Martijn Pieters.

- **bpo-30814**: Fixed a race condition when import a submodule from a package.

- **bpo-30597**: print now shows expected input in custom error message when used as a Python 2 statement. Patch by Sanyam Khurana.

**Library**

- **bpo-31499**: xml.etree: Fix a crash when a parser is part of a reference cycle.
- **bpo-28556**: typing.get_type_hints now finds the right globalns for classes and modules by default (when no `globalns` was specified by the caller).

- **bpo-28556**: Speed improvements to the `typing` module. Original PRs by Ivan Levkivskyi and Mitar.

- **bpo-31544**: The C accelerator module of ElementTree ignored exceptions raised when looking up TreeBuilder target methods in XMLParser().

- **bpo-31234**: `socket.create_connection()` now fixes manually a reference cycle: clear the variable storing the last exception on success.

- **bpo-31457**: LoggerAdapter objects can now be nested.

- **bpo-31400**: Improves SSL error handling to avoid losing error numbers.

- **bpo-28958**: `ssl.SSLContext()` now uses OpenSSL error information when a context cannot be instantiated.

- **bpo-27340**: SSLSocket.sendall() now uses memoryview to create slices of data. This fixes support for all bytes-like object. It is also more efficient and avoids costly copies.

- **bpo-31178**: Fix string concatenation bug in rare error path in the subprocess module

- **bpo-31350**: Micro-optimize `asyncio._get_running_loop()` to become up to 10% faster.

- **bpo-31170**: expat: Update libexpat from 2.2.3 to 2.2.4. Fix copying

- **bpo-29136**: Add TLS 1.3 cipher suites and OP_NO_TLSv1_3.

- **bpo-29212**: Fix `concurrent.futures.thread.ThreadPoolExecutor` threads to have a non `repr()` based thread name by default when no `thread_name_prefix` is supplied. They will now identify themselves as “ThreadPoolExecutor- y_n”.

- **bpo-9146**: Fix a segmentation fault in `_hashopenssl` when standard hash functions such as md5 are not available in the linked OpenSSL library. As in some special FIPS-140 build environments.

- **bpo-27144**: The `map()` and `as_completed()` iterators in `concurrent.futures` now avoid keeping a reference to yielded objects.

- **bpo-10746**: Fix ctypes producing wrong PEP 3118 type codes for integer types.

- **bpo-22536**: The subprocess module now sets the filename when `FileNotFoundError` is raised on POSIX systems due to the executable or `cwd` not being found.

- **bpo-31249**: `concurrent.futures`: `WorkItem.run()` used by `ThreadPoolExecutor` now breaks a reference cycle between an exception object and the `WorkItem` object.

- **bpo-31247**: `xmlrpc.server` now explicitly breaks reference cycles when using `sys.exc_info()` in code handling exceptions.

- **bpo-30102**: The `ssl` and `hashlib` modules now call
OPENSSL_add_all_algorithms_noconf() on OpenSSL < 1.1.0. The function detects CPU features and enables optimizations on some CPU architectures such as POWER8. Patch is based on research from Gustavo Serra Scalet.

- **bpo-31185**: Fixed miscellaneous errors in asyncio speedup module.

- **bpo-31135**: ttk: fix the destroy() method of LabeledScale and OptionMenu classes. Call the parent destroy() method even if the used attribute doesn’t exist. The LabeledScale.destroy() method now also explicitly clears label and scale attributes to help the garbage collector to destroy all widgets.

- **bpo-31107**: Fix `copyreg._slotnames()` mangled attribute calculation for classes whose name begins with an underscore. Patch by Shane Harvey.

- **bpo-31061**: Fixed a crash when using asyncio and threads.

- **bpo-30502**: Fix handling of long oids in ssl. Based on patch by Christian Heimes.

- **bpo-30119**: `ftpplib.FTP.putline()` now throws ValueError on commands that contains CR or LF. Patch by Dong-hee Na.

- **bpo-30595**: multiprocessing.Queue.get() with a timeout now polls its reader in non-blocking mode if it succeeded to acquire the lock but the acquire took longer than the timeout.

- **bpo-29403**: Fix unittest.mock’s autospec to not fail on method-bound builtin functions. Patch by Aaron Gallagher.

- **bpo-30961**: Fix decrementing a borrowed reference in
tracemalloc.

- **bpo-25684**: Change `ttk.OptionMenu` radiobuttons to be unique across instances of `OptionMenu`.

- **bpo-30886**: Fix `multiprocessing.Queue.join_thread()`: it now waits until the thread completes, even if the thread was started by the same process which created the queue.

- **bpo-29854**: Fix segfault in readline when using readline’s history-size option. Patch by Nir Soffer.

- **bpo-30319**: `socket.close()` now ignores ECONNRESET error.

- **bpo-30828**: Fix out of bounds write in `asyncio.CFuture.remove_done_callback()`.

- **bpo-30807**: `signal.setitimer()` may disable the timer when passed a tiny value.

  Tiny values (such as 1e-6) are valid non-zero values for `setitimer()`, which is specified as taking microsecond-resolution intervals. However, on some platform, our conversion routine could convert 1e-6 into a zero interval, therefore disabling the timer instead of (re-)scheduling it.

- **bpo-30441**: Fix bug when modifying `os.environ` while iterating over it

- **bpo-30532**: Fix email header value parser dropping folding white space in certain cases.

- **bpo-30879**: `os.listdir()` and `os.scandir()` now emit bytes names when called with bytes-like argument.
- **bpo-30746**: Prohibited the ‘=’ character in environment variable names in `os.putenv()` and `os.spawn*()`.

- **bpo-29755**: Fixed the `lgettext()` family of functions in the gettext module. They now always return bytes.

### Documentation

- **bpo-31294**: Fix incomplete code snippet in the ZeroMQSocketListener and ZeroMQSocketHandler examples and adapt them to Python 3.
- **bpo-21649**: Add RFC 7525 and Mozilla server side TLS links to SSL documentation.
- **bpo-30803**: Clarify doc on truth value testing. Original patch by Peter Thomassen.

### Tests

- **bpo-31320**: Silence traceback in test_ssl
- **bpo-25674**: Remove sha256.tbs-internet.com ssl test
- **bpo-30715**: Address ALPN callback changes for OpenSSL 1.1.0f. The latest version behaves like OpenSSL 1.0.2 and no longer aborts handshake.
- **bpo-30822**: regrtest: Exclude tzdata from regrtest –all. When running the test suite using –use=all / -u all, exclude tzdata since it makes test_datetime too slow (15-20 min on some buildbots) which then times out on some buildbots. Fix also regretest command line parser to allow passing -u extralargefile to run test_zipfile64.

### Build

- **bpo-30854**: Fix compile error when compiling –without-threads.
Patch by Masayuki Yamamoto.

Windows

- **bpo-30389**: Adds detection of Visual Studio 2017 to distutils on Windows.
- **bpo-31340**: Change to building with MSVC v141 (included with Visual Studio 2017)
- **bpo-30581**: os.cpu_count() now returns the correct number of processors on Windows when the number of logical processors is greater than 64.
- **bpo-30731**: Add a missing xmlns to python.manifest so that it matches the schema.

IDLE

- **bpo-31493**: IDLE code context – fix code update and font update timers.
  
  Canceling timers prevents a warning message when test_idle completes.

- **bpo-31488**: IDLE - Update non-key options in former extension classes. When applying configdialog changes, call .reload for each feature class. Change ParenMatch so updated options affect existing instances attached to existing editor windows.

- **bpo-31477**: IDLE - Improve rstrip entry in doc. Strip trailing whitespace strips more than blank spaces. Multiline string literals are not skipped.

- **bpo-31480**: IDLE - make tests pass with zzdummy extension disabled by default.
- **bpo-31421**: Document how IDLE runs tkinter programs. IDLE calls tcl/tk update in the background in order to make live interaction and experimentatin with tkinter applications much easier.

- **bpo-31414**: IDLE – fix tk entry box tests by deleting first. Adding to an int entry is not the same as deleting and inserting because int("") will fail.

- **bpo-31051**: Rearrange IDLE condigdialog GenPage into Window, Editor, and Help sections.

- **bpo-30617**: IDLE - Add docstrings and tests for outwin subclass of editor.

  Move some data and functions from the class to module level. Patch by Cheryl Sabella.

- **bpo-31287**: IDLE - Do not modify tkinter.message in test_configdialog.

- **bpo-27099**: Convert IDLE’s built-in ‘extensions’ to regular features.

  About 10 IDLE features were implemented as supposedly optional extensions. Their different behavior could be confusing or worse for users and not good for maintenance. Hence the conversion.

  The main difference for users is that user configurable key bindings for builtin features are now handled uniformly. Now, editing a binding in a keyset only affects its value in the keyset. All bindings are defined together in the system-specific default keysets in config-extensions.def. All custom keysets are saved as
a whole in config-extension.cfg. All take effect as soon as one clicks Apply or Ok.

Initial patch by Charles Wohlganger.

- **bpo-31206**: IDLE: Factor HighPage(Frame) class from ConfigDialog. Patch by Cheryl Sabella.
- **bpo-31001**: Add tests for configdialog highlight tab. Patch by Cheryl Sabella.
- **bpo-31205**: IDLE: Factor KeysPage(Frame) class from ConfigDialog. The slightly modified tests continue to pass. Patch by Cheryl Sabella.
- **bpo-31002**: Add tests for configdialog keys tab. Patch by Cheryl Sabella.
- **bpo-19903**: IDLE: Calltips use `inspect.signature` instead of `inspect.getfullargspec`. This improves calltips for builtins converted to use Argument Clinic. Patch by Louie Lu.
- **bpo-31083**: IDLE - Add an outline of a TabPage class in configdialog. Update existing classes to match outline. Initial
patch by Cheryl Sabella.

- **bpo-31050**: Factor GenPage(Frame) class from ConfigDialog. The slightly modified tests continue to pass. Patch by Cheryl Sabella.

- **bpo-31004**: IDLE - Factor FontPage(Frame) class from ConfigDialog.

  Slightly modified tests continue to pass. Fix General tests. Patch mostly by Cheryl Sabella.

- **bpo-30781**: IDLE - Use ttk widgets in ConfigDialog. Patches by Terry Jan Reedy and Cheryl Sabella.

- **bpo-31060**: IDLE - Finish rearranging methods of ConfigDialog Grouping methods pertaining to each tab and the buttons will aid writing tests and improving the tabs and will enable splitting the groups into classes.

- **bpo-30853**: IDLE – Factor a VarTrace class out of ConfigDialog.

  Instance tracers manages pairs consisting of a tk variable and a callback function. When tracing is turned on, setting the variable calls the function. Test coverage for the new class is 100%.

- **bpo-31003**: IDLE: Add more tests for General tab.

- **bpo-30993**: IDLE - Improve configdialog font page and tests.

  In configdialog: Document causal pathways in create_font_tab docstring. Simplify some attribute names. Move set_samples calls to var_changed_font (idea from Cheryl Sabella). Move related functions to positions after the create widgets function.
In test_configdialog: Fix test_font_set so not order dependent. Fix renamed test_indent_scale so it tests the widget. Adjust tests for movement of set_samples call. Add tests for load functions. Put all font tests in one class and tab indent tests in another. Except for two lines, these tests completely cover the related functions.

- **bpo-30981**: IDLE – Add more configdialog font page tests.
- **bpo-28523**: IDLE: replace ‘colour’ with ‘color’ in configdialog.
- **bpo-30917**: Add tests for idlelib.config.IdleConf. Increase coverage from 46% to 96%. Patch by Louie Lu.
- **bpo-30934**: Document coverage details for idlelib tests.
  - Add section to idlelib/idle-test/README.txt.
  - Include check that branches are taken both ways.
  - Exclude IDLE-specific code that does not run during unit tests.
- **bpo-30913**: IDLE: Document ConfigDialog tk Vars, methods, and widgets in docstrings This will facilitate improving the dialog and splitting up the class. Original patch by Cheryl Sabella.
- **bpo-30899**: IDLE: Add tests for ConfigParser subclasses in config. Patch by Louie Lu.
- **bpo-30881**: IDLE: Add docstrings to browser.py. Patch by Cheryl Sabella.
- **bpo-30851**: IDLE: Remove unused variables in configdialog. One is a duplicate, one is set but cannot be altered by users. Patch by Cheryl Sabella.
- **bpo-30870**: IDLE: In Settings dialog, select font with Up, Down keys as well as mouse. Initial patch by Louie Lu.
• **bpo-8231**: IDLE: call config.IdleConf.GetUserCfgDir only once.

• **bpo-30779**: IDLE: Factor ConfigChanges class from configdialog, put in config; test. * In config, put dump test code in a function; run it and unittest in ‘if __name__ == ‘__main__’’. * Add class config.ConfigChanges based on changes_class_v4.py on bpo issue. * Add class test_config.ChangesTest, partly using configdialog_tests_v1.py. * Revise configdialog to use ConfigChanges; see tracker msg297804. * Revise test_configdialog to match configdialog changes. * Remove configdialog functions unused or moved to ConfigChanges. Cheryl Sabella contributed parts of the patch.

• **bpo-30777**: IDLE: configdialog - Add docstrings and fix comments. Patch by Cheryl Sabella.

• **bpo-30495**: IDLE: Improve textview with docstrings, PEP8 names, and more tests. Patch by Cheryl Sabella.

• **bpo-30723**: IDLE: Make several improvements to parenmatch. Add 'parens' style to highlight both opener and closer. Make 'default' style, which is not default, a synonym for 'opener'. Make time-delay work the same with all styles. Add help for config dialog extensions tab, including help for parenmatch. Add new tests. Original patch by Charles Wohlganger.

• **bpo-30674**: IDLE: add docstrings to grep module. Patch by Cheryl Sabella

• **bpo-21519**: IDLE's basic custom key entry dialog now detects duplicates properly. Original patch by Saimadhav Heblikar.

• **bpo-29910**: IDLE no longer deletes a character after commenting
out a region by a key shortcut. Add `return 'break'` for this and other potential conflicts between IDLE and default key bindings.

- **bpo-6739**: IDLE: Verify user-entered key sequences by trying to bind them with tk. Add tests for all 3 validation functions. Original patch by G Polo. Tests added by Cheryl Sabella.

**Tools/Demos**

- **bpo-30983**: gdb integration commands (py-bt, etc.) work on optimized shared builds now, too. PEP 523 introduced `_PyEval_EvalFrameDefault` which inlines `PyEval_EvalFrameEx` on non-debug shared builds. This broke the ability to use py-bt, py-up, and a few other Python-specific gdb integrations. The problem is fixed by only looking for `_PyEval_EvalFrameDefault` frames in python-gdb.py. Original patch by Bruno “Polaco” Penteado.
Python 3.6.2 final?

*Release date: 2017-07-17*

No changes since release candidate 2
Python 3.6.2 release candidate 2?

Release date: 2017-07-07

Security

- **bpo-30730**: Prevent environment variables injection in subprocess on Windows. Prevent passing other environment variables and command arguments.
- **bpo-30694**: Upgrade expat copy from 2.2.0 to 2.2.1 to get fixes of multiple security vulnerabilities including: CVE-2017-9233 (External entity infinite loop DoS), CVE-2016-9063 (Integer overflow, re-fix), CVE-2016-0718 (Fix regression bugs from 2.2.0's fix to CVE-2016-0718) and CVE-2012-0876 (Counter hash flooding with SipHash). Note: the CVE-2016-5300 (Use os-specific entropy sources like getrandom) doesn’t impact Python, since Python already gets entropy from the OS to set the expat secret using XML_SetHashSalt().
- **bpo-30500**: Fix urllib.parse.splithost() to correctly parse fragments. For example, `splithost('//127.0.0.1#@evil.com/')` now correctly returns the 127.0.0.1 host, instead of treating @evil.com as the host in an authentification (login@host).
Python 3.6.2 release candidate 1?

Release date: 2017-06-17

Core and Builtins

- **bpo-30682**: Removed a too-strict assertion that failed for certain f-strings, such as eval("f\n") and eval("f\r").
- **bpo-30604**: Move co_extra_freefuncs to not be per-thread to avoid crashes.
- **bpo-29104**: Fixed parsing backslashes in f-strings.
- **bpo-27945**: Fixed various segfaults with dict when input collections are mutated during searching, inserting or comparing. Based on patches by Duane Griffin and Tim Mitchell.
- **bpo-25794**: Fixed type.__setattr__() and type.__delattr__() for non-interned attribute names. Based on patch by Eryk Sun.
- **bpo-30039**: If a KeyboardInterrupt happens when the interpreter is in the middle of resuming a chain of nested ‘yield from’ or ‘await’ calls, it’s now correctly delivered to the innermost frame.
- **bpo-12414**: sys.getsizeof() on a code object now returns the sizes which includes the code struct and sizes of objects which it references. Patch by Dong-hee Na.
- **bpo-29949**: Fix memory usage regression of set and frozenset object.
- **bpo-29935**: Fixed error messages in the index() method of tuple, list and deque when pass indices of wrong type.
- **bpo-29859**: Show correct error messages when any of the pthread_* calls in thread_pthread.h fails.
- **bpo-28876**: bool(range) works even if len(range) raises OverflowError.
- **bpo-29600**: Fix wrapping coroutine return values in StopIteration.
- **bpo-28856**: Fix an oversight that %b format for bytes should
support objects follow the buffer protocol.

- **bpo-29714**: Fix a regression that bytes format may fail when containing zero bytes inside.
- **bpo-29478**: If max_line_length=None is specified while using the Compat32 policy, it is no longer ignored. Patch by Mircea Cosbuc.

**Library**

- **bpo-30616**: Functional API of enum allows to create empty enums. Patched by Dong-hee Na
- **bpo-30038**: Fix race condition between signal delivery and wakeup file descriptor. Patch by Nathaniel Smith.
- **bpo-23894**: lib2to3 now recognizes `rb'...'` and `f'...'` strings.
- **bpo-23890**: unittest.TestCase.assertRaises() now manually breaks a reference cycle to not keep objects alive longer than expected.
- **bpo-30149**: inspect.signature() now supports callables with variable-argument parameters wrapped with partialmethod. Patch by Dong-hee Na.
- **bpo-30645**: Fix path calculation in imp.load_package(), fixing it for cases when a package is only shipped with bytecodes. Patch by Alexandru Ardelean.
- **bpo-29931**: Fixed comparison check for ipaddress.ip_interface objects. Patch by Sanjay Sundaresan.
- **bpo-30605**: re.compile() no longer raises a BytesWarning when compiling a bytes instance with misplaced inline modifier. Patch by Roy Williams.

**Security**

- **bpo-29591**: Update expat copy from 2.1.1 to 2.2.0 to get fixes of CVE-2016-0718 and CVE-2016-4472. See
Library

- **bpo-24484**: Avoid race condition in multiprocessing cleanup (#2159)
- **bpo-28994**: The traceback no longer displayed for SystemExit raised in a callback registered by atexit.
- **bpo-30508**: Don't log exceptions if Task/Future “cancel()” method was called.
- **bpo-28556**: Updates to typing module: Add generic AsyncContextManager, add support for ContextManager on all versions. Original PRs by Jelle Zijlstra and Ivan Levkivskyi
- **bpo-29870**: Fix ssl sockets leaks when connection is aborted in asyncio/ssl implementation. Patch by Michaël Sghaïer.
- **bpo-29743**: Closing transport during handshake process leaks open socket. Patch by Nikolay Kim
- **bpo-30418**: On Windows, subprocess.Popen.communicate() now also ignore EINVAL on stdin.write() if the child process is still running but closed the pipe.
- **bpo-29822**: inspect.isabstract() now works during __init_subclass__. Patch by Nate Soares.
- **bpo-29581**: ABCMeta.__new__ now accepts **kwargs, allowing abstract base classes to use keyword parameters in __init_subclass__. Patch by Nate Soares.
- **bpo-30557**: faulthandler now correctly filters and displays exception codes on Windows
- **bpo-30378**: Fix the problem that logging.handlers.SysLogHandler cannot handle IPv6 addresses.
- **bpo-29960**: Preserve generator state when _random.Random.setstate() raises an exception. Patch by Bryan Olson.
- **bpo-30414**: multiprocessing.Queue._feed background running thread do not break from main loop on exception.
- **bpo-30003**: Fix handling escape characters in HZ codec. Based on patch by Ma Lin.
- **bpo-30301**: Fix AttributeError when using SimpleQueue.empty() under *spawn* and *forkserver* start methods.
- **bpo-30329**: imaplib and poplib now catch the Windows socket WSAEINVAL error (code 10022) on shutdown(SHUT_RDWR): An invalid operation was attempted. This error occurs sometimes on SSL connections.
- **bpo-30375**: Warnings emitted when compile a regular expression now always point to the line in the user code. Previously they could point into inners of the re module if emitted from inside of groups or conditionals.
- **bpo-30048**: Fixed Task.cancel() can be ignored when the task is running coroutine and the coroutine returned without any more await.
- **bpo-30266**: contextlib.AbstractContextManager now supports anti-registration by setting __enter__ = None or __exit__ = None, following the pattern introduced in bpo-25958. Patch by Jelle Zijlstra.
- **bpo-30298**: Weaken the condition of deprecation warnings for inline modifiers. Now allowed several subsequential inline modifiers at the start of the pattern (e.g. '(?i)(?s)...'). In verbose mode whitespaces and comments now are allowed before and between inline modifiers (e.g. '(?x) (?i) (?s)...').
- **bpo-29990**: Fix range checking in GB18030 decoder. Original patch by Ma Lin.
- **bpo-26293**: Change resulted because of zipfile breakage. (See also: bpo-29094)
- **bpo-30243**: Removed the __init__ methods of _json's scanner and encoder. Misusing them could cause memory leaks or crashes. Now scanner and encoder objects are completely
initialized in the __new__ methods.

- **bpo-30185**: Avoid KeyboardInterrupt tracebacks in forkserver helper process when Ctrl-C is received.
- **bpo-28556**: Various updates to typing module: add typing.NoReturn type, use WrapperDescriptorType, minor bug-fixes. Original PRs by Jim Fasarakis-Hilliard and Ivan Levkivskyi.
- **bpo-30205**: Fix getsockname() for unbound AF_UNIX sockets on Linux.
- **bpo-30070**: Fixed leaks and crashes in errors handling in the parser module.
- **bpo-30061**: Fixed crashes in IOBase methods __next__() and.readlines() when readline() or __next__() respectively return non-sizeable object. Fixed possible other errors caused by not checking results of PyObject_Size(), PySequence_Size(), or PyMapping_Size().
- **bpo-30017**: Allowed calling the close() method of the zip entry writer object multiple times. Writing to a closed writer now always produces a ValueError.
- **bpo-30068**: _io._IOBase.readlines will check if it’s closed first when hint is present.
- **bpo-29694**: Fixed race condition in pathlib mkdir with flags parents=True. Patch by Armin Rigo.
- **bpo-29692**: Fixed arbitrary unchaining of RuntimeError exceptions in contextlib.contextmanager. Patch by Siddharth Velankar.
- **bpo-29998**: Pickling and copying ImportError now preserves name and path attributes.
- **bpo-29953**: Fixed memory leaks in the replace() method of datetime and time objects when pass out of bound fold argument.
- **bpo-29942**: Fix a crash in itertools.chain.from_iterable when encountering long runs of empty iterables.
- **bpo-27863**: Fixed multiple crashes in ElementTree caused by race conditions and wrong types.
- **bpo-28699**: Fixed a bug in pools in multiprocessing.pool that raising an exception at the very first of an iterable may swallow
the exception or make the program hang. Patch by Davin Potts and Xiang Zhang.

- **bpo-25803**: Avoid incorrect errors raised by `Path.mkdir(exist_ok=True)` when the OS gives priority to errors such as EACCES over EEXIST.
- **bpo-29861**: Release references to tasks, their arguments and their results as soon as they are finished in multiprocessing.Pool.
- **bpo-29884**: `faulthandler`: Restore the old sigaltstack during teardown. Patch by Christophe Zeitouny.
- **bpo-25455**: Fixed crashes in repr of recursive buffered file-like objects.
- **bpo-29800**: Fix crashes in `partial.__repr__` if the keys of `partial.keywords` are not strings. Patch by Michael Seifert.
- **bpo-29742**: `get_extra_info()` raises exception if get called on closed ssl transport. Patch by Nikolay Kim.
- **bpo-8256**: Fixed possible failing or crashing `input()` if attributes “encoding” or “errors” of `sys.stdin` or `sys.stdout` are not set or are not strings.
- **bpo-28298**: Fix a bug that prevented array ‘Q’, ‘L’ and ‘I’ from accepting big intables (objects that have `__int__`) as elements. Patch by Oren Milman.
- **bpo-28231**: The zipfile module now accepts path-like objects for external paths.
- **bpo-26915**: `index()` and `count()` methods of `collections.abc.Sequence` now check identity before checking equality when do comparisons.
- **bpo-29615**: `SimpleXMLRPCDispatcher` no longer chains `KeyError` (or any other exception) to exception(s) raised in the dispatched methods. Patch by Petr Motejlek.
- **bpo-30177**: `path.resolve(strict=False)` no longer cuts the path after the first element not present in the filesystem. Patch by Antoine Pietri.
• **bpo-15786**: Fix several problems with IDLE’s autocompletion box. The following should now work: clicking on selection box items; using the scrollbar; selecting an item by hitting Return. Hangs on MacOSX should no longer happen. Patch by Louie Lu.

• **bpo-25514**: Add doc subsubsection about IDLE failure to start. Popup no-connection message directs users to this section.

• **bpo-30642**: Fix reference leaks in IDLE tests. Patches by Louie Lu and Terry Jan Reedy.

• **bpo-30495**: Add docstrings for textview.py and use PEP8 names. Patches by Cheryl Sabella and Terry Jan Reedy.

• **bpo-30290**: Help-about: use pep8 names and add tests. Increase coverage to 100%. Patches by Louie Lu, Cheryl Sabella, and Terry Jan Reedy.

• **bpo-30303**: Add _utest option to textview; add new tests. Increase coverage to 100%. Patches by Louie Lu and Terry Jan Reedy.

**C API**

• **bpo-27867**: Function PySlice_GetIndicesEx() no longer replaced with a macro if Py_LIMITED_API is not set.

**Build**

• **bpo-29941**: Add --with-assertions configure flag to explicitly enable C assert() checks. Defaults to off. --with-pydebug implies --with-assertions.

• **bpo-28787**: Fix out-of-tree builds of Python when configured with --with --dtrace.

• **bpo-29243**: Prevent unnecessary rebuilding of Python during make test, make install and some other make targets when configured with --enable-optimizations.

• **bpo-23404**: Don’t regenerate generated files based on file
modification time anymore: the action is now explicit. Replace
`make touch` with `make regen-all`.
- **bpo-29643**: Fix `--enable-optimization` didn’t work.

**Documentation**

- **bpo-30176**: Add missing attribute related constants in curses documentation.

- **bpo-30052**: The link targets for `bytes()` and `bytearray()` are now their respective type definitions, rather than the corresponding builtin function entries. Use `bytes` and `bytearray` to reference the latter.

  In order to ensure this and future cross-reference updates are applied automatically, the daily documentation builds now disable the default output caching features in Sphinx.

- **bpo-26985**: Add missing info of code object in inspect documentation.

**Tools/Demos**

- **bpo-29367**: `python-gdb.py` now supports also `method-wrapper` objects.

**Tests**

- **bpo-30357**: `test_thread: setUp()` now uses `support.threading_setup()` and `support.threading_cleanup()` to wait until threads complete to avoid random side effects on following tests. Initial patch written by Grzegorz Grzywacz.
- **bpo-30197**: Enhanced functions `swap_attr()` and `swap_item()` in the `test.support` module. They now work when delete replaced attribute or item inside the `with` statement. The old value of the attribute or item (or `None` if it doesn’t exist) now will be assigned to the target of the “as” clause, if there is one.

**Windows**

- **bpo-30687**: Locate `msbuild.exe` on Windows when building rather than `vcvarsall.bat`
- **bpo-30450**: The build process on Windows no longer depends on Subversion, instead pulling external code from GitHub via a Python script. If Python 3.6 is not found on the system (via `py -3.6`), NuGet is used to download a copy of 32-bit Python.
Python 3.6.1 final?

Release date: 2017-03-21

Core and Builtins

- **bpo-29723**: The `sys.path[0]` initialization change for bpo-29139 caused a regression by revealing an inconsistency in how `sys.path` is initialized when executing `__main__` from a zipfile, directory, or other import location. The interpreter now consistently avoids ever adding the import location’s parent directory to `sys.path`, and ensures no other `sys.path` entries are inadvertently modified when inserting the import location named on the command line.

Build

- **bpo-27593**: fix format of git information used in `sys.version`
- Fix incompatible comment in `python.h`
Python 3.6.1 release candidate 1?

Release date: 2017-03-04

Core and Builtins

- **bpo-28893**: Set correct `__cause__` for errors about invalid awaitables returned from `__aiter__` and `__anext__`.
- **bpo-29683**: Fixes to memory allocation in `_PyCode_SetExtra`. Patch by Brian Coleman.
- **bpo-29684**: Fix minor regression of `PyEval_CallObjectWithKeywords`. It should raise `TypeError` when `kwargs` is not a dict. But it might cause segv when `args=NULL` and `kwargs` is not a dict.
- **bpo-28598**: Support `__rmod__` for subclasses of `str` being called before `str.__mod__`. Patch by Martijn Pieters.
- **bpo-29607**: Fix stack_effect computation for `CALL_FUNCTION_EX`. Patch by Matthieu Dartailh.
- **bpo-29602**: Fix incorrect handling of signed zeros in complex constructor for complex subclasses and for inputs having a `__complex__` method. Patch by Serhiy Storchaka.
- **bpo-29347**: Fixed possibly dereferencing undefined pointers when creating weakref objects.
- **bpo-29438**: Fixed use-after-free problem in key sharing dict.
- **bpo-29319**: Prevent `RunMainFromImporter` overwriting `sys.path[0]`.
- **bpo-29337**: Fixed possible BytesWarning when compare the code objects. Warnings could be emitted at compile time.
- **bpo-29327**: Fixed a crash when pass the iterable keyword argument to `sorted()`.
- **bpo-29034**: Fix memory leak and use-after-free in os module (path_converter).
- **bpo-29159**: Fix regression in `bytes(x)` when `x.__index__() raises`
Exception.

- **bpo-28932**: Do not include `<sys/random.h>` if it does not exist.
- **bpo-25677**: Correct the positioning of the syntax error caret for indented blocks. Based on patch by Michael Layzell.
- **bpo-29000**: Fixed bytes formatting of octals with zero padding in alternate form.
- **bpo-26919**: On Android, operating system data is now always encoded/decoded to/from UTF-8, instead of the locale encoding to avoid inconsistencies with `os.fsencode()` and `os.fsdecode()` which are already using UTF-8.
- **bpo-28991**: `functools.lru_cache()` was susceptible to an obscure reentrancy bug triggerable by a monkey-patched `len()` function.
- **bpo-28739**: f-string expressions are no longer accepted as docstrings and by `ast.literal_eval()` even if they do not include expressions.
- **bpo-28512**: Fixed setting the offset attribute of `SyntaxError` by `PyErr_SyntaxLocationEx()` and `PyErr_SyntaxLocationObject()`.
- **bpo-28918**: Fix the cross compilation of `xxlimited` when Python has been built with `Py_DEBUG` defined.
- **bpo-28731**: Optimize `_PyDict_NewPresized()` to create correct size dict. Improve speed of dict literal with constant keys up to 30%.

Library

- **bpo-29169**: Update zlib to 1.2.11.
- **bpo-29623**: Allow use of path-like object as a single argument in `ConfigParser.read()`. Patch by David Ellis.
- **bpo-28963**: Fix out of bound iteration in `asyncio.Future.remove_done_callback` implemented in C.
- **bpo-29704**: `asyncio.subprocess.SubprocessStreamProtocol` no longer closes before all pipes are closed.
- **bpo-29271**: Fix `Task.current_task` and `Task.all_tasks` implemented in C to accept None argument as their pure Python
- **bpo-29703**: Fix asyncio to support instantiation of new event loops in child processes.
- **bpo-29376**: Fix assertion error in threading._DummyThread.is_alive().
- **bpo-28624**: Add a test that checks that cwd parameter of Popen() accepts PathLike objects. Patch by Sayan Chowdhury.
- **bpo-28518**: Start a transaction implicitly before a DML statement. Patch by Aviv Palivoda.
- **bpo-29532**: Altering a kwarg dictionary passed to functools.partial() no longer affects a partial object after creation.
- **bpo-29110**: Fix file object leak in aifc.open() when file is given as a filesystem path and is not in valid AIFF format. Patch by Anthony Zhang.
- **bpo-28556**: Various updates to typing module: typing.Counter, typing.ChainMap, improved ABC caching, etc. Original PRs by Jelle Zijlstra, Ivan Levkivskyi, Manuel Krebber, and Łukasz Langa.
- **bpo-29100**: Fix datetime.fromtimestamp() regression introduced in Python 3.6.0: check minimum and maximum years.
- **bpo-29519**: Fix weakref spewing exceptions during interpreter shutdown when used with a rare combination of multiprocessing and custom codecs.
- **bpo-29416**: Prevent infinite loop in pathlib.Path.mkdir
- **bpo-29444**: Fixed out-of-bounds buffer access in the group() method of the match object. Based on patch by WGH.
- **bpo-29335**: Fix subprocess.Popen.wait() when the child process has exited to a stopped instead of terminated state (ex: when under ptrace).
- **bpo-29290**: Fix a regression in argparse that help messages would wrap at non-breaking spaces.
- **bpo-28735**: Fixed the comparison of mock.MagickMock with mock.ANY.
- **bpo-29316**: Restore the provisional status of typing module, add corresponding note to documentation. Patch by Ivan L.
- **bpo-29219**: Fixed infinite recursion in the repr of uninitialized ctypes.CDLL instances.
- **bpo-29011**: Fix an important omission by adding Deque to the typing module.
- **bpo-28969**: Fixed race condition in C implementation of functools.lru_cache. KeyErrors could be raised when cached function with full cache was simultaneously called from different threads with the same uncached arguments.
- **bpo-29142**: In urllib.request, suffixes in no_proxy environment variable with leading dots could match related hostnames again (e.g. `.b.c` matches `a.b.c`). Patch by Milan Oberkirch.
- **bpo-28961**: Fix unittest.mock._Call helper: don’t ignore the name parameter anymore. Patch written by Jiajun Huang.
- **bpo-29203**: functools.lru_cache() now respects PEP 468 and preserves the order of keyword arguments. `f(a=1, b=2)` is now cached separately from `f(b=2, a=1)` since both calls could potentially give different results.
- **bpo-15812**: inspect.getframeinfo() now correctly shows the first line of a context. Patch by Sam Breese.
- **bpo-29094**: Offsets in a ZIP file created with extern file object and modes “w” and “x” now are relative to the start of the file.
- **bpo-29085**: Allow random.Random.seed() to use high quality OS randomness rather than the pid and time.
- **bpo-29061**: Fixed bug in secrets.randbelow() which would hang when given a negative input. Patch by Brendan Donegan.
- **bpo-29079**: Prevent infinite loop in pathlib.resolve() on Windows
- **bpo-13051**: Fixed recursion errors in large or resized curses.textpad.Textbox. Based on patch by Tycho Andersen.
- **bpo-9770**: curses.ascii predicates now work correctly with negative integers.
- **bpo-28427**: old keys should not remove new values from
WeakValueDictionary when collecting from another thread.

- **bpo-28923**: Remove editor artifacts from Tix.py.
- **bpo-29055**: Neaten-up empty population error on random.choice() by suppressing the upstream exception.
- **bpo-28871**: Fixed a crash when deallocate deep ElementTree.
- **bpo-19542**: Fix bugs in WeakValueDictionary.setdefault() and WeakValueDictionary.pop() when a GC collection happens in another thread.
- **bpo-20191**: Fixed a crash in resource.prlimit() when passing a sequence that doesn't own its elements as limits.
- **bpo-28779**: multiprocessing.set_forkserver_preload() would crash the forkserver process if a preloaded module instantiated some multiprocessing objects such as locks.
- **bpo-28847**: dbm.dumb now supports reading read-only files and no longer writes the index file when it is not changed.
- **bpo-26937**: The chown() method of the tarfile.TarFile class does not fail now when the grp module cannot be imported, as for example on Android platforms.

**IDLE**

- **bpo-29071**: IDLE colors f-string prefixes (but not invalid ur prefixes).
- **bpo-28572**: Add 10% to coverage of IDLE's test_configdialog. Update and augment description of the configuration system.

**Windows**

- **bpo-29579**: Removes readme.txt from the installer
- **bpo-29326**: Ignores blank lines in .pth files (Patch by Alexey Izbieshev)
- **bpo-28164**: Correctly handle special console filenames (patch by Eryk Sun)
• **bpo-29409**: Implement PEP 529 for io.FileIO (Patch by Eryk Sun)
• **bpo-29392**: Prevent crash when passing invalid arguments into msvcrtn module.
• **bpo-25778**: winreg does not truncate string correctly (Patch by Eryk Sun)
• **bpo-28896**: Deprecate WindowsRegistryFinder and disable it by default.

**C API**

• **bpo-27867**: Function PySlice_GetIndicesEx() is replaced with a macro if Py_LIMITED_API is not set or set to the value between 0x03050400 and 0x03060000 (not including) or 0x03060100 or higher.
• **bpo-29083**: Fixed the declaration of some public API functions. PyArg_VaParse() and PyArg_VaParseTupleAndKeywords() were not available in limited API. PyArg_ParseTupleAndKeywords(), PyArg_GetKeywords(), PyArg_GetKeywordsAndVersion(), PyArg_GetKeywordsAndVersionAndObject(), PyArg_GetKeywordsAndVersionAndObjectAndKeywords(), PyArg_GetKeywordsAndVersionAndObjectAndKeywordsAndVersion(), PyArg_GetKeywordsAndVersionAndObjectAndKeywordsAndVersionAndObject(), and PyArg_GetKeywordsAndVersionAndObjectAndKeywordsAndVersionAndObjectAndKeywordsAndVersionAndObject() were not available in limited API of version < 3.3 when PY_SSIZET_CLEAN is defined.
• **bpo-29058**: All stable API extensions added after Python 3.2 are now available only when Py_LIMITED_API is set to the PY_VERSION_HEX value of the minimum Python version supporting this API.

**Documentation**

• **bpo-28929**: Link the documentation to its source file on GitHub.
• **bpo-25008**: Document smtpd.py as effectively deprecated and add a pointer to aiosmtpd, a third-party asyncio-based replacement.
• **bpo-26355**: Add canonical header link on each page to corresponding major version of the documentation. Patch by
Matthias Bussonnier.

- **bpo-29349**: Fix Python 2 syntax in code for building the documentation.

**Tests**

- **bpo-28087**: Skip test_asyncore and test_eintr poll failures on macOS. Skip some tests of select.poll when running on macOS due to unresolved issues with the underlying system poll function on some macOS versions.
- **bpo-29571**: to match the behaviour of the `re.LOCALE` flag, `test_re.test_locale_flag` now uses `locale.getpreferredencoding(False)` to determine the candidate encoding for the test regex (allowing it to correctly skip the test when the default locale encoding is a multi-byte encoding)
- **bpo-28950**: Disallow `-j0` to be combined with `-T/-I` in regtrtest command line arguments.
- **bpo-28683**: Fix the tests that bind() a unix socket and raise PermissionError on Android for a non-root user.
- **bpo-26939**: Add the `support.setswitchinterval()` function to fix test_functools hanging on the Android armv7 qemu emulator.

**Build**

- **bpo-27593**: `sys.version` and the platform module `python_build()`, `python_branch()`, and `python_revision()` functions now use git information rather than hg when building from a repo.
- **bpo-29572**: Update Windows build and OS X installers to use OpenSSL 1.0.2k.
- **bpo-26851**: Set Android compilation and link flags.
- **bpo-28768**: Fix implicit declaration of function `_setmode`. Patch by Masayuki Yamamoto
- **bpo-29080**: Removes hard dependency on `hg.exe` from...
PCBuild/build.bat

- **bpo-23903**: Added missed names to PC/python3.def.
- **bpo-28762**: `lockf()` is available on Android API level 24, but the F_LOCK macro is not defined in android-ndk-r13.
- **bpo-28538**: Fix the compilation error that occurs because `if_nameindex()` is available on Android API level 24, but the `if_nameindex` structure is not defined.
- **bpo-20211**: Do not add the directory for installing C header files and the directory for installing object code libraries to the cross compilation search paths. Original patch by Thomas Petazzoni.
- **bpo-28849**: Do not define `sys.implementation._multiarch` on Android.
Python 3.6.0 final?

Release date: 2016-12-23

No changes since release candidate 2
Python 3.6.0 release candidate 2?

Release date: 2016-12-16

Core and Builtins

- **bpo-28147**: Fix a memory leak in split-table dictionaries: setattr() must not convert combined table into split table. Patch written by INADA Naoki.
- **bpo-28990**: Fix asyncio SSL hanging if connection is closed before handshake is completed. (Patch by HoHo-Ho)

Tools/Demos

- **bpo-28770**: Fix python-gdb.py for fastcalls.

Windows

- **bpo-28896**: Deprecate WindowsRegistryFinder.

Build

- **bpo-28898**: Prevent gdb build errors due to HAVE_LONG_LONG redefinition.
Python 3.6.0 release candidate 1?

Release date: 2016-12-06

Core and Builtins

- **bpo-23722**: Rather than silently producing a class that doesn't support zero-argument `super()` in methods, failing to pass the new `__classcell__` namespace entry up to `type.__new__` now results in a `DeprecationWarning` and a class that supports zero-argument `super()`.
- **bpo-28797**: Modifying the class `__dict__` inside the `__set_name__` method of a descriptor that is used inside that class no longer prevents calling the `__set_name__` method of other descriptors.
- **bpo-28782**: Fix a bug in the implementation `yield from` when checking if the next instruction is `YIELD_FROM`. Regression introduced by WORDCODE (bpo-26647).

Library

- **bpo-27030**: Unknown escapes in `re.sub()` replacement template are allowed again. But they still are deprecated and will be disabled in 3.7.
- **bpo-28835**: Fix a regression introduced in `warnings.catch_warnings(): call warnings.showwarning()` if it was overridden inside the context manager.
- **bpo-27172**: To assist with upgrades from 2.7, the previously documented deprecation of `inspect.getfullargspec()` has been reversed. This decision may be revisited again after the Python 2.7 branch is no longer officially supported.
- **bpo-26273**: Add new `socket.TCP_CONGESTION` (Linux 2.6.13)
and socket.TCP_USER_TIMEOUT (Linux 2.6.37) constants. Patch written by Omar Sandoval.

- **bpo-24142**: Reading a corrupt config file left configparser in an invalid state. Original patch by Florian Höch.
- **bpo-28843**: Fix asyncio C Task to handle exceptions __traceback__.

**C API**

- **bpo-28808**: PyUnicode_CompareWithASCIIString() now never raises exceptions.

**Documentation**

- **bpo-23722**: The data model reference and the porting section in the What’s New guide now cover the additional __classcell__ handling needed for custom metaclasses to fully support PEP 487 and zero-argument super().

**Tools/Demos**

- **bpo-28023**: Fix python-gdb.py didn’t support new dict implementation.
Python 3.6.0 beta 4?

Release date: 2016-11-21

Core and Builtins

- **bpo-28532**: Show sys.version when -V option is supplied twice.
- **bpo-27100**: The with-statement now checks for __enter__ before it checks for __exit__. This gives less confusing error messages when both methods are missing. Patch by Jonathan Ellington.
- **bpo-28746**: Fix the set_inheritable() file descriptor method on platforms that do not have the ioctl FIOCLEX and FIONCLEX commands.
- **bpo-26920**: Fix not getting the locale’s charset upon initializing the interpreter, on platforms that do not have langinfo.
- **bpo-28648**: Fixed crash in Py_DecodeLocale() in debug build on Mac OS X when decode astral characters. Patch by Xiang Zhang.
- **bpo-19398**: Extra slash no longer added to sys.path components in case of empty compile-time PYTHONPATH components.
- **bpo-28665**: Improve speed of the STORE_DEREF opcode by 40%.
- **bpo-28583**: PyDict_SetDefault didn’t combine split table when needed. Patch by Xiang Zhang.
- **bpo-27243**: Change PendingDeprecationWarning -> DeprecationWarning. As it was agreed in the issue, __aiter__ returning an awaitable should result in PendingDeprecationWarning in 3.5 and in DeprecationWarning in 3.6.
- **bpo-26182**: Fix a refleak in code that raises DeprecationWarning.
- **bpo-28721**: Fix asynchronous generators aclose() and athrow() to handle StopAsyncIteration propagation properly.
• **bpo-28752**: Restored the `__reduce__()` methods of datetime objects.

• **bpo-28727**: Regular expression patterns, `_sre.SRE_Pattern` objects created by `re.compile()`, become comparable (only `x==y` and `x!=y` operators). This change should fix the **bpo-18383**: don’t duplicate warning filters when the warnings module is reloaded (thing usually only done in unit tests).

• **bpo-20572**: The `subprocess.Popen.wait` method’s undocumented `endtime` parameter now raises a `DeprecationWarning`.

• **bpo-25659**: In `ctypes`, prevent a crash calling the `from_buffer()` and `from_buffer_copy()` methods on abstract classes like `Array`.

• **bpo-19717**: Makes `Path.resolve()` succeed on paths that do not exist. Patch by Vajrasky Kok

• **bpo-28563**: Fixed possible DoS and arbitrary code execution when handle plural form selections in the `gettext` module. The expression parser now supports exact syntax supported by GNU `gettext`.

• **bpo-28387**: Fixed possible crash in `_io.TextIOWrapper` deallocator when the garbage collector is invoked in other thread. Based on patch by Sebastian Cufre.

• **bpo-28600**: Optimize `loop.call_soon`.

• **bpo-28613**: Fix `get_event_loop()` return the current loop if called from coroutines/callbacks.

• **bpo-28634**: Fix `asyncio.isfuture()` to support `unittest.Mock`.

• **bpo-26081**: Fix refleak in `_asyncio.Future.__iter__().throw`.

• **bpo-28639**: Fix `inspect.isawaitable` to always return bool Patch by Justin Mayfield.

• **bpo-28652**: Make loop methods reject socket kinds they do not support.

• **bpo-28653**: Fix a refleak in `functools.lru_cache`.

• **bpo-28703**: Fix `asyncio.iscoroutinefunction` to handle `Mock`
objects.

- **bpo-28704**: Fix `create_unix_server` to support Path-like objects (PEP 519).
- **bpo-28720**: Add `collections.abc.AsyncGenerator`.

### Documentation

- **bpo-28513**: Documented command-line interface of `zipfile`.

### Tests

- **bpo-28666**: Now `test.support.rmtree` is able to remove unwritable or unreadable directories.
- **bpo-23839**: Various caches now are cleared before running every test file.

### Build

- **bpo-10656**: Fix out-of-tree building on AIX. Patch by Tristan Carel and Michael Haubenwallner.
- **bpo-26359**: Rename `–with-optimiations` to `–enable-optimizations`.
- **bpo-28676**: Prevent missing ‘getentropy’ declaration warning on macOS. Patch by Gareth Rees.
Python 3.6.0 beta 3?

Release date: 2016-10-31

Core and Builtins

- **bpo-28128**: Deprecation warning for invalid str and byte escape sequences now prints better information about where the error occurs. Patch by Serhiy Storchaka and Eric Smith.
- **bpo-28509**: dict.update() no longer allocate unnecessary large memory.
- **bpo-28426**: Fixed potential crash in PyUnicode_AsDecodedObject() in debug build.
- **bpo-28517**: Fixed of-by-one error in the peephole optimizer that caused keeping unreachable code.
- **bpo-28214**: Improved exception reporting for problematic __set_name__ attributes.
- **bpo-23782**: Fixed possible memory leak in _PyTraceback_Add() and exception loss in PyTraceBack_Here().
- **bpo-28471**: Fix “Python memory allocator called without holding the GIL” crash in socket.setblocking.

Library

- **bpo-27517**: LZMA compressor and decompressor no longer raise exceptions if given empty data twice. Patch by Benjamin Fogle.
- **bpo-28549**: Fixed segfault in curses’s addch() with ncurses6.
- **bpo-28449**: tarfile.open() with mode “r” or “r:” now tries to open a tar file with compression before trying to open it without compression. Otherwise it had 50% chance failed with ignore_zeros=True.
- **bpo-23262**: The webbrowser module now supports Firefox 36+
and derived browsers. Based on patch by Oleg Broytman.

- **bpo-27939**: Fixed bugs in tkinter.ttk.LabeledScale and tkinter.Scale caused by representing the scale as float value internally in Tk. tkinter.IntVar now works if float value is set to underlying Tk variable.

- **bpo-18844**: The various ways of specifying weights for random.choices() now produce the same result sequences.

- **bpo-28255**: calendar.TextCalendar().prmonth() no longer prints a space at the start of new line after printing a month’s calendar. Patch by Xiang Zhang.

- **bpo-20491**: The various ways of specifying weights for random.choices() now produce the same result sequences.

- **bpo-28353**: os.fwalk() no longer fails on broken links.

- **bpo-28430**: Fix iterator of C implemented asyncio.Future doesn’t accept non-None value is passed to it.send(val).

- **bpo-27025**: Generated names for Tkinter widgets now start by the “!” prefix for readability.

- **bpo-25464**: Fixed HList.header_exists() in tkinter.tix module by addin a workaround to Tix library bug.

- **bpo-28488**: shutil.make_archive() no longer adds entry “./” to ZIP archive.

- **bpo-25953**: re.sub() now raises an error for invalid numerical group reference in replacement template even if the pattern is not found in the string. Error message for invalid group reference now includes the group index and the position of the reference. Based on patch by SilentGhost.

- **bpo-18219**: Optimize csv.DictWriter for large number of columns. Patch by Mariatta Wijaya.

- **bpo-28448**: Fix C implemented asyncio.Future didn’t work on Windows.

- **bpo-28480**: Fix error building socket module when multithreading is disabled.

- **bpo-24452**: Make webbrowser support Chrome on Mac OS X.

- **bpo-20766**: Fix references leaked by pdb in the handling of
SIGINT handlers.

- **bpo-28492**: Fix how StopIteration exception is raised in `_asyncio.Future`.
- **bpo-28500**: Fix asyncio to handle async gens GC from another thread.
- **bpo-26923**: Fix asyncio.Gather to refuse being cancelled once all children are done. Patch by Johannes Ebke.
- **bpo-26796**: Don’t configure the number of workers for default threadpool executor. Initial patch by Hans Lawrenz.
- **bpo-28544**: Implement asyncio.Task in C.

Windows

- **bpo-28522**: Fixes mishandled buffer reallocation in getpathp.c

Build

- **bpo-28444**: Fix missing extensions modules when cross compiling.
- **bpo-28208**: Update Windows build and OS X installers to use SQLite 3.14.2.
- **bpo-28248**: Update Windows build and OS X installers to use OpenSSL 1.0.2j.

Tests

- **bpo-26944**: Fix test_posix for Android where ‘id -G’ is entirely wrong or missing the effective gid.
- **bpo-28409**: regrtstest: fix the parser of command line arguments.
Python 3.6.0 beta 2?

Release date: 2016-10-10

Core and Builtin

- **bpo-28183**: Optimize and cleanup dict iteration.
- **bpo-26081**: Added C implementation of asyncio.Future. Original patch by Yury Selivanov.
- **bpo-28379**: Added sanity checks and tests for PyUnicode_CopyCharacters(). Patch by Xiang Zhang.
- **bpo-28376**: The type of long range iterator is now registered as Iterator. Patch by Oren Milman.
- **bpo-28376**: Creating instances of range_iterator by calling range_iterator type now is deprecated. Patch by Oren Milman.
- **bpo-28376**: The constructor of range_iterator now checks that step is not 0. Patch by Oren Milman.
- **bpo-26906**: Resolving special methods of uninitialized type now causes implicit initialization of the type instead of a fail.
- **bpo-18287**: PyTypeReady() now checks that tp_name is not NULL. Original patch by Niklas Koep.
- **bpo-24098**: Fixed possible crash when AST is changed in process of compiling it.
- **bpo-28201**: Dict reduces possibility of 2nd conflict in hash table when hashes have same lower bits.
- **bpo-28350**: String constants with null character no longer interned.
- **bpo-26617**: Fix crash when GC runs during weakref callbacks.
- **bpo-27942**: String constants now interned recursively in tuples and frozensets.
- **bpo-21578**: Fixed misleading error message when ImportError called with invalid keyword args.
- **bpo-28203**: Fix incorrect type in complex(1.0, {2:3}) error...
message. Patch by Soumya Sharma.

- **bpo-28086**: Single var-positional argument of tuple subtype was passed unscathed to the C-defined function. Now it is converted to exact tuple.

- **bpo-28214**: Now __set_name__ is looked up on the class instead of the instance.

- **bpo-27955**: Fallback on reading /dev/urandom device when the getrandom() syscall fails with EPERM, for example when blocked by SECCOMP.

- **bpo-28192**: Don't import readline in isolated mode.

- Upgrade internal unicode databases to Unicode version 9.0.0.

- **bpo-28131**: Fix a regression in zipimport's compile_source(). zipimport should use the same optimization level as the interpreter.

- **bpo-28126**: Replace Py_MEMCPY with memcpy(). Visual Studio can properly optimize memcpy().

- **bpo-28120**: Fix dict.pop() for splitted dictionary when trying to remove a “pending key” (Not yet inserted in split-table). Patch by Xiang Zhang.

- **bpo-26182**: Raise DeprecationWarning when async and await keywords are used as variable/attribute/class/function name.

**Library**

- **bpo-27998**: Fixed bytes path support in os.scandir() on Windows. Patch by Eryk Sun.

- **bpo-28317**: The disassembler now decodes FORMAT_VALUE argument.

- **bpo-26293**: Fixed writing ZIP files that starts not from the start of the file. Offsets in ZIP file now are relative to the start of the archive in conforming to the specification.
• **bpo-28380**: unittest.mock Mock autospec functions now properly support assert_called, assert_not_called, and assert_called_once.

• **bpo-27181**: remove statistics.geometric_mean and defer until 3.7.

• **bpo-28229**: Izma module now supports pathlib.

• **bpo-28321**: Fixed writing non-BMP characters with binary format in plistlib.

• **bpo-28225**: bz2 module now supports pathlib. Initial patch by Ethan Furman.

• **bpo-28227**: gzip now supports pathlib. Patch by Ethan Furman.

• **bpo-27358**: Optimized merging var-keyword arguments and improved error message when passing a non-mapping as a var-keyword argument.

• **bpo-28257**: Improved error message when passing a non-iterable as a var-positional argument. Added opcode BUILD_TUPLE_UNPACK_WITH_CALL.

• **bpo-28322**: Fixed possible crashes when unpickle itertools objects from incorrect pickle data. Based on patch by John Leitch.

• **bpo-28228**: imghdr now supports pathlib.

• **bpo-28226**: compileall now supports pathlib.

• **bpo-28314**: Fix function declaration (C flags) for the getiterator() method of xml.etree.ElementTree.Element.

• **bpo-28148**: Stop using localtime() and gmtime() in the time module.
Introduced platform independent `_PyTime_localtime` API that is similar to POSIX `localtime_r`, but available on all platforms. Patch by Ed Schouten.

- **bpo-28253**: Fixed calendar functions for extreme months: 0001-01 and 9999-12.

  Methods `itermonthdays()` and `itermonthdays2()` are reimplemented so that they don’t call `itermonthdates()` which can cause `datetime.date` under/overflow.

- **bpo-28275**: Fixed possible use after free in the `decompress()` methods of the LZMA Decompressor and BZ2 Decompressor classes. Original patch by John Leitch.

- **bpo-27897**: Fixed possible crash in `sqlite3.Connection.create_collation()` if pass invalid string-like object as a name. Patch by Xiang Zhang.

- **bpo-18844**: `random.choices()` now has `k` as a keyword-only argument to improve the readability of common cases and come into line with the signature used in other languages.

- **bpo-18893**: Fix invalid exception handling in `Lib/ctypes/macholib/dyld.py`. Patch by Madison May.

- **bpo-27611**: Fixed support of default root window in the `tkinter.tix` module. Added the `master` parameter in the `DisplayStyle` constructor.

- **bpo-27348**: In the traceback module, restore the formatting of exception messages like “Exception: None”. This fixes a regression introduced in 3.5a2.
• **bpo-25651**: Allow falsy values to be used for msg parameter of subTest().

• **bpo-27778**: Fix a memory leak in os.getrandom() when the getrandom() is interrupted by a signal and a signal handler raises a Python exception.

• **bpo-28200**: Fix memory leak on Windows in the os module (fix path_converter() function).

• **bpo-25400**: RobotFileParser now correctly returns default values for crawl_delay and request_rate. Initial patch by Peter Wirtz.

• **bpo-27932**: Prevent memory leak in win32_ver().

• Fix UnboundLocalError in socket._sendfile_use_sendfile.

• **bpo-28075**: Check for ERROR_ACCESS_DENIED in Windows implementation of os.stat(). Patch by Eryk Sun.

• **bpo-22493**: Warning message emitted by using inline flags in the middle of regular expression now contains a (truncated) regex pattern. Patch by Tim Graham.

• **bpo-25270**: Prevent codecs.escape_encode() from raising SystemError when an empty bytestring is passed.

• **bpo-28181**: Get antigravity over HTTPS. Patch by Kaartic Sivaraam.

• **bpo-25895**: Enable WebSocket URL schemes in urllib.parse.urljoin. Patch by Gergely Imreh and Markus Holtermann.

• **bpo-28114**: Fix a crash in parse_envlist() when env contains byte
strings. Patch by Eryk Sun.

- **bpo-27599**: Fixed buffer overrun in binascii.b2a_qp() and binascii.a2b_qp().

- **bpo-27906**: Fix socket accept exhaustion during high TCP traffic. Patch by Kevin Conway.

- **bpo-28174**: Handle when SO_REUSEPORT isn't properly supported. Patch by Seth Michael Larson.

- **bpo-26654**: Inspect functools.partial in asyncio.Handle.__repr__. Patch by iceboy.

- **bpo-26909**: Fix slow pipes IO in asyncio. Patch by INADA Naoki.

- **bpo-28176**: Fix callbacks race in asyncio.SelectorLoop.sock_connect.

- **bpo-27759**: Fix selectors incorrectly retain invalid file descriptors. Patch by Mark Williams.

- **bpo-28368**: Refuse monitoring processes if the child watcher has no loop attached. Patch by Vincent Michel.

- **bpo-28369**: Raise RuntimeError when transport’s FD is used with add_reader, add_writer, etc.

- **bpo-28371**: Deprecate passing asyncio.Handles to run_in_executor.

- **bpo-28372**: Fix asyncio to support formatting of non-python
coroutines.

- **bpo-28399**: Remove UNIX socket from FS before binding. Patch by Коренберг Марк.

- **bpo-27972**: Prohibit Tasks to await on themselves.

## Windows

- **bpo-28402**: Adds signed catalog files for stdlib on Windows.
- **bpo-28333**: Enables Unicode for ps1/ps2 and input() prompts. (Patch by Eryk Sun)
- **bpo-28251**: Improvements to help manuals on Windows.
- **bpo-28110**: launcher.msi has different product codes between 32-bit and 64-bit
- **bpo-28161**: Opening CON for write access fails
- **bpo-28162**: WindowsConsoleIO readall() fails if first line starts with Ctrl+Z
- **bpo-28163**: WindowsConsoleIO fileno() passes wrong flags to _open_osfhandle
- **bpo-28164**: _PyIO_get_console_type fails for various paths
- **bpo-28137**: Renames Windows path file to .pth
- **bpo-28138**: Windows .pth file should allow import site

## C API

- **bpo-28426**: Deprecated undocumented functions
  PyUnicode_AsEncodedObject(), PyUnicode_AsDecodedObject(), PyUnicode_AsDecodedUnicode() and PyUnicode_AsEncodedUnicode().

## Build
- **bpo-28258**: Fixed build with Estonian locale (python-config and distclean targets in Makefile). Patch by Arfrever Frehtes Taifersar Arahesis.
- **bpo-26661**: setup.py now detects system libffi with multiarch wrapper.
- **bpo-15819**: Remove redundant include search directory option for building outside the source tree.

**Tests**

- **bpo-28217**: Adds _testconsole module to test console input.
Python 3.6.0 beta 1?

Release date: 2016-09-12

Core and Builtins

- **bpo-23722**: The `__class__` cell used by zero-argument `super()` is now initialized from `type.__new__` rather than `__build_class__`, so class methods relying on that will now work correctly when called from metaclass methods during class creation. Patch by Martin Teichmann.
- **bpo-25221**: Fix corrupted result from `PyLong_FromLong(0)` when Python is compiled with `NSMALLPOSINTS = 0`.
- **bpo-27080**: Implement formatting support for PEP 515. Initial patch by Chris Angelico.
- **bpo-27199**: In `tarfile`, expose `copyfileobj` bufsize to improve throughput. Patch by Jason Fried.
- **bpo-27948**: In f-strings, only allow backslashes inside the braces (where the expressions are). This is a breaking change from the 3.6 alpha releases, where backslashes are allowed anywhere in an f-string. Also, require that expressions inside f-strings be enclosed within literal braces, and not escapes like `f'\x7bh1''\x7d'`.
- **bpo-28046**: Remove platform-specific directories from `sys.path`.
- **bpo-28071**: Add early-out for differencing from an empty set.
- **bpo-25758**: Prevents zipimport from unnecessarily encoding a filename (patch by Eryk Sun)
- **bpo-25856**: The `__module__` attribute of extension classes and functions now is interned. This leads to more compact pickle data with protocol 4.
- **bpo-27213**: Rework `CALL_FUNCTION*` opcodes to produce shorter and more efficient bytecode. Patch by Demur Rumel,
design by Serhiy Storchaka, reviewed by Serhiy Storchaka and Victor Stinner.

- **bpo-26331**: Implement tokenizing support for PEP 515. Patch by Georg Brandl.
- **bpo-27999**: Make “global after use” a SyntaxError, and ditto for nonlocal. Patch by Ivan Levkovskyi.
- **bpo-28003**: Implement PEP 525 – Asynchronous Generators.
- **bpo-26058**: Add a new private version to the built-in dict type, incremented at each dictionary creation and at each dictionary change. Implementation of the PEP 509.
- **bpo-27364**: A backslash-character pair that is not a valid escape sequence now generates a DeprecationWarning. Patch by Emanuel Barry.
- **bpo-27350**: `dict` implementation is changed like PyPy. It is more compact and preserves insertion order. (Concept developed by Raymond Hettinger and patch by Inada Naoki.)
- **bpo-27911**: Remove unnecessary error checks in `exec_builtin_or_dynamic()`.
- **bpo-27078**: Added `BUILD_STRING` opcode. Optimized f-strings evaluation.
- **bpo-17884**: Python now requires systems with `inttypes.h` and `stdint.h`
- **bpo-27961**: Require platforms to support `long long`. Python hasn't compiled without `long long` for years, so this is basically a formality.
- **bpo-27355**: Removed support for Windows CE. It was never finished, and Windows CE is no longer a relevant platform for Python.
- **bpo-27870**: A left shift of zero by a large integer no longer attempts to allocate large amounts of memory.
- **bpo-25402**: In int-to-decimal-string conversion, improve the
estimate of the intermediate memory required, and remove an unnecessarily strict overflow check. Patch by Serhiy Storchaka.

- **bpo-27214**: In long_invert, be more careful about modifying object returned by long_add, and remove an unnecessary check for small longs. Thanks Oren Milman for analysis and patch.

- **bpo-27506**: Support passing the bytes/bytearray.translate() “delete” argument by keyword.

- **bpo-27812**: Properly clear out a generator’s frame’s backreference to the generator to prevent crashes in frame.clear().

- **bpo-27811**: Fix a crash when a coroutine that has not been awaited is finalized with warnings-as-errors enabled.

- **bpo-27587**: Fix another issue found by PVS-Studio: Null pointer check after use of ‘def’ in _PyState_AddModule(). Initial patch by Christian Heimes.

- **bpo-27792**: The modulo operation applied to bool and other int subclasses now always returns an int. Previously the return type depended on the input values. Patch by Xiang Zhang.

- **bpo-26984**: int() now always returns an instance of exact int.

- **bpo-25604**: Fix a minor bug in integer true division; this bug could potentially have caused off-by-one-ulp results on platforms with unreliable ldexp implementations.

- **bpo-24254**: Make class definition namespace ordered by default.

- **bpo-27662**: Fix an overflow check in List_New: the original code was checking against Py_SIZE_MAX instead of the correct upper bound of Py_SSIZE_T_MAX. Patch by Xiang Zhang.

- **bpo-27782**: Multi-phase extension module import now correctly allows the _methods field to be used to add module level functions to instances of non-module types returned from Py_create_mod. Patch by Xiang Zhang.

- **bpo-27936**: The round() function accepted a second None argument for some types but not for others. Fixed the inconsistency by accepting None for all numeric types.

- **bpo-27487**: Warn if a submodule argument to “python -m” or
runpy.run_module() is found in sys.modules after parent packages are imported, but before the submodule is executed.

- **bpo-27157**: Make only type() itself accept the one-argument form. Patch by Eryk Sun and Emanuel Barry.
- **bpo-27558**: Fix a SystemError in the implementation of “raise” statement. In a brand new thread, raise a RuntimeError since there is no active exception to reraise. Patch written by Xiang Zhang.
- **bpo-28008**: Implement PEP 530 – asynchronous comprehensions.
- **bpo-27942**: Fix memory leak in codeobject.c

**Library**

- **bpo-28732**: Fix crash in os.spawnv() with no elements in args
- **bpo-28485**: Always raise ValueError for negative compileall.compile_dir(workers=...) parameter, even when multithreading is unavailable.
- **bpo-28037**: Use sqlite3_get_autocommit() instead of setting Connection->inTransaction manually.
- **bpo-25283**: Attributes tm_gmtoff and tm_zone are now available on all platforms in the return values of time.localtime() and time.gmtime().
- **bpo-24454**: Regular expression match object groups are now accessible using __getitem__. “mo[x]” is equivalent to “mo.group(x)”.
- **bpo-10740**: sqlite3 no longer implicitly commit an open transaction before DDL statements.
- **bpo-17941**: Add a module parameter to collections.namedtuple().
- **bpo-22493**: Inline flags now should be used only at the start of the regular expression. Deprecation warning is emitted if uses them in the middle of the regular expression.
- **bpo-26885**: xmlrpc now supports unmarshalling additional data types used by Apache XML-RPC implementation for numerics
and None.

- **bpo-28070**: Fixed parsing inline verbose flag in regular expressions.
- **bpo-19500**: Add client-side SSL session resumption to the ssl module.
- **bpo-28022**: Deprecate ssl-related arguments in favor of SSLContext. The deprecation include manual creation of SSLSocket and certfile/keyfile (or similar) in ftplib, httpplib, imaplib, smtplib, poplib and urllib.
- **bpo-28043**: SSLContext has improved default settings: OP_NO_SSLv2, OP_NO_SSLv3, OP_NO_COMPRESSION, OP_CIPHER_SERVER_PREFERENCE, OP_SINGLE_DH_USE, OP_SINGLE_ECDH_USE and HIGH ciphers without MD5.
- **bpo-24693**: Changed some RuntimeError’s in the zipfile module to more appropriate types. Improved some error messages and debugging output.
- **bpo-17909**: `json.load` and `json.loads` now support binary input encoded as UTF-8, UTF-16 or UTF-32. Patch by Serhiy Storchaka.
- **bpo-27137**: the pure Python fallback implementation of `functools.partial` now matches the behaviour of its accelerated C counterpart for subclassing, pickling and text representation purposes. Patch by Emanuel Barry and Serhiy Storchaka.
- **bpo-1703178**: Fix the ability to pass the –link-objects option to the distutils build_ext command.
- **bpo-28019**: `itertools.count()` no longer rounds non-integer step in range between 1.0 and 2.0 to 1.
- **bpo-18401**: Pdb now supports the ‘readrc’ keyword argument to control whether .pdbrc files should be read. Patch by Martin Matusiak and Sam Kimbrel.
- **bpo-25969**: Update the lib2to3 grammar to handle the unpacking
generalizations added in 3.5.

- **bpo-14977**: mailcap now respects the order of the lines in the mailcap files ("first match"), as required by RFC 1542. Patch by Michael Lazar.
- **bpo-28082**: Convert re flag constants to IntFlag.
- **bpo-28025**: Convert all ssl module constants to IntEnum and IntFlags. SSLContext properties now return flags and enums.
- **bpo-23591**: Add Flag, IntFlag, and auto() to enum module.
- **bpo-433028**: Added support of modifier spans in regular expressions.
- **bpo-24594**: Validates persist parameter when opening MSI database
- **bpo-17582**: xml.etree.ElementTree now preserves whitespaces in attributes (Patch by Duane Griffin. Reviewed and approved by Stefan Behnel.)
- **bpo-28047**: Fixed calculation of line length used for the base64 CTE in the new email policies.
- **bpo-27576**: Fix call order in OrderedDict.__init__().
- **email.generator.DecodedGenerator** now supports the policy keyword.
- **bpo-28027**: Remove undocumented modules from `Lib/plat-*`: IN, CDROM, DLFCN, TYPES, CDIO, and STROPTS.
- **bpo-27445**: Don't pass `str(_charset)` to MIMEText.set_payload(). Patch by Claude Paroz.
- **bpo-24277**: The new email API is no longer provisional, and the docs have been reorganized and rewritten to emphasize the new API.
- **bpo-22450**: urllib now includes an Accept: *//* header among the default headers. This makes the results of REST API requests more consistent and predictable especially when proxy servers are involved.
- lib2to3.pgen3.driver.load_grammar() now creates a stable cache file between runs given the same Grammar.txt input regardless of the hash randomization setting.
- **bpo-28005**: Allow ImportErrors in encoding implementation to propagate.
- **bpo-26667**: Support path-like objects in importlib.util.
- **bpo-27570**: Avoid zero-length memcpy() etc calls with null source pointers in the “ctypes” and “array” modules.
- **bpo-22233**: Break email header lines *only* on the RFC specified CR and LF characters, not on arbitrary unicode line breaks. This also fixes a bug in HTTP header parsing.
- **bpo-27331**: The email.mime classes now all accept an optional policy keyword.
- **bpo-27988**: Fix email iter_attachments incorrect mutation of payload list.
- **bpo-16113**: Add SHA-3 and SHAKE support to hashlib module.
- **bpo-18844**: Add random.choices().
- **bpo-25761**: Improved error reporting about truncated pickle data in C implementation of unpickler. UnpicklingError is now raised instead of AttributeError and ValueError in some cases.
- **bpo-26798**: Add BLAKE2 (blake2b and blake2s) to hashlib.
- **bpo-26032**: Optimized globbing in pathlib by using os.scandir(); it is now about 1.5–4 times faster.
- **bpo-25596**: Optimized glob() and iglob() functions in the glob module; they are now about 3–6 times faster.
- **bpo-27928**: Add scrypt (password-based key derivation function) to hashlib module (requires OpenSSL 1.1.0).
- **bpo-27850**: Remove 3DES from ssl module’s default cipher list to
counter measure sweet32 attack (CVE-2016-2183).

- **bpo-27766**: Add ChaCha20 Poly1305 to ssl module’s default cipher list. (Required OpenSSL 1.1.0 or LibreSSL).
- **bpo-25387**: Check return value of winsound.MessageBeep.
- **bpo-27866**: Add SSLContext.get_ciphers() method to get a list of all enabled ciphers.
- **bpo-27744**: Add AF_ALG (Linux Kernel crypto) to socket module.
- **bpo-26470**: Port ssl and hashlib module to OpenSSL 1.1.0.
- **bpo-11620**: Fix support for SND_MEMORY in winsound.PlaySound. Based on a patch by Tim Lesher.
- **bpo-11734**: Add support for IEEE 754 half-precision floats to the struct module. Based on a patch by Eli Stevens.
- **bpo-27919**: Deprecated extra_path distribution option in distutils packaging.
- **bpo-23229**: Add new cmath constants: cmath.inf and cmath.nan to match math.inf and math.nan, and also cmath.infj and cmath.nanj to match the format used by complex repr.
- **bpo-27842**: The csv.DictReader now returns rows of type OrderedDict. (Contributed by Steve Holden.)
- **bpo-12885**: Fix error when distutils encounters symlink.
- **bpo-27881**: Fixed possible bugs when setting sqlite3.Connection.isolation_level. Based on patch by Xiang Zhang.
- **bpo-27861**: Fixed a crash in sqlite3.Connection.cursor() when a factory creates not a cursor. Patch by Xiang Zhang.
- **bpo-19884**: Avoid spurious output on OS X with Gnu Readline.
- **bpo-10513**: Fix a regression in Connection.commit(). Statements
should not be reset after a commit.

- **bpo-12319**: Chunked transfer encoding support added to http.client.HTTPConnection requests. The urllib.request.AbstractHTTPHandler class does not enforce a Content-Length header any more. If a HTTP request has a file or iterable body, but no Content-Length header, the library now falls back to use chunked transfer-encoding.

- A new version of typing.py from https://github.com/python/typing: - Collection (only for 3.6) (**bpo-27598**) - Add FrozenSet to __all__ (upstream #261) - fix crash in __get_type_vars__() (upstream #259) - Remove the dict constraint in ForwardRef._eval_type (upstream #252)

- **bpo-27832**: Make __normalize parameter to Fraction constructor keyword-only, so that Fraction(2, 3, 4) now raises TypeError.

- **bpo-27539**: Fix unnormalised Fraction.__pow__ result in the case of negative exponent and negative base.

- **bpo-21718**: cursor.description is now available for queries using CTEs.

- **bpo-27819**: In distutils sdist, simply produce the “gztar” (gzipped tar format) distributions on all platforms unless “formats” is supplied.

- **bpo-2466**: posixpath.ismount now correctly recognizes mount points which the user does not have permission to access.

- **bpo-9998**: On Linux, ctypes.util.find_library now looks in LD_LIBRARY_PATH for shared libraries.

- **bpo-27573**: exit message for code.interact is now configurable.

- **bpo-27930**: Improved behaviour of logging.handlers.QueueListener. Thanks to Paulo Andrade and Petr Viktorin for the analysis and patch.

- **bpo-6766**: Distributed reference counting added to multiprocessing to support nesting of shared values / proxy objects.

- **bpo-21201**: Improves readability of multiprocessing error
message. Thanks to Wojciech Walczak for patch.

- asyncio: Add set_protocol / get_protocol to Transports.
- bpo-27456: asyncio: Set TCP_NODELAY by default.

**IDLE**

- **bpo-15308**: Add ‘interrupt execution’ (^C) to Shell menu. Patch by Roger Serwy, updated by Bayard Randel.
- **bpo-27922**: Stop IDLE tests from ‘flashing’ gui widgets on the screen.
- **bpo-27891**: Consistently group and sort imports within idlelib modules.
- **bpo-17642**: add larger font sizes for classroom projection.
- **bpo-17642**: Add version to title of IDLE help window.
- **bpo-25564**: In section on IDLE – console differences, mention that using exec means that __builtins__ is defined for each statement.
- **bpo-27821**: Fix 3.6.0a3 regression that prevented custom key sets from being selected when no custom theme was defined.

**C API**

- **bpo-26900**: Excluded underscored names and other private API from limited API.
- **bpo-26027**: Add support for path-like objects in PyUnicode_FSConverter() & PyUnicode_FSDecoder().

**Tests**

- **bpo-27427**: Additional tests for the math module. Patch by Francisco Couzo.
- **bpo-27953**: Skip math and cmath tests that fail on OS X 10.4 due to a poor libm implementation of tan.
- **bpo-26040**: Improve test_math and test_cmath coverage and
• **bpo-27787**: Call gc.collect() before checking each test for “dangling threads”, since the dangling threads are weak references.

## Build

• **bpo-27566**: Fix clean target in freeze makefile (patch by Lisa Roach)
• **bpo-27705**: Update message in validate_ucrtdbase.py
• **bpo-27976**: Deprecate building _ctypes with the bundled copy of libffi on non-OSX UNIX platforms.
• **bpo-27983**: Cause lack of llvm-profdata tool when using clang as required for PGO linking to be a configure time error rather than make time when –with-optimizations is enabled. Also improve our ability to find the llvm-profdata tool on MacOS and some Linuxes.
• **bpo-21590**: Support for DTrace and SystemTap probes.
• **bpo-26307**: The profile-opt build now applies PGO to the built-in modules.
• **bpo-26359**: Add the –with-optimizations flag to turn on LTO and PGO build support when available.
• **bpo-27917**: Set platform triplets for Android builds.
• **bpo-25825**: Update references to the $(LIBPL) installation path on AIX. This path was changed in 3.2a4.
• Update OS X installer to use SQLite 3.14.1 and XZ 5.2.2.
• **bpo-21122**: Fix LTO builds on OS X.
• **bpo-17128**: Build OS X installer with a private copy of OpenSSL. Also provide a sample Install Certificates command script to install a set of root certificates from the third-party certifi module.

## Tools/Demos

• **bpo-27952**: Get Tools/scripts/fixcid.py working with Python 3 and
the current “re” module, avoid invalid Python backslash escapes, and fix a bug parsing escaped C quote signs.

Windows

- **bpo-28065**: Update xz dependency to 5.2.2 and build it from source.
- **bpo-25144**: Ensures TargetDir is set before continuing with custom install.
- **bpo-1602**: Windows console doesn’t input or print Unicode (PEP 528)
- **bpo-27781**: Change file system encoding on Windows to UTF-8 (PEP 529)
- **bpo-27731**: Opt-out of MAX_PATH on Windows 10
- **bpo-6135**: Adds encoding and errors parameters to subprocess.
- **bpo-27959**: Adds oem encoding, alias ansi to mbcso, move aliasmbcs to codec lookup.
- **bpo-27982**: The functions of the winsound module now accept keyword arguments.
- **bpo-20366**: Build full text search support into SQLite on Windows.
- **bpo-27883**: Update sqlite to 3.14.1.0 on Windows.
Python 3.6.0 alpha 4?

Release date: 2016-08-15

Core and Builtins

- **bpo-27704**: Optimized creating bytes and bytearray from byte-like objects and iterables. Speed up to 3 times for short objects. Original patch by Naoki Inada.
- **bpo-26823**: Large sections of repeated lines in tracebacks are now abbreviated as “[Previous line repeated {count} more times]” by the builtin traceback rendering. Patch by Emanuel Barry.
- **bpo-27574**: Decreased an overhead of parsing keyword arguments in functions implemented with using Argument Clinic.
- **bpo-22557**: Now importing already imported modules is up to 2.5 times faster.
- **bpo-17596**: Include `<wincrypt.h>` to help with Min GW building.
- **bpo-17599**: On Windows, rename the privately defined REPARSE_DATA_BUFFER structure to avoid conflicting with the definition from Min GW.
- **bpo-27507**: Add integer overflow check in bytearray.extend(). Patch by Xiang Zhang.
- **bpo-27581**: Don’t rely on wrapping for overflow check in PySequence_Tuple(). Patch by Xiang Zhang.
- **bpo-1621**: Avoid signed integer overflow in list and tuple operations. Patch by Xiang Zhang.
- **bpo-27419**: Standard `__import__()` no longer look up “__import__” in globals or builtins for importing submodules or “from import”. Fixed a crash if raise a warning about unabling to resolve package from __spec__ or __package__.
- **bpo-27083**: Respect the PYTHONCASEOK environment variable under Windows.
- **bpo-27514**: Make having too many statically nested blocks a
• **SyntaxError instead of SystemError.**
  
  • **bpo-27366**: Implemented PEP 487 (Simpler customization of class creation). Upon subclassing, the `__init_subclass__` classmethod is called on the base class. Descriptors are initialized with `__set_name__` after class creation.

**Library**

• **bpo-26027**: Add PEP 519/`__fspath__()` support to the os and os.path modules. Includes code from Jelle Zijlstra. (See also: [bpo-27524](#))

• **bpo-27598**: Add Collections to collections.abc. Patch by Ivan Levkivskyi, docs by Neil Girdhar.

• **bpo-25958**: Support “anti-registration” of special methods from various ABCs, like `__hash__`, `__iter__` or `__len__`. All these (and several more) can be set to None in an implementation class and the behavior will be as if the method is not defined at all. (Previously, this mechanism existed only for `__hash__`, to make mutable classes unhashable.) Code contributed by Andrew Barnert and Ivan Levkivskyi.

• **bpo-16764**: Support keyword arguments to `zlib.decompress()`. Patch by Xiang Zhang.

• **bpo-27736**: Prevent segfault after interpreter re-initialization due to ref count problem introduced in code for [bpo-27038](#) in 3.6.0a3. Patch by Xiang Zhang.

• **bpo-25628**: The `verbose` and `rename` parameters for collections.namedtuple are now keyword-only.

• **bpo-12345**: Add mathematical constant tau to math and cmath. See also PEP 628.

• **bpo-26823**: traceback.StackSummary.format now abbreviates large sections of repeated lines as “[Previous line repeated {count} more times]” (this change then further affects other traceback display operations in the module). Patch by Emanuel Barry.
- **bpo-27664**: Add to concurrent.futures.thread.ThreadPoolExecutor() the ability to specify a thread name prefix.
- **bpo-27181**: Add geometric_mean and harmonic_mean to statistics module.
- **bpo-27573**: code.interact now prints a message when exiting.
- **bpo-6422**: Add autorange method to timeit.Timer objects.
- **bpo-27773**: Correct some memory management errors server_hostname in _ssl.wrap_socket().
- **bpo-26750**: unittest.mock.create_autospec() now works properly for subclasses of property() and other data descriptors. Removes the never publicly used, never documented unittest.mock.DescriptorTypes tuple.
- **bpo-26754**: Undocumented support of general bytes-like objects as path in compile() and similar functions is now deprecated.
- **bpo-26800**: Undocumented support of general bytes-like objects as paths in os functions is now deprecated.
- **bpo-26981**: Add _order_ compatibility shim to enum.Enum for Python 2/3 code bases.
- **bpo-27661**: Added tzinfo keyword argument to datetime.combine.
- In the curses module, raise an error if window.getstr() or window.instr() is passed a negative value.
- **bpo-27783**: Fix possible usage of uninitialized memory in operator.methodcaller.
- **bpo-27774**: Fix possible Py_DECREF on unowned object in _sre.
- **bpo-27760**: Fix possible integer overflow in binascii.b2a_qp.
- **bpo-27758**: Fix possible integer overflow in the _csv module for large record lengths.
- **bpo-27568**: Prevent HTTPoxy attack (CVE-2016-1000110). Ignore the HTTP_PROXY variable when REQUEST_METHOD environment is set, which indicates that the script is in CGI mode.
- **bpo-7063**: Remove dead code from the “array” module’s slice handling. Patch by Chuck.
- **bpo-27656**: Do not assume sched.h defines any SCHED_*
constants.

- **bpo-27130**: In the “zlib” module, fix handling of large buffers (typically 4 GiB) when compressing and decompressing. Previously, inputs were limited to 4 GiB, and compression and decompression operations did not properly handle results of 4 GiB.
- **bpo-24773**: Implemented PEP 495 (Local Time Disambiguation).
- **bpo-27567**: Expose the EPOLLEXCLUSIVE constant (when it is defined) in the select module.
- **bpo-1621**: Avoid signed int negation overflow in the “audioop” module.
- **bpo-27533**: Release GIL in nt._isdir
- **bpo-17711**: Fixed unpickling by the persistent ID with protocol 0. Original patch by Alexandre Vassalotti.
- **bpo-27522**: Avoid an unintentional reference cycle in email.feedparser.
- **bpo-27512**: Fix a segfault when os.fspath() called an __fspath__() method that raised an exception. Patch by Xiang Zhang.

**IDLE**

- **bpo-27714**: text_textview and test_autocomplete now pass when re-run in the same process. This occurs when test_idle fails when run with the `-w` option but without `-jn`. Fix warning from test_config.
- **bpo-27621**: Put query response validation error messages in the query box itself instead of in a separate massagebox. Redo tests to match. Add Mac OSX refinements. Original patch by Mark Roseman.
- **bpo-27620**: Escape key now closes Query box as cancelled.
- **bpo-27609**: IDLE: tab after initial whitespace should tab, not autocomplete. This fixes problem with writing docstrings at least
twice indented.

- **bpo-27609**: Explicitly return None when there are also non-None returns. In a few cases, reverse a condition and eliminate a return.
- **bpo-25507**: IDLE no longer runs buggy code because of its tkinter imports. Users must include the same imports required to run directly in Python.
- **bpo-27173**: Add ‘IDLE Modern Unix’ to the built-in key sets. Make the default key set depend on the platform. Add tests for the changes to the config module.
- **bpo-27452**: add line counter and crc to IDLE configHandler test dump.

**Tests**

- **bpo-25805**: Skip a test in test_pkgutil as needed that doesn’t work when `__name__ == __main__`. Patch by SilentGhost.
- **bpo-27472**: Add `test.support_unix_shell` as the path to the default shell.
- **bpo-27369**: In `test_pyexpat`, avoid testing an error message detail that changed in Expat 2.2.0.
- **bpo-27594**: Prevent assertion error when running `test_ast` with coverage enabled: ensure code object has a valid first line number. Patch suggested by Ivan Levkivskyi.

**Windows**

- **bpo-27647**: Update bundled Tcl/Tk to 8.6.6.
- **bpo-27610**: Adds PEP 514 metadata to Windows installer
- **bpo-27469**: Adds a shell extension to the launcher so that drag and drop works correctly.
- **bpo-27309**: Enables proper Windows styles in python[w].exe manifest.
Build

- **bpo-27713**: Suppress spurious build warnings when updating importlib’s bootstrap files. Patch by Xiang Zhang.
- **bpo-25825**: Correct the references to Modules/python.exp, which is required on AIX. The references were accidentally changed in 3.5.0a1.
- **bpo-27453**: CPP invocation in configure must use CPPFLAGS. Patch by Chi Hsuan Yen.
- **bpo-27641**: The configure script now inserts comments into the makefile to prevent the pgen and _freeze_importlib executables from being cross-compiled.
- **bpo-26662**: Set PYTHON_FOR_GEN in configure as the Python program to be used for file generation during the build.
- **bpo-10910**: Avoid C++ compilation errors on FreeBSD and OS X. Also update FreeBSD version checks for the original ctype UTF-8 workaround.
Python 3.6.0 alpha 3?

Release date: 2016-07-11

Core and Builtins

- **bpo-27473**: Fixed possible integer overflow in bytes and bytearray concatenations. Patch by Xiang Zhang.
- **bpo-23034**: The output of a special Python build with defined COUNT_ALLOCS, SHOW_ALLOC_COUNT or SHOW_TRACK_COUNT macros is now off by default. It can be re-enabled using the “-X showalloccount” option. It now outputs to stderr instead of stdout.
- **bpo-27443**: __length_hint__() of bytearray iterators no longer return a negative integer for a resized bytearray.
- **bpo-27007**: The fromhex() class methods of bytes and bytearray subclasses now return an instance of corresponding subclass.

Library

- **bpo-26844**: Fix error message for imp.find_module() to refer to ‘path’ instead of ‘name’. Patch by Lev Maximov.
- **bpo-23804**: Fix SSL zero-length recv() calls to not block and not raise an error about unclean EOF.
- **bpo-27466**: Change time format returned by http.cookie.time2netscape, confirming the netscape cookie format and making it consistent with documentation.
- **bpo-21708**: Deprecated dbm.dumb behavior that differs from common dbm behavior: creating a database in ‘r’ and ‘w’ modes and modifying a database in ‘r’ mode.
- **bpo-26721**: Change the socketserver.StreamRequestHandler.wfile attribute to implement
BufferedIOBase. In particular, the write() method no longer does partial writes.

- **bpo-22115**: Added methods trace_add, trace_remove and trace_info in the tkinter.Variable class. They replace old methods trace_variable, trace, trace_vdelete and trace_vinfo that use obsolete Tcl commands and might not work in future versions of Tcl. Fixed old tracing methods: trace_vdelete() with wrong mode no longer break tracing, trace_vinfo() now always returns a list of pairs of strings, tracing in the “u” mode now works.

- **bpo-26243**: Only the level argument to zlib.compress() is keyword argument now. The first argument is positional-only.

- **bpo-27186**: Update os.fspath()/PyOS_FSPath() to check the return value of __fspath__() to be either str or bytes.

- **bpo-18726**: All optional parameters of the dump(), dumps(), load() and loads() functions and JSONEncoder and JSONDecoder class constructors in the json module are now keyword-only.

- **bpo-27319**: Methods selection_set(), selection_add(), selection_remove() and selection_toggle() of ttk.TreeView now allow passing multiple items as multiple arguments instead of passing them as a tuple. Deprecated undocumented ability of calling the selection() method with arguments.

- **bpo-27079**: Fixed curses.ascii functions isblank(), iscntrl() and ispunct().

- **bpo-27294**: Numerical state in the repr for Tkinter event objects is now represented as a combination of known flags.

- **bpo-27177**: Match objects in the re module now support index-like objects as group indices. Based on patches by Jeroen Demeyer and Xiang Zhang.

- **bpo-26754**: Some functions (compile() etc) accepted a filename argument encoded as an iterable of integers. Now only strings and byte-like objects are accepted.

- **bpo-26536**: socket.ioctl now supports
SIO_LOOPBACK_FAST_PATH. Patch by Daniel Stokes.

- **bpo-27048**: Prevents `distutils` failing on Windows when environment variables contain non-ASCII characters.
- **bpo-27330**: Fixed possible leaks in the `ctypes` module.
- **bpo-27238**: Got rid of bare excepts in the `turtle` module. Original patch by Jelle Zijlstra.
- **bpo-27122**: When an exception is raised within the context being managed by a `contextlib.ExitStack()` and one of the exit stack generators catches and raises it in a chain, do not re-raise the original exception when exiting, let the new chained one through. This avoids the PEP 479 bug described in issue25782.

**Security**

- **bpo-27278**: Fix `os.urandom()` implementation using `getrandom()` on Linux. Truncate size to `INT_MAX` and loop until we collected enough random bytes, instead of casting a directly `Py_ssize_t` to `int`.

**Library**

- **bpo-16864**: `sqlite3.Cursor.lastrowid` now supports `REPLACE` statement. Initial patch by Alex LordThorsen.
- **bpo-26386**: Fixed `tk.TreeView` selection operations with item id's containing spaces.
- **bpo-8637**: Honor a pager set by the env var `MANPAGER` (in preference to one set by the env var `PAGER`).

**Security**

- **bpo-22636**: Avoid shell injection problems with `ctypes.util.find_library()`.
Library

- **bpo-16182**: Fix various functions in the “readline” module to use the locale encoding, and fix get_begidx() and get_endidx() to return code point indexes.
- **bpo-27392**: Add `loop.connect_accepted_socket()`. Patch by Jim Fulton.

**IDLE**

- **bpo-27477**: IDLE search dialogs now use ttk widgets.
- **bpo-27173**: Add ‘IDLE Modern Unix’ to the built-in key sets. Make the default key set depend on the platform. Add tests for the changes to the config module.
- **bpo-27452**: make command line “idle-test> python test_help.py” work. __file__ is relative when python is started in the file's directory.
- **bpo-27452**: add line counter and crc to IDLE configHandler test dump.
- **bpo-27380**: IDLE: add query.py with base Query dialog and ttk widgets. Module had subclasses SectionName, ModuleName, and HelpSource, which are used to get information from users by configdialog and file =>Load Module. Each subclass has itw own validity checks. Using ModuleName allows users to edit bad module names instead of starting over. Add tests and delete the two files combined into the new one.
- **bpo-27372**: Test_idle no longer changes the locale.
- **bpo-27365**: Allow non-ascii chars in IDLE NEWS.txt, for contributor names.
- **bpo-27245**: IDLE: Cleanly delete custom themes and key bindings. Previously, when IDLE was started from a console or by import, a cascade of warnings was emitted. Patch by Serhiy Storchaka.
bpo-24137: Run IDLE, test_idle, and htest with tkinter default root disabled. Fix code and tests that fail with this restriction. Fix htests to not create a second and redundant root and mainloop.

bpo-27310: Fix IDLE.app failure to launch on OS X due to vestigial import.

C API

bpo-26754: PyUnicode_FSDecoder() accepted a filename argument encoded as an iterable of integers. Now only strings and byte-like objects are accepted.

Build

bpo-28066: Fix the logic that searches build directories for generated include files when building outside the source tree.

bpo-27442: Expose the Android API level that python was built against, in sysconfig.get_config_vars() as ‘ANDROID_API_LEVEL’.

bpo-27434: The interpreter that runs the cross-build, found in PATH, must now be of the same feature version (e.g. 3.6) as the source being built.

bpo-26930: Update Windows builds to use OpenSSL 1.0.2h.

bpo-23968: Rename the platform directory from plat-$(MACHDEP) to plat-$(PLATFORM_TRIPLET). Rename the config directory (LIBPL) from config-$(LDVERSION) to config-$(LDVERSION)-$(PLATFORM_TRIPLET). Install the platform specific _sysconfigdata module into the platform directory and rename it to include the ABIFLAGS.

Don’t use largefile support for GNU/Hurd.

Tools/Demos
- **bpo-27332**: Fixed the type of the first argument of module-level functions generated by Argument Clinic. Patch by Petr Viktorin.
- **bpo-27418**: Fixed Tools/importbench/importbench.py.

**Documentation**

- **bpo-19489**: Moved the search box from the sidebar to the header and footer of each page. Patch by Ammar Askar.
- **bpo-27285**: Update documentation to reflect the deprecation of `pyvenv` and normalize on the term “virtual environment”. Patch by Steve Piercy.

**Tests**

- **bpo-27027**: Added test.support.is_android that is True when this is an Android build.
Python 3.6.0 alpha 2?

Release date: 2016-06-13

Core and Builtins

- **bpo-27095**: Simplified MAKE_FUNCTION and removed MAKE_CLOSURE opcodes. Patch by Demur Rumed.
- **bpo-27190**: Raise NotSupportedError if sqlite3 is older than 3.3.1. Patch by Dave Sawyer.
- **bpo-27286**: Fixed compiling BUILD_MAP_UNPACK_WITH_CALL opcode. Calling function with generalized unpacking (PEP 448) and conflicting keyword names could cause undefined behavior.
- **bpo-27140**: Added BUILD_CONST_KEY_MAP opcode.
- **bpo-27186**: Add support for os.PathLike objects to open() (part of PEP 519).
- **bpo-27066**: Fixed SystemError if a custom opener (for open()) returns a negative number without setting an exception.
- **bpo-26983**: float() now always return an instance of exact float. The deprecation warning is emitted if __float__ returns an instance of a strict subclass of float. In a future versions of Python this can be an error.
- **bpo-27097**: Python interpreter is now about 7% faster due to optimized instruction decoding. Based on patch by Demur Rumed.
- **bpo-26647**: Python interpreter now uses 16-bit wordcode instead of bytecode. Patch by Demur Rumed.
- **bpo-23275**: Allow assigning to an empty target list in round brackets: () = iterable.
- **bpo-27243**: Update the __aiter__ protocol: instead of returning an awaitable that resolves to an asynchronous iterator, the asynchronous iterator should be returned directly. Doing the former will trigger a PendingDeprecationWarning.
Library

- Comment out socket (SO_REUSEPORT) and posix (O_SHLOCK, O_EXLOCK) constants exposed on the API which are not implemented on GNU/Hurd. They would not work at runtime anyway.
- **bpo-27025**: Generated names for Tkinter widgets are now more meaningful and recognizirable.
- **bpo-25455**: Fixed crashes in repr of recursive ElementTree.Element and functools.partial objects.
- **bpo-27294**: Improved repr for Tkinter event objects.
- **bpo-20508**: Improve exception message of IPv{4,6}Network.__getitem__. Patch by Gareth Rees.

Security

- **bpo-26556**: Update expat to 2.1.1, fixes CVE-2015-1283.
- Fix TLS stripping vulnerability in smtplib, CVE-2016-0772. Reported by Team Oststrom.

Library

- **bpo-21386**: Implement missing IPv4Address.is_global property. It was documented since 07a5610bae9d. Initial patch by Roger Luethi.
- **bpo-27029**: Removed deprecated support of universal newlines mode from ZipFile.open().
- **bpo-27030**: Unknown escapes consisting of `\` and an ASCII letter in regular expressions now are errors. The re.LOCALE flag now can be used only with bytes patterns.
- **bpo-27186**: Add os.PathLike support to DirEntry (part of PEP 519). Initial patch by Jelle Zijlstra.
- bpo-20900: distutils register command now decodes HTTP responses correctly. Initial patch by ingrid.
- bpo-27186: Add os.PathLike support to pathlib, removing its provisional status (part of PEP 519). Initial patch by Dusty Phillips.
- bpo-27186: Add support for os.PathLike objects to os.fsencode() and os.fsdecode() (part of PEP 519).
- bpo-27186: Introduce os.PathLike and os.fspath() (part of PEP 519).
- A new version of typing.py provides several new classes and features: @overload outside stubs, Reversible, DefaultDict, Text, ContextManager, Type[], NewType(), TYPE_CHECKING, and numerous bug fixes (note that some of the new features are not yet implemented in mypy or other static analyzers). Also classes for PEP 492 (Awaitable, AsyncIterable, AsyncIterator) have been added (in fact they made it into 3.5.1 but were never mentioned).
- bpo-25738: Stop http.server.BaseHTTPRequestHandler.send_error() from sending a message body for 205 Reset Content. Also, don’t send Content header fields in responses that don’t have a body. Patch by Susumu Koshiba.
- bpo-21313: Fix the “platform” module to tolerate when sys.version contains truncated build information.

Security

- bpo-26839: On Linux, os.urandom() now calls getrandom() with GRND_NONBLOCK to fall back on reading /dev/urandom if the urandom entropy pool is not initialized yet. Patch written by Colm Buckley.

Library

- bpo-23883: Added missing APIs to __all__ to match the
documented APIs for the following modules:cgi, mailbox, mimetypes, plistlib and smtplib. Patches by Jacek Kołodziej.

- **bpo-27164**: In the zlib module, allow decompressing raw Deflate streams with a predefined zdict. Based on patch by Xiang Zhang.
- **bpo-24291**: Fix wsgiref.simple_server.WSGIRequestHandler to completely write data to the client. Previously it could do partial writes and truncate data. Also, wsgiref.handler.ServerHandler can now handle stdout doing partial writes, but this is deprecated.
- **bpo-21272**: Use _sysconfigdata.py to initialize distutils.sysconfig.
- **bpo-19611**: inspect now reports the implicit .0 parameters generated by the compiler for comprehension and generator expression scopes as if they were positional-only parameters called implicit0. Patch by Jelle Zijlstra.
- **bpo-26809**: Add __all__ to string. Patch by Emanuel Barry.
- **bpo-26373**: subprocess.Popen.communicate now correctly ignores BrokenPipeError when the child process dies before .communicate() is called in more/all circumstances.
- **signal, socket, and ssl module IntEnum constant name lookups now return a consistent name for values having multiple names. Ex: signal.Signals(6) now refers to itself as signal.SIGALRM rather than flipping between that and signal.SIGIOT based on the interpreter's hash randomization seed.
- **bpo-27167**: Clarify the subprocess.CalledProcessError error message text when the child process died due to a signal.
- **bpo-25931**: Don't define socketserver.Forking* names on platforms such as Windows that do not support os.fork().
- **bpo-21776**: distutils.upload now correctly handles HTTPError. Initial patch by Claudiu Popa.
- **bpo-26526**: Replace custom parse tree validation in the parser module with a simple DFA validator.
- **bpo-27114**: Fix SSLContext._load_windows_store_certs fails with PermissionError
- **bpo-18383**: Avoid creating duplicate filters when using filterwarnings and simplefilter. Based on patch by Alex Shkop.
- **bpo-23026**: `winreg.QueryValueEx()` now return an integer for REG_QWORD type.
- **bpo-26741**: `subprocess.Popen` destructor now emits a `ResourceWarning` warning if the child process is still running.
- **bpo-27056**: Optimize `pickle.load()` and `pickle.loads()`, up to 10% faster to deserialize a lot of small objects.
- **bpo-21271**: New keyword only parameters in `reset_mock` call.

**IDLE**

- **bpo-5124**: Paste with text selected now replaces the selection on X11. This matches how paste works on Windows, Mac, most modern Linux apps, and ttk widgets. Original patch by Serhiy Storchaka.
- **bpo-24750**: Switch all scrollbars in IDLE to ttk versions. Where needed, minimal tests are added to cover changes.
- **bpo-24759**: IDLE requires tk 8.5 and availability ttk widgets. Delete now unneeded tk version tests and code for older versions. Add test for IDLE syntax colorizer.
- **bpo-27239**: `idlelib.macosx.isXyzTk` functions initialize as needed.
- **bpo-27262**: move Aqua unbinding code, which enable context menus, to maxosx.
- **bpo-24759**: Make clear in `idlelib.idle_test.__init__` that the directory is a private implementation of `test.test_idle` and tool for maintainers.
- **bpo-27196**: Stop ‘ThemeChanged’ warnings when running IDLE tests. These persisted after other warnings were suppressed in #20567. Apply Serhiy Storchaka’s update_idletasks solution to four test files. Record this additional advice in idle_test/README.txt
- **bpo-20567**: Revise idle_test/README.txt with advice about avoiding tk warning messages from tests. Apply advice to several IDLE tests.
- **bpo-24225**: Update idlelib/README.txt with new file names and
event handlers.

- **bpo-27156**: Remove obsolete code not used by IDLE.
- **bpo-27117**: Make colorizer htest and turtledemo work with dark themes. Move code for configuring text widget colors to a new function.
- **bpo-24225**: Rename many `idlelib/*.py` and `idle_test/test_*`.py files. Edit files to replace old names with new names when the old name referred to the module rather than the class it contained. See the issue and IDLE section in What’s New in 3.6 for more.
- **bpo-26673**: When tk reports font size as 0, change to size 10. Such fonts on Linux prevented the configuration dialog from opening.
- **bpo-21939**: Add test for IDLE’s percolator. Original patch by Saimadhav Heblikar.
- **bpo-21676**: Add test for IDLE’s replace dialog. Original patch by Saimadhav Heblikar.
- **bpo-18410**: Add test for IDLE’s search dialog. Original patch by Westley Martínez.
- **bpo-21703**: Add test for undo delegator. Patch mostly by Saimadhav Heblikar.
- **bpo-27044**: Add `ConfigDialog.remove_var_callbacks` to stop memory leaks.
- **bpo-23977**: Add more asserts to test_delegator.

**Documentation**

- **bpo-16484**: Change the default PYTHONDOCS URL to “https:”, and fix the resulting links to use lowercase. Patch by Sean Rodman, test by Kaushik Nadikuditi.
- **bpo-24136**: Document the new PEP 448 unpacking syntax of 3.5.
- **bpo-22558**: Add remaining doc links to source code for Python-coded modules. Patch by Yoni Lavi.
Tests

- **bpo-25285**: regrtest now uses subprocesses when the -j1 command line option is used: each test file runs in a fresh child process. Before, the -j1 option was ignored.
- **bpo-25285**: Tools/buildbot/test.bat script now uses -j1 by default to run each test file in fresh child process.

Windows

- **bpo-27064**: The py.exe launcher now defaults to Python 3. The Windows launcher `py.exe` no longer prefers an installed Python 2 version over Python 3 by default when used interactively.

Build

- **bpo-27229**: Fix the cross-compiling pgen rule for in-tree builds. Patch by Xavier de Gaye.
- **bpo-26930**: Update OS X 10.5+ 32-bit-only installer to build and link with OpenSSL 1.0.2h.

Windows

- **bpo-17500**: Remove unused and outdated icons. (See also: https://github.com/python/pythondotorg/issues/945)

C API

- **bpo-27186**: Add the PyOS_FSPath() function (part of PEP 519).
- **bpo-26282**: PyArg_ParseTupleAndKeywords() now supports positional-only parameters.
Tools/Demos

- **bpo-26282**: Argument Clinic now supports positional-only and keyword parameters in the same function.
Python 3.6.0 alpha 1?

Release date: 2016-05-16

Core and Builtins

- bpo-20041: Fixed TypeError when frame.f_trace is set to None. Patch by Xavier de Gaye.
- bpo-26168: Fixed possible refleaks in failing Py_BuildValue() with the “N” format unit.
- bpo-26991: Fix possible refleak when creating a function with annotations.
- bpo-27039: Fixed bytearray.remove() for values greater than 127. Based on patch by Joe Jevnik.
- bpo-23640: int.from_bytes() no longer bypasses constructors for subclasses.
- bpo-27005: Optimized the float.fromhex() class method for exact float. It is now 2 times faster.
- bpo-18531: Single var-keyword argument of dict subtype was passed unscathed to the C-defined function. Now it is converted to exact dict.
- bpo-26811: gc.get_objects() no longer contains a broken tuple with NULL pointer.
- bpo-26249: Memory functions of the PyMem_Malloc() domain (PYMEM_DOMAIN_MEM) now use the pymalloc allocator rather than system malloc(). Applications calling PyMem_Malloc() without holding the GIL can now crash: use PYTHONMALLOC=debug environment variable to validate the
usage of memory allocators in your application.

- **bpo-26802**: Optimize function calls only using unpacking like `func(*tuple)` (no other positional argument, no keyword): avoid copying the tuple. Patch written by Joe Jevnik.
- **bpo-26659**: Make the builtin slice type support cycle collection.
- **bpo-26718**: `super.__init__` no longer leaks memory if called multiple times. NOTE: A direct call of `super.__init__` is not endorsed!
- **bpo-27138**: Fix the doc comment for `Finder.find_spec()`.
- **bpo-27147**: Mention PEP 420 in the importlib docs.
- **bpo-25339**: `PYTHONIOENCODING` now has priority over locale in setting the error handler for stdin and stdout.
- **bpo-26494**: Fixed crash on iterating exhausting iterators. Affected classes are generic sequence iterators, iterators of `str`, `bytes`, `bytearray`, `list`, `tuple`, `set`, `frozenset`, `dict`, `OrderedDict`, corresponding views and `os.scandir()` iterator.
- **bpo-26574**: Optimize `bytes.replace(b'', b'.')` and `bytearray.replace(b'', b'.')`. Patch written by Josh Snider.
- **bpo-26581**: If coding cookie is specified multiple times on a line in Python source code file, only the first one is taken to account.
- **bpo-19711**: Add tests for reloading namespace packages.
- **bpo-21099**: Switch applicable importlib tests to use PEP 451 API.
- **bpo-26563**: Debug hooks on Python memory allocators now raise a fatal error if functions of the `PyMem_Malloc()` family are called without holding the GIL.
- **bpo-26564**: On error, the debug hooks on Python memory allocators now use the `tracemalloc` module to get the traceback where a memory block was allocated.
- **bpo-26558**: The debug hooks on Python memory allocator `PyObject_Malloc()` now detect when functions are called without holding the GIL.
- **bpo-26516**: Add `PYTHONMALLOC` environment variable to set the Python memory allocators and/or install debug hooks.
- **bpo-26516**: The `PyMem_SetupDebugHooks()` function can now also be used on Python compiled in release mode.
- **bpo-26516**: The `PYTHONMALLOCSTATS` environment variable can now also be used on Python compiled in release mode. It now has no effect if set to an empty string.
- **bpo-26516**: In debug mode, debug hooks are now also installed on Python memory allocators when Python is configured without pymalloc.
- **bpo-26464**: Fix `str.translate()` when string is ASCII and first replacements removes character, but next replacement uses a non-ASCII character or a string longer than 1 character. Regression introduced in Python 3.5.0.
- **bpo-22836**: Ensure exception reports from `PyErr_Display()` and `PyErr_WriteUnraisable()` are sensible even when formatting them produces secondary errors. This affects the reports produced by `sys.__excepthook__()` and when `__del__()` raises an exception.
- **bpo-26302**: Correct behavior to reject comma as a legal character for cookie names.
- **bpo-26136**: Upgrade the warning when a generator raises `StopIteration` from `PendingDeprecationWarning` to `DeprecationWarning`. Patch by Anish Shah.
- **bpo-26204**: The compiler now ignores all constant statements: `bytes`, `str`, `int`, `float`, `complex`, `name` constants (`None`, `False`, `True`), `Ellipsis` and `ast.Constant`; not only `str` and `int`. For example, `1.0` is now ignored in `def f(): 1.0`.
- **bpo-4806**: Avoid masking the original `TypeError` exception when using star (*) unpacking in function calls. Based on patch by Hagen Fürstenau and Daniel Urban.
- **bpo-26146**: Add a new kind of AST node: `ast.Constant`. It can be used by external AST optimizers, but the compiler does not emit directly such node.
- **bpo-23601**: Sped-up allocation of dict key objects by using Python’s small object allocator. (Contributed by Julian Taylor.)
- **bpo-18018**: Import raises `ImportError` instead of `SystemError` if a
relative import is attempted without a known parent package.

- **bpo-25843**: When compiling code, don't merge constants if they are equal but have a different types. For example, \( f1, f2 = \lambda: 1, \lambda: 1.0 \) is now correctly compiled to two different functions: \( f1() \) returns \( 1 (\text{int}) \) and \( f2() \) returns \( 1.0 (\text{float}) \), even if \( 1 \) and \( 1.0 \) are equal.

- **bpo-26107**: The format of the `co_lnotab` attribute of code objects changes to support negative line number delta.

- **bpo-26154**: Add a new private `_PyThreadState_UncheckedGet()` function to get the current Python thread state, but don’t issue a fatal error if it is NULL. This new function must be used instead of accessing directly the `_PyThreadState_Current` variable. The variable is no more exposed since Python 3.5.1 to hide the exact implementation of atomic C types, to avoid compiler issues.

- **bpo-25791**: If `__package__` != `__spec__.parent` or if neither `__package__` or `__spec__` are defined then `ImportWarning` is raised.

- **bpo-22995**: [UPDATE] Comment out the one of the pickleability tests in `_PyObject_GetState()` due to regressions observed in Cython-based projects.

- **bpo-25961**: Disallowed null characters in the type name.

- **bpo-25973**: Fix segfault when an invalid nonlocal statement binds a name starting with two underscores.

- **bpo-22995**: Instances of extension types with a state that aren’t subclasses of list or dict and haven’t implemented any pickle-related methods (`__reduce__`, `__reduce_ex__`, `__getnewargs__`, `__getnewargs_ex__`, or `__getstate__`), can no longer be pickled. Including `memoryview`.

- **bpo-20440**: Massive replacing unsafe attribute setting code with special macro `Py_SETREF`.

- **bpo-25766**: Special method `__bytes__()` now works in str subclasses.

- **bpo-25421**: `__sizeof__` methods of builtin types now use dynamic basic size. This allows `sys.getsize()` to work correctly with their
subclasses with __slots__ defined.

- **bpo-25709**: Fixed problem with in-place string concatenation and utf-8 cache.
- **bpo-5319**: New Py_FinalizeEx() API allowing Python to set an exit status of 120 on failure to flush buffered streams.
- **bpo-25485**: telnetlib.Telnet is now a context manager.
- **bpo-24097**: Fixed crash in object.__reduce__() if slot name is freed inside __getattr__.
- **bpo-24731**: Fixed crash on converting objects with special methods __bytes__, __trunc__, and __float__ returning instances of subclasses of bytes, int, and float to subclasses of bytes, int, and float correspondingly.
- **bpo-25630**: Fix a possible segfault during argument parsing in functions that accept filesystem paths.
- **bpo-23564**: Fixed a partially broken sanity check in the _posixsubprocess internals regarding how fds_to_pass were passed to the child. The bug had no actual impact as subprocess.py already avoided it.
- **bpo-25388**: Fixed tokenizer crash when processing undecodable source code with a null byte.
- **bpo-25462**: The hash of the key now is calculated only once in most operations in C implementation of OrderedDict.
- **bpo-22995**: Default implementation of __reduce__ and __reduce_ex__ now rejects builtin types with not defined __new__.
- **bpo-24802**: Avoid buffer overreads when int(), float(), compile(), exec() and eval() are passed bytes-like objects. These objects are not necessarily terminated by a null byte, but the functions assumed they were.
- **bpo-25555**: Fix parser and AST: fill lineno and col_offset of “arg” node when compiling AST from Python objects.
- **bpo-24726**: Fixed a crash and leaking NULL in repr() of OrderedDict that was mutated by direct calls of dict methods.
- **bpo-25449**: Iterating OrderedDict with keys with unstable hash
now raises KeyError in C implementations as well as in Python implementation.

- **bpo-25395**: Fixed crash when highly nested OrderedDict structures were garbage collected.
- **bpo-25401**: Optimize bytes.fromhex() and bytearray.fromhex(): they are now between 2x and 3.5x faster.
- **bpo-25399**: Optimize bytearray % args using the new private _PyBytesWriter API. Formatting is now between 2.5 and 5 times faster.
- **bpo-25274**: sys.setrecursionlimit() now raises a RecursionError if the new recursion limit is too low depending at the current recursion depth. Modify also the “lower-water mark” formula to make it monotonic. This mark is used to decide when the overflowed flag of the thread state is reset.
- **bpo-24402**: Fix input() to prompt to the redirected stdout when sys.stdout.fileno() fails.
- **bpo-25349**: Optimize bytes % args using the new private _PyBytesWriter API. Formatting is now up to 2 times faster.
- **bpo-24806**: Prevent builtin types that are not allowed to be subclassed from being subclassed through multiple inheritance.
- **bpo-25301**: The UTF-8 decoder is now up to 15 times as fast for error handlers: ignore, replace and surrogateescape.
- **bpo-24848**: Fixed a number of bugs in UTF-7 decoding of misformed data.
- **bpo-25267**: The UTF-8 encoder is now up to 75 times as fast for error handlers: ignore, replace, surrogateescape, surrogatepass. Patch co-written with Serhiy Storchaka.
- **bpo-25280**: Import trace messages emitted in verbose (-v) mode are no longer formatted twice.
- **bpo-25227**: Optimize ASCII and latin1 encoders with the surrogateescape error handler: the encoders are now up to 3 times as fast. Initial patch written by Serhiy Storchaka.
- **bpo-25003**: On Solaris 11.3 or newer, os.urandom() now uses the getrandom() function instead of the getentropy() function. The
getentropy() function is blocking to generate very good quality entropy, os.urandom() doesn’t need such high-quality entropy.

- **bpo-9232**: Modify Python’s grammar to allow trailing commas in the argument list of a function declaration. For example, “def f(*, a = 3,): pass” is now legal. Patch from Mark Dickinson.
- **bpo-24965**: Implement PEP 498 “Literal String Interpolation”. This allows you to embed expressions inside f-strings, which are converted to normal strings at run time. Given x=3, then f'value={x}' == ‘value=3’. Patch by Eric V. Smith.
- **bpo-26478**: Fix semantic bugs when using binary operators with dictionary views and tuples.
- **bpo-26171**: Fix possible integer overflow and heap corruption in zipimporter.get_data().
- **bpo-25660**: Fix TAB key behaviour in REPL with readline.
- **bpo-26288**: Optimize PyLong_AsDouble.
- **bpo-26289**: Optimize floor and modulo division for single-digit longs. Microbenchmarks show 2-2.5x improvement. Built-in ‘divmod’ function is now also ~10% faster. (See also: bpo-26315)
- **bpo-25887**: Raise a `RuntimeError` when a coroutine object is awaited more than once.

**Library**

- **bpo-27057**: Fix os.set_inheritable() on Android, ioctl() is blocked by SELinux and fails with EACCESS. The function now falls back to fcntl(). Patch written by Michał Bednarski.
- **bpo-27014**: Fix infinite recursion using typing.py. Thanks to Kalle Tuure!
- **bpo-27031**: Removed dummy methods in Tkinter widget classes: `tk_menuBar()` and `tk_bindForTraversal()`.
- **bpo-14132**: Fix urllib.request redirect handling when the target
only has a query string. Original fix by Ján Janech.

- **bpo-17214**: The “urllib.request” module now percent-encodes non-ASCII bytes found in redirect target URLs. Some servers send Location header fields with non-ASCII bytes, but “http.client” requires the request target to be ASCII-encodable, otherwise a UnicodeEncodeError is raised. Based on patch by Christian Heimes.

- **bpo-27033**: The default value of the decode_data parameter for smtpd.SMTPChannel and smtpd.SMTPServer constructors is changed to False.

- **bpo-27034**: Removed deprecated class asynchat.fifo.

- **bpo-26870**: Added readline.set_auto_history(), which can stop entries being automatically added to the history list. Based on patch by Tyler Crompton.

- **bpo-26039**: zipfile.ZipFile.open() can now be used to write data into a ZIP file, as well as for extracting data. Patch by Thomas Kluyver.

- **bpo-26892**: Honor debuglevel flag in urllib.request.HTTPHandler. Patch contributed by Chi Hsuan Yen.

- **bpo-22274**: In the subprocess module, allow stderr to be redirected to stdout even when stdout is not redirected. Patch by Akira Li.

- **bpo-26807**: mock_open ‘files’ no longer error on readline at end of file. Patch from Yolanda Robla.

- **bpo-25745**: Fixed leaking a userptr in curses panel destructor.
- **bpo-26977**: Removed unnecessary, and ignored, call to sum of squares helper in statistics.pvariance.

- **bpo-26002**: Use bisect in statistics.median instead of a linear search. Patch by Upendra Kuma.

- **bpo-25974**: Make use of new Decimal.as_integer_ratio() method in statistics module. Patch by Stefan Krah.

- **bpo-26996**: Add secrets module as described in PEP 506.

- **bpo-26881**: The modulefinder module now supports extended opcode arguments.

- **bpo-23815**: Fixed crashes related to directly created instances of types in _tkinter and curses.panel modules.

- **bpo-17765**: weakref.ref() no longer silently ignores keyword arguments. Patch by Georg Brandl.

- **bpo-26873**: xmlrpc now raises ResponseError on unsupported type tags instead of silently return incorrect result.

- **bpo-26915**: The __contains__ methods in the collections ABCs now check for identity before checking equality. This better matches the behavior of the concrete classes, allows sensible handling of NaNs, and makes it easier to reason about container invariants.

- **bpo-26711**: Fixed the comparison of plistlib.Data with other types.

- **bpo-24114**: Fix an uninitialized variable in ctypes.util.

The bug only occurs on SunOS when the ctypes implementation searches for the cr1e program. Patch by Xiang Zhang. Tested on
SunOS by Kees Bos.

- **bpo-26864**: In urllib.request, change the proxy bypass host checking against no_proxy to be case-insensitive, and to not match unrelated host names that happen to have a bypassed hostname as a suffix. Patch by Xiang Zhang.

- **bpo-24902**: Print server URL on http.server startup. Initial patch by Felix Kaiser.

- **bpo-25788**: fileinput.hook_encoded() now supports an “errors” argument for passing to open. Original patch by Joseph Hackman.

- **bpo-26634**: recursive_repr() now sets __qualname__ of wrapper. Patch by Xiang Zhang.

- **bpo-26804**: urllib.request will prefer lower_case proxy environment variables over UPPER_CASE or Mixed_Case ones. Patch contributed by Hans-Peter Jansen.

- **bpo-26837**: assertSequenceEqual() now correctly outputs non-stringified differing items (like bytes in the -b mode). This affects assertListEqual() and assertTupleEqual().

- **bpo-26041**: Remove “will be removed in Python 3.7” from deprecation messages of platform.dist() and platform.linux_distribution(). Patch by Kumaripaba Miyurusara Athukorala.

- **bpo-26822**: itemgetter, attrgetter and methodcaller objects no longer silently ignore keyword arguments.

- **bpo-26733**: Disassembling a class now disassembles class and
static methods. Patch by Xiang Zhang.

- **bpo-26801**: Fix error handling in `shutil.get_terminal_size()`, catch `AttributeError` instead of `NameError`. Patch written by Emanuel Barry.

- **bpo-24838**: tarfile’s ustar and gnu formats now correctly calculate name and link field limits for multibyte character encodings like utf-8.

### Security

- **bpo-26657**: Fix directory traversal vulnerability with `http.server` on Windows. This fixes a regression that was introduced in 3.3.4rc1 and 3.4.0rc1. Based on patch by Philipp Hagemeister.

### Library

- **bpo-26782**: Add `STARTUPINFO` to `subprocess.__all__` on Windows.
- **bpo-26404**: Add context manager to `socketserver`. Patch by Aviv Palivoda.
- **bpo-26735**: Fix `os.urandom()` on Solaris 11.3 and newer when reading more than 1,024 bytes: call `getrandom()` multiple times with a limit of 1024 bytes per call.
- **bpo-26585**: Eliminate `http.server._quote_html()` and use `html.escape(quote=False)`. Patch by Xiang Zhang.
- **bpo-26685**: Raise OSError if closing a socket fails.
- **bpo-16329**: Add `.webm` to `mimetypes.types_map`. Patch by Giampaolo Rodola.
- **bpo-13952**: Add `.csv` to `mimetypes.types_map`. Patch by Geoff
Wilson.

- **bpo-26587**: the site module now allows .pth files to specify files to be added to sys.path (e.g. zip files).
- **bpo-25609**: Introduce contextlib(AbstractContextManager and typing.ContextManager).
- **bpo-26709**: Fixed Y2038 problem in loading binary PLists.
- **bpo-23735**: Handle terminal resizing with Readline 6.3+ by installing our own SIGWINCH handler. Patch by Eric Price.
- **bpo-25951**: Change SSLSocket.sendall() to return None, as explicitly documented for plain socket objects. Patch by Aviv Palivoda.
- **bpo-26586**: In http.server, respond with “413 Request header fields too large” if there are too many header fields to parse, rather than killing the connection and raising an unhandled exception. Patch by Xiang Zhang.
- **bpo-26676**: Added missing XMLPullParser to ElementTree.__all__.
- **bpo-22854**: Change BufferedReader.writable() and BufferedWriter.readable() to always return False.
- **bpo-26492**: Exhausted iterator of array.array now conforms with the behavior of iterators of other mutable sequences: it leaves exhausted even if iterated array is extended.
- **bpo-26641**: doctest.DocFileTest and doctest.testfile() now support packages (module splitted into multiple directories) for the package parameter.
- **bpo-25195**: Fix a regression in mock.MagicMock. _`Call` is a subclass of tuple (change set 3603bae63c13 only works for classes) so we need to implement __`ne`__ ourselves. Patch by Andrew Plummer.
- **bpo-26644**: Raise ValueError rather than SystemError when a negative length is passed to SSLSocket.recv() or read().
- **bpo-23804**: Fix SSL recv(0) and read(0) methods to return zero bytes instead of up to 1024.
- **bpo-26616**: Fixed a bug in datetime.astimezone() method.
• bpo-26637: The importlib module now emits an ImportError rather than a TypeError if __import__() is tried during the Python shutdown process but sys.path is already cleared (set to None).

• bpo-21925: warnings.formatwarning() now catches exceptions when calling linecache.getline() and tracemalloc.get_object_traceback() to be able to log ResourceWarning emitted late during the Python shutdown process.

• bpo-23848: On Windows, faulthandler.enable() now also installs an exception handler to dump the traceback of all Python threads on any Windows exception, not only on UNIX signals (SIGSEGV, SIGFPE, SIGABRT).

• bpo-26530: Add C functions _PyTraceMalloc_Track() and _PyTraceMalloc_Untrack() to track memory blocks using the tracemalloc module. Add _PyTraceMalloc_GetTraceback() to get the traceback of an object.

• bpo-26588: The _tracemalloc now supports tracing memory allocations of multiple address spaces (domains).

• bpo-24266: Ctrl+C during Readline history search now cancels the search mode when compiled with Readline 7.

• bpo-26590: Implement a safe finalizer for the _socket.socket type. It now releases the GIL to close the socket.

• bpo-18787: spwd.getspnam() now raises a PermissionError if the user doesn’t have privileges.

• bpo-26560: Avoid potential ValueError in BaseHandler.start_response. Initial patch by Peter Inglesby.

• bpo-26567: Add a new function PyErr_ResourceWarning() function to pass the destroyed object. Add a source attribute to warnings.WarningMessage. Add warnings._showwarnmsg() which uses tracemalloc to get the traceback where source object was allocated.
Security

- **bpo-26313**: ssl.py `_load_windows_store_certs` fails if windows cert store is empty. Patch by Baji.

Library

- **bpo-26569**: Fix `pyclbr.readmodule()` and `pyclbr.readmodule_ex()` to support importing packages.
- **bpo-26499**: Account for remaining Content-Length in `HTTPRequest.readline()` and `read1()`. Based on patch by Silent Ghost. Also document that `HTTPRequest` now supports these methods.
- **bpo-25320**: Handle sockets in directories unittest discovery is scanning. Patch from Victor van den Elzen.
- **bpo-16181**: `cookiejar.http2time()` now returns None if year is higher than datetime.MAXYEAR.
- **bpo-26513**: Fixes platform module detection of Windows Server
- **bpo-23718**: Fixed parsing time in week 0 before Jan 1. Original patch by Tamás Bence Gedai.
- **bpo-26323**: Add `Mock.assert_called()` and `Mock.assert_called_once()` methods to `unittest.mock`. Patch written by Amit Saha.
- **bpo-20589**: Invoking `Path.owner()` and `Path.group()` on Windows now raise `NotImplementedError` instead of `ImportError`.
- **bpo-26177**: Fixed the `keys()` method for Canvas and Scrollbar widgets.
- **bpo-15068**: Got rid of excessive buffering in fileinput. The bufsize parameter is now deprecated and ignored.
- **bpo-19475**: Added an optional argument `timespec` to the `datetime.isoformat()` method to choose the precision of the time component.
- **bpo-2202**: Fix UnboundLocalError in
AbstractDigestAuthHandler.get_algorithm_impls. Initial patch by Mathieu Dupuy.

- **bpo-26167**: Minimized overhead in copy.copy() and copy.deepcopy(). Optimized copying and deepcopying bytearrays, NotImplemented, slices, short lists, tuples, dicts, sets.
- **bpo-25718**: Fixed pickling and copying the accumulate() iterator with total is None.
- **bpo-26475**: Fixed debugging output for regular expressions with the (?x) flag.
- **bpo-26482**: Allowed pickling recursive dequeues.
- **bpo-26335**: Make mmap.write() return the number of bytes written like other write methods. Patch by Jakub Stasiak.
- **bpo-26457**: Fixed the subnets() methods in IP network classes for the case when resulting prefix length is equal to maximal prefix length. Based on patch by Xiang Zhang.
- **bpo-26385**: Remove the file if the internal open() call in NamedTemporaryFile() fails. Patch by Silent Ghost.
- **bpo-26402**: Fix XML-RPC client to retry when the server shuts down a persistent connection. This was a regression related to the new http.client.RemoteDisconnected exception in 3.5.0a4.
- **bpo-25913**: Leading `<~` is optional now in base64.a85decode() with adobe=True. Patch by Swati Jaiswal.
- **bpo-26186**: Remove an invalid type check in importlib.util.LazyLoader.
- **bpo-26367**: importlib.__import__() raises ImportError like builtins.__import__() when level is specified but without an accompanying package specified.
- **bpo-26309**: In the “socketserver” module, shut down the request (closing the connected socket) when verify_request() returns false. Patch by Aviv Palivoda.
- **bpo-23430**: Change the socketserver module to only catch exceptions raised from a request handler that are derived from Exception (instead of BaseException). Therefore SystemExit and KeyboardInterrupt no longer trigger the handle_error() method,
and will now to stop a single-threaded server.

Security

- **bpo-25939**: On Windows open the cert store readonly in ssl.enum_certificates.

Library

- **bpo-25995**: os.walk() no longer uses FDs proportional to the tree depth.
- **bpo-25994**: Added the close() method and the support of the context manager protocol for the os.scandir() iterator.
- **bpo-23992**: multiprocessing: make MapResult not fail-fast upon exception.
- **bpo-26243**: Support keyword arguments to zlib.compress(). Patch by Aviv Palivoda.
- **bpo-26117**: The os.scandir() iterator now closes file descriptor not only when the iteration is finished, but when it was failed with error.
- **bpo-25949**: __dict__ for an OrderedDict instance is now created only when needed.
- **bpo-25911**: Restored support of bytes paths in os.walk() on Windows.
- **bpo-26045**: Add UTF-8 suggestion to error message when posting a non-Latin-1 string with http.client.
- **bpo-12923**: Reset FancyURLopener’s redirect counter even if there is an exception. Based on patches by Brian Brazil and Daniel Rocco.
- **bpo-25945**: Fixed a crash when unpickle the functools.partial object with wrong state. Fixed a leak in failed functools.partial
constructor. “args” and “keywords” attributes of `functools.partial` have now always types tuple and dict correspondingly.

- **bpo-26202**: `copy.deepcopy()` now correctly copies `range()` objects with non-atomic attributes.
- **bpo-23076**: `Path.glob()` now raises a `ValueError` if it’s called with an invalid pattern. Patch by Thomas Nyberg.
- **bpo-19883**: Fixed possible integer overflows in `zipimport`.
- **bpo-26227**: On Windows, `getnameinfo()`, `gethostbyaddr()` and `gethostbyname_ex()` functions of the `socket` module now decode the hostname from the ANSI code page rather than UTF-8.
- **bpo-26099**: The `site` module now writes an error into `stderr` if `sitecustomize` module can be imported but executing the module raise an `ImportError`. Same change for `usercustomize`.
- **bpo-26147**: `xmlrpc` now works with strings not encodable with used non-UTF-8 encoding.
- **bpo-25935**: Garbage collector now breaks reference loops with `OrderedDict`.
- **bpo-26013**: Added compatibility with broken protocol 2 pickles created in old Python 3 versions (3.4.3 and lower).
- **bpo-26129**: Deprecated accepting non-integers in `grp.getgrgid()`.
- **bpo-25850**: Use cross-compilation by default for 64-bit Windows.
- **bpo-25822**: Add docstrings to the fields of `urllib.parse` results. Patch contributed by Swati Jaiswal.
- **bpo-22642**: Convert trace module option parsing mechanism to `argparse`. Patch contributed by SilentGhost.
- **bpo-24705**: Fix `sysconfig._parse_makefile` not expanding ${} vars appearing before {} vars.
- **bpo-25822**: Remove the deprecated apis in the trace module.
- **bpo-22138**: Fix `mock.patch` behavior when patching descriptors. Restore original values after patching. Patch contributed by Sean McCully.
- **bpo-25672**: In the `ssl` module, enable the `SSL_MODE_RELEASE_BUFFERS` mode option if it is safe to do
so.

- **bpo-26012**: Don't traverse into symlinks for `**` pattern in `pathlib.Path.[r]glob()`.

- **bpo-21815**: Accept `]` characters in the data portion of imap responses, in order to handle the flags with square brackets accepted and produced by servers such as gmail.

- **bpo-25447**: `fileinput` now uses `sys.stdin` as-is if it does not have a buffer attribute (restores backward compatibility).

- **bpo-25971**: Optimized creating Fractions from floats by 2 times and from Decimals by 3 times.

- **bpo-25802**: Document as deprecated the remaining implementations of `importlib.abc.Loader.load_module()`.

- **bpo-25928**: Add `Decimal.as_integer_ratio()`.

- **bpo-25447**: Copying the `lru_cache()` wrapper object now always works, independently from the type of the wrapped object (by returning the original object unchanged).

- **bpo-25768**: Have the functions in `compileall` return booleans instead of ints and add proper documentation and tests for the return values.

- **bpo-24103**: Fixed possible use after free in `ElementTree.XMLPullParser`.

- **bpo-25860**: `os.fwalk()` no longer skips remaining directories when error occurs. Original patch by Samson Lee.

- **bpo-25914**: Fixed and simplified `OrderedDict.__sizeof__`.

- **bpo-25869**: Optimized deepcopying `ElementTree`; it is now 20 times faster.

- **bpo-25873**: Optimized iterating `ElementTree`. Iterating elements `Element.iter()` is now 40% faster, iterating text `Element.itertext()` is now up to 2.5 times faster.

- **bpo-25902**: Fixed various refcount issues in `ElementTree` iteration.

- **bpo-22227**: The `TarFile` iterator is reimplemented using generator.
This implementation is simpler that using class.

- **bpo-25638**: Optimized `ElementTree.iterparse()`; it is now 2x faster. Optimized `ElementTree` parsing; it is now 10% faster.
- **bpo-25761**: Improved detecting errors in broken pickle data.
- **bpo-25717**:Restore the previous behaviour of tolerating most `fstat()` errors when opening files. This was a regression in 3.5a1, and stopped anonymous temporary files from working in special cases.
- **bpo-24903**: Fix regression in number of arguments `compileall` accepts when ‘-d’ is specified. The check on the number of arguments has been dropped completely as it never worked correctly anyway.
- **bpo-25764**: In the subprocess module, preserve any exception caused by `fork()` failure when `preexec_fn` is used.
- **bpo-25771**: Tweak the exception message for `importlib.util.resolve_name()` when ‘package’ isn’t specified but necessary.
- **bpo-6478**: `strptime`’s regexp cache now is reset after changing timezone with time.tzset().
- **bpo-14285**: When executing a package with the “python -m package” option, and package initialization fails, a proper traceback is now reported. The “runpy” module now lets exceptions from package initialization pass back to the caller, rather than raising ImportError.
- **bpo-19771**: Also in runpy and the “-m” option, omit the irrelevant message “… is a package and cannot be directly executed” if the package could not even be initialized (e.g. due to a bad *.pyc file).
- **bpo-25177**: Fixed problem with the mean of very small and very large numbers. As a side effect, `statistics.mean` and `statistics.variance` should be significantly faster.
- **bpo-25718**: Fixed copying object with state with boolean value is false.
- **bpo-10131**: Fixed deep copying of minidom documents. Based on
patch by Marian Ganisin.

- **bpo-7990**: `dir()` on `ElementTree.Element` now lists properties: “tag”, “text”, “tail” and “attrib”. Original patch by Santoso Wijaya.
- **bpo-25725**: Fixed a reference leak in `pickle.loads()` when unpickling invalid data including tuple instructions.
- **bpo-25663**: In the Readline completer, avoid listing duplicate global names, and search the global namespace before searching builtins.
- **bpo-25688**: Fixed file leak in `ElementTree.iterparse()` raising an error.
- **bpo-23914**: Fixed `SystemError` raised by unpickler on broken pickle data.
- **bpo-25691**: Fixed crash on deleting `ElementTree.Element` attributes.
- **bpo-25624**: ZipFile now always writes a ZIP_STORED header for directory entries. Patch by Dingyuan Wang.
- **bpo-25626**: Change three zlib functions to accept sizes that fit in Py_ssize_t, but internally cap those sizes to UINT_MAX. This resolves a regression in 3.5 where `GzipFile.read()` failed to read chunks larger than 2 or 4 GiB. The change affects the `zlib.Decompress.decompress()` `max_length` parameter, the `zlib.decompress()` `bufsize` parameter, and the `zlib.Decompress.flush()` length parameter.
- **bpo-25583**: Avoid incorrect errors raised by `os.makedirs(exist_ok=True)` when the OS gives priority to errors such as EACCES over EEXIST.
- **bpo-25593**: Change semantics of `EventLoop.stop()` in asyncio.
- **bpo-6973**: When we know a subprocess.Popen process has died, do not allow the `send_signal()`, `terminate()`, or `kill()` methods to do anything as they could potentially signal a different process.
- **bpo-23883**: Added missing APIs to `__all__` to match the documented APIs for the following modules: calendar, csv, enum, fileinput, ftplib, logging, optparse, tarfile, threading and wave. Also added a `test.support.check__all__()` helper. Patches by Jacek
• **bpo-25590**: In the Readline completer, only call getattr() once per attribute. Also complete names of attributes such as properties and slots which are listed by dir() but not yet created on an instance.

• **bpo-25498**: Fix a crash when garbage-collecting ctypes objects created by wrapping a memoryview. This was a regression made in 3.5a1. Based on patch by Eryksun.

• **bpo-25584**: Added “escape” to the __all__ list in the glob module.

• **bpo-25584**: Fixed recursive glob() with patterns starting with **.

• **bpo-25446**: Fix regression in smtplib’s AUTH LOGIN support.

• **bpo-18010**: Fix the pydoc web server’s module search function to handle exceptions from importing packages.

• **bpo-25554**: Got rid of circular references in regular expression parsing.

• **bpo-18973**: Command-line interface of the calendar module now uses argparse instead of optparse.

• **bpo-25510**: fileinput.FileInput.readline() now returns b"" instead of "" at the end if the FileInput was opened with binary mode. Patch by Ryosuke Ito.

• **bpo-25503**: Fixed inspect.getdoc() for inherited docstrings of properties. Original patch by John Mark Vandenberg.

• **bpo-25515**: Always use os.urandom as a source of randomness in uuid.uuid4.

• **bpo-21827**: Fixed textwrap.dedent() for the case when largest common whitespace is a substring of smallest leading whitespace. Based on patch by Robert Li.

• **bpo-25447**: The lru_cache() wrapper objects now can be copied and pickled (by returning the original object unchanged).

• **bpo-25390**: typing: Don’t crash on Union[str, Pattern].

• **bpo-25441**: asyncio: Raise error from drain() when socket is closed.

• **bpo-25410**: Cleaned up and fixed minor bugs in C implementation of OrderedDict.
- **bpo-25411**: Improved Unicode support in SMTPHandler through better use of the email package. Thanks to user simon04 for the patch.
- Move the imp module from a PendingDeprecationWarning to DeprecationWarning.
- **bpo-25407**: Remove mentions of the formatter module being removed in Python 3.6.
- **bpo-25406**: Fixed a bug in C implementation of OrderedDict.move_to_end() that caused segmentation fault or hang in iterating after moving several items to the start of ordered dict.
- **bpo-25382**: pickletools.dis() now outputs implicit memo index for the MEMOIZE opcode.
- **bpo-25357**: Add an optional newline paramer to binascii.b2a_base64(). base64.b64encode() uses it to avoid a memory copy.
- **bpo-24164**: Objects that need calling __new__ with keyword arguments, can now be pickled using pickle protocols older than protocol version 4.
- **bpo-25364**: zipfile now works in threads disabled builds.
- **bpo-25328**: smtpd's SMTPChannel now correctly raises a ValueError if both decode_data and enable_SMTPUTF8 are set to true.
- **bpo-16099**: RobotFileParser now supports Crawl-delay and Request-rate extensions. Patch by Nikolay Bogoychev.
- **bpo-25316**: distutils raises OSError instead of DistutilsPlatformError when MSVC is not installed.
- **bpo-25380**: Fixed protocol for the STACK_GLOBAL opcode in pickletools.opcodes.
- **bpo-23972**: Updates asyncio datagram create method allowing reuseport and reuseaddr socket options to be set prior to binding the socket. Mirroring the existing asyncio create_server method the reuseaddr option for datagram sockets defaults to True if the O/S is ‘posix’ (except if the platform is Cygwin). Patch by Chris
Laws.

- **bpo-25304**: Add asyncio.run_coroutine_threadsafe(). This lets you submit a coroutine to a loop from another thread, returning a concurrent.futures.Future. By Vincent Michel.
- **bpo-25232**: Fix CGIRequestHandler to split the query from the URL at the first question mark (?) rather than the last. Patch from Xiang Zhang.
- **bpo-24657**: Prevent CGIRequestHandler from collapsing slashes in the query part of the URL as if it were a path. Patch from Xiang Zhang.
- **bpo-25287**: Don’t add crypt.METHOD_CRYPT to crypt.methods if it’s not supported. Check if it is supported, it may not be supported on OpenBSD for example.
- **bpo-23600**: Default implementation of tzinfo.fromutc() was returning wrong results in some cases.
- **bpo-25203**: Failed readline.set_completer_delims() no longer left the module in inconsistent state.
- **bpo-25011**: rlcompleter now omits private and special attribute names unless the prefix starts with underscores.
- **bpo-25209**: rlcompleter now can add a space or a colon after completed keyword.
- **bpo-22241**: timezone.utc name is now plain ‘UTC’, not ‘UTC-00:00’.
- **bpo-23517**: fromtimestamp() and utcfromtimestamp() methods of datetime.datetime now round microseconds to nearest with ties going to nearest even integer (ROUND_HALF_EVEN), as round(float), instead of rounding towards -Infinity (ROUND_FLOOR).
- **bpo-23552**: Timeit now warns when there is substantial (4x) variance between best and worst times. Patch from Serhiy Storchaka.
- **bpo-24633**: site-packages/README -> README.txt.
- **bpo-24879**: help() and pydoc can now list named tuple fields in the order they were defined rather than alphabetically. The
ordering is determined by the _fields attribute if present.

- **bpo-24874**: Improve speed of itertools.cycle() and make its pickle more compact.
- **bpo-20059**: urllib.parse raises ValueError on all invalid ports. Patch by Martin Panter.
- **bpo-24360**: Improve __repr__ of argparse.Namespace() for invalid identifiers. Patch by Matthias Bussonnier.
- **bpo-23426**: run_setup was broken in distutils. Patch from Alexander Belopolsky.
- **bpo-13938**: 2to3 converts StringTypes to a tuple. Patch from Mark Hammond.
- **bpo-2091**: open() accepted a ‘U’ mode string containing ‘+’, but ‘U’ can only be used with ‘r’. Patch from Jeff Balogh and John O’Connor.
- **bpo-8585**: improved tests for zipimporter2. Patch from Mark Lawrence.
- **bpo-18622**: unittest.mock.mock_open().reset_mock would recurse infinitely. Patch from Nicola Palumbo and Laurent De Buyst.
- **bpo-24426**: Fast searching optimization in regular expressions now works for patterns that starts with capturing groups. Fast searching optimization now can’t be disabled at compile time.
- **bpo-23661**: unittest.mock side_effects can now be exceptions again. This was a regression vs Python 3.4. Patch from Ignacio Rossi
- **bpo-13248**: Remove deprecated inspect.getmoduleinfo function.
- **bpo-25578**: Fix (another) memory leak in SSLSocket.getpeercer().
- **bpo-25530**: Disable the vulnerable SSLv3 protocol by default when creating ssl.SSLContext.
- **bpo-25569**: Fix memory leak in SSLSocket.getpeercert().
- **bpo-25471**: Sockets returned from accept() shouldn’t appear to be nonblocking.
- **bpo-25319**: When threading.Event is reinitialized, the underlying
condition should use a regular lock rather than a recursive lock.

- Skip getaddrinfo if host is already resolved. Patch by A. Jesse Jiryu Davis.
- bpo-25924: Avoid unnecessary serialization of getaddrinfo(3) calls on OS X versions 10.5 or higher. Original patch by A. Jesse Jiryu Davis.
- bpo-26406: Avoid unnecessary serialization of getaddrinfo(3) calls on current versions of OpenBSD and NetBSD. Patch by A. Jesse Jiryu Davis.
- bpo-27040: Add loop.get_exception_handler method
- bpo-27041: asyncio: Add loop.create_future method

IDLE

- In the ‘IDLE-console differences’ section of the IDLE doc, clarify how running with IDLE affects sys.modules and the standard streams.
- bpo-25507: fix incorrect change in IOBinding that prevented printing. Augment IOBinding htest to include all major IOBinding functions.
- bpo-25905: Revert unwanted conversion of ‘ to ’ RIGHT SINGLE QUOTATION MARK in README.txt and open this and NEWS.txt with ‘ascii’. Re-encode CREDITS.txt to utf-8 and open it with ‘utf-8’.
- bpo-15348: Stop the debugger engine (normally in a user process) before closing the debugger window (running in the IDLE process). This prevents the RuntimeErrors that were being caught and ignored.
• **bpo-24455**: Prevent IDLE from hanging when a) closing the shell while the debugger is active (15347); b) closing the debugger with the [X] button (15348); and c) activating the debugger when already active (24455). The patch by Mark Roseman does this by making two changes. 1. Suspend and resume the gui.interaction method with the tcl vwait mechanism intended for this purpose (instead of root.mainloop & .quit). 2. In gui.run, allow any existing interaction to terminate first.

• Change ‘The program’ to ‘Your program’ in an IDLE ‘kill program?’ message to make it clearer that the program referred to is the currently running user program, not IDLE itself.

• **bpo-24750**: Improve the appearance of the IDLE editor window status bar. Patch by Mark Roseman.

• **bpo-25313**: Change the handling of new built-in text color themes to better address the compatibility problem introduced by the addition of IDLE Dark. Consistently use the revised idleConf.CurrentTheme everywhere in idlelib.

• **bpo-24782**: Extension configuration is now a tab in the IDLE Preferences dialog rather than a separate dialog. The former tabs are now a sorted list. Patch by Mark Roseman.

• **bpo-22726**: Re-activate the config dialog help button with some content about the other buttons and the new IDLE Dark theme.

• **bpo-24820**: IDLE now has an ‘IDLE Dark’ built-in text color theme. It is more or less IDLE Classic inverted, with a cobalt blue background. Strings, comments, keywords, … are still green, red, orange, … . To use it with IDLEs released before November 2015, hit the ‘Save as New Custom Theme' button and enter a new name, such as ‘Custom Dark’. The custom theme will work with any IDLE release, and can be modified.

• **bpo-25224**: README.txt is now an idlelib index for IDLE developers and curious users. The previous user content is now in the IDLE doc chapter. ‘IDLE’ now means ‘Integrated Development and Learning Environment’.

• **bpo-24820**: Users can now set breakpoint colors in Settings -→
Custom Highlighting. Original patch by Mark Roseman.

- **bpo-24972**: Inactive selection background now matches active selection background, as configured by users, on all systems. Found items are now always highlighted on Windows. Initial patch by Mark Roseman.

- **bpo-24570**: Idle: make calltip and completion boxes appear on Macs affected by a tk regression. Initial patch by Mark Roseman.

- **bpo-24988**: Idle ScrolledList context menus (used in debugger) now work on Mac Aqua. Patch by Mark Roseman.

- **bpo-24801**: Make right-click for context menu work on Mac Aqua. Patch by Mark Roseman.

- **bpo-25173**: Associate tkinter messageboxes with a specific widget. For Mac OSX, make them a ‘sheet’. Patch by Mark Roseman.

- **bpo-25198**: Enhance the initial html viewer now used for Idle Help. * Properly indent fixed-pitch text (patch by Mark Roseman). * Give code snippet a very Sphinx-like light blueish-gray background. * Re-use initial width and height set by users for shell and editor. * When the Table of Contents (TOC) menu is used, put the section header at the top of the screen.

- **bpo-25225**: Condense and rewrite Idle doc section on text colors.

- **bpo-21995**: Explain some differences between IDLE and console Python.

- **bpo-22820**: Explain need for `print` when running file from Idle editor.

- **bpo-25224**: Doc: augment Idle feature list and no-subprocess section.

- **bpo-25219**: Update doc for Idle command line options. Some were missing and notes were not correct.

- **bpo-24861**: Most of idlelib is private and subject to change. Use `idlelib.idle.*` to start Idle. See `idlelib.__init__.doc`.

- **bpo-25199**: Idle: add synchronization comments for future maintainers.

- **bpo-16893**: Replace help.txt with help.html for Idle doc display.
The new idlelib/help.html is rstripped Doc/build/html/library/idle.html. It looks better than help.txt and will better document Idle as released. The tkinter html viewer that works for this file was written by Rose Roseman. The now unused EditorWindow.HelpDialog class and helt.txt file are deprecated.

- **bpo-24199**: Deprecate unused idlelib.idlever with possible removal in 3.6.
- **bpo-24790**: Remove extraneous code (which also create 2 & 3 conflicts).

### Documentation

- **bpo-26736**: Used HTTPS for external links in the documentation if possible.
- **bpo-6953**: Rework the Readline module documentation to group related functions together, and add more details such as what underlying Readline functions and variables are accessed.
- **bpo-23606**: Adds note to ctypes documentation regarding cdll.msvcr.
- **bpo-24952**: Clarify the default size argument of stack_size() in the “threading” and “_thread” modules. Patch from Mattip.
- **bpo-26014**: Update 3.x packaging documentation: * “See also” links to the new docs are now provided in the legacy pages * links to setuptools documentation have been updated

### Tests

- **bpo-21916**: Added tests for the turtle module. Patch by ingrid, Gregory Loyse and Jelle Zijlstra.
- **bpo-26295**: When using “python3 -m test –testdir=TESTDIR”, regrtest doesn’t add “test.” prefix to test module names.
- **bpo-26523**: The multiprocessing thread pool (multiprocessing.dummy.Pool) was untested.
• **bpo-26015**: Added new tests for pickling iterators of mutable sequences.
• **bpo-26325**: Added `test.support.check_no_resource_warning()` to check that no `ResourceWarning` is emitted.
• **bpo-25940**: Changed `test_ssl` to use its internal local server more. This avoids relying on `svn.python.org`, which recently changed root certificate.
• **bpo-25616**: Tests for `OrderedDict` are extracted from `test_collections` into separate file `test_ordered_dict`.
• **bpo-25449**: Added tests for `OrderedDict` subclasses.
• **bpo-25188**: Add `-P/-pgo` to `test.regrtest` to suppress error output when running the test suite for the purposes of a PGO build. Initial patch by Alecsandru Patrascu.
• **bpo-22806**: Add `python -m test --list-tests` command to list tests.
• **bpo-18174**: `python -m test --huntrleaks ...` now also checks for leak of file descriptors. Patch written by Richard Oudkerk.
• **bpo-25260**: Fix `python -m test --coverage` on Windows. Remove the list of ignored directories.
• **PCbuild\rt.bat** now accepts an unlimited number of arguments to pass along to `regrtest.py`. Previously there was a limit of 9.
• **bpo-26583**: Skip `test_timestamp_overflow` in `test_import` if bytecode files cannot be written.

**Build**

• **bpo-21277**: Don’t try to link `_ctypes` with a `ffi_convenience` library.
• **bpo-26884**: Fix linking extension modules for cross builds. Patch by Xavier de Gaye.
• **bpo-26932**: Fixed support of `RTLD_*` constants defined as enum values, not via macros (in particular on Android). Patch by Chi
Hsuan Yen.

- **bpo-22359**: Disable the rules for running _freeze_importlib and pgen when cross-compiling. The output of these programs is normally saved with the source code anyway, and is still regenerated when doing a native build. Patch by Xavier de Gaye.
- **bpo-21668**: Link audioop, _datetime, _ctypes_test modules to libm, except on Mac OS X. Patch written by Chi Hsuan Yen.
- **bpo-25702**: A –with-lto configure option has been added that will enable link time optimizations at build time during a make profile-opt. Some compilers and toolchains are known to not produce stable code when using LTO, be sure to test things thoroughly before relying on it. It can provide a few % speed up over profile-opt alone.
- **bpo-26624**: Adds validation of ucrtbase[d].dll version with warning for old versions.
- **bpo-17603**: Avoid error about nonexistant fileblocks.o file by using a lower-level check for st_blocks in struct stat.
- **bpo-26079**: Fixing the build output folder for tix-8.4.3.6. Patch by Bjoern Thiel.
- **bpo-26465**: Update Windows builds to use OpenSSL 1.0.2g.
- **bpo-25348**: Added --pgo and --pgo-job arguments to PCbuild\build.bat for building with Profile-Guided Optimization. The old PCbuild\build_pgo.bat script is removed.
- **bpo-25827**: Add support for building with ICC to configure, including a new --with-icc flag.
- **bpo-25696**: Fix installation of Python on UNIX with make -j9.
- **bpo-24986**: It is now possible to build Python on Windows without errors when external libraries are not available.
- **bpo-24421**: Compile Modules/_math.c once, before building extensions. Previously it could fail to compile properly if the math and cmath builds were concurrent.
- **bpo-26465**: Update OS X 10.5+ 32-bit-only installer to build and link with OpenSSL 1.0.2g.
• **bpo-26268**: Update Windows builds to use OpenSSL 1.0.2f.
• **bpo-25136**: Support Apple Xcode 7’s new textual SDK stub libraries.
• **bpo-24324**: Do not enable unreachable code warnings when using gcc as the option does not work correctly in older versions of gcc and has been silently removed as of gcc-4.5.

**Windows**

• **bpo-27053**: Updates make_zip.py to correctly generate library ZIP file.
• **bpo-26268**: Update the prepare_ssl.py script to handle OpenSSL releases that don’t include the contents of the include directory (that is, 1.0.2e and later).
• **bpo-26071**: bdist_wininst created binaries fail to start and find 32bit Python
• **bpo-26073**: Update the list of magic numbers in launcher
• **bpo-26065**: Excludes venv from library when generating embeddable distro.
• **bpo-25022**: Removed very outdated PC/example_nt/ directory.

**Tools/Demos**

• **bpo-26799**: Fix python-gdb.py: don’t get C types once when the Python code is loaded, but get C types on demand. The C types can change if python- gdb.py is loaded before the Python executable. Patch written by Thomas Ilsche.
• **bpo-26271**: Fix the Freeze tool to properly use flags passed through configure. Patch by Daniel Shaulov.
• **bpo-26489**: Add dictionary unpacking support to Tools/parser/unparse.py. Patch by Guo Ci Teo.
• **bpo-26316**: Fix variable name typo in Argument Clinic.
• **bpo-25440**: Fix output of python-config –extension-suffix.
• **bpo-25154**: The pyvenv script has been deprecated in favour of `python3 -m venv`.

**C API**

• **bpo-26312**: SystemError is now raised in all programming bugs with using `PyArg_ParseTupleAndKeywords()`. `RuntimeError` did raised before in some programming bugs.

• **bpo-26198**: ValueError is now raised instead of TypeError on buffer overflow in parsing “es#” and “et#” format units. SystemError is now raised instead of TypeError on programmical error in parsing format string.
Python 3.5.3 final?

Release date: 2017-01-17

There were no code changes between 3.5.3rc1 and 3.5.3 final.
Python 3.5.3 release candidate 1?

*Release date: 2017-01-02*

Core and Builtins

- **bpo-29073**: bytearray formatting no longer truncates on first null byte.
- **bpo-28932**: Do not include `<sys/random.h>` if it does not exist.
- **bpo-28147**: Fix a memory leak in split-table dictionaries: `setattr()` must not convert combined table into split table.
- **bpo-25677**: Correct the positioning of the syntax error caret for indented blocks. Based on patch by Michael Layzell.
- **bpo-29000**: Fixed bytes formatting of octals with zero padding in alternate form.
- **bpo-28512**: Fixed setting the offset attribute of SyntaxError by `PyErr_SyntaxLocationEx()` and `PyErr_SyntaxLocationObject()`.
- **bpo-28991**: `functools.lru_cache()` was susceptible to an obscure reentrancy bug caused by a monkey-patched `len()` function.
- **bpo-28648**: Fixed crash in `Py_DecodeLocale()` in debug build on Mac OS X when decode astral characters. Patch by Xiang Zhang.
- **bpo-19398**: Extra slash no longer added to `sys.path` components in case of empty compile- time `PYTHONPATH` components.
- **bpo-28426**: Fixed potential crash in `PyUnicode_AsDecodedObject()` in debug build.
- **bpo-23782**: Fixed possible memory leak in `_PyTraceback_Add()` and exception loss in `PyTraceBack_Here()`.
- **bpo-28379**: Added sanity checks and tests for `PyUnicode_CopyCharacters()`. Patch by Xiang Zhang.
- **bpo-28376**: The type of long range iterator is now registered as `Iterator`. Patch by Oren Milman.
- **bpo-28376**: The constructor of range_iterator now checks that step is not 0. Patch by Oren Milman.
- **bpo-26906**: Resolving special methods of uninitialized type now causes implicit initialization of the type instead of a fail.
- **bpo-18287**: `PyType_Ready()` now checks that `tp_name` is not NULL. Original patch by Niklas Koep.
- **bpo-24098**: Fixed possible crash when AST is changed in process of compiling it.
- **bpo-28350**: String constants with null character no longer interned.
- **bpo-26617**: Fix crash when GC runs during weakref callbacks.
- **bpo-27942**: String constants now interned recursively in tuples and frozensets.
- **bpo-21578**: Fixed misleading error message when `ImportError` called with invalid keyword args.
- **bpo-28203**: Fix incorrect type in error message from `complex(1.0, {2:3})`. Patch by Soumya Sharma.
- **bpo-27955**: Fallback on reading /dev/urandom device when the getrandom() syscall fails with EPERM, for example when blocked by SECCOMP.
- **bpo-28131**: Fix a regression in zipimport's `compile_source()`. zipimport should use the same optimization level as the interpreter.
- **bpo-25221**: Fix corrupted result from `PyLong_FromLong(0)` when Python is compiled with NSMALLPOSINTS = 0.
- **bpo-25758**: Prevents zipimport from unnecessarily encoding a filename (patch by Eryk Sun)
- **bpo-28189**: `dictitems_contains` no longer swallows compare errors. (Patch by Xiang Zhang)
- **bpo-27812**: Properly clear out a generator's frame's backreference to the generator to prevent crashes in `frame.clear()`.
- **bpo-27811**: Fix a crash when a coroutine that has not been awaited is finalized with warnings-as-errors enabled.
- **bpo-27587**: Fix another issue found by PVS-Studio: Null pointer check after use of ‘def’ in `_PyState_AddModule()`. Initial patch by
Christian Heimes.

- **bpo-26020**: set literal evaluation order did not match documented behaviour.

- **bpo-27782**: Multi-phase extension module import now correctly allows the `m_methods` field to be used to add module level functions to instances of non-module types returned from `Py_create_mod`. Patch by Xiang Zhang.

- **bpo-27936**: The `round()` function accepted a second None argument for some types but not for others. Fixed the inconsistency by accepting None for all numeric types.

- **bpo-27487**: Warn if a submodule argument to “python -m” or `runpy.run_module()` is found in `sys.modules` after parent packages are imported, but before the submodule is executed.

- **bpo-27558**: Fix a SystemError in the implementation of “raise” statement. In a brand new thread, raise a `RuntimeError` since there is no active exception to reraise. Patch written by Xiang Zhang.

- **bpo-27419**: Standard `__import__() no longer look up “__import__” in globals or builtins for importing submodules or “from import”. Fixed handling an error of non- string package name.

- **bpo-27083**: Respect the PYTHONCASEOK environment variable under Windows.

- **bpo-27514**: Make having too many statically nested blocks a SyntaxError instead of SystemError.

- **bpo-27473**: Fixed possible integer overflow in bytes and bytearray concatenations. Patch by Xiang Zhang.

- **bpo-27507**: Add integer overflow check in `bytearray.extend()`. Patch by Xiang Zhang.

- **bpo-27581**: Don’t rely on wrapping for overflow check in `PySequence_Tuple()`. Patch by Xiang Zhang.

- **bpo-27443**: `__length_hint__()` of bytearray iterators no longer return a negative integer for a resized bytearray.

- **bpo-27942**: Fix memory leak in `codeobject.c`
Library

- **bpo-15812**: `inspect.getframeinfo()` now correctly shows the first line of a context. Patch by Sam Breese.

- **bpo-29094**: Offsets in a ZIP file created with `extern` file object and modes “w” and “x” now are relative to the start of the file.

- **bpo-13051**: Fixed recursion errors in large or resized `curses.textpad.Textbox`. Based on patch by Tycho Andersen.

- **bpo-9770**: `curses.ascii` predicates now work correctly with negative integers.

- **bpo-28427**: Old keys should not remove new values from `WeakValueDictionary` when collecting from another thread.

- **bpo-28923**: Remove editor artifacts from `Tix.py`.

- **bpo-28871**: Fixed a crash when deallocate deep `ElementTree`.

- **bpo-19542**: Fix bugs in `WeakValueDictionary.setdefault()` and `WeakValueDictionary.pop()` when a GC collection happens in another thread.

- **bpo-20191**: Fixed a crash in `resource.prlimit()` when pass a sequence that doesn’t own its elements as limits.

- **bpo-28779**: `multiprocessing.set_forkserver_preload()` would crash the forkserver process if a preloaded module instantiated some
multiprocessing objects such as locks.

- **bpo-28847**: dbm.dumb now supports reading read-only files and no longer writes the index file when it is not changed.

- **bpo-25659**: In ctypes, prevent a crash calling the from_buffer() and from_buffer_copy() methods on abstract classes like Array.

- **bpo-28732**: Fix crash in os.spawnv() with no elements in args

- **bpo-28485**: Always raise ValueError for negative compileall.compile_dir(workers=…) parameter, even when multithreading is unavailable.

- **bpo-28387**: Fixed possible crash in _io.TextIOWrapper deallocator when the garbage collector is invoked in other thread. Based on patch by Sebastian Cufre.

- **bpo-27517**: LZMA compressor and decompressor no longer raise exceptions if given empty data twice. Patch by Benjamin Fogle.

- **bpo-28549**: Fixed segfault in curses's addch() with ncurses6.

- **bpo-28449**: tarfile.open() with mode “r” or “r:” now tries to open a tar file with compression before trying to open it without compression. Otherwise it had 50% chance failed with ignore_zeros=True.

- **bpo-23262**: The webbrowser module now supports Firefox 36+ and derived browsers. Based on patch by Oleg Broytman.

- **bpo-27939**: Fixed bugs in tkinter.ttk.LabeledScale and tkinter.Scale caused by representing the scale as float value internally in Tk. tkinter.IntVar now works if float value is set to underlying Tk variable.
• **bpo-28255**: calendar.TextCalendar().prmonth() no longer prints a space at the start of new line after printing a month’s calendar. Patch by Xiang Zhang.

• **bpo-20491**: The textwrap.TextWrapper class now honors non-breaking spaces. Based on patch by Kaarle Ritvanen.

• **bpo-28353**: os.fwalk() no longer fails on broken links.

• **bpo-25464**: Fixed HList.header_exists() in tkinter.tix module by addin a workaround to Tix library bug.

• **bpo-28488**: shutil.make_archive() no longer add entry “./” to ZIP archive.

• **bpo-24452**: Make webbrowser support Chrome on Mac OS X.

• **bpo-20766**: Fix references leaked by pdb in the handling of SIGINT handlers.

• **bpo-26293**: Fixed writing ZIP files that starts not from the start of the file. Offsets in ZIP file now are relative to the start of the archive in conforming to the specification.

• **bpo-28321**: Fixed writing non-BMP characters with binary format in plistlib.

• **bpo-28322**: Fixed possible crashes when unpickle itertools objects from incorrect pickle data. Based on patch by John Leitch.

• Fix possible integer overflows and crashes in the mmap module with unusual usage patterns.

• **bpo-1703178**: Fix the ability to pass the –link-objects option to the
distutils build_ext command.

- **bpo-28253**: Fixed calendar functions for extreme months: 0001-01 and 9999-12.

  Methods `itermonthdays()` and `itermonthdays2()` are reimplemented so that they don’t call `itermonthdates()` which can cause `datetime.date` under/overflow.

- **bpo-28275**: Fixed possible use after free in the decompress() methods of the LZMADecompressor and BZ2Decompressor classes. Original patch by John Leitch.

- **bpo-27897**: Fixed possible crash in `sqlite3.Connection.create_collation()` if pass invalid string-like object as a name. Patch by Xiang Zhang.

- **bpo-18893**: Fix invalid exception handling in `Lib/ctypes/macholib/dyld.py`. Patch by Madison May.

- **bpo-27611**: Fixed support of default root window in the `tkinter.tix` module.

- **bpo-27348**: In the traceback module, restore the formatting of exception messages like “Exception: None”. This fixes a regression introduced in 3.5a2.

- **bpo-25651**: Allow falsy values to be used for msg parameter of `subTest()`.

- **bpo-27932**: Prevent memory leak in `win32_ver()`.

- Fix `UnboundLocalError` in `socket._sendfile_use_sendfile`.

- **bpo-28075**: Check for `ERROR_ACCESS_DENIED` in Windows
implementation of os.stat(). Patch by Eryk Sun.

- **bpo-25270**: Prevent codecs.escape_encode() from raising SystemError when an empty bytestring is passed.

- **bpo-28181**: Get antigravity over HTTPS. Patch by Kaartic Sivaraam.

- **bpo-25895**: Enable WebSocket URL schemes in urllib.parse.urljoin. Patch by Gergely Imreh and Markus Holtermann.

- **bpo-27599**: Fixed buffer overrun in binascii.b2a_qp() and binascii.a2b_qp().

- **bpo-19003**: `email.generator` now replaces only `\r` and/or `\n` line endings, per the RFC, instead of all unicode line endings.

- **bpo-28019**: `itertools.count()` no longer rounds non-integer step in range between 1.0 and 2.0 to 1.

- **bpo-25969**: Update the lib2to3 grammar to handle the unpacking generalizations added in 3.5.

- **bpo-14977**: `mailcap` now respects the order of the lines in the mailcap files (“first match”), as required by RFC 1542. Patch by Michael Lazar.

- **bpo-24594**: Validates persist parameter when opening MSI database

- **bpo-17582**: `xml.etree.ElementTree` now preserves whitespaces in attributes (Patch by Duane Griffin. Reviewed and approved by Stefan Behnel.)
• **bpo-28047**: Fixed calculation of line length used for the base64 CTE in the new email policies.

• **bpo-27445**: Don’t pass `str(_charset)` to `MIMEText.set_payload()`. Patch by Claude Paroz.

• **bpo-22450**: `urllib` now includes an `Accept: */*` header among the default headers. This makes the results of REST API requests more consistent and predictable especially when proxy servers are involved.

• **lib2to3.pgen3.driver.load_grammar()** now creates a stable cache file between runs given the same Grammar.txt input regardless of the hash randomization setting.

• **bpo-27570**: Avoid zero-length memcpy() etc calls with null source pointers in the “ctypes” and “array” modules.

• **bpo-22233**: Break email header lines *only* on the RFC specified CR and LF characters, not on arbitrary unicode line breaks. This also fixes a bug in HTTP header parsing.

• **bpo-27988**: Fix email iter_attachments incorrect mutation of payload list.

• **bpo-27691**: Fix ssl module’s parsing of GEN_RID subject alternative name fields in X.509 certs.

• **bpo-27850**: Remove 3DES from ssl module’s default cipher list to counter measure sweet32 attack (CVE-2016-2183).

• **bpo-27766**: Add ChaCha20 Poly1305 to ssl module’s default cipher list. (Required OpenSSL 1.1.0 or LibreSSL).
- **bpo-26470**: Port ssl and hashlib module to OpenSSL 1.1.0.

- Remove support for passing a file descriptor to os.access. It never worked but previously didn’t raise.

- **bpo-12885**: Fix error when distutils encounters symlink.

- **bpo-27881**: Fixed possible bugs when setting sqlite3.Connection.isolation_level. Based on patch by Xiang Zhang.

- **bpo-27861**: Fixed a crash in sqlite3.Connection.cursor() when a factory creates not a cursor. Patch by Xiang Zhang.

- **bpo-19884**: Avoid spurious output on OS X with Gnu Readline.

- **bpo-10513**: Fix a regression in Connection.commit(). Statements should not be reset after a commit.

- A new version of typing.py from https://github.com/python/typing: - Collection (only for 3.6) (**bpo-27598**) - Add FrozenSet to __all__ (upstream #261) - fix crash in _get_type_vars() (upstream #259) - Remove the dict constraint in ForwardRef._eval_type (upstream #252)

- **bpo-27539**: Fix unnormalised Fraction.__pow__ result in the case of negative exponent and negative base.

- **bpo-21718**: cursor.description is now available for queries using
CTEs.

- **bpo-2466**: posixpath.ismount now correctly recognizes mount points which the user does not have permission to access.

- **bpo-27773**: Correct some memory management errors server_hostname in _ssl.wrap_socket().

- **bpo-26750**: unittest.mock.create_autospec() now works properly for subclasses of property() and other data descriptors.

- In the curses module, raise an error if window.getstr() or window.instr() is passed a negative value.

- **bpo-27783**: Fix possible usage of uninitialized memory in operator.methodcaller.

- **bpo-27774**: Fix possible Py_DECREF on unowned object in _sre.

- **bpo-27760**: Fix possible integer overflow in binascii.b2a_qp.

- **bpo-27758**: Fix possible integer overflow in the _csv module for large record lengths.

- **bpo-27568**: Prevent HTTPoxy attack (CVE-2016-1000110). Ignore the HTTP_PROXY variable when REQUEST_METHOD environment is set, which indicates that the script is in CGI mode.

- **bpo-27656**: Do not assume sched.h defines any SCHED_* constants.

- **bpo-27130**: In the “zlib” module, fix handling of large buffers (typically 4 GiB) when compressing and decompressing. Previously, inputs were limited to 4 GiB, and compression and decompression operations did not properly handle results of 4
GiB.

- **bpo-27533**: Release GIL in nt._isdir
- **bpo-17711**: Fixed unpickling by the persistent ID with protocol 0. Original patch by Alexandre Vassalotti.
- **bpo-27522**: Avoid an unintentional reference cycle in email.feedparser.
- **bpo-26844**: Fix error message for imp.find_module() to refer to ‘path’ instead of ‘name’. Patch by Lev Maximov.
- **bpo-23804**: Fix SSL zero-length recv() calls to not block and not raise an error about unclean EOF.
- **bpo-27466**: Change time format returned by http.cookie.time2netscape, confirming the netscape cookie format and making it consistent with documentation.
- **bpo-26664**: Fix activate.fish by removing mis-use of $.
- **bpo-22115**: Fixed tracing Tkinter variables: trace_vdelete() with wrong mode no longer break tracing, trace_vinfo() now always returns a list of pairs of strings, tracing in the “u” mode now works.
- Fix a scoping issue in importlib.util.LazyLoader which triggered an UnboundLocalError when lazy-loading a module that was already put into sys.modules.
- **bpo-27079**: Fixed curses.ascii functions isblank(), iscntrl() and ispunct().
- **bpo-26754**: Some functions (compile() etc) accepted a filename argument encoded as an iterable of integers. Now only strings
and byte-like objects are accepted.

- **bpo-27048**: Prevents distutils failing on Windows when environment variables contain non-ASCII characters.

- **bpo-27330**: Fixed possible leaks in the ctypes module.

- **bpo-27238**: Got rid of bare excepts in the turtle module. Original patch by Jelle Zijlstra.

- **bpo-27122**: When an exception is raised within the context being managed by a contextlib.ExitStack() and one of the exit stack generators catches and raises it in a chain, do not re-raise the original exception when exiting, let the new chained one through. This avoids the PEP 479 bug described in issue25782.

**Security**

- **bpo-27278**: Fix os.urandom() implementation using getrandom() on Linux. Truncate size to INT_MAX and loop until we collected enough random bytes, instead of casting a directly Py_ssize_t to int.

**Library**

- **bpo-26386**: Fixed ttk.TreeView selection operations with item id's containing spaces.

**Security**

- **bpo-22636**: Avoid shell injection problems with ctypes.util.find_library().
Library

- **bpo-16182**: Fix various functions in the “readline” module to use the locale encoding, and fix get_begidx() and get_endidx() to return code point indexes.
- **bpo-27392**: Add loop.connect_accepted_socket(). Patch by Jim Fulton.
- **bpo-27930**: Improved behaviour of logging.handlers.QueueListener. Thanks to Paulo Andrade and Petr Viktorin for the analysis and patch.
- **bpo-21201**: Improves readability of multiprocessing error message. Thanks to Wojciech Walczak for patch.
- **bpo-27456**: asyncio: Set TCP_NODELAY by default.
- **bpo-27906**: Fix socket accept exhaustion during high TCP traffic. Patch by Kevin Conway.
- **bpo-28174**: Handle when SO_REUSEPORT isn’t properly supported. Patch by Seth Michael Larson.
- **bpo-26654**: Inspect functools.partial in asyncio.Handle.__repr__. Patch by iceboy.
- **bpo-26909**: Fix slow pipes IO in asyncio. Patch by INADA Naoki.
- **bpo-28176**: Fix callbacks race in asyncio.SelectorLoop.sock_connect.
- **bpo-27759**: Fix selectors incorrectly retain invalid file descriptors. Patch by Mark Williams.
- **bpo-28368**: Refuse monitoring processes if the child watcher has no loop attached. Patch by Vincent Michel.
- **bpo-28369**: Raise RuntimeError when transport’s FD is used with add_reader, add_writer, etc.
- **bpo-28371**: Deprecate passing asyncio.Handles to run_in_executor.
- **bpo-28372**: Fix asyncio to support formatting of non-python
coroutines.

- **bpo-28399**: Remove UNIX socket from FS before binding. Patch by Коренберг Марк.
- **bpo-27972**: Prohibit Tasks to await on themselves.
- **bpo-26923**: Fix asyncio.Gather to refuse being cancelled once all children are done. Patch by Johannes Ebke.
- **bpo-26796**: Don’t configure the number of workers for default threadpool executor. Initial patch by Hans Lawrenz.
- **bpo-28600**: Optimize loop.call_soon().
- **bpo-28613**: Fix get_event_loop() return the current loop if called from coroutines/callbacks.
- **bpo-28639**: Fix inspect.isawaitable to always return bool Patch by Justin Mayfield.
- **bpo-28652**: Make loop methods reject socket kinds they do not support.
- **bpo-28653**: Fix a refleak in functools.lru_cache.
- **bpo-28703**: Fix asyncio.iscoroutinefunction to handle Mock objects.
- **bpo-24142**: Reading a corrupt config file left the parser in an invalid state. Original patch by Florian Höch.
- **bpo-28990**: Fix SSL hanging if connection is closed before handshake completed. (Patch by HoHo-Ho)

### IDLE

- **bpo-15308**: Add ‘interrupt execution’ (^C) to Shell menu. Patch by Roger Serwy, updated by Bayard Randel.
- **bpo-27922**: Stop IDLE tests from ‘flashing’ gui widgets on the screen.
- Add version to title of IDLE help window.
- **bpo-25564**: In section on IDLE – console differences, mention that using exec means that __builtins__ is defined for each statement.
- **bpo-27714**: text_textview and test_autocomplete now pass when re-run in the same process. This occurs when test_idle fails when
run with the -w option but without -jn. Fix warning from test_config.

- **bpo-25507**: IDLE no longer runs buggy code because of its tkinter imports. Users must include the same imports required to run directly in Python.
- **bpo-27452**: add line counter and crc to IDLE configHandler test dump.
- **bpo-27365**: Allow non-ascii chars in IDLE NEWS.txt, for contributor names.
- **bpo-27245**: IDLE: Cleanly delete custom themes and key bindings. Previously, when IDLE was started from a console or by import, a cascade of warnings was emitted. Patch by Serhiy Storchaka.

### C API

- **bpo-28808**: PyUnicode_CompareWithASCIIString() now never raises exceptions.
- **bpo-26754**: PyUnicode_FSDecoder() accepted a filename argument encoded as an iterable of integers. Now only strings and bytes-like objects are accepted.

### Documentation

- **bpo-28513**: Documented command-line interface of zipfile.

### Tests

- **bpo-28950**: Disallow -j0 to be combined with -T/-I/-M in regrtest command line arguments.
- **bpo-28666**: Now test.support.rmtree is able to remove unwritable or unreadable directories.
- **bpo-23839**: Various caches now are cleared before running every
test file.

- **bpo-28409**: regrtest: fix the parser of command line arguments.
- **bpo-27787**: Call gc.collect() before checking each test for “dangling threads”, since the dangling threads are weak references.
- **bpo-27369**: In test_pyexpat, avoid testing an error message detail that changed in Expat 2.2.0.

Tools/Demos

- **bpo-27952**: Get Tools/scripts/fixcid.py working with Python 3 and the current “re” module, avoid invalid Python backslash escapes, and fix a bug parsing escaped C quote signs.
- **bpo-27332**: Fixed the type of the first argument of module-level functions generated by Argument Clinic. Patch by Petr Viktorin.
- **bpo-27418**: Fixed Tools/importbench/importbench.py.

Windows

- **bpo-28251**: Improvements to help manuals on Windows.
- **bpo-28110**: launcher.msi has different product codes between 32-bit and 64-bit
- **bpo-25144**: Ensures TargetDir is set before continuing with custom install.
- **bpo-27469**: Adds a shell extension to the launcher so that drag and drop works correctly.
- **bpo-27309**: Enabled proper Windows styles in python[w].exe manifest.

Build

- **bpo-29080**: Removes hard dependency on hg.exe from PCBUILD/build.bat
- **bpo-23903**: Added missed names to PC/python3.def.
- **bpo-10656**: Fix out-of-tree building on AIX. Patch by Tristan Carel and Michael Haubenwallner.
- **bpo-26359**: Rename –with-optimizations to –enable-optimizations.
- **bpo-28444**: Fix missing extensions modules when cross compiling.
- **bpo-28248**: Update Windows build and OS X installers to use OpenSSL 1.0.2j.
- **bpo-28258**: Fixed build with Estonian locale (python-config and distclean targets in Makefile). Patch by Arfrever Frehtes Taifersar Arahas. 
- **bpo-26661**: setup.py now detects system libffi with multiarch wrapper.
- **bpo-28066**: Fix the logic that searches build directories for generated include files when building outside the source tree.
- **bpo-15819**: Remove redundant include search directory option for building outside the source tree.
- **bpo-27566**: Fix clean target in freeze makefile (patch by Lisa Roach)
- **bpo-27705**: Update message in validate_uerctbase.py
- **bpo-27983**: Cause lack of llvm-profdata tool when using clang as required for PGO linking to be a configure time error rather than make time when –with- optimizations is enabled. Also improve our ability to find the llvm-profdata tool on MacOS and some Linuxes.
- **bpo-26307**: The profile-opt build now applies PGO to the built-in modules.
- **bpo-26359**: Add the –with-optimizations configure flag.
- **bpo-27713**: Suppress spurious build warnings when updating importlib's bootstrap files. Patch by Xiang Zhang
- **bpo-25825**: Correct the references to Modules/python.exp and ld_so_aix, which are required on AIX. This updates references to an installation path that was changed in 3.2a4, and undoes changed references to the build tree that were made in 3.5.0a1.
- **bpo-27453**: CPP invocation in configure must use CPPFLAGS.
Patch by Chi Hsuan Yen.

- **bpo-27641**: The configure script now inserts comments into the makefile to prevent the pgen and `_freeze_importlib` executables from being cross-compiled.
- **bpo-26662**: Set `PYTHON_FOR_GEN` in configure as the Python program to be used for file generation during the build.
- **bpo-10910**: Avoid C++ compilation errors on FreeBSD and OS X. Also update FreeBSD version checks for the original `ctype UTF-8` workaround.
- **bpo-28676**: Prevent missing `getentropy` declaration warning on macOS. Patch by Gareth Rees.
Python 3.5.2 final?

*Release date: 2016-06-26*

Core and Builtins

- **bpo-26930**: Update Windows builds to use OpenSSL 1.0.2h.

Tests

- **bpo-26867**: Ubuntu's openssl OP_NO_SSLv3 is forced on by default; fix test.

IDLE

- **bpo-27365**: Allow non-ascii in idlelib/NEWS.txt - minimal part for 3.5.2.
Python 3.5.2 release candidate 1?

Release date: 2016-06-12

Core and Builtins

- **bpo-27066**: Fixed SystemError if a custom opener (for open()) returns a negative number without setting an exception.
- **bpo-20041**: Fixed TypeError when frame.f_trace is set to None. Patch by Xavier de Gaye.
- **bpo-26168**: Fixed possible refleaks in failing Py_BuildValue() with the “N” format unit.
- **bpo-26991**: Fix possible refleak when creating a function with annotations.
- **bpo-27039**: Fixed bytearray.remove() for values greater than 127. Patch by Joe Jevnik.
- **bpo-23640**: int.from_bytes() no longer bypasses constructors for subclasses.
- **bpo-26811**: gc.get_objects() no longer contains a broken tuple with NULL pointer.
- **bpo-20120**: Use RawConfigParser for .pypirc parsing, removing support for interpolation unintentionally added with move to Python 3. Behavior no longer does any interpolation in .pypirc files, matching behavior in Python 2.7 and Setuptools 19.0.
- **bpo-26659**: Make the builtin slice type support cycle collection.
- **bpo-26718**: super.__init__ no longer leaks memory if called multiple times. NOTE: A direct call of super.__init__ is not endorsed!
- **bpo-25339**: PYTHONIOENCODING now has priority over locale in setting the error handler for stdin and stdout.
- **bpo-26494**: Fixed crash on iterating exhausting iterators. Affected classes are generic sequence iterators, iterators of str, bytes, bytearray, list, tuple, set, frozenset, dict, OrderedDict,
corresponding views and os.scandir() iterator.

- **bpo-26581**: If coding cookie is specified multiple times on a line in Python source code file, only the first one is taken to account.
- **bpo-26464**: Fix str.translate() when string is ASCII and first replacements removes character, but next replacement uses a non-ASCII character or a string longer than 1 character. Regression introduced in Python 3.5.0.
- **bpo-22836**: Ensure exception reports from PyErr_Display() and PyErr_WriteUnraisable() are sensible even when formatting them produces secondary errors. This affects the reports produced by sys.__excepthook__() and when __del__() raises an exception.
- **bpo-26302**: Correct behavior to reject comma as a legal character for cookie names.
- **bpo-4806**: Avoid masking the original TypeError exception when using star (*) unpacking in function calls. Based on patch by Hagen Fürstenau and Daniel Urban.
- **bpo-27138**: Fix the doc comment for FileFinder.find_spec().
- **bpo-26154**: Add a new private _PyThreadState_UncheckedGet() function to get the current Python thread state, but don’t issue a fatal error if it is NULL. This new function must be used instead of accessing directly the _PyThreadState_Current variable. The variable is no more exposed since Python 3.5.1 to hide the exact implementation of atomic C types, to avoid compiler issues.
- **bpo-26194**: Deque.insert() gave odd results for bounded deques that had reached their maximum size. Now an IndexError will be raised when attempting to insert into a full deque.
- **bpo-25843**: When compiling code, don’t merge constants if they are equal but have a different types. For example, f1, f2 = lambda: 1, lambda: 1.0 is now correctly compiled to two different functions: f1() returns 1 (int) and f2() returns 1.0 (int), even if 1 and 1.0 are equal.
- **bpo-22995**: [UPDATE] Comment out the one of the pickleability tests in _PyObject_GetState() due to regressions observed in Cython-based projects.
• **bpo-25961**: Disallowed null characters in the type name.
• **bpo-25973**: Fix segfault when an invalid nonlocal statement binds a name starting with two underscores.
• **bpo-22995**: Instances of extension types with a state that aren’t subclasses of list or dict and haven’t implemented any pickle-related methods (**reduce___**, **reduce_ex___**, **getnewargs___**, **getnewargs_ex___**, or **getstate___**), can no longer be pickled. Including memoryview.
• **bpo-20440**: Massive replacing unsafe attribute setting code with special macro Py_SETREF.
• **bpo-25766**: Special method **bytes__()** now works in str subclasses.
• **bpo-25421**: **sizeof** methods of builtin types now use dynamic basic size. This allows sys.getsize() to work correctly with their subclasses with **slots** defined.
• **bpo-25709**: Fixed problem with in-place string concatenation and utf-8 cache.
• **bpo-27147**: Mention PEP 420 in the importlib docs.
• **bpo-24097**: Fixed crash in object.**reduce___**() if slot name is freed inside **getattr**.
• **bpo-24731**: Fixed crash on converting objects with special methods **bytes___**, **trunc___**, and **float___** returning instances of subclasses of bytes, int, and float to subclasses of bytes, int, and float correspondingly.
• **bpo-26478**: Fix semantic bugs when using binary operators with dictionary views and tuples.
• **bpo-26171**: Fix possible integer overflow and heap corruption in zipimporter.get_data().
• **bpo-25660**: Fix TAB key behaviour in REPL with readline.
• **bpo-25887**: Raise a RuntimeError when a coroutine object is awaited more than once.
• **bpo-27243**: Update the **aiter** protocol: instead of returning an awaitable that resolves to an asynchronous iterator, the asynchronous iterator should be returned directly. Doing the
former will trigger a PendingDeprecationWarning.

Security

- **bpo-26556**: Update expat to 2.1.1, fixes CVE-2015-1283.
- Fix TLS stripping vulnerability in smtplib, CVE-2016-0772. Reported by Team Oststrom

Library

- **bpo-21386**: Implement missing IPv4Address.is_global property. It was documented since 07a5610bae9d. Initial patch by Roger Luethi.
- **bpo-20900**: distutils register command now decodes HTTP responses correctly. Initial patch by ingrid.
- A new version of typing.py provides several new classes and features: @overload outside stubs, Reversible, DefaultDict, Text, ContextManager, Type[], NewType(), TYPE_CHECKING, and numerous bug fixes (note that some of the new features are not yet implemented in mypy or other static analyzers). Also classes for PEP 492 (Awaitable, AsyncIterable, AsyncIterator) have been added (in fact they made it into 3.5.1 but were never mentioned).
- **bpo-25738**: Stop http.server.BaseHTTPRequestHandler.send_error() from sending a message body for 205 Reset Content. Also, don’t send Content header fields in responses that don’t have a body. Patch by Susumu Koshiba.
- **bpo-21313**: Fix the “platform” module to tolerate when sys.version contains truncated build information.

Security

- **bpo-26839**: On Linux, os.urandom() now calls getrandom()
with `GRND_NONBLOCK` to fall back on reading `/dev/urandom` if the urandom entropy pool is not initialized yet. Patch written by Colm Buckley.

Library

- **bpo-27164**: In the zlib module, allow decompressing raw Deflate streams with a predefined zdict. Based on patch by Xiang Zhang.

- **bpo-24291**: Fix `wsgiref.simple_server.WSGIRequestHandler` to completely write data to the client. Previously it could do partial writes and truncate data. Also, `wsgiref.handler.ServerHandler` can now handle stdout doing partial writes, but this is deprecated.

- **bpo-26809**: Add `__all__` to `string`. Patch by Emanuel Barry.

- **bpo-26373**: `subprocess.Popen.communicate` now correctly ignores `BrokenPipeError` when the child process dies before `.communicate()` is called in more/all circumstances.

- **bpo-21776**: `distutils.upload` now correctly handles `HTTPError`. Initial patch by Claudiu Popa.

- **bpo-27114**: Fix `SSLContext._load_windows_store_certs` fails with `PermissionError`.

- **bpo-18383**: Avoid creating duplicate filters when using `filterwarnings` and `simplefilter`. Based on patch by Alex Shkop.

- **bpo-27057**: Fix `os.set_inheritable()` on Android, `ioctl()` is blocked by SELinux and fails with EACCESS. The function now falls back to `fcntl()`. Patch written by Michał Bednarski.

- **bpo-27014**: Fix infinite recursion using typing.py. Thanks to Kalle
• **bpo-14132**: Fix urllib.request redirect handling when the target only has a query string. Original fix by Ján Janech.

• **bpo-17214**: The “urllib.request” module now percent-encodes non-ASCII bytes found in redirect target URLs. Some servers send Location header fields with non-ASCII bytes, but “http.client” requires the request target to be ASCII-encodable, otherwise a UnicodeEncodeError is raised. Based on patch by Christian Heimes.

• **bpo-26892**: Honor debuglevel flag in urllib.request.HTTPHandler. Patch contributed by Chi Hsuan Yen.

• **bpo-22274**: In the subprocess module, allow stderr to be redirected to stdout even when stdout is not redirected. Patch by Akira Li.

• **bpo-26807**: mock_open ‘files’ no longer error on readline at end of file. Patch from Yolanda Robla.

• **bpo-25745**: Fixed leaking a userptr in curses panel destructor.

• **bpo-26977**: Removed unnecessary, and ignored, call to sum of squares helper in statistics.pvariance.

• **bpo-26881**: The modulefinder module now supports extended opcode arguments.

• **bpo-23815**: Fixed crashes related to directly created instances of types in _tkinter and curses.panel modules.

• **bpo-17765**: weakref.ref() no longer silently ignores keyword arguments. Patch by Georg Brandl.
- **bpo-26873**: xmlrpc now raises ResponseError on unsupported type tags instead of silently return incorrect result.

- **bpo-26711**: Fixed the comparison of plistlib.Data with other types.

- **bpo-24114**: Fix an uninitialized variable in ctypes.util.

The bug only occurs on SunOS when the ctypes implementation searches for the crle program. Patch by Xiang Zhang. Tested on SunOS by Kees Bos.

- **bpo-26864**: In urllib.request, change the proxy bypass host checking against no_proxy to be case-insensitive, and to not match unrelated host names that happen to have a bypassed hostname as a suffix. Patch by Xiang Zhang.

- **bpo-26634**: recursive_repr() now sets __qualname__ of wrapper. Patch by Xiang Zhang.

- **bpo-26804**: urllib.request will prefer lower_case proxy environment variables over UPPER_CASE or Mixed Case ones. Patch contributed by Hans-Peter Jansen.

- **bpo-26837**: assertSequenceEqual() now correctly outputs non-stringified differing items (like bytes in the -b mode). This affects assertListEqual() and assertTupleEqual().

- **bpo-26041**: Remove “will be removed in Python 3.7” from deprecation messages of platform.dist() and platform.linux_distribution(). Patch by Kumaripaba Miyurusara Athukorala.

- **bpo-26822**: itemgetter, attrgetter and methodcaller objects no
longer silently ignore keyword arguments.

- **bpo-26733**: Disassembling a class now disassembles class and static methods. Patch by Xiang Zhang.

- **bpo-26801**: Fix error handling in `shutil.get_terminal_size()`, catch `AttributeError` instead of `NameError`. Patch written by Emanuel Barry.

- **bpo-24838**: `tarfile`'s ustar and gnu formats now correctly calculate name and link field limits for multibyte character encodings like utf-8.

**Security**

- **bpo-26657**: Fix directory traversal vulnerability with `http.server` on Windows. This fixes a regression that was introduced in 3.3.4rc1 and 3.4.0rc1. Based on patch by Philipp Hagemeister.

**Library**

- **bpo-26735**: Fix `os.urandom()` on Solaris 11.3 and newer when reading more than 1,024 bytes: call `getrandom()` multiple times with a limit of 1024 bytes per call.

- **bpo-16329**: Add `.webm` to `mimetypes.types_map`. Patch by Giampaolo Rodola’.

- **bpo-13952**: Add `.csv` to `mimetypes.types_map`. Patch by Geoff Wilson.

- **bpo-26709**: Fixed Y2038 problem in loading binary PLists.

- **bpo-23735**: Handle terminal resizing with Readline 6.3+ by installing our own SIGWINCH handler. Patch by Eric Price.
- **bpo-26586**: In http.server, respond with “413 Request header fields too large” if there are too many header fields to parse, rather than killing the connection and raising an unhandled exception. Patch by Xiang Zhang.

- **bpo-22854**: Change BufferedReader.writable() and BufferedWriter.readable() to always return False.

- **bpo-25195**: Fix a regression in mock.MagicMock. _Call is a subclass of tuple (changeset 3603bae63c13 only works for classes) so we need to implement __ne__ ourselves. Patch by Andrew Plummer.

- **bpo-26644**: Raise ValueError rather than SystemError when a negative length is passed to SSLSocket.recv() or read().

- **bpo-23804**: Fix SSL recv(0) and read(0) methods to return zero bytes instead of up to 1024.

- **bpo-26616**: Fixed a bug in datetime.astimezone() method.

- **bpo-21925**: warnings.formatwarning() now catches exceptions on linecache.getline(...) to be able to log ResourceWarning emitted late during the Python shutdown process.

- **bpo-24266**: Ctrl+C during Readline history search now cancels the search mode when compiled with Readline 7.

- **bpo-26560**: Avoid potential ValueError in BaseHandler.start_response. Initial patch by Peter Inglesby.

**Security**

- **bpo-26313**: ssl.py _load_windows_store_certs fails if windows cert store is empty. Patch by Baji.

**Library**

- **bpo-26569**: Fix `pyclbr.readmodule()` and `pyclbr.readmodule_ex()` to support importing packages.
- **bpo-26499**: Account for remaining Content-Length in HTTPResponse.readline() and read1(). Based on patch by Silent Ghost. Also document that HTTPResponse now supports these methods.
- **bpo-25320**: Handle sockets in directories unittest discovery is scanning. Patch from Victor van den Elzen.
- **bpo-16181**: cookiejar.http2time() now returns None if year is higher than datetime.MAXYEAR.
- **bpo-26513**: Fixes platform module detection of Windows Server
- **bpo-23718**: Fixed parsing time in week 0 before Jan 1. Original patch by Tamás Bence Gedai.
- **bpo-20589**: Invoking Path.owner() and Path.group() on Windows now raise NotImplementedError instead of ImportError.
- **bpo-26177**: Fixed the keys() method for Canvas and Scrollbar widgets.
- **bpo-15068**: Got rid of excessive buffering in the fileinput module. The bufsize parameter is no longer used.
- **bpo-2202**: Fix UnboundLocalError in AbstractDigestAuthHandler.get_algorithm_impls. Initial patch by Mathieu Dupuy.
- **bpo-25718**: Fixed pickling and copying the accumulate() iterator with total is None.
- **bpo-26475**: Fixed debugging output for regular expressions with the (?x) flag.
- **bpo-26457**: Fixed the subnets() methods in IP network classes for the case when resulting prefix length is equal to maximal prefix length. Based on patch by Xiang Zhang.
- **bpo-26385**: Remove the file if the internal open() call in NamedTemporaryFile() fails. Patch by Silent Ghost.
- **bpo-26402**: Fix XML-RPC client to retry when the server shuts down a persistent connection. This was a regression related to the new http.client.RemoteDisconnected exception in 3.5.0a4.
- **bpo-25913**: Leading `<~` is optional now in base64.a85decode() with adobe=True. Patch by Swati Jaiswal.
- **bpo-26186**: Remove an invalid type check in importlib.util.LazyLoader.
- **bpo-26367**: importlib.__import__() raises SystemError like builtins.__import__() when level is specified but without an accompanying package specified.
- **bpo-26309**: In the “socketserver” module, shut down the request (closing the connected socket) when verify_request() returns false. Patch by Aviv Palivoda.

**Security**

- **bpo-25939**: On Windows open the cert store readonly in ssl.enum_certificates.

**Library**

- **bpo-25995**: os.walk() no longer uses FDs proportional to the tree depth.
- **bpo-26117**: The os.scandir() iterator now closes file descriptor not only when the iteration is finished, but when it was failed with error.
- **bpo-25911**: Restored support of bytes paths in os.walk() on Windows.
- **bpo-26045**: Add UTF-8 suggestion to error message when posting a non-Latin-1 string with http.client.
- **bpo-12923**: Reset FancyURLopener’s redirect counter even if there is an exception. Based on patches by Brian Brazil and Daniel Rocco.
- **bpo-25945**: Fixed a crash when unpickle the functools.partial object with wrong state. Fixed a leak in failed functools.partial constructor. “args” and “keywords” attributes of functools.partial have now always types tuple and dict correspondingly.
- **bpo-26202**: copy.deepcopy() now correctly copies range() objects
with non-atomic attributes.

- **bpo-23076**: Path.glob() now raises a ValueError if it's called with an invalid pattern. Patch by Thomas Nyberg.
- **bpo-19883**: Fixed possible integer overflows in zipimport.
- **bpo-26227**: On Windows, getnameinfo(), gethostbyaddr() and gethostbyname_ex() functions of the socket module now decode the hostname from the ANSI code page rather than UTF-8.
- **bpo-26147**: xmlrpc now works with strings not encodable with used non-UTF-8 encoding.
- **bpo-25935**: Garbage collector now breaks reference loops with OrderedDict.
- **bpo-16620**: Fixed AttributeError in msilib.Directory.glob().
- **bpo-26013**: Added compatibility with broken protocol 2 pickles created in old Python 3 versions (3.4.3 and lower).
- **bpo-25850**: Use cross-compilation by default for 64-bit Windows.
- **bpo-17633**: Improve zipimport's support for namespace packages.
- **bpo-24705**: Fix sysconfig._parse_makefile not expanding ${} vars appearing before ${} vars.
- **bpo-22138**: Fix mock.patch behavior when patching descriptors. Restore original values after patching. Patch contributed by Sean McCully.
- **bpo-25672**: In the ssl module, enable the SSL_MODE_RELEASE_BUFFERS mode option if it is safe to do so.
- **bpo-26012**: Don't traverse into symlinks for ** pattern in pathlib.Path.[r]glob().
- **bpo-24120**: Ignore PermissionError when traversing a tree with pathlib.Path.[r]glob(). Patch by Ulrich Petri.
- **bpo-25447**: fileinput now uses sys.stdin as-is if it does not have a buffer attribute (restores backward compatibility).
- **bpo-25447**: Copying the lru_cache() wrapper object now always works, independently from the type of the wrapped object (by returning the original object unchanged).
- bpo-24103: Fixed possible use after free in ElementTree.XMLPullParser.
- bpo-25914: Fixed and simplified OrderedDict.__sizeof__.
- bpo-25902: Fixed various refcount issues in ElementTree iteration.
- bpo-25717: Restore the previous behaviour of tolerating most fstat() errors when opening files. This was a regression in 3.5a1, and stopped anonymous temporary files from working in special cases.
- bpo-24903: Fix regression in number of arguments compileall accepts when ‘-d’ is specified. The check on the number of arguments has been dropped completely as it never worked correctly anyway.
- bpo-25764: In the subprocess module, preserve any exception caused by fork() failure when preexec_fn is used.
- bpo-6478: _strptime’s regexp cache now is reset after changing timezone with time.tzset().
- bpo-14285: When executing a package with the “python -m package” option, and package initialization fails, a proper traceback is now reported. The “runpy” module now lets exceptions from package initialization pass back to the caller, rather than raising ImportError.
- bpo-19771: Also in runpy and the “-m” option, omit the irrelevant message “… is a package and cannot be directly executed” if the package could not even be initialized (e.g. due to a bad * .pyc file).
- bpo-25177: Fixed problem with the mean of very small and very large numbers. As a side effect, statistics.mean and statistics.variance should be significantly faster.
- bpo-25718: Fixed copying object with state with boolean value is false.
- bpo-10131: Fixed deep copying of minidom documents. Based on
patch by Marian Ganisin.

- **bpo-25725**: Fixed a reference leak in pickle.loads() when unpickling invalid data including tuple instructions.
- **bpo-25663**: In the Readline completer, avoid listing duplicate global names, and search the global namespace before searching builtins.
- **bpo-25688**: Fixed file leak in ElementTree.iterparse() raising an error.
- **bpo-23914**: Fixed SystemError raised by unpickler on broken pickle data.
- **bpo-25691**: Fixed crash on deleting ElementTree.Element attributes.
- **bpo-25624**: ZipFile now always writes a ZIP_STORED header for directory entries. Patch by Dingyuan Wang.
- Skip getaddrinfo if host is already resolved. Patch by A. Jesse Jiryu Davis.
- **bpo-25924**: Avoid unnecessary serialization of getaddrinfo(3) calls on OS X versions 10.5 or higher. Original patch by A. Jesse Jiryu Davis.
- **bpo-26406**: Avoid unnecessary serialization of getaddrinfo(3) calls on current versions of OpenBSD and NetBSD. Patch by A. Jesse Jiryu Davis.
- **bpo-26848**: Fix asyncio/subprocess.communicate() to handle empty input. Patch by Jack O’Connor.
- **bpo-27040**: Add loop.get_exception_handler method
- **bpo-27041**: asyncio: Add loop.create_future method
- **bpo-27223**: asyncio: Fix _read_ready and _write_ready to respect _conn_lost. Patch by Łukasz Langa.

IDLE
- **bpo-5124**: Paste with text selected now replaces the selection on X11. This matches how paste works on Windows, Mac, most modern Linux apps, and ttk widgets. Original patch by Serhiy Storchaka.

- **bpo-24759**: Make clear in idlelib.idle_test.__init__ that the directory is a private implementation of test.test_idle and tool for maintainers.

- **bpo-27196**: Stop ‘ThemeChanged’ warnings when running IDLE tests. These persisted after other warnings were suppressed in #20567. Apply Serhiy Storchaka’s update_idletasks solution to four test files. Record this additional advice in idle_test/README.txt

- **bpo-20567**: Revise idle_test/README.txt with advice about avoiding tk warning messages from tests. Apply advice to several IDLE tests.

- **bpo-27117**: Make colorizer htest and turtledemo work with dark themes. Move code for configuring text widget colors to a new function.

- **bpo-26673**: When tk reports font size as 0, change to size 10. Such fonts on Linux prevented the configuration dialog from opening.

- **bpo-21939**: Add test for IDLE’s percolator. Original patch by Saimadhav Heblikar.

- **bpo-21676**: Add test for IDLE’s replace dialog. Original patch by Saimadhav Heblikar.

- **bpo-18410**: Add test for IDLE’s search dialog. Original patch by Westley Martínez.

- **bpo-21703**: Add test for IDLE’s undo delegator. Original patch by Saimadhav Heblikar.

- **bpo-27044**: Add ConfigDialog.remove_varcallbacks to stop memory leaks.

- **bpo-23977**: Add more asserts to test_delegator.

- **bpo-20640**: Add tests for idlelib.configHelpSourceEdit. Patch by
Saimadhav Heblikar.

- In the ‘IDLE-console differences’ section of the IDLE doc, clarify how running with IDLE affects sys.modules and the standard streams.
- **bpo-25507**: fix incorrect change in IOBinding that prevented printing. Augment IOBinding htest to include all major IOBinding functions.
- **bpo-25905**: Revert unwanted conversion of ‘ to ’ RIGHT SINGLE QUOTATION MARK in README.txt and open this and NEWS.txt with ‘ascii’. Re-encode CREDITS.txt to utf-8 and open it with ‘utf-8’.

**Documentation**

- **bpo-19489**: Moved the search box from the sidebar to the header and footer of each page. Patch by Ammar Askar.
- **bpo-24136**: Document the new PEP 448 unpacking syntax of 3.5.
- **bpo-26736**: Used HTTPS for external links in the documentation if possible.
- **bpo-6953**: Rework the Readline module documentation to group related functions together, and add more details such as what underlying Readline functions and variables are accessed.
- **bpo-23606**: Adds note to ctypes documentation regarding cdll.msvcr.
- **bpo-25500**: Fix documentation to not claim that __import__ is searched for in the global scope.
- **bpo-26014**: Update 3.x packaging documentation:
  * “See also” links to the new docs are now provided in the legacy pages
  * links to setuptools documentation have been updated

**Tests**

- **bpo-21916**: Added tests for the turtle module. Patch by ingrid,
Gregory Loyse and Jelle Zijlstra.

- **bpo-26523**: The multiprocessing thread pool (multiprocessing.dummy.Pool) was untested.
- **bpo-26015**: Added new tests for pickling iterators of mutable sequences.
- **bpo-26325**: Added test.support.check_no_resource_warning() to check that no ResourceWarning is emitted.
- **bpo-25940**: Changed test_ssl to use self-signed.pythontest.net. This avoids relying on svn.python.org, which recently changed root certificate.
- **bpo-25616**: Tests for OrderedDict are extracted from test_collections into separate file test_ordered_dict.
- **bpo-26583**: Skip test_timestamp_overflow in test_import if bytecode files cannot be written.

**Build**

- **bpo-26884**: Fix linking extension modules for cross builds. Patch by Xavier de Gaye.
- **bpo-22359**: Disable the rules for running _freeze_importlib and pgen when cross-compiling. The output of these programs is normally saved with the source code anyway, and is still regenerated when doing a native build. Patch by Xavier de Gaye.
- **bpo-27229**: Fix the cross-compiling pgen rule for in-tree builds. Patch by Xavier de Gaye.
- **bpo-21668**: Link audioop, _datetime, _ctypes_test modules to libm, except on Mac OS X. Patch written by Xavier de Gaye.
- **bpo-25702**: A –with-lto configure option has been added that will enable link time optimizations at build time during a make profile-opt. Some compilers and toolchains are known to not produce stable code when using LTO, be sure to test things thoroughly before relying on it. It can provide a few % speed up over profile-opt alone.
- **bpo-26624**: Adds validation of ucrtbase[d].dll version with warning
for old versions.

- **bpo-17603**: Avoid error about nonexistant fileblocks.o file by using a lower-level check for st_blocks in struct stat.
- **bpo-26079**: Fixing the build output folder for tix-8.4.3.6. Patch by Bjoern Thiel.
- **bpo-26465**: Update Windows builds to use OpenSSL 1.0.2g.
- **bpo-24421**: Compile Modules/_math.c once, before building extensions. Previously it could fail to compile properly if the math and cmath builds were concurrent.
- **bpo-25348**: Added `--pgo` and `--pgo-job` arguments to `PCbuild\build.bat` for building with Profile-Guided Optimization. The old `PCbuild\build_pgo.bat` script is now deprecated, and simply calls `PCbuild\build.bat --pgo %*`.
- **bpo-25827**: Add support for building with ICC to `configure`, including a new `--with-icc` flag.
- **bpo-25696**: Fix installation of Python on UNIX with make -j9.
- **bpo-26930**: Update OS X 10.5+ 32-bit-only installer to build and link with OpenSSL 1.0.2h.
- **bpo-26268**: Update Windows builds to use OpenSSL 1.0.2f.
- **bpo-25136**: Support Apple Xcode 7’s new textual SDK stub libraries.
- **bpo-24324**: Do not enable unreachable code warnings when using gcc as the option does not work correctly in older versions of gcc and has been silently removed as of gcc-4.5.

## Windows

- **bpo-27053**: Updates `make_zip.py` to correctly generate library ZIP file.
- **bpo-26268**: Update the prepare_ssl.py script to handle OpenSSL releases that don’t include the contents of the include directory (that is, 1.0.2e and later).
- **bpo-26071**: bdist_wininst created binaries fail to start and find
32bit Python
- **bpo-26073**: Update the list of magic numbers in launcher
- **bpo-26065**: Excludes venv from library when generating embeddable distro.

**Tools/Demos**

- **bpo-26799**: Fix python-gdb.py: don’t get C types once when the Python code is loaded, but get C types on demand. The C types can change if python-gdb.py is loaded before the Python executable. Patch written by Thomas Ilsche.
- **bpo-26271**: Fix the Freeze tool to properly use flags passed through configure. Patch by Daniel Shaulov.
- **bpo-26489**: Add dictionary unpacking support to Tools/parser/unparse.py. Patch by Guo Ci Teo.
- **bpo-26316**: Fix variable name typo in Argument Clinic.

**Windows**

- **bpo-17500**: Remove unused and outdated icons. (See also: https://github.com/python/pythondotorg/issues/945)
Python 3.5.1 final?

Release date: 2015-12-06

Core and Builtins

- **bpo-25709**: Fixed problem with in-place string concatenation and utf-8 cache.

Windows

- **bpo-25715**: Python 3.5.1 installer shows wrong upgrade path and incorrect logic for launcher detection.
Python 3.5.1 release candidate 1?

Release date: 2015-11-22

Core and Builtins

- **bpo-25630**: Fix a possible segfault during argument parsing in functions that accept filesystem paths.
- **bpo-23564**: Fixed a partially broken sanity check in the _posixsubprocess internals regarding how fds_to_pass were passed to the child. The bug had no actual impact as subprocess.py already avoided it.
- **bpo-25388**: Fixed tokenizer crash when processing undecodable source code with a null byte.
- **bpo-25462**: The hash of the key now is calculated only once in most operations in C implementation of OrderedDict.
- **bpo-22995**: Default implementation of __reduce__ and __reduce_ex__ now rejects builtin types with not defined __new__.
- **bpo-25555**: Fix parser and AST: fill lineno and col_offset of “arg” node when compiling AST from Python objects.
- **bpo-24802**: Avoid buffer overreads when int(), float(), compile(), exec() and eval() are passed bytes-like objects. These objects are not necessarily terminated by a null byte, but the functions assumed they were.
- **bpo-24726**: Fixed a crash and leaking NULL in repr() of OrderedDict that was mutated by direct calls of dict methods.
- **bpo-25449**: Iterating OrderedDict with keys with unstable hash now raises KeyError in C implementations as well as in Python implementation.
- **bpo-25395**: Fixed crash when highly nested OrderedDict structures were garbage collected.
- **bpo-25274**: sys.setrecursionlimit() now raises a RecursionError if
the new recursion limit is too low depending at the current recursion depth. Modify also the “lower-water mark” formula to make it monotonic. This mark is used to decide when the overflowed flag of the thread state is reset.

- **bpo-24402**: Fix input() to prompt to the redirected stdout when sys.stdout.fileno() fails.
- **bpo-24806**: Prevent builtin types that are not allowed to be subclassed from being subclassed through multiple inheritance.
- **bpo-24848**: Fixed a number of bugs in UTF-7 decoding of misformed data.
- **bpo-25280**: Import trace messages emitted in verbose (-v) mode are no longer formatted twice.
- **bpo-25003**: On Solaris 11.3 or newer, os.urandom() now uses the getrandom() function instead of the getentropy() function. The getentropy() function is blocking to generate very good quality entropy, os.urandom() doesn’t need such high-quality entropy.
- **bpo-25182**: The stdprinter (used as sys.stderr before the io module is imported at startup) now uses the backslashreplace error handler.
- **bpo-25131**: Make the line number and column offset of set/dict literals and comprehensions correspond to the opening brace.
- **bpo-25150**: Hide the private _Py_atomic_XXX symbols from the public Python.h header to fix a compilation error with OpenMP. PyThreadState_GET() becomes an alias to PyThreadState_Get() to avoid ABI incompatibilities.

**Library**

- **bpo-25626**: Change three zlib functions to accept sizes that fit in Py_ssize_t, but internally cap those sizes to UINT_MAX. This resolves a regression in 3.5 where GzipFile.read() failed to read chunks larger than 2 or 4 GiB. The change affects the zlib.Decompress.decompress() max_length parameter, the zlib.decompress() bufsize parameter, and the
zlib.Decompress.flush() length parameter.

- **bpo-25583**: Avoid incorrect errors raised by os.makedirs(exist_ok=True) when the OS gives priority to errors such as EACCES over EEXIST.
- **bpo-25593**: Change semantics of EventLoop.stop() in asyncio.
- **bpo-6973**: When we know a subprocess.Popen process has died, do not allow the send_signal(), terminate(), or kill() methods to do anything as they could potentially signal a different process.
- **bpo-25590**: In the Readline completer, only call getattr() once per attribute.
- **bpo-25498**: Fix a crash when garbage-collecting ctypes objects created by wrapping a memoryview. This was a regression made in 3.5a1. Based on patch by Eryksun.
- **bpo-25584**: Added “escape” to the __all__ list in the glob module.
- **bpo-25584**: Fixed recursive glob() with patterns starting with **.
- **bpo-25446**: Fix regression in smtplib’s AUTH LOGIN support.
- **bpo-18010**: Fix the pydoc web server’s module search function to handle exceptions from importing packages.
- **bpo-25554**: Got rid of circular references in regular expression parsing.
- **bpo-25510**: fileinput.FileInput.readline() now returns b"" instead of "" at the end if the FileInput was opened with binary mode. Patch by Ryosuke Ito.
- **bpo-25503**: Fixed inspect.getdoc() for inherited docstrings of properties. Original patch by John Mark Vandenberg.
- **bpo-25515**: Always use os.urandom as a source of randomness in uuid.uuid4.
- **bpo-21827**: Fixed textwrap.dedent() for the case when largest common whitespace is a substring of smallest leading whitespace. Based on patch by Robert Li.
- **bpo-25447**: The lru_cache() wrapper objects now can be copied and pickled (by returning the original object unchanged).
- **bpo-25390**: typing: Don’t crash on Union[str, Pattern].
- **bpo-25441**: asyncio: Raise error from drain() when socket is
closed.

- **bpo-25410**: Cleaned up and fixed minor bugs in C implementation of OrderedDict.
- **bpo-25411**: Improved Unicode support in SMTPHandler through better use of the email package. Thanks to user simon04 for the patch.
- **bpo-25407**: Remove mentions of the formatter module being removed in Python 3.6.
- **bpo-25406**: Fixed a bug in C implementation of OrderedDict.move_to_end() that caused segmentation fault or hang in iterating after moving several items to the start of ordered dict.
- **bpo-25364**: zipfile now works in threads disabled builds.
- **bpo-25328**: smtpd’s SMTPChannel now correctly raises a ValueError if both decode_data and enable_SMTPUTF8 are set to true.
- **bpo-25316**: distutils raises OSError instead of DistutilsPlatformError when MSVC is not installed.
- **bpo-25380**: Fixed protocol for the STACK_GLOBAL opcode in pickletools.opcodes.
- **bpo-23972**: Updates asyncio datagram create method allowing reuseport and reuseaddr socket options to be set prior to binding the socket. Mirroring the existing asyncio create_server method the reuseaddr option for datagram sockets defaults to True if the O/S is ‘posix’ (except if the platform is Cygwin). Patch by Chris Laws.
- **bpo-25304**: Add asyncio.run_coroutine_threadsafe(). This lets you submit a coroutine to a loop from another thread, returning a concurrent.futures.Future. By Vincent Michel.
- **bpo-25232**: Fix CGIRequestHandler to split the query from the URL at the first question mark (?) rather than the last. Patch from Xiang Zhang.
- **bpo-24657**: Prevent CGIRequestHandler from collapsing slashes in the query part of the URL as if it were a path. Patch from Xiang
- **bpo-24483**: C implementation of functools.lru_cache() now calculates key’s hash only once.
- **bpo-22958**: Constructor and update method of weakref.WeakValueDictionary now accept the self and the dict keyword arguments.
- **bpo-22609**: Constructor of collections.UserDict now accepts the self keyword argument.
- **bpo-25111**: Fixed comparison of traceback.FrameSummary.
- **bpo-25262**: Added support for BINBYTES8 opcode in Python implementation of unpickler. Highest 32 bits of 64-bit size for BINUNICODE8 and BINBYTES8 opcodes no longer silently ignored on 32-bit platforms in C implementation.
- **bpo-25233**: Rewrite the guts of asyncio.Queue and asyncio.Semaphore to be more understandable and correct.
- **bpo-25203**: Failed readline.set_completer(delims) no longer left the module in inconsistent state.
- **bpo-23600**: Default implementation of tzinfo.fromutc() was returning wrong results in some cases.
- **bpo-23329**: Allow the ssl module to be built with older versions of LibreSSL.
- Prevent overflow in _Unpickler_Read.
- **bpo-25047**: The XML encoding declaration written by Element Tree now respects the letter case given by the user. This restores the ability to write encoding names in uppercase like “UTF-8”, which worked in Python 2.
- **bpo-25135**: Make deque.clear() safer by emptying the deque before clearing. This helps avoid possible reentrancy issues.
- **bpo-19143**: platform module now reads Windows version from kernel32.dll to avoid compatibility shims.
- **bpo-25092**: Fix datetime.strptime() failure when errno was already set to EINVAL.
• **bpo-23517**: Fix rounding in `fromtimestamp()` and `utcfromtimestamp()` methods of `datetime.datetime`: microseconds are now rounded to nearest with ties going to nearest even integer (ROUND_HALF_EVEN), instead of being rounding towards minus infinity (ROUND_FLOOR). It's important that these methods use the same rounding mode than `datetime.timedelta` to keep the property: `(datetime(1970,1,1) + timedelta(seconds=t)) == datetime.utcfromtimestamp(t)`. It also the rounding mode used by `round(float)` for example.

• **bpo-25155**: Fix `datetime.datetime.now()` and `datetime.datetime.utcnow()` on Windows to support date after year 2038. It was a regression introduced in Python 3.5.0.

• **bpo-25108**: Omitted internal frames in traceback functions `print_stack()`, `format_stack()`, and `extract_stack()` called without arguments.

• **bpo-25118**: Fix a regression of Python 3.5.0 in `os.waitpid()` on Windows.

• **bpo-24684**: `socket.socket.getaddrinfo()` now calls `PyUnicode_AsEncodedString()` instead of calling the `encode()` method of the host, to handle correctly custom string with an `encode()` method which doesn’t return a byte string. The encoder of the IDNA codec is now called directly instead of calling the `encode()` method of the string.

• **bpo-25060**: Correctly compute stack usage of the BUILD_MAP opcode.

• **bpo-24857**: Comparing `call_args` to a long sequence now correctly returns a boolean result instead of raising an exception. Patch by A Kaptur.

• **bpo-23144**: Make sure that `HTMLParser.feed()` returns all the data, even when `convert_charrefs` is True.

• **bpo-24982**: `shutil.make_archive()` with the “zip” format now adds entries for directories (including empty directories) in ZIP file.

• **bpo-25019**: Fixed a crash caused by setting non-string key of expat parser. Based on patch by John Leitch.
- **bpo-16180**: Exit pdb if file has syntax error, instead of trapping user in an infinite loop. Patch by Xavier de Gaye.
- **bpo-24891**: Fix a race condition at Python startup if the file descriptor of stdin (0), stdout (1) or stderr (2) is closed while Python is creating sys.stdin, sys.stdout and sys.stderr objects. These attributes are now set to None if the creation of the object failed, instead of raising an IOError exception. Initial patch written by Marco Paolini.
- **bpo-24992**: Fix error handling and a race condition (related to garbage collection) in collections.OrderedDict constructor.
- **bpo-24881**: Fixed setting binary mode in Python implementation of FileIO on Windows and Cygwin. Patch from Akira Li.
- **bpo-25578**: Fix (another) memory leak in SSLSocket.getpeercert().
- **bpo-25530**: Disable the vulnerable SSLv3 protocol by default when creating ssl.SSLContext.
- **bpo-25569**: Fix memory leak in SSLSocket.getpeercert().
- **bpo-25471**: Sockets returned from accept() shouldn’t appear to be nonblocking.
- **bpo-25319**: When threading.Event is reinitialized, the underlying condition should use a regular lock rather than a recursive lock.
- **bpo-21112**: Fix regression in unittest.expectedFailure on subclasses. Patch from Berker Peksag.
- **bpo-24764**: cgi.FieldStorage.read_multi() now ignores the Content-Length header in part headers. Patch written by Peter Landry and reviewed by Pierre Quentel.
- **bpo-24913**: Fix overrun error in deque.index(). Found by John Leitch and Bryce Darling.
- **bpo-20362**: Honour TestCase.longMessage correctly in assertRegex. Patch from Ilia Kurenkov.
• **bpo-23572**: Fixed `functools singledispatch` on classes with falsy metaclasses. Patch by Ethan Furman.

• **asyncio**: `ensure_future()` now accepts awaitable objects.

**IDLE**

• **bpo-15348**: Stop the debugger engine (normally in a user process) before closing the debugger window (running in the IDLE process). This prevents the RuntimeErrors that were being caught and ignored.

• **bpo-24455**: Prevent IDLE from hanging when a) closing the shell while the debugger is active (15347); b) closing the debugger with the [X] button (15348); and c) activating the debugger when already active (24455). The patch by Mark Roseman does this by making two changes. 1. Suspend and resume the `gui.interaction` method with the tcl vwait mechanism intended for this purpose (instead of `root.mainloop & .quit`). 2. In `gui.run`, allow any existing interaction to terminate first.

• Change ‘The program’ to ‘Your program’ in an IDLE ‘kill program?’ message to make it clearer that the program referred to is the currently running user program, not IDLE itself.

• **bpo-24750**: Improve the appearance of the IDLE editor window status bar. Patch by Mark Roseman.

• **bpo-25313**: Change the handling of new built-in text color themes to better address the compatibility problem introduced by the addition of IDLE Dark. Consistently use the revised `idleConf.CurrentTheme` everywhere in `idlelib`.

• **bpo-24782**: Extension configuration is now a tab in the IDLE Preferences dialog rather than a separate dialog. The former tabs are now a sorted list. Patch by Mark Roseman.

• **bpo-22726**: Re-activate the config dialog help button with some content about the other buttons and the new IDLE Dark theme.

• **bpo-24820**: IDLE now has an ‘IDLE Dark’ built-in text color theme. It is more or less IDLE Classic inverted, with a cobalt blue
background. Strings, comments, keywords, ... are still green, red, orange, ... . To use it with IDLEs released before November 2015, hit the ‘Save as New Custom Theme' button and enter a new name, such as ‘Custom Dark’. The custom theme will work with any IDLE release, and can be modified.

- **bpo-25224**: README.txt is now an idlelib index for IDLE developers and curious users. The previous user content is now in the IDLE doc chapter. ‘IDLE’ now means ‘Integrated Development and Learning Environment’.
- **bpo-24820**: Users can now set breakpoint colors in Settings -> Custom Highlighting. Original patch by Mark Roseman.
- **bpo-24972**: Inactive selection background now matches active selection background, as configured by users, on all systems. Found items are now always highlighted on Windows. Initial patch by Mark Roseman.
- **bpo-24570**: Idle: make calltip and completion boxes appear on Macs affected by a tk regression. Initial patch by Mark Roseman.
- **bpo-24988**: Idle ScrolledList context menus (used in debugger) now work on Mac Aqua. Patch by Mark Roseman.
- **bpo-24801**: Make right-click for context menu work on Mac Aqua. Patch by Mark Roseman.
- **bpo-25173**: Associate tkinter messageboxes with a specific widget. For Mac OSX, make them a 'sheet'. Patch by Mark Roseman.
- **bpo-25198**: Enhance the initial html viewer now used for Idle Help. * Properly indent fixed-pitch text (patch by Mark Roseman). * Give code snippet a very Sphinx- like light blueish-gray background. * Re-use initial width and height set by users for shell and editor. * When the Table of Contents (TOC) menu is used, put the section header at the top of the screen.
- **bpo-25225**: Condense and rewrite Idle doc section on text colors.
- **bpo-21995**: Explain some differences between IDLE and console Python.
- **bpo-22820**: Explain need for *print* when running file from Idle
editor.

- **bpo-25224**: Doc: augment Idle feature list and no-subprocess section.
- **bpo-25219**: Update doc for Idle command line options. Some were missing and notes were not correct.
- **bpo-24861**: Most of idlelib is private and subject to change. Use idlelib.idle.* to start Idle. See idlelib.__init__.__doc__.
- **bpo-25199**: Idle: add synchronization comments for future maintainers.
- **bpo-16893**: Replace help.txt with help.html for Idle doc display. The new idlelib/help.html is rstripped Doc/build/html/library/idle.html. It looks better than help.txt and will better document Idle as released. The tkinter html viewer that works for this file was written by Mark Roseman. The now unused EditorWindow.HelpDialog class and help.txt file are deprecated.
- **bpo-24199**: Deprecate unused idlelib.idlever with possible removal in 3.6.
- **bpo-24790**: Remove extraneous code (which also create 2 & 3 conflicts).

**Documentation**

- **bpo-22558**: Add remaining doc links to source code for Python-coded modules. Patch by Yoni Lavi.
- **bpo-12067**: Rewrite Comparisons section in the Expressions chapter of the language reference. Some of the details of comparing mixed types were incorrect or ambiguous. NotImplemented is only relevant at a lower level than the Expressions chapter. Added details of comparing range() objects, and default behaviour and consistency suggestions for user-defined classes. Patch from Andy Maier.
- **bpo-24952**: Clarify the default size argument of stack_size() in the “threading” and “_thread” modules. Patch from Mattip.
- **bpo-23725**: Overhaul tempfile docs. Note deprecated status of
mktemp. Patch from Zbigniew Jędrzejewski-Szemek.

- **bpo-24808**: Update the types of some PyTypeObject fields. Patch by Joseph Weston.
- **bpo-22812**: Fix unittest discovery examples. Patch from Pam McA‘Nulty.

**Tests**

- **bpo-25449**: Added tests for OrderedDict subclasses.
- **bpo-25099**: Make test_compileall not fail when an entry on sys.path cannot be written to (commonly seen in administrative installs on Windows).
- **bpo-23919**: Prevents assert dialogs appearing in the test suite.
- **PCbuild\rt.bat** now accepts an unlimited number of arguments to pass along to regrtest.py. Previously there was a limit of 9.

**Build**

- **bpo-24915**: Add LLVM support for PGO builds and use the test suite to generate the profile data. Initial patch by Alecsandru Patrascu of Intel.
- **bpo-24910**: Windows MSIs now have unique display names.
- **bpo-24986**: It is now possible to build Python on Windows without errors when external libraries are not available.

**Windows**

- **bpo-25450**: Updates shortcuts to start Python in installation directory.
- **bpo-25164**: Changes default all-users install directory to match per-user directory.
- **bpo-25143**: Improves installer error messages for unsupported
platforms.

- **bpo-25163**: Display correct directory in installer when using non-default settings.
- **bpo-25361**: Disables use of SSE2 instructions in Windows 32-bit build
- **bpo-25089**: Adds logging to installer for case where launcher is not selected on upgrade.
- **bpo-25165**: Windows uninstallation should not remove launcher if other versions remain
- **bpo-25112**: py.exe launcher is missing icons
- **bpo-25102**: Windows installer does not precompile for -O or -OO.
- **bpo-25081**: Makes Back button in installer go back to upgrade page when upgrading.
- **bpo-25091**: Increases font size of the installer.
- **bpo-25126**: Clarifies that the non-web installer will download some components.
- **bpo-25213**: Restores requestedExecutionLevel to manifest to disable UAC virtualization.
- **bpo-25022**: Removed very outdated PC/example_nt/ directory.

**Tools/Demos**

- **bpo-25440**: Fix output of python-config --extension-suffix.
Python 3.5.0 final?

Release date: 2015-09-13

Build

- **bpo-25071**: Windows installer should not require TargetDir parameter when installing quietly.
Python 3.5.0 release candidate 4?

Release date: 2015-09-09

Library

- **bpo-25029**: Fixes MemoryError in test_strptime.

Build

- **bpo-25027**: Reverts partial-static build options and adds vcruntime140.dll to Windows installation.
Python 3.5.0 release candidate 3?

Release date: 2015-09-07

Core and Builtins

- **bpo-24305**: Prevent import subsystem stack frames from being counted by the warnings.warn(stacklevel=) parameter.
- **bpo-24912**: Prevent __class__ assignment to immutable built-in objects.
- **bpo-24975**: Fix AST compilation for PEP 448 syntax.

Library

- **bpo-24917**: time_strftime() buffer over-read.
- **bpo-24748**: To resolve a compatibility problem found with py2exe and pywin32, imp.load_dynamic() once again ignores previously loaded modules to support Python modules replacing themselves with extension modules. Patch by Petr Viktorin.
- **bpo-24635**: Fixed a bug in typing.py where isinstance([], typing.Iterable) would return True once, then False on subsequent calls.
- **bpo-24989**: Fixed buffer overread in BytesIO.readline() if a position is set beyond size. Based on patch by John Leitch.
- **bpo-24913**: Fix overrun error in deque.index(). Found by John Leitch and Bryce Darling.
Python 3.5.0 release candidate 2?

Release date: 2015-08-25

Core and Builtins

- **bpo-24769**: Interpreter now starts properly when dynamic loading is disabled. Patch by Petr Viktorin.
- **bpo-21167**: NAN operations are now handled correctly when python is compiled with ICC even if -fp-model strict is not specified.
- **bpo-24492**: A “package” lacking a `__name__` attribute when trying to perform a `from .. import ...` statement will trigger an `ImportError` instead of an `AttributeError`.

Library

- **bpo-24847**: Removes vcruntime140.dll dependency from Tcl/Tk.
- **bpo-24839**: `platform._syscmd_ver` raises `DeprecationWarning`
- **bpo-24867**: Fix `Task.get_stack()` for ‘async def’ coroutines
Python 3.5.0 release candidate 1?

Release date: 2015-08-09

Core and Builtins

- **bpo-24667**: Resize odict in all cases that the underlying dict resizes.

Library

- **bpo-24824**: Signatures of codecs.encode() and codecs.decode() now are compatible with pydoc.
- **bpo-24634**: Importing uuid should not try to load libc on Windows
- **bpo-24798**: _msvccompiler.py doesn't properly support manifests
- **bpo-4395**: Better testing and documentation of binary operators. Patch by Martin Panter.
- **bpo-23973**: Update typing.py from GitHub repo.
- **bpo-23004**: mock_open() now reads binary data correctly when the type of read_data is bytes. Initial patch by Aaron Hill.
- **bpo-23888**: Handle fractional time in cookie expiry. Patch by ssh.
- **bpo-23652**: Make it possible to compile the select module against the libc headers from the Linux Standard Base, which do not include some EPOLL macros. Patch by Matt Frank.
- **bpo-22932**: Fix timezones in email.utils.formatdate. Patch from Dmitry Shachnev.
- **bpo-23779**: imaplib raises TypeError if authenticator tries to abort. Patch from Craig Holmquist.
- **bpo-23254**: Document how to close the TCPServer listening socket. Patch from Martin Panter.
- **bpo-19450**: Update Windows and OS X installer builds to use SQLite 3.8.11.
- **bpo-17527**: Add PATCH to wsgiref.validator. Patch from Luca Sbardella.
- **bpo-24791**: Fix grammar regression for call syntax: `g(*a or b')`.

**IDLE**

- **bpo-23672**: Allow Idle to edit and run files with astral chars in name. Patch by Mohd Sanad Zaki Rizvi.
- **bpo-24745**: Idle editor default font. Switch from Courier to platform-sensitive TkFixedFont. This should not affect current customized font selections. If there is a problem, edit `$HOME/.idlerc/config-main.cfg` and remove ‘fontxxx’ entries from [Editor Window]. Patch by Mark Roseman.
- **bpo-21192**: Idle editor. When a file is run, put its name in the restart bar. Do not print false prompts. Original patch by Adnan Umer.
- **bpo-13884**: Idle menus. Remove tearoff lines. Patch by Roger Serwy.

**Documentation**

- **bpo-24129**: Clarify the reference documentation for name resolution. This includes removing the assumption that readers will be familiar with the name resolution scheme Python used prior to the introduction of lexical scoping for function namespaces. Patch by Ivan Levkivskyi.
- **bpo-20769**: Improve reload() docs. Patch by Dorian Pula.
- **bpo-23589**: Remove duplicate sentence from the FAQ. Patch by Yongzhi Pan.
- **bpo-24729**: Correct IO tutorial to match implementation regarding encoding parameter to open function.
Tests

- **bpo-24751**: When running regrtest with the `-w` command line option, a test run is no longer marked as a failure if all tests succeed when re-run.
Python 3.5.0 beta 4?

Release date: 2015-07-26

Core and Builtins

- **bpo-23573**: Restored optimization of bytes.rfind() and bytearray.rfind() for single-byte argument on Linux.
- **bpo-24569**: Make PEP 448 dictionary evaluation more consistent.
- **bpo-24583**: Fix crash when set is mutated while being updated.
- **bpo-24407**: Fix crash when dict is mutated while being updated.
- **bpo-24619**: New approach for tokenizing async/await. As a consequence, it is now possible to have one-line ‘async def foo(): await ..’ functions.
- **bpo-24687**: Plug refleak on SyntaxError in function parameters annotations.
- **bpo-15944**: memoryview: Allow arbitrary formats when casting to bytes. Patch by Martin Panter.

Library

- **bpo-23441**: rcompleter now prints a tab character instead of displaying possible completions for an empty word. Initial patch by Martin Sekera.
- **bpo-24683**: Fixed crashes in _json functions called with arguments of inappropriate type.
- **bpo-21697**: shutil.copytree() now correctly handles symbolic links that point to directories. Patch by Eduardo Seabra and Thomas Kluyver.
- **bpo-14373**: Fixed segmentation fault when gc.collect() is called during constructing lru_cache (C implementation).
- **bpo-24695**: Fix a regression in traceback.print_exception(). If
exc_traceback is None we shouldn't print a traceback header like described in the documentation.

- **bpo-24620**: Random.setstate() now validates the value of state last element.
- **bpo-22485**: Fixed an issue that caused `inspect.getsource` to return incorrect results on nested functions.
- **bpo-22153**: Improve unittest docs. Patch from Martin Panter and evilzero.
- **bpo-24580**: Symbolic group references to open group in re patterns now are explicitly forbidden as well as numeric group references.
- **bpo-24206**: Fixed `__eq__` and `__ne__` methods of inspect classes.
- **bpo-24631**: Fixed regression in the timeit module with multiline setup.
- **bpo-18622**: unittest.mock.mock_open().reset_mock would recurse infinitely. Patch from Nicola Palumbo and Laurent De Buyst.
- **bpo-23661**: unittest.mock side_effects can now be exceptions again. This was a regression vs Python 3.4. Patch from Ignacio Rossi
- **bpo-24608**: chunk.Chunk.read() now always returns bytes, not str.
- **bpo-18684**: Fixed reading out of the buffer in the re module.
- **bpo-24259**: tarfile now raises a ReadError if an archive is truncated inside a data segment.
- **bpo-15014**: SMTP.auth() and SMTP.login() now support RFC 4954's optional initial- response argument to the SMTP AUTH command.
- **bpo-24669**: Fix inspect.getsource() for ‘async def’ functions. Patch by Kai Groner.
- **bpo-24688**: ast.get_docstring() for ‘async def’ functions.

**Build**

- **bpo-24603**: Update Windows builds and OS X 10.5 installer to
use OpenSSL 1.0.2d.
Python 3.5.0 beta 3?

Release date: 2015-07-05

Core and Builtins

- **bpo-24467**: Fixed possible buffer over-read in bytearray. The bytearray object now always allocates place for trailing null byte and it’s buffer now is always null-terminated.
- **bpo-24345**: Add Py_tp_finalize slot for the stable ABI.
- **bpo-24400**: Introduce a distinct type for PEP 492 coroutines; add types.CoroutineType, inspect.getcoroutinestate, inspect.getcoroutinelocals; coroutines no longer use CO_GENERATOR flag; sys.set_coroutine_wrapper works only for ‘async def’ coroutines; inspect.iscoroutine no longer uses collections.abcCoroutine, it’s intended to test for pure ‘async def’ coroutines only; add new opcode: GET_YIELD_FROM_ITER; fix generators wrapper used in types.coroutine to be instance of collections.abcGenerator; collections.abcAwaitable and collections.abcCoroutine can no longer be used to detect generator-based coroutines–use inspect.isawaitable instead.
- **bpo-24450**: Add gi_yieldfrom to generators and cr_await to coroutines. Contributed by Benno Leslie and Yury Selivanov.

Library

- **bpo-21750**: mock_open.read_data can now be read from each instance, as it could in Python 3.3.
- **bpo-24552**: Fix use after free in an error case of the _pickle
module.

- **bpo-24514**: tarfile now tolerates number fields consisting of only whitespace.
- **bpo-19176**: Fixed doctype() related bugs in C implementation of ElementTree. A deprecation warning no longer issued by XMLParser subclass with default doctype() method. Direct call of doctype() now issues a warning. Parser's doctype() now is not called if target's doctype() is called. Based on patch by Martin Panter.
- **bpo-20387**: Restore semantic round-trip correctness in tokenize/untokenize for tab- indented blocks.
- **bpo-24456**: Fixed possible buffer over-read in adpcm2lin() and lin2adpcm() functions of the audioop module.
- **bpo-24336**: The contextmanager decorator now works with functions with keyword arguments called “func” and “self”. Patch by Martin Panter.
- **bpo-24522**: Fix possible integer overflow in json accelerator module.
- **bpo-24489**: ensure a previously set C errno doesn't disturb cmath.polar().
- **bpo-24408**: Fixed AttributeError in measure() and metrics() methods of tkinter.Font.
- **bpo-14373**: C implementation of functools.lru_cache() now can be used with methods.
- **bpo-24347**: Set KeyError if PyDict_GetItemWithError returns NULL.
- **bpo-24348**: Drop superfluous incref/decref.
- **bpo-24359**: Check for changed OrderedDict size during iteration.
- **bpo-24368**: Support keyword arguments in OrderedDict methods.
- **bpo-24362**: Simplify the C OrderedDict fast nodes resize logic.
- **bpo-24377**: Fix a ref leak in OrderedDict.__repr__.
- **bpo-24369**: Defend against key-changes during iteration.

Tests
• **bpo-24373**: _testmultiphase and xxlimited now use tp_traverse and tp_finalize to avoid reference leaks encountered when combining tp_dealloc with PyType_FromSpec (see bpo-16690 for details)

**Documentation**

• **bpo-24458**: Update documentation to cover multi-phase initialization for extension modules (PEP 489). Patch by Petr Viktorin.

• **bpo-24351**: Clarify what is meant by “identifier” in the context of string.Template instances.

**Build**

• **bpo-24432**: Update Windows builds and OS X 10.5 installer to use OpenSSL 1.0.2c.
Python 3.5.0 beta 2?

Release date: 2015-05-31

Core and Builtins

- **bpo-24284**: The startswith and endswith methods of the str class no longer return True when finding the empty string and the indexes are completely out of range.
- **bpo-24115**: Update uses of PyObject_IsTrue(), PyObject_Not(), PyObject_IsInstance(), PyObject_RichCompareBool() and _PyDict_Contains() to check for and handle errors correctly.
- **bpo-24328**: Fix importing one character extension modules.
- **bpo-11205**: In dictionary displays, evaluate the key before the value.
- **bpo-24285**: Fixed regression that prevented importing extension modules from inside packages. Patch by Petr Viktorin.

Library

- **bpo-23247**: Fix a crash in the StreamWriter.reset() of CJK codecs.
- **bpo-24270**: Add math.isclose() and cmath.isclose() functions as per PEP 485. Contributed by Chris Barker and Tal Einat.
- **bpo-5633**: Fixed timeit when the statement is a string and the setup is not.
- **bpo-24326**: Fixed audioop.ratecv() with non-default weightB argument. Original patch by David Moore.
- **bpo-16991**: Add a C implementation of OrderedDict.
- **bpo-23934**: Fix inspect.signature to fail correctly for builtin types lacking signature information. Initial patch by James Powell.
Python 3.5.0 beta 1?

*Release date: 2015-05-24*

**Core and Bultins**

- **bpo-24276**: Fixed optimization of property descriptor getter.
- **bpo-24268**: PEP 489: Multi-phase extension module initialization. Patch by Petr Viktorin.
- **bpo-23955**: Add pyvenv.cfg option to suppress registry/environment lookup for generating sys.path on Windows.
- **bpo-24257**: Fixed system error in the comparison of faked types.SimpleNamespace.
- **bpo-22939**: Fixed integer overflow in iterator object. Patch by Clement Rouault.
- **bpo-23985**: Fix a possible buffer overrun when deleting a slice from the front of a bytearray and then appending some other bytes data.
- **bpo-24102**: Fixed exception type checking in standard error handlers.
- **bpo-15027**: The UTF-32 encoder is now 3x to 7x faster.
- **bpo-23290**: Optimize set_merge() for cases where the target is empty. (Contributed by Serhiy Storchaka.)
- **bpo-2292**: PEP 448: Additional Unpacking Generalizations.
- **bpo-24096**: Make warnings.warn_explicit more robust against mutation of the warnings.filters list.
- **bpo-23996**: Avoid a crash when a delegated generator raises an unnormalized StopIteration exception. Patch by Stefan Behnel.
- **bpo-23910**: Optimize property() getter calls. Patch by Joe Jevnik.
- **bpo-23911**: Move path-based importlib bootstrap code to a separate frozen module.
- **bpo-24192**: Fix namespace package imports.
- **bpo-24022**: Fix tokenizer crash when processing undecodable
source code.

- **bpo-9951**: Added a hex() method to bytes, bytearray, and memoryview.
- **bpo-22906**: PEP 479: Change StopIteration handling inside generators.
- **bpo-24017**: PEP 492: Coroutines with async and await syntax.

**Library**

- **bpo-14373**: Added C implementation of functools.lru_cache(). Based on patches by Matt Joiner and Alexey Kachayev.
- **bpo-24230**: The tempfile module now accepts bytes for prefix, suffix and dir parameters and returns bytes in such situations (matching the os module APIs).
- **bpo-22189**: collections.UserString now supports __getnewargs__() , __rmod__(), casefold(), format_map(), isprintable(), and maketrans(). Patch by Joe Jevnik.
- **bpo-24244**: Prevents termination when an invalid format string is encountered on Windows in strftime.
- **bpo-23973**: PEP 484: Add the typing module.
- **bpo-23086**: The collections.abc.Sequence() abstract base class added start and stop parameters to the index() mixin. Patch by Devin Jeanpierre.
- **bpo-20035**: Replaced the tkinter._fix module used for setting up the Tcl/Tk environment on Windows with a private function in the _tkinter module that makes no permanent changes to the environment.
- **bpo-24257**: Fixed segmentation fault in sqlite3.Row constructor with faked cursor type.
- **bpo-15836**: assertRaises(), assertRaisesRegex(), assertWarns() and assertWarnsRegex() assertions now check the type of the first argument to prevent possible user error. Based on patch by Daniel Wagner-Hall.
- **bpo-9858**: Add missing method stubs to _io.RawIOBase. Patch by
Laura Rupprecht.

- **bpo-22955**: attrgetter, itemgetter and methodcaller objects in the operator module now support pickling. Added readable and evaluable repr for these objects. Based on patch by Josh Rosenberg.
- **bpo-22107**: tempfile.gettempdir() and tempfile.mkdtemp() now try again when a directory with the chosen name already exists on Windows as well as on Unix. tempfile.mkstemp() now fails early if parent directory is not valid (not exists or is a file) on Windows.
- **bpo-23780**: Improved error message in os.path.join() with single argument.
- **bpo-6598**: Increased time precision and random number range in email.utils.make_msgid() to strengthen the uniqueness of the message ID.
- **bpo-24091**: Fixed various crashes in corner cases in C implementation of ElementTree.
- **bpo-21931**: msilib.FCiCreate() now raises TypeError in the case of a bad argument instead of a ValueError with a bogus FCI error number. Patch by Jeffrey Armstrong.
- **bpo-13866**: quote_via argument added to urllib.parse.urlencode.
- **bpo-20098**: New mangle_from policy option for email, default True for compat32, but False for all other policies.
- **bpo-24211**: The email library now supports RFC 6532: it can generate headers using utf-8 instead of encoded words.
- **bpo-16314**: Added support for the LZMA compression in distutils.
- **bpo-21804**: poplib now supports RFC 6856 (UTF8).
- **bpo-18682**: Optimized pprint functions for built-in scalar types.
- **bpo-22027**: smtplib now supports RFC 6531 (SMTPUTF8).
- **bpo-23488**: Random generator objects now consume 2x less memory on 64-bit.
- **bpo-1322**: platform.dist() and platform.linux_distribution() functions are now deprecated. Initial patch by Vajrasky Kok.
- **bpo-22486**: Added the math.gcd() function. The fractions.gcd() function now is deprecated. Based on patch by Mark Dickinson.
• **bpo-24064**: Property() docstrings are now writeable. (Patch by Berker Peksag.)
• **bpo-22681**: Added support for the koi8_t encoding.
• **bpo-22682**: Added support for the kz1048 encoding.
• **bpo-23796**: peek and read1 methods of BufferedReader now raise ValueError if they called on a closed object. Patch by John Hergenroeder.
• **bpo-21795**: smtpd now supports the 8BITMIME extension whenever the new decode_data constructor argument is set to False.
• **bpo-24155**: optimize heapq.heapify() for better cache performance when heapifying large lists.
• **bpo-21800**: imaplib now supports RFC 5161 (enable), RFC 6855 (utf8/internationalized email) and automatically encodes non-ASCII usernames and passwords to UTF8.
• **bpo-20274**: When calling a _sqlite.Connection, it now complains if passed any keyword arguments. Previously it silently ignored them.
• **bpo-20274**: Remove ignored and erroneous “kwargs” parameters from three METH_VARARGS methods on _sqlite.Connection.
• **bpo-24134**: assertRaises(), assertRaisesRegex(), assertWarns() and assertWarnsRegex() checks now emits a deprecation warning when callable is None or keyword arguments except msg is passed in the context manager mode.
• **bpo-24018**: Add a collections.abc.Generator abstract base class. Contributed by Stefan Behnel.
• **bpo-23880**: Tkinter’s getint() and getdouble() now support Tcl_Obj. Tkinter’s getdouble() now supports any numbers (in particular int).
• **bpo-22619**: Added negative limit support in the traceback module. Based on patch by Dmitry Kazakov.
• **bpo-24094**: Fix possible crash in json.encode with poorly behaved dict subclasses.
• **bpo-9246**: On POSIX, os.getcwd() now supports paths longer
than 1025 bytes. Patch written by William Orr.

- **bpo-17445**: add difflib.diff_bytes() to support comparison of byte strings (fixes a regression from Python 2).
- **bpo-23917**: Fall back to sequential compilation when ProcessPoolExecutor doesn’t exist. Patch by Claudiu Popa.
- **bpo-23008**: Fixed resolving attributes with boolean value is False in pydoc.
- Fix asyncio issue 235: LifoQueue and PriorityQueue’s put didn’t increment unfinished tasks (this bug was introduced when JoinableQueue was merged with Queue).
- **bpo-23908**: os functions now reject paths with embedded null character on Windows instead of silently truncating them.
- **bpo-23728**: binascii.crc_hqx() could return an integer outside of the range 0-0xffff for empty data.
- **bpo-23887**: urllib.error.HTTPError now has a proper repr() representation. Patch by Berker Peksag.
- asyncio: New event loop APIs: set_task_factory() and get_task_factory().
- asyncio: async() function is deprecated in favour of ensure_future().
- **bpo-24178**: asyncio.Lock, Condition, Semaphore, and BoundedSemaphore support new ‘async with’ syntax. Contributed by Yury Selivanov.
- **bpo-24184**: Add AsyncIterator and AsyncIterable ABCs to collections.abc. Contributed by Yury Selivanov.
- **bpo-22547**: Implement informative __repr__ for inspect.BoundArguments. Contributed by Yury Selivanov.
- **bpo-20691**: Add ‘follow_wrapped’ argument to inspect.Signature.from_callable() and inspect.signature(). Contributed by Yury Selivanov.
• **bpo-24248**: Deprecate `inspect.Signature.from_function()` and `inspect.Signature.from_builtin()`.

• **bpo-23898**: Fix `inspect.classify_class_attrs()` to support attributes with overloaded `__eq__` and `__bool__`. Patch by Mike Bayer.

• **bpo-24298**: Fix `inspect.signature()` to correctly unwrap wrappers around bound methods.

**IDLE**

• **bpo-23184**: remove unused names and imports in idlelib. Initial patch by Al Sweigart.

**Tests**

• **bpo-21520**: `test_zipfile` no longer fails if the word ‘bad’ appears anywhere in the name of the current directory.
• **bpo-9517**: Move `script_helper` into the support package. Patch by Christie Wilson.

**Documentation**

• **bpo-22155**: Add File Handlers subsection with `createfilehandler` to `tkinter` doc. Remove obsolete example from FAQ. Patch by Martin Panter.

• **bpo-24029**: Document the name binding behavior for submodule imports.

• **bpo-24077**: Fix typo in man page for `-I` command option: `-s`, not `-S`

**Tools/Demos**

• **bpo-24000**: Improved Argument Clinic’s mapping of converters to legacy “format units”. Updated the documentation to match.
• **bpo-24001**: Argument Clinic converters now use accept={type} instead of types={'type'} to specify the types the converter accepts.
• **bpo-23330**: h2py now supports arbitrary filenames in `#include`.
• **bpo-24031**: make patchcheck now supports git checkouts, too.
Python 3.5.0 alpha 4?

Release date: 2015-04-19

Core and Builtins

- **bpo-22980**: Under Linux, GNU/KFreeBSD and the Hurd, C extensions now include the architecture triplet in the extension name, to make it easy to test builds for different ABIs in the same working tree. Under OS X, the extension name now includes PEP 3149-style information.
- **bpo-22631**: Added Linux-specific socket constant CAN_RAW_FD_FRAMES. Patch courtesy of Joe Jevnik.
- **bpo-23731**: Implement PEP 488: removal of .pyo files.
- **bpo-23726**: Don't enable GC for user subclasses of non-GC types that don't add any new fields. Patch by Eugene Toder.
- **bpo-23309**: Avoid a deadlock at shutdown if a daemon thread is aborted while it is holding a lock to a buffered I/O object, and the main thread tries to use the same I/O object (typically stdout or stderr). A fatal error is emitted instead.
- **bpo-22977**: Fixed formatting Windows error messages on Wine. Patch by Martin Panter.
- **bpo-23466**: %c, %o, %x, and %X in bytes formatting now raise TypeError on non-integer input.
- **bpo-24044**: Fix possible null pointer dereference in list.sort in out of memory conditions.
- **bpo-21354**: PyCFunction_New function is exposed by python DLL again.

Library

- **bpo-23840**: tokenize.open() now closes the temporary binary file
on error to fix a resource warning.

- **bpo-16914**: new debuglevel 2 in smtplib adds timestamps to debug output.
- **bpo-7159**: urllib.request now supports sending auth credentials automatically after the first 401. This enhancement is a superset of the enhancement from bpo-19494 and supersedes that change.
- **bpo-23703**: Fix a regression in urljoin() introduced in 901e4e52b20a. Patch by Demian Brecht.
- **bpo-4254**: Adds _curses.update_lines_cols(). Patch by Arnon Yaari
- **bpo-19933**: Provide default argument for ndigits in round. Patch by Vajrasky Kok.
- **bpo-23342**: Add a subprocess.run() function than returns a CalledProcess instance for a more consistent API than the existing call* functions.
- **bpo-21217**: inspect.getsourcelines() now tries to compute the start and end lines from the code object, fixing an issue when a lambda function is used as decorator argument. Patch by Thomas Ballinger and Allison Kaptur.
- **bpo-24521**: Fix possible integer overflows in the pickle module.
- **bpo-22931**: Allow ‘[’ and ‘]’ in cookie values.
- **bpo-23811**: Add missing newline to the PyCompileError error message. Patch by Alex Shkop.
- **bpo-21116**: Avoid blowing memory when allocating a multiprocessing shared array that's larger than 50% of the available RAM. Patch by Médéric Boquien.
- **bpo-22982**: Improve BOM handling when seeking to multiple positions of a writable text file.
- **bpo-23464**: Removed deprecated asyncio JoinableQueue.
- **bpo-23529**: Limit the size of decompressed data when reading from GzipFile, BZ2File or LZMAFile. This defeats denial of service attacks using compressed bombs (i.e. compressed payloads which decompress to a huge size). Patch by Martin Panter and Nikolaus Rath.
- **bpo-21859**: Added Python implementation of io.FileIO.
- **bpo-23865**: close() methods in multiple modules now are idempotent and more robust at shutdown. If they need to release multiple resources, all are released even if errors occur.
- **bpo-23400**: Raise same exception on both Python 2 and 3 if sem_open is not available. Patch by Davin Potts.
- **bpo-10838**: The subprocess now module includes SubprocessError and TimeoutError in its list of exported names for the users wild enough to use `from subprocess import *`. Patch by Martin Panter.
- **bpo-23411**: Added DefragResult, ParseResult, SplitResult, DefragResultBytes, ParseResultBytes, and SplitResultBytes to urllib.parse.__all__. Patch by Martin Panter.
- **bpo-23881**: urllib.request.ftpwrapper constructor now closes the socket if the FTP connection failed to fix a ResourceWarning.
- **bpo-23853**: `socket.socket.sendall()` does no more reset the socket timeout each time data is sent successfully. The socket timeout is now the maximum total duration to send all data.
- **bpo-22721**: An order of multiline pprint output of set or dict containing orderable and non-orderable elements no longer depends on iteration order of set or dict.
- **bpo-15133**: `_tkinter.tkapp.getboolean()` now supports Tcl_Obj and always returns bool. _tkinter.BooleanVar now validates input values (accepted bool, int, str, and Tcl_Obj). _tkinter.BooleanVar.get() now always returns bool.
- **bpo-10590**: xml.sax.parseString() now supports string argument.
- **bpo-23338**: Fixed formatting ctypes error messages on Cygwin. Patch by Makoto Kato.
- **bpo-15582**: inspect.getdoc() now follows inheritance chains.
- **bpo-2175**: SAX parsers now support a character stream of InputSource object.
- **bpo-16840**: Tkinter now supports 64-bit integers added in Tcl 8.4 and arbitrary precision integers added in Tcl 8.5.
- **bpo-23834**: Fix socket.sendto(), use the C Py_ssize_t type to store the result of sendto() instead of the C int type.
- **bpo-23618**: `socket.socket.connect()` now waits until the connection completes instead of raising `InterruptedError` if the connection is interrupted by signals, signal handlers don't raise an exception and the socket is blocking or has a timeout. `socket.socket.connect()` still raise `InterruptedError` for non-blocking sockets.
- **bpo-21526**: Tkinter now supports new boolean type in Tcl 8.5.
- **bpo-23836**: Fix the faulthandler module to handle reentrant calls to its signal handlers.
- **bpo-23838**: linecache now clears the cache and returns an empty result on MemoryError.
- **bpo-10395**: Added `os.path.commonpath()`. Implemented in posixpath and ntpath. Based on patch by Rafik Draoui.
- **bpo-23611**: Serializing more “lookable” objects (such as unbound methods or nested classes) now are supported with pickle protocols < 4.
- **bpo-13583**: sqlite3.Row now supports slice indexing.
- **bpo-18473**: Fixed 2to3 and 3to2 compatible pickle mappings. Fixed ambiguous reverse mappings. Added many new mappings. Import mapping is no longer applied to modules already mapped with full name mapping.
- **bpo-23485**: `select.select()` is now retried automatically with the recomputed timeout when interrupted by a signal, except if the signal handler raises an exception. This change is part of the PEP 475.
- **bpo-23752**: When built from an existing file descriptor, io.FileIO() now only calls fstat() once. Before fstat() was called twice, which was not necessary.
• **bpo-23704**: collections.deque() objects now support `__add__`, `__mul__`, and `__imul__()`.
• **bpo-23171**: csv.Writer.writerow() now supports arbitrary iterables.
• **bpo-23745**: The new email header parser now handles duplicate MIME parameter names without error, similar to how `get_param` behaves.
• **bpo-22117**: Fix `os.utime()`, it now rounds the timestamp towards minus infinity (-inf) instead of rounding towards zero.
• **bpo-23310**: Fix MagicMock’s initializer to work with `__methods__`, just like `configure_mock()`. Patch by Kasia Jachim.

**Build**

• **bpo-23817**: FreeBSD now uses “1.0” in the SOVERSION as other operating systems, instead of just “1”.
• **bpo-23501**: Argument Clinic now generates code into separate files by default.

**Tests**

• **bpo-23799**: Added `test.support.start_threads()` for running and cleaning up multiple threads.
• **bpo-22390**: `test.regrtest` now emits a warning if temporary files or directories are left after running a test.

**Tools/Demos**

• **bpo-18128**: pygettext now uses standard +NNNN format in the POT-Creation-Date header.
• **bpo-23935**: Argument Clinic’s understanding of format units accepting bytes, bytearrays, and buffers is now consistent with both the documentation and the implementation.
• **bpo-23944**: Argument Clinic now wraps long impl prototypes at
• **bpo-20586**: Argument Clinic now ensures that functions without docstrings have signatures.
• **bpo-23492**: Argument Clinic now generates argument parsing code with PyArg_Parse instead of PyArg_ParseTuple if possible.
• **bpo-23500**: Argument Clinic is now smarter about generating the “#ifndef” (empty) definition of the methoddef macro: it’s only generated once, even if Argument Clinic processes the same symbol multiple times, and it’s emitted at the end of all processing rather than immediately after the first use.

**C API**

• **bpo-23998**: PyImport_ReInitLock() now checks for lock allocation error
Python 3.5.0 alpha 3?

Release date: 2015-03-28

Core and Builtins

- **bpo-23573**: Increased performance of string search operations (str.find, str.index, str.count, the in operator, str.split, str.partition) with arguments of different kinds (UCS1, UCS2, UCS4).
- **bpo-23753**: Python doesn’t support anymore platforms without stat() or fstat(), these functions are always required.
- **bpo-23681**: The -b option now affects comparisons of bytes with int.
- **bpo-23632**: Memoryviews now allow tuple indexing (including for multi-dimensional memoryviews).
- **bpo-23192**: Fixed generator lambdas. Patch by Bruno Cauet.
- **bpo-23629**: Fix the default __sizeof__ implementation for variable-sized objects.

Library

- **bpo-14260**: The groupindex attribute of regular expression pattern object now is non-modifiable mapping.
- **bpo-23792**: Ignore KeyboardInterrupt when the pydoc pager is active. This mimics the behavior of the standard unix pagers, and prevents pipepager from shutting down while the pager itself is still running.
- **bpo-23775**: pprint() of OrderedDict now outputs the same representation as repr().
- **bpo-23765**: Removed IsBadStringPtr calls in ctypes
- **bpo-22364**: Improved some re error messages using regex for hints.
- **bpo-23742**: `ntpath.expandvars()` no longer loses unbalanced single quotes.
- **bpo-21717**: The `zipfile.ZipFile.open` function now supports ‘x’ (exclusive creation) mode.
- **bpo-21802**: The reader in `BufferedRWPair` now is closed even when closing writer failed in `BufferedRWPair.close()`.
- **bpo-23622**: Unknown escapes in regular expressions that consist of '\\' and ASCII letter now raise a deprecation warning and will be forbidden in Python 3.6.
- **bpo-23671**: `string.Template` now allows specifying the “self” parameter as a keyword argument. `string.Formatter` now allows specifying the “self” and the “format_string” parameters as keyword arguments.
- **bpo-23502**: The `pprint` module now supports mapping proxies.
- **bpo-17530**: `pprint` now wraps long bytes objects and bytearrays.
- **bpo-22687**: Fixed some corner cases in breaking words in `textwrap`. Got rid of quadratic complexity in breaking long words.
- **bpo-4727**: The `copy` module now uses pickle protocol 4 (PEP 3154) and supports copying of instances of classes whose `__new__` method takes keyword-only arguments.
- **bpo-23491**: Added a `zipapp` module to support creating executable zip file archives of Python code. Registered “.pyz” and “.pyzw” extensions on Windows for these archives (PEP 441).
- **bpo-23657**: Avoid explicit checks for `str` in `zipapp`, adding support for `pathlib.Path` objects as arguments.
- **bpo-23252**: Added support for writing ZIP files to unseekable streams.
- **bpo-23647**: Increase `impalib`’s `MAXLINE` to accommodate modern mailbox sizes.
- **bpo-23539**: If body is None, `http.client.HTTPConnection.request` now sets Content-Length to 0 for PUT, POST, and PATCH
headers to avoid 411 errors from some web servers.

- **bpo-22351**: The nntplib.NNTP constructor no longer leaves the connection and socket open until the garbage collector cleans them up. Patch by Martin Panter.
- **bpo-23704**: collections.deque() objects now support methods for index(), insert(), and copy(). This allows deques to be registered as a MutableSequence and it improves their substitutability for lists.
- **bpo-23715**: `signal.sigwaitinfo()` and `signal.sigtimedwait()` are now retried when interrupted by a signal not in the `sigset` parameter, if the signal handler does not raise an exception. `signal.sigtimedwait()` recomputes the timeout with a monotonic clock when it is retried.
- **bpo-23001**: Few functions in modules mmap, ossaudiodev, socket, ssl, and codecs, that accepted only read-only bytes-like object now accept writable bytes-like object too.
- **bpo-23646**: If `time.sleep()` is interrupted by a signal, the sleep is now retried with the recomputed delay, except if the signal handler raises an exception (PEP 475).
- **bpo-23136**: `_strptime` now uniformly handles all days in week 0, including Dec 30 of previous year. Based on patch by Jim Carroll.
- **bpo-23700**: Iterator of NamedTemporaryFile now keeps a reference to NamedTemporaryFile instance. Patch by Bohuslav Kabrda.
- **bpo-22903**: The fake test case created by unittest.loader when it fails importing a test module is now picklable.
- **bpo-22181**: On Linux, os.urandom() now uses the new getrandom() syscall if available, syscall introduced in the Linux kernel 3.17. It is more reliable and more secure, because it avoids the need of a file descriptor and waits until the kernel has enough entropy.
- **bpo-2211**: Updated the implementation of the http.cookies.Morsel class. Setting attributes key, value and coded_value directly now is deprecated. `update()` and `setdefault()` now transform and check
keys. Comparing for equality now takes into account attributes key, value and coded_value. copy() now returns a Morsel, not a dict. repr() now contains all attributes. Optimized checking keys and quoting values. Added new tests. Original patch by Demian Brecht.

- **bpo-18983**: Allow selection of output units in timeit. Patch by Julian Gindi.
- **bpo-23631**: Fix traceback.format_list when a traceback has been mutated.
- **bpo-23568**: Add rdivmod support to MagicMock() objects. Patch by Håkan Lövdahl.
- **bpo-2052**: Add charset parameter to HtmlDiff.make_file().
- **bpo-23668**: Support os.truncate and os.ftruncate on Windows.
- **bpo-23138**: Fixed parsing cookies with absent keys or values in cookiejar. Patch by Demian Brecht.
- **bpo-23051**: multiprocessing.Pool methods imap() and imap_unordered() now handle exceptions raised by an iterator. Patch by Alon Diamant and Davin Potts.
- **bpo-23581**: Add matmul support to MagicMock. Patch by Håkan Lövdahl.
- **bpo-23566**: enable(), register(), dump_traceback() and dump_traceback_later() functions of faulthandler now accept file descriptors. Patch by Wei Wu.
- **bpo-23615**: Modules bz2, tarfile and tokenize now can be reloaded with imp.reload(). Patch by Thomas Kluyver.
- **bpo-23605**: os.walk() now calls os.scandir() instead of os.listdir(). The usage of os.scandir() reduces the number of calls to os.stat(). Initial patch written by Ben Hoyt.

### Build

- **bpo-23585**: make patchcheck will ensure the interpreter is built.
Tests

- **bpo-23583**: Added tests for standard IO streams in IDLE.
- **bpo-22289**: Prevent test_urlib2net failures due to ftp connection timeout.

Tools/Demos

- **bpo-22826**: The result of open() in Tools/freeze/bkfile.py is now better compatible with regular files (in particular it now supports the context management protocol).
Python 3.5.0 alpha 2?

*Release date: 2015-03-09*

**Core and Builtins**

- **bpo-23571**: PyObject_Call() and PyCFunction_Call() now raise a SystemError if a function returns a result and raises an exception. The SystemError is chained to the previous exception.

**Library**

- **bpo-22524**: New os.scandir() function, part of the PEP 471: “os.scandir() function – a better and faster directory iterator”. Patch written by Ben Hoyt.

- **bpo-23103**: Reduced the memory consumption of IPv4Address and IPv6Address.

- **bpo-21793**: BaseHTTPRequestHandler again logs response code as numeric, not as stringified enum. Patch by Demian Brecht.

- **bpo-23476**: In the ssl module, enable OpenSSL's X509_V_FLAG_TRUSTED_FIRST flag on certificate stores when it is available.

- **bpo-23576**: Avoid stalling in SSL reads when EOF has been reached in the SSL layer but the underlying connection hasn't been closed.

- **bpo-23504**: Added an `__all__` to the types module.
- **bpo-23563**: Optimized utility functions in urllib.parse.

- **bpo-7830**: Flatten nested functools.partial.

- **bpo-20204**: Added the `__module__` attribute to _tkinter classes.

- **bpo-19980**: Improved `help()` for non-recognized strings. `help('')` now shows the help on str. `help('help')` now shows the help on `help()`. Original patch by Mark Lawrence.

- **bpo-23521**: Corrected pure python implementation of timedelta division.

  Eliminated `OverflowError` from `timedelta * float` for some floats; Corrected rounding in timedelta true division.

- **bpo-21619**: Popen objects no longer leave a zombie after exit in the with statement if the pipe was broken. Patch by Martin Panter.

- **bpo-22936**: Make it possible to show local variables in tracebacks for both the traceback module and unittest.

- **bpo-15955**: Add an option to limit the output size in bz2.decompress(). Patch by Nikolaus Rath.

- **bpo-6639**: Module-level turtle functions no longer raise TclError after closing the window.

- **bpo-814253**: Group references and conditional group references now work in lookbehind assertions in regular expressions. (See also: **bpo-9179**)

- **bpo-23215**: Multibyte codecs with custom error handlers that ignores errors consumed too much memory and raised SystemError or MemoryError. Original patch by Aleksi Torhamo.
- **bpo-5700**: `io.FileIO()` called `flush()` after closing the file. `flush()` was not called in `close()` if `closefd=False`.

- **bpo-23374**: Fixed `pydoc` failure with non-ASCII files when `stdout` encoding differs from file system encoding (e.g. on Mac OS).

- **bpo-23481**: Remove RC4 from the SSL module's default cipher list.

- **bpo-21548**: Fix `pydoc.synopsis()` and `pydoc.apropos()` on modules with empty docstrings.

- **bpo-22885**: Fixed arbitrary code execution vulnerability in the `dbm.dumb` module. Original patch by Claudiu Popa.

- **bpo-23239**: `ssl.match_hostname()` now supports matching of IP addresses.

- **bpo-23146**: Fix mishandling of absolute Windows paths with forward slashes in `pathlib`.

- **bpo-23096**: Pickle representation of floats with protocol 0 now is the same for both Python and C implementations.

- **bpo-19105**: `pprint` now more efficiently uses free space at the right.

- **bpo-14910**: Add `allow_abbrev` parameter to `argparse.ArgumentParser`. Patch by Jonathan Paugh, Steven Bethard, paul j3 and Daniel Eriksson.

- **bpo-21717**: `tarfile.open()` now supports ‘x’ (exclusive creation) mode.

- **bpo-23344**: `marshal.dumps()` is now 20-25% faster on average.
• **bpo-20416**: marshal.dumps() with protocols 3 and 4 is now 40-50% faster on average.

• **bpo-23421**: Fixed compression in tarfile CLI. Patch by wdv4758h.

• **bpo-23367**: Fix possible overflows in the unicodedata module.

• **bpo-23361**: Fix possible overflow in Windows subprocess creation code.

• `logging.handlers.QueueListener` now takes a `respect_handler_level` keyword argument which, if set to True, will pass messages to handlers taking handler levels into account.

• **bpo-19705**: turtledemo now has a visual sorting algorithm demo. Original patch from Jason Yeo.

• **bpo-23801**: Fix issue where cgi.FieldStorage did not always ignore the entire preamble to a multipart body.

**Build**

• **bpo-23445**: pydebug builds now use “gcc -Og” where possible, to make the resulting executable faster.

• **bpo-23686**: Update OS X 10.5 installer build to use OpenSSL 1.0.2a.

**C API**

• **bpo-20204**: Deprecation warning is now raised for builtin types without the `__module__` attribute.

**Windows**
• **bpo-23465**: Implement PEP 486 - Make the Python Launcher aware of virtual environments. Patch by Paul Moore.
• **bpo-23437**: Make user scripts directory versioned on Windows. Patch by Paul Moore.
Python 3.5.0 alpha 1?

Release date: 2015-02-08

Core and Builtins

- bpo-23285: PEP 475 - EINTR handling.
- bpo-22735: Fix many edge cases (including crashes) involving custom mro() implementations.
- bpo-22896: Avoid using PyObject_AsCharBuffer(), PyObject_AsReadBuffer() and PyObject_AsWriteBuffer().
- bpo-21295: Revert some changes (bpo-16795) to AST line numbers and column offsets that constituted a regression.
- bpo-22986: Allow changing an object’s __class__ between a dynamic type and static type in some cases.
- bpo-15859: PyUnicode_EncodeFSDefault(), PyUnicode_EncodeMBCS() and PyUnicode_EncodeCodePage() now raise an exception if the object is not a Unicode object. For PyUnicode_EncodeFSDefault(), it was already the case on platforms other than Windows. Patch written by Campbell Barton.
- bpo-21408: The default __ne__() now returns NotImplemented if __eq__() returned NotImplemented. Original patch by Martin Panter.
- bpo-23321: Fixed a crash in str.decode() when error handler returned replacement string longer than malformed input data.
- bpo-22286: The “backslashreplace” error handlers now works with decoding and translating.
- bpo-22038: pyatomic.h now uses stdatomic.h or GCC built-in functions for atomic memory access if available. Patch written by Vitor de Lima and Gustavo Temple.
- bpo-20284: %-interpolation (aka printf) formatting added for bytes
and bytearray.

- **bpo-23048**: Fix jumping out of an infinite while loop in the pdb.
- **bpo-20335**: bytes constructor now raises TypeError when encoding or errors is specified with non-string argument. Based on patch by Renaud Blanch.
- **bpo-22834**: If the current working directory ends up being set to a non-existent directory then import will no longer raise FileNotFoundError.
- **bpo-22869**: Move the interpreter startup & shutdown code to a new dedicated pylifecycle.c module.
- **bpo-22847**: Improve method cache efficiency.
- **bpo-22335**: Fix crash when trying to enlarge a bytearray to 0x7fffffff bytes on a 32-bit platform.
- **bpo-22653**: Fix an assertion failure in debug mode when doing a reentrant dict insertion in debug mode.
- **bpo-22643**: Fix integer overflow in Unicode case operations (upper, lower, title, swapcase, casefold).
- **bpo-17636**: Circular imports involving relative imports are now supported.
- **bpo-22604**: Fix assertion error in debug mode when dividing a complex number by (nan+0j).
- **bpo-21052**: Do not raise ImportWarning when sys.path_hooks or sys.meta_path are set to None.
- **bpo-16518**: Use ‘bytes-like object required’ in error messages that previously used the far more cryptic ‘“x’ does not support the buffer protocol.
- **bpo-22470**: Fixed integer overflow issues in “backslashreplace”, “xmlcharrefreplace”, and “surrogatepass” error handlers.
- **bpo-22540**: speed up PyObject_IsInstance and PyObject_IsSubclass in the common case that the second argument has metaclass type.
- **bpo-18711**: Add a new PyErr_FormatV function, similar to PyErr_Format but accepting a va_list argument.
- **bpo-22520**: Fix overflow checking when generating the repr of a
unicode object.

- **bpo-22519**: Fix overflow checking in PyBytes_Repr.
- **bpo-22518**: Fix integer overflow issues in latin-1 encoding.
- **bpo-16324**: _charset parameter of MIMEText now also accepts email.charset.Charset instances. Initial patch by Claude Paroz.
- **bpo-1764286**: Fix inspect.getsource() to support decorated functions. Patch by Claudiu Popa.
- **bpo-18554**: os.__all__ includes posix functions.
- **bpo-21391**: Use os.path.abspath in the shutil module.
- **bpo-11471**: avoid generating a JUMP_FORWARD instruction at the end of an if-block if there is no else-clause. Original patch by Eugene Toder.
- **bpo-22215**: Now ValueError is raised instead of TypeError when str or bytes argument contains not permitted null character or byte.
- **bpo-22258**: Fix the internal function set_inheritable() on Illumos. This platform exposes the function \texttt{ioctl(FIOCLEX)}, but calling it fails with errno is ENOTTY: “Inappropriate ioctl for device”. set_inheritable() now falls back to the slower \texttt{fcntl()} (F_GETFD and then F_SETFD).
- **bpo-21389**: Displaying the \texttt{__qualname__} of the underlying function in the repr of a bound method.
- **bpo-22206**: Using pthread, PyThread_create_key() now sets errno to ENOMEM and returns -1 (error) on integer overflow.
- **bpo-20184**: Argument Clinic based signature introspection added for 30 of the builtin functions.
- **bpo-22116**: C functions and methods (of the ‘builtin_function_or_method’ type) can now be weakref’ed. Patch by Wei Wu.
- **bpo-22077**: Improve index error messages for bytearrays, bytes, lists, and tuples by adding ‘or slices’. Added ‘, not <typename>’ for bytearrays. Original patch by Claudiu Popa.
- **bpo-20179**: Apply Argument Clinic to bytes and bytearray. Patch by Tal Einat.
- **bpo-22082**: Clear interned strings in slotdefs.
- Upgrade Unicode database to Unicode 7.0.0.
- **bpo-21897**: Fix a crash with the f_locals attribute with closure variables when frame.clear() has been called.
- **bpo-21205**: Add a new __qualname__ attribute to generator, the qualified name, and use it in the representation of a generator (repr(gen)). The default name of the generator (__name__ attribute) is now get from the function instead of the code. Use gen.gi_code.co_name to get the name of the code.
- **bpo-21669**: With the aid of heuristics in SyntaxError.__init__, the parser now attempts to generate more meaningful (or at least more search engine friendly) error messages when “exec” and “print” are used as statements.
- **bpo-21642**: In the conditional if-else expression, allow an integer written with no space between itself and the else keyword (e.g. True if 42else False) to be valid syntax.
- **bpo-21523**: Fix over-pessimistic computation of the stack effect of some opcodes in the compiler. This also fixes a quadratic compilation time issue noticeable when compiling code with a large number of “and” and “or” operators.
- **bpo-21418**: Fix a crash in the builtin function super() when called without argument and without current frame (ex: embedded Python).
- **bpo-21425**: Fix flushing of standard streams in the interactive interpreter.
- **bpo-21435**: In rare cases, when running finalizers on objects in cyclic trash a bad pointer dereference could occur due to a subtle flaw in internal iteration logic.
- **bpo-21377**: PyBytes_Concat() now tries to concatenate in-place when the first argument has a reference count of 1. Patch by Nikolaus Rath.
- **bpo-20355**: -W command line options now have higher priority than the PYTHONWARNINGS environment variable. Patch by Arfrever.
• **bpo-21274**: Define PATH_MAX for GNU/Hurd in Python/pythonrun.c.
• **bpo-20904**: Support setting FPU precision on m68k.
• **bpo-21209**: Fix sending tuples to custom generator objects with the yield from syntax.
• **bpo-21193**: `pow(a, b, c)` now raises ValueError rather than TypeError when b is negative. Patch by Josh Rosenberg.
• **bpo-21176**: PEP 465: Add the ‘@’ operator for matrix multiplication.
• **bpo-21134**: Fix segfault when str is called on an uninitialized UnicodeEncodeError, UnicodeDecodeError, or UnicodeTranslateError object.
• **bpo-19537**: Fix PyUnicode_DATA() alignment under m68k. Patch by Andreas Schwab.
• **bpo-20929**: Add a type cast to avoid shifting a negative number.
• **bpo-20731**: Properly position in source code files even if they are opened in text mode. Patch by Serhiy Storchaka.
• **bpo-20637**: Key-sharing now also works for instance dictionaries of subclasses. Patch by Peter Ingebretson.
• **bpo-8297**: Attributes missing from modules now include the module name in the error text. Original patch by ysj.ray.
• **bpo-19995**: `%c`, `%o`, `%x`, and `%X` now raise TypeError on non-integer input.
• **bpo-19655**: The ASDL parser - used by the build process to generate code for managing the Python AST in C - was rewritten. The new parser is self contained and does not require to carry long the spark.py parser-generator library; spark.py was removed from the source base.
• **bpo-12546**: Allow `\x00` to be used as a fill character when using str, int, float, and complex `__format__` methods.
• **bpo-20480**: Add ipaddress.reverse_pointer. Patch by Leon Weber.
• **bpo-13598**: Modify string.Formatter to support auto-numbering of replacement fields. It now matches the behavior of str.format() in this regard. Patches by Phil Elson and Ramchandra Apte.
- **bpo-8931**: Make alternate formatting (‘#’) for type ‘c’ raise an exception. In versions prior to 3.5, ‘#’ with ‘c’ had no effect. Now specifying it is an error. Patch by Torsten Landschoff.
- **bpo-23165**: Perform overflow checks before allocating memory in the `_Py_char2wchar` function.

**Library**

- **bpo-23399**: `pyenv` creates relative symlinks where possible.
- **bpo-20289**: `cgi.FieldStorage()` now supports the context management protocol.
- **bpo-13128**: Print response headers for CONNECT requests when `debuglevel > 0`. Patch by Demian Brecht.
- **bpo-15381**: Optimized `io.BytesIO` to make less allocations and copyings.
- **bpo-22818**: Splitting on a pattern that could match an empty string now raises a warning. Patterns that can only match empty strings are now rejected.
- **bpo-23099**: Closing `io.BytesIO` with exported buffer is rejected now to prevent corrupting exported buffer.
- **bpo-23326**: Removed `__ne__` implementations. Since fixing default `__ne__` implementation in **bpo-21408** they are redundant.
- **bpo-23363**: Fix possible overflow in `itertools.permutations`.
- **bpo-23364**: Fix possible overflow in `itertools.product`.
- **bpo-23366**: Fixed possible integer overflow in `itertools.combinations`.
- **bpo-23369**: Fixed possible integer overflow in `_json.encode_basestring_ascii`.
- **bpo-23353**: Fix the exception handling of generators in `PyEval_EvalFrameEx()`. At entry, save or swap the exception state even if `PyEval_EvalFrameEx()` is called with `throwflag=0`. At exit, the exception state is now always restored or swapped, not only if `why` is `WHY_YIELD` or `WHY_RETURN`. Patch co-written with Antoine Pitrou.
- **bpo-14099**: Restored support of writing ZIP files to tellable but non-seekable streams.
- **bpo-14099**: Writing to ZipFile and reading multiple ZipExtFiles is threadsafe now.
- **bpo-19361**: JSON decoder now raises JSONDecodeError instead of ValueError.
- **bpo-18518**: timeit now rejects statements which can't be compiled outside a function or a loop (e.g. “return” or “break”).
- **bpo-23094**: Fixed readline with frames in Python implementation of pickle.
- **bpo-23268**: Fixed bugs in the comparison of ipaddress classes.
- **bpo-21408**: Removed incorrect implementations of __ne__() which didn't returned NotImplemented if __eq__() returned NotImplemented. The default __ne__() now works correctly.
- **bpo-19996**: email.feedparser.FeedParser now handles (malformed) headers with no key rather than assuming the body has started.
- **bpo-20188**: Support Application-Layer Protocol Negotiation (ALPN) in the ssl module.
- **bpo-23133**: Pickling of ipaddress objects now produces more compact and portable representation.
- **bpo-23248**: Update ssl error codes from latest OpenSSL git master.
- **bpo-23266**: Much faster implementation of ipaddress.collapse_addresses() when there are many non-consecutive addresses.
- **bpo-23098**: 64-bit dev_t is now supported in the os module.
- **bpo-21817**: When an exception is raised in a task submitted to a ProcessPoolExecutor, the remote traceback is now displayed in the parent process. Patch by Claudiu Popa.
- **bpo-15955**: Add an option to limit output size when decompressing LZMA data. Patch by Nikolaus Rath and Martin Panter.
- **bpo-23250**: In the http.cookies module, capitalize “HttpOnly” and
“Secure” as they are written in the standard.

- **bpo-23063**: In the disutils' check command, fix parsing of reST with code or code-block directives.
- **bpo-23209**: `selectors.BaseSelector.get_key()` now raises a `RuntimeError` if the selector is closed. And `selectors.BaseSelector.close()` now clears its internal reference to the selector mapping to break a reference cycle. Initial patch written by Martin Richard. (See also: **bpo-23225**)
- **bpo-17911**: Provide a way to seed the linecache for a PEP-302 module without actually loading the code.
- **bpo-17911**: Provide a new object API for traceback, including the ability to not lookup lines at all until the traceback is actually rendered, without any trace of the original objects being kept alive.
- **bpo-19777**: Provide a `home()` classmethod on `Path` objects. Contributed by Victor Salgado and Mayank Tripathi.
- **bpo-23206**: Make `json.dumps(..., ensure_ascii=False)` as fast as the default case of `ensure_ascii=True`. Patch by Naoki Inada.
- **bpo-23185**: Add `math.inf` and `math.nan` constants.
- **bpo-23186**: Add `ssl.SSLObject.shared_ciphers()` and `ssl.SSLSocket.shared_ciphers()` to fetch the client's list ciphers sent at handshake.
- **bpo-23143**: Remove compatibility with OpenSSLs older than 0.9.8.
- **bpo-23132**: Improve performance and introspection support of comparison methods created by `functool.total_ordering`.
- **bpo-19776**: Add an `expanduser()` method on `Path` objects.
- **bpo-23112**: Fix `SimpleHTTPServer` to correctly carry the query string and fragment when it redirects to add a trailing slash.
- **bpo-21793**: Added `http.HTTPStatus` enums (i.e. `HTTPStatus.OK`, `HTTPStatus.NOT_FOUND`). Patch by Demian Brecht.
- **bpo-23093**: In the `io`, module allow more operations to work on detached streams.
• **bpo-23111**: In the ftplib, make ssl.PROTOCOL_SSLv23 the default protocol version.
• **bpo-22585**: On OpenBSD 5.6 and newer, os.urandom() now calls getentropy(), instead of reading /dev/urandom, to get pseudo-random bytes.
• **bpo-19104**: pprint now produces evaluable output for wrapped strings.
• **bpo-23071**: Added missing names to codecs.__all__. Patch by Martin Panter.
• **bpo-22783**: Pickling now uses the NEWOBJ opcode instead of the NEWOBJ_EX opcode if possible.
• **bpo-15513**: Added a __sizeof__ implementation for pickle classes.
• **bpo-19858**: pickletools.optimize() now aware of the MEMOIZE opcode, can produce more compact result and no longer produces invalid output if input data contains MEMOIZE opcodes together with PUT or BINPUT opcodes.
• **bpo-22095**: Fixed HTTPConnection.set_tunnel with default port. The port value in the host header was set to “None”. Patch by Demian Brecht.
• **bpo-23016**: A warning no longer produces an AttributeError when the program is run with pythonw.exe.
• **bpo-21775**: shutil.copytree(): fix crash when copying to VFAT. An exception handler assumed that OSError objects always have a ‘winerror’ attribute. That is not the case, so the exception handler itself raised AttributeError when run on Linux (and, presumably, any other non-Windows OS). Patch by Greg Ward.
• **bpo-1218234**: Fix inspect.getsource() to load updated source of reloaded module. Initial patch by Berker Peksag.
• **bpo-21740**: Support wrapped callables in doctest. Patch by Claudiu Popa.
• **bpo-23009**: Make sure selectors.EpollSelectrtor.select() works when no FD is registered.
• **bpo-22959**: In the constructor of http.client.HTTPSConnection,
prefer the context’s check_hostname attribute over the check_hostname parameter.

- **bpo-22696**: Add function `sys.is_finalizing()` to know about interpreter shutdown.
- **bpo-16043**: Add a default limit for the amount of data `xmlrpclib.gzip_decode` will return. This resolves CVE-2013-1753.
- **bpo-14099**: `ZipFile.open()` no longer reopen the underlying file. Objects returned by `ZipFile.open()` can now operate independently of the ZipFile even if the ZipFile was created by passing in a file-like object as the first argument to the constructor.
- **bpo-22966**: Fix `__pycache__ pyc file name clobber` when `pyc_compile` is asked to compile a source file containing multiple dots in the source file name.
- **bpo-21971**: Update turtledemo doc and add module to the index.
- **bpo-21032**: Fixed socket leak if `HTTPConnection.getresponse()` fails. Original patch by Martin Panter.
- **bpo-22407**: Deprecated the use of `re.LOCALE` flag with `str` patterns or `re.ASCII`. It was newer worked.
- **bpo-22902**: The “ip” command is now used on Linux to determine MAC address in `uuid.getnode()`. Patch by Bruno Cauet.
- **bpo-22960**: Add a context argument to `xmlrpclib.ServerProxy` constructor.
- **bpo-22389**: Add `contextlib.redirect_stderr()`.
- **bpo-21356**: Make `ssl.RAND_egd()` optional to support LibreSSL. The availability of the function is checked during the compilation. Patch written by Bernard Spil.
- **bpo-22915**: SAX parser now supports files opened with file descriptor or bytes path.
- **bpo-22609**: Constructors and update methods of mapping classes in the collections module now accept the `self` keyword argument.
- **bpo-22940**: Add `readline.append_history_file`.
- **bpo-19676**: Added the “namereplace” error handler.
- **bpo-22788**: Add `context` parameter to `logging.handlers.HTTPHandler`. 
- **bpo-22921**: Allow SSLContext to take the `hostname` parameter even if OpenSSL doesn’t support SNI.
- **bpo-22894**: `TestCase.subTest()` would cause the test suite to be stopped when in failfast mode, even in the absence of failures.
- **bpo-22796**: HTTP cookie parsing is now stricter, in order to protect against potential injection attacks.
- **bpo-22370**: Windows detection in `pathlib` is now more robust.
- **bpo-19494**: Added `urllib.request.HTTPBasicPriorAuthHandler`. Patch by Matej Cepl.
- **bpo-22578**: Added attributes to the `re.error` class.
- **bpo-22849**: Fix possible double free in the `io.TextIOWrapper` constructor.
- **bpo-12728**: Different Unicode characters having the same uppercase but different lowercase are now matched in case-insensitive regular expressions.
- **bpo-22821**: Fixed `fcntl()` with integer argument on 64-bit big-endian platforms.
- **bpo-21650**: Add an `--sort-keys` option to `json.tool` CLI.
- **bpo-22824**: Updated `reprlib` output format for sets to use set literals. Patch contributed by Berker Peksag.
- **bpo-22824**: Updated `reprlib` output format for arrays to display empty arrays without an unnecessary empty list. Suggested by Serhiy Storchaka.
- **bpo-22406**: Fixed the `uu_codec` codec incorrectly ported to 3.x. Based on patch by Martin Panter.
- **bpo-17293**: `uuid.getnode()` now determines MAC address on AIX using `netstat`. Based on patch by Aivars Kalvâns.
- **bpo-22769**: Fixed `ttk.Treeview.tag_has()` when called without arguments.
- **bpo-22417**: Verify certificates by default in `httplib` (PEP 476).
- **bpo-22776**: Brought excluded code into the scope of a try block in `SysLogHandler.emit()`.
- **bpo-22665**: Add missing `get_terminal_size` and `SameFileError` to `shutil.__all__`.
- **bpo-6623**: Remove deprecated `Netrc` class in the `ftplib` module. Patch by Matt Chaput.
- **bpo-17381**: Fixed handling of case-insensitive ranges in regular expressions.
- **bpo-22410**: Module level functions in the `re` module now cache compiled locale-dependent regular expressions taking into account the locale.
- **bpo-22759**: Query methods on `pathlib.Path` (exists(), is_dir(), etc.) now return False when the underlying stat call raises `NotADirectoryError`.
- **bpo-8876**: `distutils` now falls back to copying files when hard linking doesn’t work. This allows use with special filesystems such as VirtualBox shared folders.
- **bpo-22217**: Implemented reprs of classes in the `zipfile` module.
- **bpo-22457**: Honour `load_tests` in the `start_dir` of discovery.
- **bpo-18216**: `gettext` now raises an error when a `.mo` file has an unsupported major version number. Patch by Aaron Hill.
- **bpo-13918**: Provide a `locale.delocalize()` function which can remove locale-specific number formatting from a string representing a number, without then converting it to a specific type. Patch by Cédric Krier.
- **bpo-22676**: Make the pickling of global objects which don’t have a `__module__` attribute less slow.
- **bpo-18853**: Fixed `ResourceWarning` in `shlex.__nain__`.
- **bpo-9351**: Defaults set with `set_defaults` on an `argparse` subparser are no longer ignored when also set on the parent parser.
- **bpo-7559**: `unittest` test loading `ImportErrors` are reported as import errors with their import exception rather than as attribute errors after the import has already failed.
- **bpo-19746**: Make it possible to examine the errors from unittest discovery without executing the test suite. The new errors attribute on TestLoader exposes these non-fatal errors encountered during discovery.
- **bpo-21991**: Make email.headerregistry’s header ‘params’ attributes be read-only (MappingProxyType). Previously the dictionary was modifiable but a new one was created on each access of the attribute.
- **bpo-22638**: SSLv3 is now disabled throughout the standard library. It can still be enabled by instantiating a SSLContext manually.
- **bpo-22641**: In asyncio, the default SSL context for client connections is now created using ssl.create_default_context(), for stronger security.
- **bpo-17401**: Include closefd in io.FileIO repr.
- **bpo-21338**: Add silent mode for compileall. quiet parameters of compile_{dir, file, path} functions now have a multilevel value. Also, -q option of the CLI now have a multilevel value. Patch by Thomas Kluyver.
- **bpo-20152**: Convert the array and cmath modules to Argument Clinic.
- **bpo-18643**: Add socket.socketpair() on Windows.
- **bpo-22435**: Fix a file descriptor leak when socketserver bind fails.
- **bpo-13096**: Fixed segfault in CTypes POINTER handling of large values.
- **bpo-11694**: Raise ConversionError in xdrlib as documented. Patch by Filip Gruszczynski and Claudiu Popa.
- **bpo-19380**: Optimized parsing of regular expressions.
- **bpo-1519638**: Now unmatched groups are replaced with empty strings in re.sub() and re.subn().
- **bpo-18615**: sndhdr.what/whathdr now return a namedtuple.
- **bpo-22462**: Fix pyexpat’s creation of a dummy frame to make it appear in exception tracebacks.
- **bpo-21965**: Add support for in-memory SSL to the ssl module.
Patch by Geert Jansen.

- **bpo-21173**: Fix `len()` on a `WeakKeyDictionary` when `.clear()` was called with an iterator alive.
- **bpo-11866**: Eliminated race condition in the computation of names for new threads.
- **bpo-21905**: Avoid `RuntimeError` in `pickle.whichmodule()` when `sys.modules` is mutated while iterating. Patch by Olivier Grisel.
- **bpo-11271**: `concurrent.futures.Executor.map()` now takes a *chunksize* argument to allow batching of tasks in child processes and improve performance of `ProcessPoolExecutor`. Patch by Dan O'Reilly.
- **bpo-21883**: `os.path.join()` and `os.path.relpath()` now raise a `TypeError` with more helpful error message for unsupported or mismatched types of arguments.
- **bpo-22219**: The zipfile module CLI now adds entries for directories (including empty directories) in ZIP file.
- **bpo-22449**: In the `ssl.SSLContext.load_default_certs`, consult the environmental variables `SSL_CERT_DIR` and `SSL_CERT_FILE` on Windows.
- **bpo-22508**: The `email.__version__` variable has been removed; the email code is no longer shipped separately from the stdlib, and `__version__` hasn’t been updated in several releases.
- **bpo-20076**: Added non derived UTF-8 aliases to locale aliases table.
- **bpo-20079**: Added locales supported in glibc 2.18 to locale aliases table.
- **bpo-20218**: Added convenience methods `read_text/write_text` and `read_bytes/write_bytes` to `pathlib.Path` objects.
- **bpo-22396**: On 32-bit AIX platform, don’t expose `os.posix_fadvise()` nor `os.posix_fallocate()` because their prototypes in system headers are wrong.
- **bpo-22517**: When an `io.BufferedRWPair` object is deallocated, clear its weakrefs.
- **bpo-22437**: Number of capturing groups in regular expression is
no longer limited by 100.

- **bpo-17442**: InteractiveInterpreter now displays the full chained traceback in its showtraceback method, to match the built in interactive interpreter.

- **bpo-23392**: Added tests for marshal C API that works with FILE*.  

- **bpo-10510**: distutils register and upload methods now use HTML standards compliant CRLF line endings.

- **bpo-9850**: Fixed `macpath.join()` for empty first component. Patch by Oleg Oshmyan.

- **bpo-5309**: distutils' `build` and `build_ext` commands now accept a `-j` option to enable parallel building of extension modules.

- **bpo-22448**: Improve canceled timer handles cleanup to prevent unbound memory usage. Patch by Joshua Moore-Oliva.

- **bpo-22427**: `TemporaryDirectory` no longer attempts to clean up twice when used in the with statement in generator.

- **bpo-22362**: Forbidden ambiguous octal escapes out of range 0-0o377 in regular expressions.

- **bpo-20912**: Now directories added to ZIP file have correct Unix and MS-DOS directory attributes.

- **bpo-21866**: `ZipFile.close()` no longer writes ZIP64 central directory records if `allowZip64` is false.

- **bpo-22278**: Fix `urljoin` problem with relative urls, a regression observed after changes to issue22118 were submitted.

- **bpo-22415**: Fixed debugging output of the GROUPREF_EXISTS opcode in the re module. Removed trailing spaces in debugging output.

- **bpo-22423**: Unhandled exception in thread no longer causes unhandled AttributeError when `sys.stderr` is None.

- **bpo-21332**: Ensure that `bufsize=1` in subprocess.Popen() selects line buffering, rather than block buffering. Patch by Akira Li.

- **bpo-21091**: Fix API bug: `email.message.EmailMessage.is_attachment` is now a method.

- **bpo-21079**: Fix `email.message.EmailMessage.is_attachment` to
return the correct result when the header has parameters as well as a value.

- **bpo-22247**: Add NNTPError to nntplib.__all__.
- **bpo-22366**: urllib.request.urlopen will accept a context object (SSLContext) as an argument which will then be used for HTTPS connection. Patch by Alex Gaynor.
- **bpo-4180**: The warnings registries are now reset when the filters are modified.
- **bpo-22419**: Limit the length of incoming HTTP request in wsgiref server to 65536 bytes and send a 414 error code for higher lengths. Patch contributed by Devin Cook.
- Lax cookie parsing in http.cookies could be a security issue when combined with non-standard cookie handling in some Web browsers. Reported by Sergey Bobrov.
- **bpo-20537**: logging methods now accept an exception instance as well as a Boolean value or exception tuple. Thanks to Yury Selivanov for the patch.
- **bpo-22384**: An exception in Tkinter callback no longer crashes the program when it is run with pythonw.exe.
- **bpo-22168**: Prevent turtle AttributeError with non-default Canvas on OS X.
- **bpo-21147**: sqlite3 now raises an exception if the request contains a null character instead of truncating it. Based on patch by Victor Stinner.
- **bpo-13968**: The glob module now supports recursive search in subdirectories using the ** pattern.
- **bpo-21951**: Fixed a crash in Tkinter on AIX when called Tcl command with empty string or tuple argument.
- **bpo-21951**: Tkinter now most likely raises MemoryError instead of crash if the memory allocation fails.
- **bpo-22338**: Fix a crash in the json module on memory allocation failure.
- **bpo-12410**: imaplib.IMAP4 now supports the context management protocol. Original patch by Tarek Ziadé.
- **bpo-21270**: We now override tuple methods in mock.call objects so that they can be used as normal call attributes.
- **bpo-16662**: `load_tests()` is now unconditionally run when it is present in a package’s `__init__.py`. `TestLoader.loadTestsFromModule()` still accepts `use_load_tests`, but it is deprecated and ignored. A new keyword-only attribute pattern is added and documented. Patch given by Robert Collins, tweaked by Barry Warsaw.
- **bpo-22226**: First letter no longer is stripped from the “status” key in the result of `Treeview.heading()`.
- **bpo-19524**: Fixed resource leak in the HTTP connection when an invalid response is received. Patch by Martin Panter.
- **bpo-20421**: Add a `.version()` method to SSL sockets exposing the actual protocol version in use.
- **bpo-19546**: configparser exceptions no longer expose implementation details. Chained KeyErrors are removed, which leads to cleaner traces. Patch by Claudiu Popa.
- **bpo-22051**: turtledemo no longer reloads examples to re-run them. Initialization of variables and gui setup should be done in `main()`, which is called each time a demo is run, but not on import.
- **bpo-21933**: Turtledemo users can change the code font size with a menu selection or control(command) ‘-‘ or ‘+’ or control-mousewheel. Original patch by Lita Cho.
- **bpo-21597**: The separator between the turtledemo text pane and the drawing canvas can now be grabbed and dragged with a mouse. The code text pane can be widened to easily view or copy the full width of the text. The canvas can be widened on small screens. Original patches by Jan Kanis and Lita Cho.
- **bpo-18132**: Turtledemo buttons no longer disappear when the window is shrunk. Original patches by Jan Kanis and Lita Cho.
- **bpo-22043**: `time.monotonic()` is now always available. `threading.Lock.acquire()`, `threading.RLock.acquire()` and socket operations now use a monotonic clock, instead of the system clock, when a timeout is
used.

- **bpo-21527**: Add a default number of workers to ThreadPoolExecutor equal to 5 times the number of CPUs. Patch by Claudiu Popa.
- **bpo-22216**: smtplib now resets its state more completely after a quit. The most obvious consequence of the previous behavior was a STARTTLS failure during a connect/starttls/quit/connect/starttls sequence.
- **bpo-22098**: ctypes’ BigEndianStructure and LittleEndianStructure now define an empty __slots__ so that subclasses don’t always get an instance dict. Patch by Claudiu Popa.
- **bpo-22185**: Fix an occasional RuntimeError in threading.Condition.wait() caused by mutation of the waiters queue without holding the lock. Patch by Doug Zongker.
- **bpo-22287**: On UNIX, _PyTime_gettimeofday() now uses clock_gettime(CLOCK_REALTIME) if available. As a side effect, Python now depends on the librt library on Solaris and on Linux (only with glibc older than 2.17).
- **bpo-22182**: Use e.args to unpack exceptions correctly in distutils.file_util.move_file. Patch by Claudiu Popa.
- The webbrowser module now uses subprocess’s start_new_session=True rather than a potentially risky preexec_fn=os.setsid call.
- **bpo-22042**: signal.set_wakeup_fd(fd) now raises an exception if the file descriptor is in blocking mode.
- **bpo-16808**: inspect.stack() now returns a named tuple instead of a tuple. Patch by Daniel Shahaf.
- **bpo-22236**: Fixed Tkinter images copying operations in NoDefaultRoot mode.
- **bpo-2527**: Add a globals argument to timeit functions, in order to override the globals namespace in which the timed code is executed. Patch by Ben Roberts.
- **bpo-22118**: Switch urllib.parse to use RFC 3986 semantics for the resolution of relative URLs, rather than RFCs 1808 and 2396.
Patch by Demian Brecht.

- **bpo-21549**: Added the “members” parameter to TarFile.list().
- **bpo-19628**: Allow compileall recursion depth to be specified with a -r option.
- **bpo-15696**: Add a __sizeof__ implementation for mmap objects on Windows.
- **bpo-22068**: Avoided reference loops with Variables and Fonts in Tkinter.
- **bpo-22165**: SimpleHTTPRequestHandler now supports undecodable file names.
- **bpo-15381**: Optimized line reading in io.BytesIO.
- **bpo-8797**: Raise HTTPError on failed Basic Authentication immediately. Initial patch by Sam Bull.
- **bpo-20729**: Restored the use of lazy iterkeys()/itervalues()/iteritems() in the mailbox module.
- **bpo-21448**: Changed FeedParser feed() to avoid O(N**2) behavior when parsing long line. Original patch by Raymond Hettinger.
- **bpo-22184**: The functools LRU Cache decorator factory now gives an earlier and clearer error message when the user forgets the required parameters.
- **bpo-17923**: glob() patterns ending with a slash no longer match non-dirs on AIX. Based on patch by Delhallt.
- **bpo-21725**: Added support for RFC 6531 (SMTPUTF8) in smtpd.
- **bpo-22176**: Update the ctypes module’s libffi to v3.1. This release adds support for the Linux AArch64 and POWERPC ELF ABIV2 little endian architectures.
- **bpo-5411**: Added support for the “xztar” format in the shutil module.
- **bpo-21121**: Don’t force 3rd party C extensions to be built with -Werror=declaration- after-statement.
- **bpo-20170**: Convert posixmodule to use Argument Clinic.
- **bpo-21539**: Add an *exists_ok* argument to Pathlib.mkdir() to mimic *mkdir -p* and *os.makedirs()* functionality. When true, ignore FileExistsErrors. Patch by Berker Peksag.
- **bpo-22127**: Bypass IDNA for pure-ASCII host names in the socket module (in particular for numeric IPs).
- **bpo-21047**: set the default value for the *convert_charrefs* argument of HTMLParser to True. Patch by Berker Peksag.
- **bpo-15114**: the strict mode and argument of HTMLParser, HTMLParser.error, and the HTMLParserError exception have been removed.
- **bpo-22085**: Dropped support of Tk 8.3 in Tkinter.
- **bpo-21580**: Now Tkinter correctly handles bytes arguments passed to Tk. In particular this allows initializing images from binary data.
- **bpo-22003**: When initialized from a bytes object, io.BytesIO() now defers making a copy until it is mutated, improving performance and memory use on some use cases. Patch by David Wilson.
- **bpo-22018**: On Windows, signal.set_wakeup_fd() now also supports sockets. A side effect is that Python depends to the WinSock library.
- **bpo-22054**: Add *os.get_blocking()* and *os.set_blocking()* functions to get and set the blocking mode of a file descriptor (False if the O_NONBLOCK flag is set, True otherwise). These functions are not available on Windows.
- **bpo-17172**: Make turtledemo start as active on OS X even when run with subprocess. Patch by Lita Cho.
- **bpo-21704**: Fix build error for _multiprocessing when semaphores are not available. Patch by Arfrever Frehtes Taifersar Arahesis.
- **bpo-20173**: Convert sha1, sha256, sha512 and md5 to ArgumentClinic. Patch by Vajrasky Kok.
- **bpo-20173**: Fix repr(_socket.socket) on Windows 64-bit: don’t fail with OverflowError on closed socket. repr(socket.socket) already
works fine.

- **bpo-22033**: Reprs of most Python implemented classes now contain actual class name instead of hardcoded one.
- **bpo-21947**: The dis module can now disassemble generator-iterator objects based on their gi_code attribute. Patch by Clement Rouault.
- **bpo-16133**: The asynchat.async_chat.handle_read() method now ignores BlockingIOError exceptions.
- **bpo-22044**: Fixed premature DECREF in call_tzinfo_method. Patch by Tom Flanagan.
- **bpo-19884**: readline: Disable the meta modifier key if stdout is not a terminal to not write the ANSI sequence \"\033[1034h\" into stdout. This sequence is used on some terminal (ex: TERM=xterm-256color”) to enable support of 8 bit characters.
- **bpo-4350**: Removed a number of out-of-dated and non-working for a long time Tkinter methods.
- **bpo-6167**: Scrollbar.activate() now returns the name of active element if the argument is not specified. Scrollbar.set() now always accepts only 2 arguments.
- **bpo-15275**: Clean up and speed up the ntpath module.
- **bpo-21888**: plistlib’s load() and loads() now work if the fmt parameter is specified.
- **bpo-22032**: __qualname__ instead of __name__ is now always used to format fully qualified class names of Python implemented classes.
- **bpo-22031**: Reprs now always use hexadecimal format with the “0x” prefix when contain an id in form ” at 0x…”.
- **bpo-22018**: signal.set_wakeup_fd() now raises an OSError instead of a ValueError on fstat() failure.
- **bpo-21044**: tarfile.open() now handles fileobj with an integer ‘name’ attribute. Based on patch by Antoine Pietri.
- **bpo-21966**: Respect -q command-line option when code module is ran.
- **bpo-19076**: Don’t pass the redundant ‘file’ argument to self.error().
- bpo-16382: Improve exception message of warnings.warn() for bad category. Initial patch by Phil Elson.
- bpo-21932: os.read() now uses a Py_ssize_t() type instead of int for the size to support reading more than 2 GB at once. On Windows, the size is truncated to INT_MAX. As any call to os.read(), the OS may read less bytes than the number of requested bytes.
- bpo-21942: Fixed source file viewing in pydoc's server mode on Windows.
- bpo-11259: asyncchat.async_chat().set_terminator() now raises a ValueError if the number of received bytes is negative.
- bpo-12523: asyncchat.async_chat.push() now raises a TypeError if it doesn't get a bytes string
- bpo-21707: Add missing kwonlyargcount argument to ModuleFinder.replace_paths_in_code().
- bpo-20639: calling Path.with_suffix('') allows removing the suffix again. Patch by July Tikhonov.
- bpo-21714: Disallow the construction of invalid paths using Path.with_name(). Original patch by Antony Lee.
- bpo-15014: Added 'auth' method to smtplib to make implementing auth mechanisms simpler, and used it internally in the login method.
- bpo-21151: Fixed a segfault in the winreg module when None is passed as a REG_BINARY value to SetValueEx. Patch by John Ehresman.
- bpo-21090: io.FileIO.readall() does not ignore I/O errors anymore. Before, it ignored I/O errors if at least the first C call read() succeed.
- bpo-5800: headers parameter of wsgiref.headers.Headers is now optional. Initial patch by Pablo Torres Navarrete and SilentGhost.
- bpo-21781: ssl.RAND_add() now supports strings longer than 2 GB.
- bpo-21679: Prevent extraneous fstat() calls during open(). Patch by Bohuslav Kabrda.
• **bpo-21863**: cProfile now displays the module name of C extension functions, in addition to their own name.

• **bpo-11453**: asyncore: emit a ResourceWarning when an unclosed file_wrapper object is destroyed. The destructor now closes the file if needed. The close() method can now be called twice: the second call does nothing.

• **bpo-21858**: Better handling of Python exceptions in the sqlite3 module.

• **bpo-21476**: Make sure the email.parser.BytesParser TextIOWrapper is discarded after parsing, so the input file isn't unexpectedly closed.

• **bpo-20295**: imghdr now recognizes OpenEXR format images.

• **bpo-21729**: Used the “with” statement in the dbm.dumb module to ensure files closing. Patch by Claudiu Popa.

• **bpo-21491**: socketserver: Fix a race condition in child processes reaping.

• **bpo-21719**: Added the `st_file_attributes` field to `os.stat_result` on Windows.

• **bpo-21832**: Require named tuple inputs to be exact strings.

• **bpo-21722**: The distutils “upload” command now exits with a non-zero return code when uploading fails. Patch by Martin Dengler.

• **bpo-21723**: asyncio.Queue: support any type of number (ex: float) for the maximum size. Patch written by Vajrasky Kok.

• **bpo-21711**: support for “site-python” directories has now been removed from the site module (it was deprecated in 3.4).

• **bpo-17552**: new socket.sendfile() method allowing a file to be sent over a socket by using high-performance os.sendfile() on UNIX. Patch by Giampaolo Rodola’.

• **bpo-18039**: dbm.dump.open() now always creates a new database when the flag has the value ‘n’. Patch by Claudiu Popa.

• **bpo-21326**: Add a new `is_closed()` method to asyncio.BaseEventLoop. `run_forever()` and `run_until_complete()` methods of asyncio.BaseEventLoop now raise an exception if the event loop was closed.
- **bpo-21766**: Prevent a security hole in CGIHTTPServer by URL unquoting paths before checking for a CGI script at that path.
- **bpo-21310**: Fixed possible resource leak in failed open().
- **bpo-21256**: Printout of keyword args should be in deterministic order in a mock function call. This will help to write better doctests.
- **bpo-21677**: Fixed chaining nonnormalized exceptions in io close() methods.
- **bpo-11709**: Fix the pydoc.help function to not fail when sys.stdin is not a valid file.
- **bpo-21515**: tempfile.TemporaryFile now uses os.O_TMPFILE flag is available.
- **bpo-13223**: Fix pydoc.writedoc so that the HTML documentation for methods that use ‘self’ in the example code is generated correctly.
- **bpo-21463**: In urllib.request, fix pruning of the FTP cache.
- **bpo-21618**: The subprocess module could fail to close open fds that were inherited by the calling process and already higher than POSIX resource limits would otherwise allow. On systems with a functioning /proc/self/fd or /dev/fd interface the max is now ignored and all fds are closed.
- **bpo-20383**: Introduce importlib.util.module_from_spec() as the preferred way to create a new module.
- **bpo-21552**: Fixed possible integer overflow of too long string lengths in the tkinter module on 64-bit platforms.
- **bpo-14315**: The zipfile module now ignores extra fields in the central directory that are too short to be parsed instead of letting a struct.unpack error bubble up as this “bad data” appears in many real world zip files in the wild and is ignored by other zip tools.
- **bpo-13742**: Added “key” and “reverse” parameters to heapq.merge(). (First draft of patch contributed by Simon Sapin.)
- **bpo-21402**: tkinter.ttk now works when default root window is not set.
- **bpo-3015**: _tkinter.create() now creates tkapp object with
wantobject=1 by default.

- **bpo-10203**: sqlite3.Row now truly supports sequence protocol. In particular it supports reverse() and negative indices. Original patch by Claudiu Popa.
- **bpo-18807**: If copying (no symlinks) specified for a venv, then the python interpreter aliases (python, python3) are now created by copying rather than symlinking.
- **bpo-20197**: Added support for the WebP image type in the imghdr module. Patch by Fabrice Aneche and Claudiu Popa.
- **bpo-21513**: Speedup some properties of IP addresses (IPv4Address, IPv6Address) such as .is_private or .is_multicast.
- **bpo-21137**: Improve the repr for threading.Lock() and its variants by showing the “locked” or “unlocked” status. Patch by Berker Peksag.
- **bpo-21538**: The plistlib module now supports loading of binary plist files when reference or offset size is not a power of two.
- **bpo-21455**: Add a default backlog to socket.listen().
- **bpo-21525**: Most Tkinter methods which accepted tuples now accept lists too.
- **bpo-22166**: With the assistance of a new internal _codecs._forget_codec helping function, test_codecs now clears the encoding caches to avoid the appearance of a reference leak.
- **bpo-22236**: Tkinter tests now don’t reuse default root window. New root window is created for every test class.
- **bpo-10744**: Fix PEP 3118 format strings on ctypes objects with a nontrivial shape.
- **bpo-20826**: Optimize ipaddress.collapse_addresses().
- **bpo-21487**: Optimize ipaddress.summarize_address_range() and ipaddress.{IPv4Network,IPv6Network}.subnets().
- **bpo-21486**: Optimize parsing of netmasks in ipaddress.IPv4Network and ipaddress.IPv6Network.
- **bpo-13916**: Disallowed the surrogatepass error handler for non UTF-* encodings.
- **bpo-20998**: Fixed re.fullmatch() of repeated single character
pattern with ignore case. Original patch by Matthew Barnett.

- **bpo-21075**: fileinput.FileInput now reads bytes from standard stream if binary mode is specified. Patch by Sam Kimbrel.
- **bpo-19775**: Add a samefile() method to pathlib Path objects. Initial patch by Vajrasky Kok.
- **bpo-21226**: Set up modules properly in PyImport_ExecCodeModuleObject (and friends).
- **bpo-21398**: Fix a unicode error in the pydoc pager when the documentation contains characters not encodable to the stdout encoding.
- **bpo-16531**: ipaddress.IPv4Network and ipaddress.IPv6Network now accept an (address, netmask) tuple argument, so as to easily construct network objects from existing addresses.
- **bpo-21156**: importlib.abc.InspectLoader.source_to_code() is now a staticmethod.
- **bpo-21424**: Simplified and optimized heapq.nlargest() and nsmallest() to make fewer tuple comparisons.
- **bpo-21396**: Fix TextIOWrapper(…, write_through=True) to not force a flush() on the underlying binary stream. Patch by akira.
- **bpo-18314**: Unlink now removes junctions on Windows. Patch by Kim Gräsman
- **bpo-21088**: Bugfix for curses.window.addch() regression in 3.4.0. In porting to Argument Clinic, the first two arguments were reversed.
- **bpo-21407**: _decimal: The module now supports function signatures.
- **bpo-10650**: Remove the non-standard ‘watchexp’ parameter from the Decimal.quantize() method in the Python version. It had never been present in the C version.
- **bpo-21469**: Reduced the risk of false positives in robotparser by checking to make sure that robots.txt has been read or does not exist prior to returning True in can_fetch().
- **bpo-19414**: Have the OrderedDict mark deleted links as unusable. This gives an early failure if the link is deleted during iteration.
• **bpo-21421**: Add `__slots__` to the MappingViews ABC. Patch by Josh Rosenberg.
• **bpo-21101**: Eliminate double hashing in the C speed-up code for collections.Counter().
• **bpo-21321**: `itertools.islice()` now releases the reference to the source iterator when the slice is exhausted. Patch by Anton Afanasyev.
• **bpo-21057**: TextIOWrapper now allows the underlying binary stream’s `read()` or `read1()` method to return an arbitrary bytes-like object (such as a memoryview). Patch by Nikolaus Rath.
• **bpo-20951**: SSLSocket.send() now raises either SSLWantReadError or SSLWantWriteError on a non-blocking socket if the operation would block. Previously, it would return 0. Patch by Nikolaus Rath.
• **bpo-13248**: removed previously deprecated asyncore.dispatcher `__getattr__` cheap inheritance hack.
• **bpo-9815**: `assertRaises` now tries to clear references to local variables in the exception’s traceback.
• **bpo-19940**: `ssl.cert_time_to_seconds()` now interprets the given time string in the UTC timezone (as specified in RFC 5280), not the local timezone.
• **bpo-13204**: Calling `sys.flags.__new__` would crash the interpreter, now it raises a TypeError.
• **bpo-19385**: Make operations on a closed dbm.dumb database always raise the same exception.
• **bpo-21207**: Detect when the os.urandom cached fd has been closed or replaced, and open it anew.
• **bpo-21291**: subprocess's `Popen.wait()` is now thread safe so that multiple threads may be calling `wait()` or `poll()` on a Popen instance at the same time without losing the Popen.returncode value.
• **bpo-21127**: Path objects can now be instantiated from `str` subclass instances (such as `numpy.str_`).
• **bpo-15002**: `urllib.response` object to use `_TemporaryFileWrapper`
(and _TemporaryFileCloser) facility. Provides a better way to handle file descriptor close. Patch contributed by Christian Theune.

- **bpo-12220**: mindom now raises a custom ValueError indicating it doesn't support spaces in URIs instead of letting a ‘split’ ValueError bubble up.
- **bpo-21068**: The ssl.PROTOCOL* constants are now enum members.
- **bpo-21276**: posixmodule: Don’t define USE_XATTRS on KFreeBSD and the Hurd.
- **bpo-21262**: New method assert_not_called for Mock. It raises AssertionError if the mock has been called.
- **bpo-21238**: New keyword argument unsafe to Mock. It raises AttributeError incase of an attribute startswith assert or assert.
- **bpo-20896**: ssl.get_server_certificate() now uses PROTOCOL_SSLv23, not PROTOCOL_SSLv3, for maximum compatibility.
- **bpo-21239**: patch.stopall() didn’t work deterministically when the same name was patched more than once.
- **bpo-21203**: Updated fileConfig and dictConfig to remove inconsistencies. Thanks to Jure Koren for the patch.
- **bpo-21222**: Passing name keyword argument to mock.create_autospec now works.
- **bpo-21197**: Add lib64 -> lib symlink in venvs on 64-bit non-OS X POSIX.
- **bpo-17498**: Some SMTP servers disconnect after certain errors, violating strict RFC conformance. Instead of losing the error code when we issue the subsequent RSET, smtplib now returns the error code and defers raising the SMTPServerDisconnected error until the next command is issued.
- **bpo-17826**: setting an iterable side_effect on a mock function created by create_autospec now works. Patch by Kushal Das.
- **bpo-7776**: Fix `Host:` header and reconnection when using
http.client.HTTPConnection.set_tunnel(). Patch by Nikolaus Rath.

- **bpo-21529**: Fix arbitrary memory access in JSONDecoder.raw_decode with a negative second parameter. Bug reported by Guido Vranken. (See also: CVE-2014-4616)
- **bpo-21169**: getpass now handles non-ascii characters that the input stream encoding cannot encode by re-encoding using the replace error handler.
- **bpo-21171**: Fixed undocumented filter API of the rot13 codec. Patch by Berker Peksag.
- **bpo-20539**: Improved math.factorial error message for large positive inputs and changed exception type (OverflowError -> ValueError) for large negative inputs.
- **bpo-21172**: isinstance check relaxed from dict to collections.Mapping.
- **bpo-21155**: asyncio.EventLoop.create_unix_server() now raises a ValueError if path and sock are specified at the same time.
- **bpo-21136**: Avoid unnecessary normalization of Fractions resulting from power and other operations. Patch by Raymond Hettinger.
- **bpo-17621**: Introduce importlib.util.LazyLoader.
- **bpo-21076**: signal module constants were turned into enums. Patch by Giampaolo Rodola'.
- **bpo-20636**: Improved the repr of Tkinter widgets.
- **bpo-19505**: The items, keys, and values views of OrderedDict now support reverse iteration using reversed().
- **bpo-21149**: Improved thread-safety in logging cleanup during interpreter shutdown. Thanks to Devin Jeanpierre for the patch.
- **bpo-21058**: Fix a leak of file descriptor in tempfile.NamedTemporaryFile(), close the file descriptor if io.open() fails
- **bpo-21200**: Return None from pkgutil.get_loader() when __spec__ is missing.
- **bpo-21013**: Enhance `ssl.create_default_context()` when used for server side sockets to provide better security by default.
- **bpo-20145**: `assertRaisesRegex` and `assertWarnsRegex` now raise a `TypeError` if the second argument is not a string or compiled regex.
- **bpo-20633**: Replace relative import by absolute import.
- **bpo-20980**: Stop wrapping exception when using ThreadPool.
- **bpo-21082**: In `os.makedirs`, do not set the process-wide umask. Note this changes behavior of makedirs when `exist_ok=True`.
- **bpo-20990**: Fix issues found by pyflakes for multiprocessing.
- **bpo-21015**: SSL contexts will now automatically select an elliptic curve for ECDH key exchange on OpenSSL 1.0.2 and later, and otherwise default to “prime256v1”.
- **bpo-21000**: Improve the command-line interface of `json.tool`.
- **bpo-20995**: Enhance default ciphers used by the ssl module to enable better security and prioritize perfect forward secrecy.
- **bpo-20884**: Don’t assume that `__file__` is defined on `importlib.__init__`.
- **bpo-21499**: Ignore `__builtins__` in several `test_importlib.test_api` tests.
- **bpo-20627**: `xmlrpc.client.ServerProxy` is now a context manager.
- **bpo-19165**: The formatter module now raises `DeprecationWarning` instead of `PendingDeprecationWarning`.
- **bpo-13936**: Remove the ability of `datetime.time` instances to be considered false in boolean contexts.
- **bpo-18931**: `selectors` module now supports `/dev/poll` on Solaris. Patch by Giampaolo Rodola’.
- **bpo-19977**: When the `LC_TYPE` locale is the POSIX locale (C locale), `sys.stdin` and `sys.stdout` are now using the `surrogateescape` error handler, instead of the `strict` error handler.
- **bpo-20574**: Implement incremental decoder for cp65001 code (Windows code page 65001, Microsoft UTF-8).
- **bpo-20879**: Delay the initialization of encoding and decoding
tables for base32, ascii85 and base85 codecs in the base64 module, and delay the initialization of the unquote_to_bytes() table of the urllib.parse module, to not waste memory if these modules are not used.

- **bpo-19157**: Include the broadcast address in the usable hosts for IPv6 in ipaddress.
- **bpo-11599**: When an external command (e.g. compiler) fails, distutils now prints out the whole command line (instead of just the command name) if the environment variable DISTUTILS_DEBUG is set.
- **bpo-4931**: distutils should not produce unhelpful “error: None” messages anymore. distutils.util.grok_environment_error is kept but doc-deprecated.
- **bpo-20875**: Prevent possible gzip “‘read’ is not defined” NameError. Patch by Claudiu Popa.
- **bpo-11558**: email.message.Message.attach now returns a more useful error message if attach is called on a message for which is_multipart is False.
- **bpo-20283**: RE pattern methods now accept the string keyword parameters as documented. The pattern and source keyword parameters are left as deprecated aliases.
- **bpo-20778**: Fix modulefinder to work with bytecode-only modules.
- **bpo-20791**: copy.copy() now doesn’t make a copy when the input is a bytes object. Initial patch by Peter Otten.
- **bpo-19748**: On AIX, time.mktime() now raises an OverflowError for year outsize range [1902; 2037].
- **bpo-19573**: inspect.signature: Use enum for parameter kind constants.
- **bpo-20726**: inspect.signature: Make Signature and Parameter picklable.
- **bpo-17373**: Add inspect.Signature.from_callable method.
- **bpo-20378**: Improve repr of inspect.Signature and inspect.Parameter.
- **bpo-20816**: Fix inspect.getcallargs() to raise correct TypeError for
missing keyword-only arguments. Patch by Jeremiah Lowin.

- **bpo-20817**: Fix inspect.getcallargs() to fail correctly if more than 3 arguments are missing. Patch by Jeremiah Lowin.
- **bpo-6676**: Ensure a meaningful exception is raised when attempting to parse more than one XML document per pyexpat xmlparser instance. (Original patches by Hirokazu Yamamoto and Amaury Forgeot d'Arc, with suggested wording by David Gutteridge)
- **bpo-21117**: Fix inspect.signature to better support functools.partial. Due to the specifics of functools.partial implementation, positional-or-keyword arguments passed as keyword arguments become keyword-only.
- **bpo-20334**: inspect.Signature and inspect.Parameter are now hashable. Thanks to Antony Lee for bug reports and suggestions.
- **bpo-15916**: doctest.DocTestSuite returns an empty unittest.TestSuite instead of raising ValueError if it finds no tests
- **bpo-21209**: Fix asyncio.tasks.Coroutine to workaround a bug in yield-from implementation in CPython prior to 3.4.1.
- asyncio: Add gi_{frame,running,code} properties to CoroWrapper (upstream bpo-163).
- **bpo-21311**: Avoid exception in _osx_support with non-standard compiler configurations. Patch by John Szakmeister.
- **bpo-11571**: Ensure that the turtle window becomes the topmost window when launched on OS X.
- **bpo-21801**: Validate that __signature__ is None or an instance of Signature.
- **bpo-21923**: Prevent AttributeError in distutils.sysconfig.customize_compiler due to possible uninitialized _config_vars.
- **bpo-21323**: Fix http.server to again handle scripts in CGI subdirectories, broken by the fix for security bpo-19435. Patch by Zach Byrne.
- **bpo-22733**: Fix ffi_prep_args not zero-extending argument values correctly on 64-bit Windows.
- **bpo-23302**: Default to TCP_NODELAY=1 upon establishing an HTTPConnection. Removed use of hard-coded MSS as it’s an optimization that’s no longer needed with Nagle disabled.

**IDLE**

- **bpo-20577**: Configuration of the max line length for the FormatParagraph extension has been moved from the General tab of the Idle preferences dialog to the FormatParagraph tab of the Config Extensions dialog. Patch by Tal Einat.
- **bpo-16893**: Update Idle doc chapter to match current Idle and add new information.
- **bpo-3068**: Add Idle extension configuration dialog to Options menu. Changes are written to HOME/.idlerc/config-extensions.cfg. Original patch by Tal Einat.
- **bpo-16233**: A module browser (File : Class Browser, Alt+C) requires an editor window with a filename. When Class Browser is requested otherwise, from a shell, output window, or ‘Untitled’ editor, Idle no longer displays an error box. It now pops up an Open Module box (Alt+M). If a valid name is entered and a module is opened, a corresponding browser is also opened.
- **bpo-4832**: Save As to type Python files automatically adds .py to the name you enter (even if your system does not display it). Some systems automatically add .txt when type is Text files.
- **bpo-21986**: Code objects are not normally pickled by the pickle module. To match this, they are no longer pickled when running under Idle.
- **bpo-17390**: Adjust Editor window title; remove ‘Python’, move version to end.
- **bpo-14105**: Idle debugger breakpoints no longer disappear when inserting or deleting lines.
- **bpo-17172**: Turtledemo can now be run from Idle. Currently, the entry is on the Help menu, but it may move to Run. Patch by Ramchandra Apt and Lita Cho.
- **bpo-21765**: Add support for non-ascii identifiers to HyperParser.
- **bpo-21940**: Add unittest for WidgetRedirector. Initial patch by Saimadhav Heblikar.
- **bpo-18592**: Add unittest for SearchDialogBase. Patch by Phil Webster.
- **bpo-21694**: Add unittest for ParenMatch. Patch by Saimadhav Heblikar.
- **bpo-21686**: Add unittest for HyperParser. Original patch by Saimadhav Heblikar.
- **bpo-12387**: Add missing upper(lower)case versions of default Windows key bindings for Idle so Caps Lock does not disable them. Patch by Roger Serwy.
- **bpo-21695**: Closing a Find-in-files output window while the search is still in progress no longer closes Idle.
- **bpo-18910**: Add unittest for textView. Patch by Phil Webster.
- **bpo-18292**: Add unittest for AutoExpand. Patch by Saihadhav Heblikar.
- **bpo-18409**: Add unittest for AutoComplete. Patch by Phil Webster.
- **bpo-21477**: htest.py - Improve framework, complete set of tests. Patches by Saimadhav Heblikar
- **bpo-18104**: Add idlelib/idle_test/htest.py with a few sample tests to begin consolidating and improving human-validated tests of Idle. Change other files as needed to work with htest. Running the module as __main__ runs all tests.
- **bpo-21139**: Change default paragraph width to 72, the PEP 8 recommendation.
- **bpo-21284**: Paragraph reformat test passes after user changes reformat width.
- **bpo-17654**: Ensure IDLE menus are customized properly on OS X for non-framework builds and for all variants of Tk.
- **bpo-23180**: Rename IDLE “Windows” menu item to “Window”. Patch by Al Sweigart.

**Build**
- **bpo-15506**: Use standard `PKG_PROG_PKG_CONFIG` autoconf macro in the configure script.
- **bpo-22935**: Allow the ssl module to be compiled if openssl doesn't support SSL 3.
- **bpo-22592**: Drop support of the Borland C compiler to build Python. The distutils module still supports it to build extensions.
- **bpo-22591**: Drop support of MS-DOS, especially of the DJGPP compiler (MS-DOSS port of GCC).
- **bpo-16537**: Check whether `self.extensions` is empty in `setup.py`. Patch by Jonathan Hosmer.
- **bpo-22359**: Remove incorrect uses of recursive make. Patch by Jonas Wagner.
- **bpo-18093**: the programs that embed the CPython runtime are now in a separate “Programs” directory, rather than being kept in the Modules directory.
- **bpo-15759**: “make suspicious”, “make linkcheck” and “make doctest” in Doc/ now display special message when and only when there are failures.
- **bpo-21141**: The Windows build process no longer attempts to find Perl, instead relying on OpenSSL source being configured and ready to build. The PCbuild\build_ssl.py script has been re-written and re-named to PCbuild\prepare_ssl.py, and takes care of configuring OpenSSL source for both 32 and 64 bit platforms. OpenSSL sources obtained from svn.python.org will always be pre-configured and ready to build.
- **bpo-21037**: Add a build option to enable AddressSanitizer support.
- **bpo-19962**: The Windows build process now creates “python.bat” in the root of the source tree, which passes all arguments through to the most recently built interpreter.
- **bpo-21285**: Refactor and fix curses configure check to always
search in a ncursesw directory.

- **bpo-15234**: For BerkelyDB and Sqlite, only add the found library and include directories if they aren’t already being searched. This avoids an explicit runtime library dependency.
- **bpo-17861**: Tools/scripts/generate_opcode_h.py automatically regenerates Include/opcode.h from Lib/opcode.py if the latter gets any change.
- **bpo-20644**: OS X installer build support for documentation build changes in 3.4.1: assume externally supplied sphinx-build is available in /usr/bin.
- **bpo-20022**: Eliminate use of deprecated bundlebuilder in OS X builds.
- **bpo-15968**: Incorporated Tcl, Tk, and Tix builds into the Windows build solution.
- **bpo-17095**: Fix Modules/Setup shared support.
- **bpo-21811**: Anticipated fixes to support OS X versions > 10.9.
- **bpo-21166**: Prevent possible segfaults and other random failures of python –generate- posix-vars in pybuilddir.txt build target.
- **bpo-18096**: Fix library order returned by python-config.
- **bpo-17219**: Add library build dir for Python extension cross-builds.
- **bpo-22919**: Windows build updated to support VC 14.0 (Visual Studio 2015), which will be used for the official release.
- **bpo-21236**: Build _msi.pyd with cabinet.lib instead of fci.lib
- **bpo-17128**: Use private version of OpenSSL for OS X 10.5+ installer.

**C API**

- **bpo-14203**: Remove obsolete support for view==NULL in PyBuffer_FillInfo(), bytearray_getbuffer(), bytesiobuf_getbuffer() and array_buffer_getbuf(). All functions now raise BufferError in that case.
- **bpo-22445**: PyBuffer_IsContiguous() now implements precise contiguity tests, compatible with NumPy’s
NPY_RELAXED_STRIDES_CHECKING compilation flag. Previously the function reported false negatives for corner cases.

- **bpo-22079**: PyType_Ready() now checks that statically allocated type has no dynamically allocated bases.
- **bpo-22453**: Removed non-documented macro PyObject_REPR().
- **bpo-18395**: Rename _Py_char2wchar() to Py_DecodeLocale(), rename _Py_wchar2char() to Py_EncodeLocale(), and document these functions.
- **bpo-21233**: Add new C functions: PyMem_RawCalloc(), PyMem_Calloc(), PyObject_Calloc(), _PyObject_GC_Calloc().
  - bytes(int) is now using calloc() instead of malloc() for large objects which is faster and use less memory.
- **bpo-20942**: PyImport_ImportFrozenModuleObject() no longer sets __file__ to match what importlib does; this affects _frozen_importlib as well as any module loaded using imp.init_frozen().

**Documentation**

- **bpo-19548**: Update the codecs module documentation to better cover the distinction between text encodings and other codecs, together with other clarifications. Patch by Martin Panter.
- **bpo-22394**: Doc/Makefile now supports make venv PYTHON=../python to create a venv for generating the documentation, e.g., make html PYTHON=venv/bin/python3.
- **bpo-21514**: The documentation of the json module now refers to new JSON RFC 7159 instead of obsoleted RFC 4627.
- **bpo-21777**: The binary sequence methods on bytes and bytearray are now documented explicitly, rather than assuming users will be able to derive the expected behaviour from the behaviour of the corresponding str methods.
- **bpo-6916**: undocument deprecated asynchat.fifo class.
• bpo-17386: Expanded functionality of the `Doc/make.bat` script to make it much more comparable to `Doc/Makefile`.
• bpo-21312: Update the `thread_foobar.h` template file to include newer threading APIs. Patch by Jack McCracken.
• bpo-21043: Remove the recommendation for specific CA organizations and to mention the ability to load the OS certificates.
• bpo-20765: Add missing documentation for `PurePath.with_name()` and `PurePath.with_suffix()`.
• bpo-19407: New package installation and distribution guides based on the Python Packaging Authority tools. Existing guides have been retained as legacy links from the distutils docs, as they still contain some required reference material for tool developers that isn’t recorded anywhere else.
• bpo-19697: Document cases where `__main__.__spec__` is None.

Tests

• bpo-18982: Add tests for CLI of the calendar module.
• bpo-19548: Added some additional checks to `test_codecs` to ensure that statements in the updated documentation remain accurate. Patch by Martin Panter.
• bpo-22838: All `test_re` tests now work with unittest test discovery.
• bpo-22173: Update `lib2to3` tests to use unittest test discovery.
• bpo-16000: Convert `test_curses` to use unittest.
• bpo-21456: Skip two tests in `test_urllib2net.py` if `__ssl` module not present. Patch by Remi Pointel.
• bpo-20746: Fix `test_pdb` to run in refleak mode (-R). Patch by Xavier de Gaye.
• bpo-22060: `test_ctypes` has been somewhat cleaned up and simplified; it now uses unittest test discovery to find its tests.
• bpo-22104: `regrtest.py` no longer holds a reference to the suite of tests loaded from test modules that don’t define `test_main()`.
• bpo-22111: Assorted cleanups in `test_imaplib`. Patch by Milan
Oberkirch.

- **bpo-22002**: Added `load_package_tests` function to `test.support` and used it to implement/augment test discovery in `test_asyncio, test_email, test_importlib, test_json, and test_tools.`
- **bpo-21976**: Fix `test_ssl` to accept LibreSSL version strings. Thanks to William Orr.
- **bpo-21918**: Converted `test_tools` from a module to a package containing separate test files for each tested script.
- **bpo-9554**: Use modern unittest features in `test_argparse`. Initial patch by Denver Coneybeare and Radu Voicilas.
- **bpo-20155**: Changed HTTP method names in failing tests in `test_httpservers` so that packet filtering software (specifically Windows Base Filtering Engine) does not interfere with the transaction semantics expected by the tests.
- **bpo-19493**: Refactored the `ctypes` test package to skip tests explicitly rather than silently.
- **bpo-18492**: All resources are now allowed when tests are not run by `regrtest.py`.
- **bpo-21634**: Fix pystone micro-benchmark: use floor division instead of true division to benchmark integers instead of floating point numbers. Set pystone version to 1.2. Patch written by Lennart Regebro.
- **bpo-21605**: Added tests for Tkinter images.
- **bpo-21493**: Added test for `ntpath.expanduser()`. Original patch by Claudiu Popa.
- **bpo-19925**: Added tests for the `spwd` module. Original patch by Vajrasky Kok.
- **bpo-21522**: Added Tkinter tests for `Listbox.itemconfigure()`, `PanedWindow.paneconfigure()`, and `Menu.entryconfigure()`.
- **bpo-17756**: Fix `test_code` test when run from the installed location.
- **bpo-17752**: Fix distutils tests when run from the installed location.
- **bpo-18604**: Consolidated checks for GUI availability. All platforms now at least check whether Tk can be instantiated when the GUI
resource is requested.

- **bpo-21275**: Fix a socket test on KFreeBSD.
- **bpo-21223**: Pass test_site/test_startup_imports when some of the extensions are built as builtins.
- **bpo-20635**: Added tests for Tk geometry managers.
- **bpo-20743**: Fix a reference leak in test_tcl.
- **bpo-21097**: Move test_namespace_pkgs into test_importlib.
- **bpo-21503**: Use test_both() consistently in test_importlib.
- **bpo-20668**: asyncio tests no longer rely on tests.txt file. (Patch by Vajrasky Kok)
- **bpo-21093**: Prevent failures of ctypes test_macholib on OS X if a copy of libz exists in $HOME/lib or /usr/local/lib.
- **bpo-22770**: Prevent some Tk segfaults on OS X when running gui tests.
- **bpo-23211**: Workaround test_logging failure on some OS X 10.6 systems.
- **bpo-23345**: Prevent test_ssl failures with large OpenSSL patch level values (like 0.9.8zc).

### Tools/Demos

- **bpo-22314**: pydoc now works when the LINES environment variable is set.
- **bpo-22615**: Argument Clinic now supports the “type” argument for the int converter. This permits using the int converter with enums and typedefs.
- **bpo-20076**: The makelocalealias.py script no longer ignores UTF-8 mapping.
- **bpo-20079**: The makelocalealias.py script now can parse the SUPPORTED file from glibc sources and supports command line
options for source paths.

- **bpo-22120**: For functions using an unsigned integer return converter, Argument Clinic now generates a cast to that type for the comparison to -1 in the generated code. (This suppresses a compilation warning.)

- **bpo-18974**: Tools/scripts/diff.py now uses argparse instead of optparse.

- **bpo-21906**: Make Tools/scripts/md5sum.py work in Python 3. Patch by Zachary Ware.

- **bpo-21629**: Fix Argument Clinic's “--converters” feature.

- **Add support for `yield from` to 2to3.**

- **Add support for the PEP 465 matrix multiplication operator to 2to3.**

- **bpo-16047**: Fix module exception list and `__file__` handling in freeze. Patch by Meador Inge.

- **bpo-11824**: Consider ABI tags in freeze. Patch by Meador Inge.

- **bpo-20535**: PYTHONWARNING no longer affects the run_tests.py script. Patch by Arfrever Frehtes Taifersar Arahesis.

## Windows

- **bpo-23260**: Update Windows installer

- The bundled version of Tcl/Tk has been updated to 8.6.3. The most visible result of this change is the addition of new native file dialogs when running on Windows Vista or newer. See Tcl/Tk’s TIP 432 for more information. Also, this version of Tcl/Tk includes support for Windows 10.

- **bpo-17896**: The Windows build scripts now expect external library sources to be in `PCbuild\..\externals` rather than `PCbuild\..\..`
- **bpo-17717**: The Windows build scripts now use a copy of NASM pulled from svn.python.org to build OpenSSL.
- **bpo-21907**: Improved the batch scripts provided for building Python.
- **bpo-22644**: The bundled version of OpenSSL has been updated to 1.0.1j.
- **bpo-10747**: Use versioned labels in the Windows start menu. Patch by Olive Kilburn.
- **bpo-22980**: .pyd files with a version and platform tag (for example, “.cp35-win32.pyd”) will now be loaded in preference to those without tags.

*(For information about older versions, consult the HISTORY file.)*
1. Whetting Your Appetite

If you do much work on computers, eventually you find that there’s some task you’d like to automate. For example, you may wish to perform a search-and-replace over a large number of text files, or rename and rearrange a bunch of photo files in a complicated way. Perhaps you’d like to write a small custom database, or a specialized GUI application, or a simple game.

If you’re a professional software developer, you may have to work with several C/C++/Java libraries but find the usual write/compile/test/re-compile cycle is too slow. Perhaps you’re writing a test suite for such a library and find writing the testing code a tedious task. Or maybe you’ve written a program that could use an extension language, and you don’t want to design and implement a whole new language for your application.

Python is just the language for you.

You could write a Unix shell script or Windows batch files for some of these tasks, but shell scripts are best at moving around files and changing text data, not well-suited for GUI applications or games. You could write a C/C++/Java program, but it can take a lot of development time to get even a first-draft program. Python is simpler to use, available on Windows, Mac OS X, and Unix operating systems, and will help you get the job done more quickly.

Python is simple to use, but it is a real programming language, offering much more structure and support for large programs than shell scripts or batch files can offer. On the other hand, Python also offers much more error checking than C, and, being a very-high-level language, it has high-level data types built in, such as flexible arrays and
dictionaries. Because of its more general data types Python is applicable to a much larger problem domain than Awk or even Perl, yet many things are at least as easy in Python as in those languages.

Python allows you to split your program into modules that can be reused in other Python programs. It comes with a large collection of standard modules that you can use as the basis of your programs — or as examples to start learning to program in Python. Some of these modules provide things like file I/O, system calls, sockets, and even interfaces to graphical user interface toolkits like Tk.

Python is an interpreted language, which can save you considerable time during program development because no compilation and linking is necessary. The interpreter can be used interactively, which makes it easy to experiment with features of the language, to write throw-away programs, or to test functions during bottom-up program development. It is also a handy desk calculator.

Python enables programs to be written compactly and readably. Programs written in Python are typically much shorter than equivalent C, C++, or Java programs, for several reasons:

- the high-level data types allow you to express complex operations in a single statement;
- statement grouping is done by indentation instead of beginning and ending brackets;
- no variable or argument declarations are necessary.

Python is extensible: if you know how to program in C it is easy to add a new built-in function or module to the interpreter, either to perform critical operations at maximum speed, or to link Python programs to libraries that may only be available in binary form (such as a vendor-specific graphics library). Once you are really hooked, you can link the
Python interpreter into an application written in C and use it as an extension or command language for that application.

By the way, the language is named after the BBC show “Monty Python’s Flying Circus” and has nothing to do with reptiles. Making references to Monty Python skits in documentation is not only allowed, it is encouraged!

Now that you are all excited about Python, you’ll want to examine it in some more detail. Since the best way to learn a language is to use it, the tutorial invites you to play with the Python interpreter as you read.

In the next chapter, the mechanics of using the interpreter are explained. This is rather mundane information, but essential for trying out the examples shown later.

The rest of the tutorial introduces various features of the Python language and system through examples, beginning with simple expressions, statements and data types, through functions and modules, and finally touching upon advanced concepts like exceptions and user-defined classes.
2. Using the Python Interpreter
2.1. Invoking the Interpreter

The Python interpreter is usually installed as `/usr/local/bin/python3.6` on those machines where it is available; putting `/usr/local/bin` in your Unix shell's search path makes it possible to start it by typing the command:

```
python3.6
```

to the shell. [1] Since the choice of the directory where the interpreter lives is an installation option, other places are possible; check with your local Python guru or system administrator. (E.g., `/usr/local/python` is a popular alternative location.)

On Windows machines, the Python installation is usually placed in `C:\Python36`, though you can change this when you’re running the installer. To add this directory to your path, you can type the following command into the command prompt in a DOS box:

```
set path=%path%;C:\python36
```

Typing an end-of-file character (Control-D on Unix, Control-Z on Windows) at the primary prompt causes the interpreter to exit with a zero exit status. If that doesn’t work, you can exit the interpreter by typing the following command: `quit()`.

The interpreter's line-editing features include interactive editing, history substitution and code completion on systems that support readline. Perhaps the quickest check to see whether command line editing is supported is typing Control-P to the first Python prompt you get. If it beeps, you have command line editing; see Appendix Interactive Input.
Editing and History Substitution for an introduction to the keys. If nothing appears to happen, or if ^P is echoed, command line editing isn't available; you'll only be able to use backspace to remove characters from the current line.

The interpreter operates somewhat like the Unix shell: when called with standard input connected to a tty device, it reads and executes commands interactively; when called with a file name argument or with a file as standard input, it reads and executes a script from that file.

A second way of starting the interpreter is python -c command [arg] ..., which executes the statement(s) in command, analogous to the shell's -c option. Since Python statements often contain spaces or other characters that are special to the shell, it is usually advised to quote command in its entirety with single quotes.

Some Python modules are also useful as scripts. These can be invoked using python -m module [arg] ..., which executes the source file for module as if you had spelled out its full name on the command line.

When a script file is used, it is sometimes useful to be able to run the script and enter interactive mode afterwards. This can be done by passing -i before the script.

All command line options are described in Command line and environment.

2.1.1. Argument Passing

When known to the interpreter, the script name and additional arguments thereafter are turned into a list of strings and assigned to
the `argv` variable in the `sys` module. You can access this list by executing `import sys`. The length of the list is at least one; when no script and no arguments are given, `sys.argv[0]` is an empty string. When the script name is given as `-` (meaning standard input), `sys.argv[0]` is set to `-`. When `-c command` is used, `sys.argv[0]` is set to `-c`. When `-m module` is used, `sys.argv[0]` is set to the full name of the located module. Options found after `-c command` or `-m module` are not consumed by the Python interpreter’s option processing but left in `sys.argv` for the command or module to handle.

2.1.2. Interactive Mode

When commands are read from a tty, the interpreter is said to be in interactive mode. In this mode it prompts for the next command with the primary prompt, usually three greater-than signs (>>>); for continuation lines it prompts with the secondary prompt, by default three dots (...). The interpreter prints a welcome message stating its version number and a copyright notice before printing the first prompt:

```
$ python3.6
Python 3.6 (default, Sep 16 2015, 09:25:04)
[GCC 4.8.2] on linux
Type "help", "copyright", "credits" or "license" for more information.
>>> 
```

Continuation lines are needed when entering a multi-line construct. As an example, take a look at this `if` statement:

```
>>> the_world_is_flat = True
>>> if the_world_is_flat:
```
... print("Be careful not to fall off!")
...
Be careful not to fall off!

For more on interactive mode, see Interactive Mode.
2.2. The Interpreter and Its Environment

2.2.1. Source Code Encoding

By default, Python source files are treated as encoded in UTF-8. In that encoding, characters of most languages in the world can be used simultaneously in string literals, identifiers and comments — although the standard library only uses ASCII characters for identifiers, a convention that any portable code should follow. To display all these characters properly, your editor must recognize that the file is UTF-8, and it must use a font that supports all the characters in the file.

To declare an encoding other than the default one, a special comment line should be added as the first line of the file. The syntax is as follows:

```plaintext
# -*- coding: encoding -*-
```

where `encoding` is one of the valid `codecs` supported by Python.

For example, to declare that Windows-1252 encoding is to be used, the first line of your source code file should be:

```plaintext
# -*- coding: cp-1252 -*-
```

One exception to the first line rule is when the source code starts with a UNIX “shebang” line. In this case, the encoding declaration should be added as the second line of the file. For example:

```plaintext
#!/usr/bin/env python3
# -*- coding: cp-1252 -*-
```
Footnotes

[1] On Unix, the Python 3.x interpreter is by default not installed with the executable named python, so that it does not conflict with a simultaneously installed Python 2.x executable.
3. An Informal Introduction to Python

In the following examples, input and output are distinguished by the presence or absence of prompts (```>>>``` and `...`): to repeat the example, you must type everything after the prompt, when the prompt appears; lines that do not begin with a prompt are output from the interpreter. Note that a secondary prompt on a line by itself in an example means you must type a blank line; this is used to end a multi-line command.

Many of the examples in this manual, even those entered at the interactive prompt, include comments. Comments in Python start with the hash character, `#`, and extend to the end of the physical line. A comment may appear at the start of a line or following whitespace or code, but not within a string literal. A hash character within a string literal is just a hash character. Since comments are to clarify code and are not interpreted by Python, they may be omitted when typing in examples.

Some examples:

```python
# this is the first comment
spam = 1  # and this is the second comment
         # ... and now a third!
text = "# This is not a comment because it's inside
```
3.1. Using Python as a Calculator

Let's try some simple Python commands. Start the interpreter and wait for the primary prompt, >>>. (It shouldn't take long.)

3.1.1. Numbers

The interpreter acts as a simple calculator: you can type an expression at it and it will write the value. Expression syntax is straightforward: the operators +, -, *, and / work just like in most other languages (for example, Pascal or C); parentheses (()) can be used for grouping. For example:

```
>>> 2 + 2
4
>>> 50 - 5*6
20
>>> (50 - 5*6) / 4
5.0
>>> 8 / 5  # division always returns a floating point
1.6
```

The integer numbers (e.g. 2, 4, 20) have type int, the ones with a fractional part (e.g. 5.0, 1.6) have type float. We will see more about numeric types later in the tutorial.

Division (/) always returns a float. To do floor division and get an integer result (discarding any fractional result) you can use the // operator; to calculate the remainder you can use %:

```
>>> 17 / 3  # classic division returns a float
```

With Python, it is possible to use the `**` operator to calculate powers [1]:

```plaintext
>>> 5 ** 2  # 5 squared
25
>>> 2 ** 7  # 2 to the power of 7
128
```

The equal sign (`=`) is used to assign a value to a variable. Afterwards, no result is displayed before the next interactive prompt:

```plaintext
>>> width = 20
>>> height = 5 * 9
>>> width * height
900
```

If a variable is not “defined” (assigned a value), trying to use it will give you an error:

```plaintext
>>> n  # try to access an undefined variable
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
NameError: name 'n' is not defined
```

There is full support for floating point; operators with mixed type
operands convert the integer operand to floating point:

```python
g4 = 4 * 3.75 - 1
14.0
```

In interactive mode, the last printed expression is assigned to the variable `_.` This means that when you are using Python as a desk calculator, it is somewhat easier to continue calculations, for example:

```python
tax = 12.5 / 100
price = 100.50
price * tax
12.5625
price + _
113.0625
round(_, 2)
113.06
```

This variable should be treated as read-only by the user. Don't explicitly assign a value to it — you would create an independent local variable with the same name masking the built-in variable with its magic behavior.

In addition to `int` and `float`, Python supports other types of numbers, such as `Decimal` and `Fraction`. Python also has built-in support for `complex numbers`, and uses the `j` or `J` suffix to indicate the imaginary part (e.g. `3+5j`).

### 3.1.2. Strings

Besides numbers, Python can also manipulate strings, which can be expressed in several ways. They can be enclosed in single quotes (`'...'`) or double quotes (`"..."`) with the same result [2]. \ can be
used to escape quotes:

```
>>> 'spam eggs'  # single quotes
'spam eggs'
>>> 'doesn\'t'  # use \' to escape the single quote.
'doesn\'t'
>>> "doesn't"  # ...or use double quotes instead
'doesn't'
>>> '"Yes," he said.'
"Yes," he said.'
>>> ""Yes,\" he said."
"Yes," he said.'
>>> '"Isn\'t," she said.'
"Isn\'t," she said.'
```

In the interactive interpreter, the output string is enclosed in quotes and special characters are escaped with backslashes. While this might sometimes look different from the input (the enclosing quotes could change), the two strings are equivalent. The string is enclosed in double quotes if the string contains a single quote and no double quotes, otherwise it is enclosed in single quotes. The `print()` function produces a more readable output, by omitting the enclosing quotes and by printing escaped and special characters:

```
>>> '"Isn\'t," she said.'
"Isn\'t," she said.'
>>> print("Isn\'t," she said.)
"Isn't," she said.
>>> s = 'First line.\nSecond line.'  # \n means newline
>>> s  # without print(), \n is included in the output
'First line.\nSecond line.'
>>> print(s)  # with print(), \n produces a new line
First line.  # with print(), \n produces a new line
Second line.
```
If you don't want characters prefaced by \ to be interpreted as special characters, you can use raw strings by adding an r before the first quote:

```python
>>> print('C:\some\name')  # here \n means newline!
C:some
ame
>>> print(r'C:\some\name')  # note the r before the quote
C:some\name
```

String literals can span multiple lines. One way is using triple-quotes: """..."""" or '''...'''. End of lines are automatically included in the string, but it's possible to prevent this by adding a \ at the end of the line. The following example:

```python
print("\nUsage: thingy [OPTIONS]
    -h                  Display this usage message
    -H hostname        Hostname to connect to
")
```

produces the following output (note that the initial newline is not included):

```python
Usage: thingy [OPTIONS]
    -h                  Display this usage message
    -H hostname        Hostname to connect to
```

Strings can be concatenated (glued together) with the + operator, and repeated with *:

```python
>>> # 3 times 'un', followed by 'ium'
```
Two or more string literals (i.e. the ones enclosed between quotes) next to each other are automatically concatenated.

This only works with two literals though, not with variables or expressions:

If you want to concatenate variables or a variable and a literal, use +:

This feature is particularly useful when you want to break long strings:

Strings can be indexed (subscripted), with the first character having index 0. There is no separate character type; a character is simply a
string of size one:

```python
>>> word = 'Python'
>>> word[0]  # character in position 0
'P'
>>> word[5]  # character in position 5
'n'
```

Indices may also be negative numbers, to start counting from the right:

```python
>>> word[-1]  # last character
'n'
>>> word[-2]  # second-last character
'o'
>>> word[-6]
'P'
```

Note that since -0 is the same as 0, negative indices start from -1.

In addition to indexing, *slicing* is also supported. While indexing is used to obtain individual characters, *slicing* allows you to obtain substring:

```python
>>> word[0:2]  # characters from position 0 (include)
'Py'
>>> word[2:5]  # characters from position 2 (include)
'th'
```

Note how the start is always included, and the end always excluded. This makes sure that `s[:i] + s[i:]` is always equal to `s`:

```python
>>> word[:2] + word[2:]
'Python'
>>> word[:4] + word[4:]
'Python'
```
Slice indices have useful defaults; an omitted first index defaults to zero, an omitted second index defaults to the size of the string being sliced.

```python
>>> word[2:]  # character from the beginning to position 2
'Py'
>>> word[4:]  # characters from position 4 (inclusive) to the end
'on'
>>> word[-2:] # characters from the second-last (inclusive) to the end
'on'
```

One way to remember how slices work is to think of the indices as pointing between characters, with the left edge of the first character numbered 0. Then the right edge of the last character of a string of `n` characters has index `n`, for example:

```
+---+---+---+---+---+---+
| P | y | t | h | o | n |
+---+---+---+---+---+---+
0   1   2   3   4   5   6
-6  -5  -4  -3  -2  -1
```

The first row of numbers gives the position of the indices 0…6 in the string; the second row gives the corresponding negative indices. The slice from `i` to `j` consists of all characters between the edges labeled `i` and `j`, respectively.

For non-negative indices, the length of a slice is the difference of the indices, if both are within bounds. For example, the length of `word[1:3]` is 2.

Attempting to use an index that is too large will result in an error:
```python
>>> word[42]  # the word only has 6 characters
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
IndexError: string index out of range

However, out of range slice indexes are handled gracefully when used for slicing:

```python
>>> word[4:42]
'on'
``` python

```python
>>> word[42:]
''
``` python

Python strings cannot be changed — they are immutable. Therefore, assigning to an indexed position in the string results in an error:

```python
>>> word[0] = 'J'
...  
TypeError: 'str' object does not support item assignment
>>> word[2:] = 'py'
...
TypeError: 'str' object does not support item assignment

If you need a different string, you should create a new one:

```python
>>> 'J' + word[1:]
'Jython'
``` python

```python
>>> word[:2] + 'py'
'Pypy'
``` python

The built-in function `len()` returns the length of a string:

```python
>>> s = 'supercalifragilisticexpialidocious'
>>> len(s)
``` python
See also:

Text Sequence Type — str
Strings are examples of sequence types, and support the common operations supported by such types.

String Methods
Strings support a large number of methods for basic transformations and searching.

Formatted string literals
String literals that have embedded expressions.

Format String Syntax
Information about string formatting with str.format().

printf-style String Formatting
The old formatting operations invoked when strings are the left operand of the % operator are described in more detail here.

3.1.3. Lists

Python knows a number of compound data types, used to group together other values. The most versatile is the list, which can be written as a list of comma-separated values (items) between square brackets. Lists might contain items of different types, but usually the items all have the same type.

```python
>>> squares = [1, 4, 9, 16, 25]
>>> squares
[1, 4, 9, 16, 25]
```

Like strings (and all other built-in sequence type), lists can be indexed
and sliced:

```python
>>> squares[0]  # indexing returns the item
1
>>> squares[-1]
25
>>> squares[-3:]  # slicing returns a new list
[9, 16, 25]
```

All slice operations return a new list containing the requested elements. This means that the following slice returns a new (shallow) copy of the list:

```python
>>> squares[:]
[1, 4, 9, 16, 25]
```

Lists also support operations like concatenation:

```python
>>> squares + [36, 49, 64, 81, 100]
[1, 4, 9, 16, 25, 36, 49, 64, 81, 100]
```

Unlike strings, which are immutable, lists are a mutable type, i.e. it is possible to change their content:

```python
>>> cubes = [1, 8, 27, 65, 125]  # something's wrong
>>> 4 ** 3  # the cube of 4 is 64, not 65!
64
>>> cubes[3] = 64  # replace the wrong value
>>> cubes
[1, 8, 27, 64, 125]
```

You can also add new items at the end of the list, by using the `append()` method (we will see more about methods later):
Assignment to slices is also possible, and this can even change the size of the list or clear it entirely:

```python
>>> letters = ['a', 'b', 'c', 'd', 'e', 'f', 'g']
>>> letters
['a', 'b', 'c', 'd', 'e', 'f', 'g']
>>> # replace some values
>>> letters
['a', 'b', 'C', 'D', 'E', 'f', 'g']
>>> # now remove them
>>> letters[2:5] = []
>>> letters
['a', 'b', 'f', 'g']
>>> # clear the list by replacing all the elements with an empty list
>>> letters[:]=[]
[]
```

The built-in function `len()` also applies to lists:

```python
>>> letters = ['a', 'b', 'c', 'd']
>>> len(letters)
4
```

It is possible to nest lists (create lists containing other lists), for example:

```python
>>> a = ['a', 'b', 'c']
>>> n = [1, 2, 3]
```
```python
>>> x = [a, n]
>>> x
[['a', 'b', 'c'], [1, 2, 3]]
>>> x[0]
['a', 'b', 'c']
>>> x[0][1]
'b'
```
3.2. First Steps Towards Programming

Of course, we can use Python for more complicated tasks than adding two and two together. For instance, we can write an initial sub-sequence of the Fibonacci series as follows:

```python
>>> # Fibonacci series:
... # the sum of two elements defines the next
... a, b = 0, 1
>>> while b < 10:
...     print(b)
...     a, b = b, a+b
...
1
1
2
3
5
8
```

This example introduces several new features.

- The first line contains a *multiple assignment*: the variables `a` and `b` simultaneously get the new values 0 and 1. On the last line this is used again, demonstrating that the expressions on the right-hand side are all evaluated first before any of the assignments take place. The right-hand side expressions are evaluated from the left to the right.

- The *while* loop executes as long as the condition (here: `b < 10`) remains true. In Python, like in C, any non-zero integer value is true; zero is false. The condition may also be a string or list value, in fact any sequence; anything with a non-zero length is
true, empty sequences are false. The test used in the example is a simple comparison. The standard comparison operators are written the same as in C: < (less than), > (greater than), == (equal to), <= (less than or equal to), >= (greater than or equal to) and != (not equal to).

- The **body** of the loop is *indented*: indentation is Python's way of grouping statements. At the interactive prompt, you have to type a tab or space(s) for each indented line. In practice you will prepare more complicated input for Python with a text editor; all decent text editors have an auto-indent facility. When a compound statement is entered interactively, it must be followed by a blank line to indicate completion (since the parser cannot guess when you have typed the last line). Note that each line within a basic block must be indented by the same amount.

- The `print()` function writes the value of the argument(s) it is given. It differs from just writing the expression you want to write (as we did earlier in the calculator examples) in the way it handles multiple arguments, floating point quantities, and strings. Strings are printed without quotes, and a space is inserted between items, so you can format things nicely, like this:

```python
>>> i = 256*256
>>> print('The value of i is', i)
The value of i is 65536
```

The keyword argument *end* can be used to avoid the newline after the output, or end the output with a different string:

```python
>>> a, b = 0, 1
>>> while b < 1000:
...     print(b, end=', ')
```
... a, b = b, a+b
...
1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987,

Footnotes

Since ** has higher precedence than -, -3**2 will be interpreted as -(3**2) and thus result in -9. To avoid this and get 9, you can use (-3)**2.

Unlike other languages, special characters such as \n have the same meaning with both single (' . . ') and double (" . . ") quotes. The only difference between the two is that within single quotes you don't need to escape " (but you have to escape \ ) and vice versa.
4. More Control Flow Tools

Besides the `while` statement just introduced, Python knows the usual control flow statements known from other languages, with some twists.
4.1. *if* Statements

Perhaps the most well-known statement type is the *if* statement. For example:

```python
>>> x = int(input("Please enter an integer: "))
Please enter an integer: 42
>>> if x < 0:
...    x = 0
...    print('Negative changed to zero')
...    elif x == 0:
...        print('Zero')
...        elif x == 1:
...            print('Single')
...        else:
...            print('More')
... More
```

There can be zero or more *elif* parts, and the *else* part is optional. The keyword ‘*elif*’ is short for ‘else if’, and is useful to avoid excessive indentation. An *if* ... *elif* ... *elif* ... sequence is a substitute for the *switch* or *case* statements found in other languages.
4.2. **for** Statements

The **for** statement in Python differs a bit from what you may be used to in C or Pascal. Rather than always iterating over an arithmetic progression of numbers (like in Pascal), or giving the user the ability to define both the iteration step and halting condition (as C), Python’s **for** statement iterates over the items of any sequence (a list or a string), in the order that they appear in the sequence. For example (no pun intended):

```python
>>> # Measure some strings:
... words = ['cat', 'window', 'defenestrate']
>>> for w in words:
...     print(w, len(w))
... cat 3
window 6
defenestrate 12
```

If you need to modify the sequence you are iterating over while inside the loop (for example to duplicate selected items), it is recommended that you first make a copy. Iterating over a sequence does not implicitly make a copy. The slice notation makes this especially convenient:

```python
>>> for w in words[:]: # Loop over a slice copy of...
...     if len(w) > 6:
...         words.insert(0, w)
... >>> words
['defenestrate', 'cat', 'window', 'defenestrate']
```

With **for w in words:**, the example would attempt to create an
infinite list, inserting *defenestrate* over and over again.
4.3. The `range()` Function

If you do need to iterate over a sequence of numbers, the built-in function `range()` comes in handy. It generates arithmetic progressions:

```python
>>> for i in range(5):
...     print(i)
...
0
1
2
3
4
```

The given end point is never part of the generated sequence; `range(10)` generates 10 values, the legal indices for items of a sequence of length 10. It is possible to let the range start at another number, or to specify a different increment (even negative; sometimes this is called the 'step'):

```python
range(5, 10)  # 5 through 9
range(0, 10, 3)  # 0, 3, 6, 9
range(-10, -100, -30)  # -10, -40, -70
```

To iterate over the indices of a sequence, you can combine `range()` and `len()` as follows:
In most such cases, however, it is convenient to use the `enumerate()` function, see Looping Techniques.

A strange thing happens if you just print a range:

```python
>>> print(range(10))
range(0, 10)
```

In many ways the object returned by `range()` behaves as if it is a list, but in fact it isn’t. It is an object which returns the successive items of the desired sequence when you iterate over it, but it doesn’t really make the list, thus saving space.

We say such an object is iterable, that is, suitable as a target for functions and constructs that expect something from which they can obtain successive items until the supply is exhausted. We have seen that the `for` statement is such an iterator. The function `list()` is another; it creates lists from iterables:

```python
>>> list(range(5))
[0, 1, 2, 3, 4]
```

Later we will see more functions that return iterables and take iterables as argument.
4.4. **break** and **continue** Statements, and **else** Clauses on Loops

The **break** statement, like in C, breaks out of the innermost enclosing **for** or **while** loop.

Loop statements may have an **else** clause; it is executed when the loop terminates through exhaustion of the list (with **for**) or when the condition becomes false (with **while**), but not when the loop is terminated by a **break** statement. This is exemplified by the following loop, which searches for prime numbers:

```python
>>> for n in range(2, 10):
    ...   for x in range(2, n):
    ...     if n % x == 0:
    ...       print(n, 'equals', x, '*', n//x)
    ...     break
    ...
    else:
    ...       # loop fell through without finding a factor
    ...       print(n, 'is a prime number')
...
2 is a prime number
3 is a prime number
4 equals 2 * 2
5 is a prime number
6 equals 2 * 3
7 is a prime number
8 equals 2 * 4
9 equals 3 * 3
```

(Yes, this is the correct code. Look closely: the **else** clause belongs to the **for** loop, **not** the **if** statement.)
When used with a loop, the `else` clause has more in common with the `else` clause of a `try` statement than it does that of `if` statements: a `try` statement’s `else` clause runs when no exception occurs, and a loop’s `else` clause runs when no `break` occurs. For more on the `try` statement and exceptions, see *Handling Exceptions*.

The `continue` statement, also borrowed from C, continues with the next iteration of the loop:

```python
>>> for num in range(2, 10):
...     if num % 2 == 0:
...         print("Found an even number", num)
...         continue
...     print("Found a number", num)
Found an even number 2
Found a number 3
Found an even number 4
Found a number 5
Found an even number 6
Found a number 7
Found an even number 8
Found a number 9
```
4.5. **pass** Statements

The **pass** statement does nothing. It can be used when a statement is required syntactically but the program requires no action. For example:

```python
>>> while True:
    ...
    pass  # Busy-wait for keyboard interrupt (Ctrl+C)
    ...
```

This is commonly used for creating minimal classes:

```python
>>> class MyEmptyClass:
    ...
    pass
    ...
```

Another place **pass** can be used is as a place-holder for a function or conditional body when you are working on new code, allowing you to keep thinking at a more abstract level. The **pass** is silently ignored:

```python
>>> def initlog(*args):
    ...
    pass  # Remember to implement this!
    ...
```
4.6. Defining Functions

We can create a function that writes the Fibonacci series to an arbitrary boundary:

```python
>>> def fib(n):  # write Fibonacci series up to n
...     """Print a Fibonacci series up to n.""
...     a, b = 0, 1
...     while a < n:
...         print(a, end=' ')
...         a, b = b, a+b
...     print()
... # Now call the function we just defined:
... fib(2000)
0 1 1 2 3 5 8 13 21 34 55 89 144 233 377 610 987 1597
```

The keyword `def` introduces a function definition. It must be followed by the function name and the parenthesized list of formal parameters. The statements that form the body of the function start at the next line, and must be indented.

The first statement of the function body can optionally be a string literal; this string literal is the function’s documentation string, or docstring. (More about docstrings can be found in the section Documentation Strings.) There are tools which use docstrings to automatically produce online or printed documentation, or to let the user interactively browse through code; it’s good practice to include docstrings in code that you write, so make a habit of it.

The execution of a function introduces a new symbol table used for the local variables of the function. More precisely, all variable assignments
in a function store the value in the local symbol table; whereas variable references first look in the local symbol table, then in the local symbol tables of enclosing functions, then in the global symbol table, and finally in the table of built-in names. Thus, global variables cannot be directly assigned a value within a function (unless named in a `global` statement), although they may be referenced.

The actual parameters (arguments) to a function call are introduced in the local symbol table of the called function when it is called; thus, arguments are passed using `call by value` (where the `value` is always an object `reference`, not the value of the object). [1] When a function calls another function, a new local symbol table is created for that call.

A function definition introduces the function name in the current symbol table. The value of the function name has a type that is recognized by the interpreter as a user-defined function. This value can be assigned to another name which can then also be used as a function. This serves as a general renaming mechanism:

```
>>> fib
<function fib at 10042ed0>
>>> f = fib
>>> f(100)
0 1 1 2 3 5 8 13 21 34 55 89
```

Coming from other languages, you might object that `fib` is not a function but a procedure since it doesn’t return a value. In fact, even functions without a `return` statement do return a value, albeit a rather boring one. This value is called `None` (it’s a built-in name). Writing the value `None` is normally suppressed by the interpreter if it would be the only value written. You can see it if you really want to using `print()`:
It is simple to write a function that returns a list of the numbers of the Fibonacci series, instead of printing it:

```python
>>> def fib2(n):
...     # return Fibonacci series up to n
...     """Return a list containing the Fibonacci series up to n."
...     result = []
...     a, b = 0, 1
...     while a < n:
...         result.append(a)  # see below
...         a, b = b, a+b
...     return result
...
>>> f100 = fib2(100)  # call it
>>> f100
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
```

This example, as usual, demonstrates some new Python features:

- The `return` statement returns with a value from a function. `return` without an expression argument returns `None`. Falling off the end of a function also returns `None`.
- The statement `result.append(a)` calls a method of the list object `result`. A method is a function that 'belongs' to an object and is named `obj.methodname`, where `obj` is some object (this may be an expression), and `methodname` is the name of a method that is defined by the object's type. Different types define different methods. Methods of different types may have the same name without causing ambiguity. (It is possible to define your own object types and methods, using `classes`, see `Classes`) The method `append()` shown in the example is defined for list...
objects; it adds a new element at the end of the list. In this example it is equivalent to `result = result + [a]`, but more efficient.
4.7. More on Defining Functions

It is also possible to define functions with a variable number of arguments. There are three forms, which can be combined.

4.7.1. Default Argument Values

The most useful form is to specify a default value for one or more arguments. This creates a function that can be called with fewer arguments than it is defined to allow. For example:

```python
def ask_ok(prompt, retries=4, reminder='Please try again!'):
    while True:
        ok = input(prompt)
        if ok in ('y', 'ye', 'yes'):
            return True
        if ok in ('n', 'no', 'nop', 'nope'):
            return False
        retries = retries - 1
        if retries < 0:
            raise ValueError('invalid user response')
    print(reminder)
```

This function can be called in several ways:

- giving only the mandatory argument: `ask_ok('Do you really want to quit?')`
- giving one of the optional arguments: `ask_ok('OK to overwrite the file?', 2)`
- or even giving all arguments: `ask_ok('OK to overwrite the file?', 2, 'Come on, only yes or no!')`
This example also introduces the \texttt{in} keyword. This tests whether or not a sequence contains a certain value.

The default values are evaluated at the point of function definition in the \textit{defining} scope, so that

\begin{verbatim}
i = 5

def f(arg=i):
    print(arg)

i = 6
f()
\end{verbatim}

will print 5.

\textbf{Important warning:} The default value is evaluated only once. This makes a difference when the default is a mutable object such as a list, dictionary, or instances of most classes. For example, the following function accumulates the arguments passed to it on subsequent calls:

\begin{verbatim}
def f(a, L=[]):
    L.append(a)
    return L

print(f(1))
print(f(2))
print(f(3))
\end{verbatim}

This will print

\begin{verbatim}
[1]
[1, 2]
[1, 2, 3]
\end{verbatim}
If you don't want the default to be shared between subsequent calls, you can write the function like this instead:

```python
def f(a, L=None):
    if L is None:
        L = []
    L.append(a)
    return L
```

### 4.7.2. Keyword Arguments

Functions can also be called using keyword arguments of the form `kwarg=value`. For instance, the following function:

```python
def parrot(voltage, state='a stiff', action='voom',
          print("-- This parrot wouldn't", action, end=''
          print("if you put", voltage, "volts through it."
          print("-- Lovely plumage, the", type)
          print("-- It's", state, "!")
```

accepts one required argument (`voltage`) and three optional arguments (`state`, `action`, and `type`). This function can be called in any of the following ways:

```
parrot(1000)
parrot(voltage=1000)
parrot(voltage=1000000, action='VOOOOOM')
parrot(action='VOOOOOM', voltage=1000000)
parrot('a million', 'bereft of life', 'jump')
parrot('a thousand', state='pushing up the daisies')
```

but all the following calls would be invalid:
In a function call, keyword arguments must follow positional arguments. All the keyword arguments passed must match one of the arguments accepted by the function (e.g. `actor` is not a valid argument for the `parrot` function), and their order is not important. This also includes non-optional arguments (e.g. `parrot(voltage=1000)` is valid too). No argument may receive a value more than once. Here's an example that fails due to this restriction:

```python
>>> def function(a):
...     pass
...
>>> function(0, a=0)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: function() got multiple values for keyword argument 'a'
```

When a final formal parameter of the form `**name` is present, it receives a dictionary (see Mapping Types — `dict`) containing all keyword arguments except for those corresponding to a formal parameter. This may be combined with a formal parameter of the form `*name` (described in the next subsection) which receives a tuple containing the positional arguments beyond the formal parameter list. (*name must occur before **name.*) For example, if we define a function like this:

```python
def cheeseshop(kind, *arguments, **keywords):
```
print("-- Do you have any", kind, "?")
print("-- I'm sorry, we're all out of", kind)
for arg in arguments:
    print(arg)
print("-")
for kw in keywords:
    print(kw, ":", keywords[kw])

It could be called like this:

cheeseshop("Limburger", "It's very runny, sir.", "It's really very, VERY runny, sir.", shopkeeper="Michael Palin", client="John Cleese", sketch="Cheese Shop Sketch")

and of course it would print:

-- Do you have any Limburger ?
-- I'm sorry, we're all out of Limburger
It's very runny, sir.
It's really very, VERY runny, sir.

----------------------------------------
shopkeeper : Michael Palin
client : John Cleese
sketch : Cheese Shop Sketch

Note that the order in which the keyword arguments are printed is guaranteed to match the order in which they were provided in the function call.

4.7.3. Arbitrary Argument Lists

Finally, the least frequently used option is to specify that a function can be called with an arbitrary number of arguments. These arguments will
be wrapped up in a tuple (see Tuples and Sequences). Before the variable number of arguments, zero or more normal arguments may occur.

```python
def write_multiple_items(file, separator, *args):
    file.write(separator.join(args))
```

Normally, these variadic arguments will be last in the list of formal parameters, because they scoop up all remaining input arguments that are passed to the function. Any formal parameters which occur after the `*args` parameter are ‘keyword-only’ arguments, meaning that they can only be used as keywords rather than positional arguments.

```python
>>> def concat(*args, sep="/"): ...
...    return sep.join(args) ...

>>> concat("earth", "mars", "venus")
'earth/mars/venus'
>>> concat("earth", "mars", "venus", sep=".")
'earth.mars.venus'
```

### 4.7.4. Unpacking Argument Lists

The reverse situation occurs when the arguments are already in a list or tuple but need to be unpacked for a function call requiring separate positional arguments. For instance, the built-in `range()` function expects separate `start` and `stop` arguments. If they are not available separately, write the function call with the `*`-operator to unpack the arguments out of a list or tuple:

```python
>>> list(range(3, 6))  # normal call with [3, 4, 5]
>>> args = [3, 6]
```
In the same fashion, dictionaries can deliver keyword arguments with the **-operator:

```python
>>> def parrot(voltage, state='a stiff', action='voom', **d):
...     print("-- This parrot wouldn't", action, end='')
...     print(" if you put", voltage, "volts through it.", sep='')
...     print("E's", state, "!")
...     print("-- This parrot wouldn't VOOM if you put four million volts through it. E's bleedin' demised!")
```

### 4.7.5. Lambda Expressions

Small anonymous functions can be created with the `lambda` keyword. This function returns the sum of its two arguments: `lambda a, b: a+b`. Lambda functions can be used wherever function objects are required. They are syntactically restricted to a single expression. Semantically, they are just syntactic sugar for a normal function definition. Like nested function definitions, lambda functions can reference variables from the containing scope:

```python
>>> def make_incrementor(n):
...     return lambda x: x + n
...     print("-- This parrot wouldn't VOOM if you put four million volts through it. E's bleedin' demised!")
```

```python
>>> f = make_incrementor(42)
>>> f(0)
42
>>> f(1)
43
```
The above example uses a lambda expression to return a function. Another use is to pass a small function as an argument:

```python
>>> pairs = [(1, 'one'), (2, 'two'), (3, 'three'), (4, 'four')]
>>> pairs.sort(key=lambda pair: pair[1])
>>> pairs
[(4, 'four'), (1, 'one'), (3, 'three'), (2, 'two')]
```

4.7.6. Documentation Strings

Here are some conventions about the content and formatting of documentation strings.

The first line should always be a short, concise summary of the object’s purpose. For brevity, it should not explicitly state the object’s name or type, since these are available by other means (except if the name happens to be a verb describing a function’s operation). This line should begin with a capital letter and end with a period.

If there are more lines in the documentation string, the second line should be blank, visually separating the summary from the rest of the description. The following lines should be one or more paragraphs describing the object’s calling conventions, its side effects, etc.

The Python parser does not strip indentation from multi-line string literals in Python, so tools that process documentation have to strip indentation if desired. This is done using the following convention. The first non-blank line after the first line of the string determines the amount of indentation for the entire documentation string. (We can’t use the first line since it is generally adjacent to the string’s opening quotes so its indentation is not apparent in the string literal.)
Whitespace “equivalent” to this indentation is then stripped from the start of all lines of the string. Lines that are indented less should not occur, but if they occur all their leading whitespace should be stripped. Equivalence of whitespace should be tested after expansion of tabs (to 8 spaces, normally).

Here is an example of a multi-line docstring:

```python
>>> def my_function():
    ...     """Do nothing, but document it.
    ...     No, really, it doesn't do anything.
    ...     ""
    ...     pass
    ...
>>> print(my_function.__doc__)
Do nothing, but document it.

                        No, really, it doesn't do anything.
```

4.7.7. Function Annotations

Function annotations are completely optional metadata information about the types used by user-defined functions (see PEP 484 for more information).

Annotations are stored in the __annotations__ attribute of the function as a dictionary and have no effect on any other part of the function. Parameter annotations are defined by a colon after the parameter name, followed by an expression evaluating to the value of the annotation. Return annotations are defined by a literal ->, followed by an expression, between the parameter list and the colon denoting the end of the def statement. The following example has a positional
argument, a keyword argument, and the return value annotated:

```python
def f(ham: str, eggs: str = 'eggs') -> str:
    ...
    print("Annotations:", f.__annotations__)
    ...
    print("Arguments:", ham, eggs)
    ...
    return ham + ' and ' + eggs

>>> f('spam')
Annotations: {'ham': <class 'str'>, 'return': <class 'str'>, 'eggs': <class 'str'>}
Arguments: spam eggs
'spam and eggs'
```
4.8. Intermezzo: Coding Style

Now that you are about to write longer, more complex pieces of Python, it is a good time to talk about coding style. Most languages can be written (or more concise, formatted) in different styles; some are more readable than others. Making it easy for others to read your code is always a good idea, and adopting a nice coding style helps tremendously for that.

For Python, PEP 8 has emerged as the style guide that most projects adhere to; it promotes a very readable and eye-pleasing coding style. Every Python developer should read it at some point; here are the most important points extracted for you:

- Use 4-space indentation, and no tabs.
  
  4 spaces are a good compromise between small indentation (allows greater nesting depth) and large indentation (easier to read). Tabs introduce confusion, and are best left out.

- Wrap lines so that they don’t exceed 79 characters.
  
  This helps users with small displays and makes it possible to have several code files side-by-side on larger displays.

- Use blank lines to separate functions and classes, and larger blocks of code inside functions.

- When possible, put comments on a line of their own.

- Use docstrings.

- Use spaces around operators and after commas, but not directly
inside bracketing constructs: \( a = f(1, 2) + g(3, 4) \).

- Name your classes and functions consistently; the convention is to use CamelCase for classes and lower_case_with_underscores for functions and methods. Always use self as the name for the first method argument (see A First Look at Classes for more on classes and methods).

- Don’t use fancy encodings if your code is meant to be used in international environments. Python’s default, UTF-8, or even plain ASCII work best in any case.

- Likewise, don’t use non-ASCII characters in identifiers if there is only the slightest chance people speaking a different language will read or maintain the code.

**Footnotes**

Actually, *call by object reference* would be a better description, since if a mutable object is passed, the caller will see any changes the callee makes to it (items inserted into a list).

[1]
5. Data Structures

This chapter describes some things you’ve learned about already in more detail, and adds some new things as well.
5.1. More on Lists

The list data type has some more methods. Here are all of the methods of list objects:

list.\texttt{append}(x)

Add an item to the end of the list. Equivalent to \texttt{a[len(a):] = [x]}.

list.\texttt{extend}(iterable)

Extend the list by appending all the items from the iterable. Equivalent to \texttt{a[len(a):] = iterable}.

list.\texttt{insert}(i, x)

Insert an item at a given position. The first argument is the index of the element before which to insert, so \texttt{a.insert(0, x)} inserts at the front of the list, and \texttt{a.insert(len(a), x)} is equivalent to \texttt{a.append(x)}.

list.\texttt{remove}(x)

Remove the first item from the list whose value is \textit{x}. It is an error if there is no such item.

list.\texttt{pop}([i])

Remove the item at the given position in the list, and return it. If no index is specified, \texttt{a.pop()} removes and returns the last item in the list. (The square brackets around the \textit{i} in the method signature denote that the parameter is optional, not that you should type square brackets at that position. You will see this notation frequently in the Python Library Reference.)
```
list.clear()
Remove all items from the list. Equivalent to del a[:].

list.index(x[, start[, end]])
Return zero-based index in the list of the first item whose value is x. Raises a ValueError if there is no such item.

The optional arguments start and end are interpreted as in the slice notation and are used to limit the search to a particular subsequence of the list. The returned index is computed relative to the beginning of the full sequence rather than the start argument.

list.count(x)
Return the number of times x appears in the list.

list.sort(key=None, reverse=False)
Sort the items of the list in place (the arguments can be used for sort customization, see sorted() for their explanation).

list.reverse()
Reverse the elements of the list in place.

list.copy()
Return a shallow copy of the list. Equivalent to a[:].

An example that uses most of the list methods:
```
```
You might have noticed that methods like `insert`, `remove` or `sort` that only modify the list have no return value printed – they return the default `None`. [1] This is a design principle for all mutable data structures in Python.

5.1.1. Using Lists as Stacks

The list methods make it very easy to use a list as a stack, where the last element added is the first element retrieved ("last-in, first-out"). To add an item to the top of the stack, use `append()`. To retrieve an item from the top of the stack, use `pop()` without an explicit index. For example:

```python
>>> stack = [3, 4, 5]
>>> stack.append(6)
>>> stack.append(7)
>>> stack
[3, 4, 5, 6, 7]
>>> stack.pop()
```
5.1.2. Using Lists as Queues

It is also possible to use a list as a queue, where the first element added is the first element retrieved (“first-in, first-out”); however, lists are not efficient for this purpose. While appends and pops from the end of list are fast, doing inserts or pops from the beginning of a list is slow (because all of the other elements have to be shifted by one).

To implement a queue, use collections.deque which was designed to have fast appends and pops from both ends. For example:

```python
>>> from collections import deque
>>> queue = deque(['Eric', 'John', 'Michael'])
>>> queue.append('Terry')  # Terry arrives
>>> queue.append('Graham')  # Graham arrives
>>> queue.popleft()  # The first to arrive now leaves
'Eric'
>>> queue.popleft()  # The second to arrive now leaves
'John'
>>> queue  # Remaining queue
deque(['Michael', 'Terry', 'Graham'])
```
5.1.3. List Comprehensions

List comprehensions provide a concise way to create lists. Common applications are to make new lists where each element is the result of some operations applied to each member of another sequence or iterable, or to create a subsequence of those elements that satisfy a certain condition.

For example, assume we want to create a list of squares, like:

```python
>>> squares = []
>>> for x in range(10):
...    squares.append(x**2)
... >>> squares
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

Note that this creates (or overwrites) a variable named `x` that still exists after the loop completes. We can calculate the list of squares without any side effects using:

```python
squares = list(map(lambda x: x**2, range(10)))
```

or, equivalently:

```python
squares = [x**2 for x in range(10)]
```

which is more concise and readable.

A list comprehension consists of brackets containing an expression followed by a `for` clause, then zero or more `for` or `if` clauses. The result will be a new list resulting from evaluating the expression in the context of the `for` and `if` clauses which follow it. For example, this
listcomp combines the elements of two lists if they are not equal:

```python
>>> [(x, y) for x in [1, 2, 3] for y in [3, 1, 4] if x != y]
[(1, 3), (1, 4), (2, 3), (2, 1), (2, 4), (3, 1), (3, 4)]
```

and it's equivalent to:

```python
>>> combs = []
>>> for x in [1, 2, 3]:
...     for y in [3, 1, 4]:
...         if x != y:
...             combs.append((x, y))
...   
>>> combs
[(1, 3), (1, 4), (2, 3), (2, 1), (2, 4), (3, 1), (3, 4)]
```

Note how the order of the `for` and `if` statements is the same in both these snippets.

If the expression is a tuple (e.g. the `(x, y)` in the previous example), it must be parenthesized.

```python
>>> vec = [-4, -2, 0, 2, 4]
>>> # create a new list with the values doubled
... [x*2 for x in vec]
[-8, -4, 0, 4, 8]
>>> # filter the list to exclude negative numbers
... [x for x in vec if x >= 0]
[0, 2, 4]
>>> # apply a function to all the elements
... [abs(x) for x in vec]
[4, 2, 0, 2, 4]
>>> # call a method on each element
... freshfruit = ['banana', 'loganberry', 'pass']
```
List comprehensions can contain complex expressions and nested functions:

```python
>>> from math import pi
>>> [str(round(pi, i)) for i in range(1, 6)]
['3.1', '3.14', '3.142', '3.1416', '3.14159']
```

5.1.4. Nested List Comprehensions

The initial expression in a list comprehension can be any arbitrary expression, including another list comprehension.

Consider the following example of a 3x4 matrix implemented as a list of 3 lists of length 4:

```python
>>> matrix = [
...     [1, 2, 3, 4],
...     [5, 6, 7, 8],
...     ...
```
The following list comprehension will transpose rows and columns:

```python
>>> [[row[i] for row in matrix] for i in range(4)]
[[[1, 5, 9], [2, 6, 10], [3, 7, 11], [4, 8, 12]]
```

As we saw in the previous section, the nested listcomp is evaluated in the context of the `for` that follows it, so this example is equivalent to:

```python
>>> transposed = []
>>> for i in range(4):
...     transposed.append([row[i] for row in matrix])
... <<< transposed
[[[1, 5, 9], [2, 6, 10], [3, 7, 11], [4, 8, 12]]
```

which, in turn, is the same as:

```python
>>> transposed = []
>>> for i in range(4):
...     # the following 3 lines implement the nested
...     transposed_row = []
...     for row in matrix:
...         transposed_row.append(row[i])
...     transposed.append(transposed_row)
... <<< transposed
[[[1, 5, 9], [2, 6, 10], [3, 7, 11], [4, 8, 12]]
```

In the real world, you should prefer built-in functions to complex flow statements. The `zip()` function would do a great job for this use case:
See Unpacking Argument Lists for details on the asterisk in this line.
5.2. The `del` statement

There is a way to remove an item from a list given its index instead of its value: the `del` statement. This differs from the `pop()` method which returns a value. The `del` statement can also be used to remove slices from a list or clear the entire list (which we did earlier by assignment of an empty list to the slice). For example:

```python
>>> a = [-1, 1, 66.25, 333, 333, 1234.5]
>>> del a[0]
>>> a
[1, 66.25, 333, 333, 1234.5]
>>> del a[2:4]
>>> a
[1, 66.25, 1234.5]
>>> del a[:]
>>> a
[]
```

`del` can also be used to delete entire variables:

```python
>>> del a
```

Referencing the name `a` hereafter is an error (at least until another value is assigned to it). We'll find other uses for `del` later.
5.3. Tuples and Sequences

We saw that lists and strings have many common properties, such as indexing and slicing operations. They are two examples of sequence data types (see Sequence Types — list, tuple, range). Since Python is an evolving language, other sequence data types may be added. There is also another standard sequence data type: the tuple.

A tuple consists of a number of values separated by commas, for instance:

```
>>> t = 12345, 54321, 'hello!

>>> t[0]
12345

>>> t
(12345, 54321, 'hello!')

>>> # Tuples may be nested:
...

>>> u = t, (1, 2, 3, 4, 5)

>>> u
((12345, 54321, 'hello!'), (1, 2, 3, 4, 5))

>>> # Tuples are immutable:
...

>>> t[0] = 88888

Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: 'tuple' object does not support item assignment

>>> # but they can contain mutable objects:
...

>>> v = ([1, 2, 3], [3, 2, 1])

>>> v
([1, 2, 3], [3, 2, 1])
```

As you see, on output tuples are always enclosed in parentheses, so that nested tuples are interpreted correctly; they may be input with or without surrounding parentheses, although often parentheses are
necessary anyway (if the tuple is part of a larger expression). It is not possible to assign to the individual items of a tuple, however it is possible to create tuples which contain mutable objects, such as lists.

Though tuples may seem similar to lists, they are often used in different situations and for different purposes. Tuples are immutable, and usually contain a heterogeneous sequence of elements that are accessed via unpacking (see later in this section) or indexing (or even by attribute in the case of namedtuples). Lists are mutable, and their elements are usually homogeneous and are accessed by iterating over the list.

A special problem is the construction of tuples containing 0 or 1 items: the syntax has some extra quirks to accommodate these. Empty tuples are constructed by an empty pair of parentheses; a tuple with one item is constructed by following a value with a comma (it is not sufficient to enclose a single value in parentheses). Ugly, but effective. For example:

```python
>>> empty = ()
>>> singleton = 'hello',       # <-- note trailing comma
>>> len(empty)
0
>>> len(singleton)
1
>>> singleton
('hello',)
```

The statement `t = 12345, 54321, 'hello!'` is an example of tuple packing: the values `12345, 54321` and `'hello!'` are packed together in a tuple. The reverse operation is also possible:

```python
>>> x, y, z = t
```
This is called, appropriately enough, sequence unpacking and works for any sequence on the right-hand side. Sequence unpacking requires that there are as many variables on the left side of the equals sign as there are elements in the sequence. Note that multiple assignment is really just a combination of tuple packing and sequence unpacking.
5.4. Sets

Python also includes a data type for sets. A set is an unordered collection with no duplicate elements. Basic uses include membership testing and eliminating duplicate entries. Set objects also support mathematical operations like union, intersection, difference, and symmetric difference.

Curly braces or the `set()` function can be used to create sets. Note: to create an empty set you have to use `set()`, not `{}`; the latter creates an empty dictionary, a data structure that we discuss in the next section.

Here is a brief demonstration:

```python
>>> basket = {'apple', 'orange', 'apple', 'pear', 'crabgrass'}
>>> print(basket)  # show that duplicates have been removed
{'orange', 'banana', 'pear', 'apple'}
>>> 'orange' in basket  # fast membership testing
True
>>> 'crabgrass' in basket
False

>>> # Demonstrate set operations on unique letters from two words...
>>> a = set('abracadabra')
>>> b = set('alacazam')
>>> a  # unique letters in a
{'a', 'r', 'b', 'c', 'd'}
>>> a - b  # letters in a but not in b
{'r', 'd', 'b'}
>>> a | b  # letters in a or b or both
{'a', 'c', 'r', 'd', 'b', 'm', 'z', 'l'}
>>> a & b  # letters in both a and b
```
Similarly to list comprehensions, set comprehensions are also supported:

```python
>>> a = {x for x in 'abracadabra' if x not in 'abc'}
>>> a
{'r', 'd'}
```
5.5. Dictionaries

Another useful data type built into Python is the dictionary (see Mapping Types — dict). Dictionaries are sometimes found in other languages as “associative memories” or “associative arrays”. Unlike sequences, which are indexed by a range of numbers, dictionaries are indexed by keys, which can be any immutable type; strings and numbers can always be keys. Tuples can be used as keys if they contain only strings, numbers, or tuples; if a tuple contains any mutable object either directly or indirectly, it cannot be used as a key. You can’t use lists as keys, since lists can be modified in place using index assignments, slice assignments, or methods like append() and extend().

It is best to think of a dictionary as an unordered set of key: value pairs, with the requirement that the keys are unique (within one dictionary). A pair of braces creates an empty dictionary: `{}`. Placing a comma-separated list of key:value pairs within the braces adds initial key:value pairs to the dictionary; this is also the way dictionaries are written on output.

The main operations on a dictionary are storing a value with some key and extracting the value given the key. It is also possible to delete a key:value pair with del. If you store using a key that is already in use, the old value associated with that key is forgotten. It is an error to extract a value using a non-existent key.

Performing list(d.keys()) on a dictionary returns a list of all the keys used in the dictionary, in arbitrary order (if you want it sorted, just use sorted(d.keys()) instead). [2] To check whether a single key is in the dictionary, use the in keyword.
Here is a small example using a dictionary:

```python
>>> tel = {'jack': 4098, 'sape': 4139}
>>> tel['guido'] = 4127
>>> tel
{'sape': 4139, 'guido': 4127, 'jack': 4098}
>>> tel['jack']
4098
>>> del tel['sape']
>>> tel['irv'] = 4127
>>> tel
{'guido': 4127, 'irv': 4127, 'jack': 4098}
>>> list(tel.keys())
['irv', 'guido', 'jack']
>>> sorted(tel.keys())
['guido', 'irv', 'jack']
>>> 'guido' in tel
True
>>> 'jack' not in tel
False
```

The `dict()` constructor builds dictionaries directly from sequences of key-value pairs:

```python
>>> dict([( 'sape', 4139), ('guido', 4127), ('jack',
{ 'sape': 4139, 'jack': 4098, 'guido': 4127}
```

In addition, dict comprehensions can be used to create dictionaries from arbitrary key and value expressions:

```python
>>> {x: x**2 for x in (2, 4, 6)}
{2: 4, 4: 16, 6: 36}
```

When the keys are simple strings, it is sometimes easier to specify pairs using keyword arguments:
```
>>> dict(sape=4139, guido=4127, jack=4098)
{'sape': 4139, 'jack': 4098, 'guido': 4127}
```
5.6. Looping Techniques

When looping through dictionaries, the key and corresponding value can be retrieved at the same time using the `items()` method.

```python
>>> knights = {'gallahad': 'the pure', 'robin': 'the brave'}
>>> for k, v in knights.items():
...     print(k, v)
...gallahad the pure
robin the brave
```

When looping through a sequence, the position index and corresponding value can be retrieved at the same time using the `enumerate()` function.

```python
>>> for i, v in enumerate(['tic', 'tac', 'toe']):
...     print(i, v)
...0 tic
1 tac
2 toe
```

To loop over two or more sequences at the same time, the entries can be paired with the `zip()` function.

```python
>>> questions = ['name', 'quest', 'favorite color']
>>> answers = ['lancelot', 'the holy grail', 'blue']
>>> for q, a in zip(questions, answers):
...     print('What is your {0}? It is {1}.'.format(q, a))
...What is your name? It is lancelot.
What is your quest? It is the holy grail.
```
What is your favorite color? It is blue.

To loop over a sequence in reverse, first specify the sequence in a forward direction and then call the `reversed()` function.

```python
>>> for i in reversed(range(1, 10, 2)):
...     print(i)
9
7
5
3
1
```

To loop over a sequence in sorted order, use the `sorted()` function which returns a new sorted list while leaving the source unaltered.

```python
>>> basket = ['apple', 'orange', 'apple', 'pear', 'orange']
>>> for f in sorted(set(basket)):
...     print(f)
...     apple
banana
orange
pear
```

It is sometimes tempting to change a list while you are looping over it; however, it is often simpler and safer to create a new list instead.

```python
>>> import math
>>> raw_data = [56.2, float('NaN'), 51.7, 55.3, 52.5]
>>> filtered_data = []
>>> for value in raw_data:
...     if not math.isnan(value):
...         filtered_data.append(value):
```
>>> filtered_data
[56.2, 51.7, 55.3, 52.5, 47.8]
5.7. More on Conditions

The conditions used in while and if statements can contain any operators, not just comparisons.

The comparison operators in and not in check whether a value occurs (does not occur) in a sequence. The operators is and is not compare whether two objects are really the same object; this only matters for mutable objects like lists. All comparison operators have the same priority, which is lower than that of all numerical operators.

Comparisons can be chained. For example, a < b == c tests whether a is less than b and moreover b equals c.

Comparisons may be combined using the Boolean operators and and or, and the outcome of a comparison (or of any other Boolean expression) may be negated with not. These have lower priorities than comparison operators; between them, not has the highest priority and or the lowest, so that A and not B or C is equivalent to (A and (not B)) or C. As always, parentheses can be used to express the desired composition.

The Boolean operators and and or are so-called short-circuit operators: their arguments are evaluated from left to right, and evaluation stops as soon as the outcome is determined. For example, if A and C are true but B is false, A and B and C does not evaluate the expression C. When used as a general value and not as a Boolean, the return value of a short-circuit operator is the last evaluated argument.

It is possible to assign the result of a comparison or other Boolean
expression to a variable. For example,

```python
>>> string1, string2, string3 = '', 'Trondheim', 'Hammer Dance'
>>> non_null = string1 or string2 or string3
>>> non_null
'Trondheim'
```

Note that in Python, unlike C, assignment cannot occur inside expressions. C programmers may grumble about this, but it avoids a common class of problems encountered in C programs: typing `=` in an expression when `==` was intended.
5.8. Comparing Sequences and Other Types

Sequence objects may be compared to other objects with the same sequence type. The comparison uses lexicographical ordering: first the first two items are compared, and if they differ this determines the outcome of the comparison; if they are equal, the next two items are compared, and so on, until either sequence is exhausted. If two items to be compared are themselves sequences of the same type, the lexicographical comparison is carried out recursively. If all items of two sequences compare equal, the sequences are considered equal. If one sequence is an initial sub-sequence of the other, the shorter sequence is the smaller (lesser) one. Lexicographical ordering for strings uses the Unicode code point number to order individual characters. Some examples of comparisons between sequences of the same type:

```
(1, 2, 3) < (1, 2, 4)
[1, 2, 3] < [1, 2, 4]
'ABC' < 'C' < 'Pascal' < 'Python'
(1, 2, 3, 4) < (1, 2, 4)
(1, 2) < (1, 2, -1)
(1, 2, 3) == (1.0, 2.0, 3.0)
(1, 2, ('aa', 'ab')) < (1, 2, ('abc', 'a'), 4)
```

Note that comparing objects of different types with < or > is legal provided that the objects have appropriate comparison methods. For example, mixed numeric types are compared according to their numeric value, so 0 equals 0.0, etc. Otherwise, rather than providing an arbitrary ordering, the interpreter will raise a TypeError exception.
Footnotes

[1] Other languages may return the mutated object, which allows method chaining, such as `d->insert("a")-remove("b")->sort();`.

[2] Calling `d.keys()` will return a *dictionary view* object. It supports operations like membership test and iteration, but its contents are not independent of the original dictionary – it is only a *view*.
6. Modules

If you quit from the Python interpreter and enter it again, the definitions you have made (functions and variables) are lost. Therefore, if you want to write a somewhat longer program, you are better off using a text editor to prepare the input for the interpreter and running it with that file as input instead. This is known as creating a script. As your program gets longer, you may want to split it into several files for easier maintenance. You may also want to use a handy function that you’ve written in several programs without copying its definition into each program.

To support this, Python has a way to put definitions in a file and use them in a script or in an interactive instance of the interpreter. Such a file is called a module; definitions from a module can be imported into other modules or into the main module (the collection of variables that you have access to in a script executed at the top level and in calculator mode).

A module is a file containing Python definitions and statements. The file name is the module name with the suffix .py appended. Within a module, the module’s name (as a string) is available as the value of the global variable __name__. For instance, use your favorite text editor to create a file called fibo.py in the current directory with the following contents:

```python
# Fibonacci numbers module

def fib(n):  # write Fibonacci series up to n
    a, b = 0, 1
    while b < n:
        print(b, end=' ')
```

a, b = b, a+b
print()

def fib2(n):
    # return Fibonacci series up to n
    result = []
    a, b = 0, 1
    while b < n:
        result.append(b)
        a, b = b, a+b
    return result

Now enter the Python interpreter and import this module with the following command:

```python
>>> import fibo
```

This does not enter the names of the functions defined in fibo directly in the current symbol table; it only enters the module name fibo there. Using the module name you can access the functions:

```python
>>> fibo.fib(1000)
1 1 2 3 5 8 13 21 34 55 89 144 233 377 610 987
>>> fibo.fib2(100)
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
>>> fibo.__name__
'fibo'
```

If you intend to use a function often you can assign it to a local name:

```python
>>> fib = fibo.fib
>>> fib(500)
1 1 2 3 5 8 13 21 34 55 89 144 233 377```
6.1. More on Modules

A module can contain executable statements as well as function definitions. These statements are intended to initialize the module. They are executed only the first time the module name is encountered in an import statement. [1] (They are also run if the file is executed as a script.)

Each module has its own private symbol table, which is used as the global symbol table by all functions defined in the module. Thus, the author of a module can use global variables in the module without worrying about accidental clashes with a user's global variables. On the other hand, if you know what you are doing you can touch a module's global variables with the same notation used to refer to its functions, modname.itemname.

Modules can import other modules. It is customary but not required to place all import statements at the beginning of a module (or script, for that matter). The imported module names are placed in the importing module's global symbol table.

There is a variant of the import statement that imports names from a module directly into the importing module's symbol table. For example:

```
>>> from fibo import fib, fib2
>>> fib(500)
1 1 2 3 5 8 13 21 34 55 89 144 233 377
```

This does not introduce the module name from which the imports are taken in the local symbol table (so in the example, fibo is not defined).
There is even a variant to import all names that a module defines:

```python
>>> from fibo import *
>>> fib(500)
1 1 2 3 5 8 13 21 34 55 89 144 233 377
```

This imports all names except those beginning with an underscore (_). In most cases Python programmers do not use this facility since it introduces an unknown set of names into the interpreter, possibly hiding some things you have already defined.

Note that in general the practice of importing * from a module or package is frowned upon, since it often causes poorly readable code. However, it is okay to use it to save typing in interactive sessions.

**Note:** For efficiency reasons, each module is only imported once per interpreter session. Therefore, if you change your modules, you must restart the interpreter – or, if it’s just one module you want to test interactively, use `importlib.reload()`, e.g. `import importlib; importlib.reload(modulename)`.

### 6.1.1. Executing modules as scripts

When you run a Python module with

```bash
python fibo.py <arguments>
```

the code in the module will be executed, just as if you imported it, but with the `__name__` set to "`__main__". That means that by adding this code at the end of your module:

```python
if __name__ == '__main__':
    import sys
```
fib(int(sys.argv[1]))

you can make the file usable as a script as well as an importable module, because the code that parses the command line only runs if the module is executed as the “main” file:

```
$ python fibo.py 50
1 1 2 3 5 8 13 21 34
```

If the module is imported, the code is not run:

```
>>> import fibo

>>> 
```

This is often used either to provide a convenient user interface to a module, or for testing purposes (running the module as a script executes a test suite).

### 6.1.2. The Module Search Path

When a module named spam is imported, the interpreter first searches for a built-in module with that name. If not found, it then searches for a file named spam.py in a list of directories given by the variable sys.path. **sys.path** is initialized from these locations:

- The directory containing the input script (or the current directory when no file is specified).
- PYTHONPATH (a list of directory names, with the same syntax as the shell variable PATH).
- The installation-dependent default.

**Note:** On file systems which support symlinks, the directory containing the input script is calculated after the symlink is followed.
In other words the directory containing the symlink is not added to the module search path.

After initialization, Python programs can modify `sys.path`. The directory containing the script being run is placed at the beginning of the search path, ahead of the standard library path. This means that scripts in that directory will be loaded instead of modules of the same name in the library directory. This is an error unless the replacement is intended. See section **Standard Modules** for more information.

### 6.1.3. “Compiled” Python files

To speed up loading modules, Python caches the compiled version of each module in the `__pycache__` directory under the name `module.version.pyc`, where the version encodes the format of the compiled file; it generally contains the Python version number. For example, in CPython release 3.3 the compiled version of `spam.py` would be cached as `__pycache__/spam.cpython-33.pyc`. This naming convention allows compiled modules from different releases and different versions of Python to coexist.

Python checks the modification date of the source against the compiled version to see if it's out of date and needs to be recompiled. This is a completely automatic process. Also, the compiled modules are platform-independent, so the same library can be shared among systems with different architectures.

Python does not check the cache in two circumstances. First, it always recompiles and does not store the result for the module that's loaded directly from the command line. Second, it does not check the cache if there is no source module. To support a non-source (compiled only) distribution, the compiled module must be in the source directory, and
there must not be a source module.

Some tips for experts:

- You can use the `-O` or `-OO` switches on the Python command to reduce the size of a compiled module. The `-O` switch removes assert statements, the `-OO` switch removes both assert statements and `__doc__` strings. Since some programs may rely on having these available, you should only use this option if you know what you’re doing. “Optimized” modules have an opt- tag and are usually smaller. Future releases may change the effects of optimization.

- A program doesn’t run any faster when it is read from a `.pyc` file than when it is read from a `.py` file; the only thing that’s faster about `.pyc` files is the speed with which they are loaded.

- The module `compileall` can create `.pyc` files for all modules in a directory.

- There is more detail on this process, including a flow chart of the decisions, in PEP 3147.
6.2. Standard Modules

Python comes with a library of standard modules, described in a separate document, the Python Library Reference (“Library Reference” hereafter). Some modules are built into the interpreter; these provide access to operations that are not part of the core of the language but are nevertheless built in, either for efficiency or to provide access to operating system primitives such as system calls. The set of such modules is a configuration option which also depends on the underlying platform. For example, the `winreg` module is only provided on Windows systems. One particular module deserves some attention: `sys`, which is built into every Python interpreter. The variables `sys.ps1` and `sys.ps2` define the strings used as primary and secondary prompts:

```python
>>> import sys
>>> sys.ps1
'>>>
>>> sys.ps2
'...
>>> sys.ps1 = 'C> '  
C> print('Yuck!')
Yuck!
C>
```

These two variables are only defined if the interpreter is in interactive mode.

The variable `sys.path` is a list of strings that determines the interpreter’s search path for modules. It is initialized to a default path taken from the environment variable `PYTHONPATH`, or from a built-in default if `PYTHONPATH` is not set. You can modify it using standard list
operations:

```python
>>> import sys
>>> sys.path.append('/ufs/guido/lib/python')
```
6.3. The \texttt{dir()} Function

The built-in function \texttt{dir()} is used to find out which names a module defines. It returns a sorted list of strings:

\begin{verbatim}
>>> import fibo, sys
>>> dir(fibo)
['__name__', 'fib', 'fib2']
>>> dir(sys)
\end{verbatim}

Without arguments, \texttt{dir()} lists the names you have defined currently:

\begin{verbatim}
>>> a = [1, 2, 3, 4, 5]
>>> import fibo
>>> fib = fibo.fib
>>> dir()
['__builtins__', '__name__', 'a', 'fib', 'fibo', 'sys']
\end{verbatim}
Note that it lists all types of names: variables, modules, functions, etc.

dir() does not list the names of built-in functions and variables. If you want a list of those, they are defined in the standard module `builtins`:

```python
>>> import builtins
>>> dir(builtins)
```
6.4. Packages

Packages are a way of structuring Python’s module namespace by using “dotted module names”. For example, the module name `A.B` designates a submodule named `B` in a package named `A`. Just like the use of modules saves the authors of different modules from having to worry about each other’s global variable names, the use of dotted module names saves the authors of multi-module packages like NumPy or the Python Imaging Library from having to worry about each other’s module names.

Suppose you want to design a collection of modules (a “package”) for the uniform handling of sound files and sound data. There are many different sound file formats (usually recognized by their extension, for example: `.wav`, `.aiff`, `.au`), so you may need to create and maintain a growing collection of modules for the conversion between the various file formats. There are also many different operations you might want to perform on sound data (such as mixing, adding echo, applying an equalizer function, creating an artificial stereo effect), so in addition you will be writing a never-ending stream of modules to perform these operations. Here’s a possible structure for your package (expressed in terms of a hierarchical filesystem):

```
sound/
    __init__.py
    formats/
        __init__.py
        wavread.py
        wavwrite.py
        aiffread.py
        aiffwrite.py
        auread.py
```

Top-level package
Initialize the sound package
Subpackage for file formats
When importing the package, Python searches through the directories on `sys.path` looking for the package subdirectory.

The `__init__.py` files are required to make Python treat the directories as containing packages; this is done to prevent directories with a common name, such as `string`, from unintentionally hiding valid modules that occur later on the module search path. In the simplest case, `__init__.py` can just be an empty file, but it can also execute initialization code for the package or set the `__all__` variable, described later.

Users of the package can import individual modules from the package, for example:

```
import sound.effects.echo
```

This loads the submodule `sound.effects.echo`. It must be referenced with its full name.
An alternative way of importing the submodule is:

```python
from sound.effects import echo
```

This also loads the submodule echo, and makes it available without its package prefix, so it can be used as follows:

```python
echo.echofilter(input, output, delay=0.7, atten=4)
```

Yet another variation is to import the desired function or variable directly:

```python
from sound.effects.echo import echofilter
```

Again, this loads the submodule echo, but this makes its function `echofilter()` directly available:

```python
echofilter(input, output, delay=0.7, atten=4)
```

Note that when using `from package import item`, the item can be either a submodule (or subpackage) of the package, or some other name defined in the package, like a function, class or variable. The `import` statement first tests whether the item is defined in the package; if not, it assumes it is a module and attempts to load it. If it fails to find it, an `ImportError` exception is raised.

Contrarily, when using syntax like `import item.subitem.subsubitem`, each item except for the last must be a package; the last item can be a module or a package but can’t be a class or function or variable defined in the previous item.
6.4.1. Importing * From a Package

Now what happens when the user writes `from sound.effects import *`? Ideally, one would hope that this somehow goes out to the filesystem, finds which submodules are present in the package, and imports them all. This could take a long time and importing submodules might have unwanted side-effects that should only happen when the sub-module is explicitly imported.

The only solution is for the package author to provide an explicit index of the package. The `import` statement uses the following convention: if a package's `__init__.py` code defines a list named `__all__`, it is taken to be the list of module names that should be imported when `from package import *` is encountered. It is up to the package author to keep this list up-to-date when a new version of the package is released. Package authors may also decide not to support it, if they don't see a use for importing * from their package. For example, the file `sound/effects/__init__.py` could contain the following code:

```
__all__ = ["echo", "surround", "reverse"]
```

This would mean that `from sound.effects import *` would import the three named submodules of the sound package.

If `__all__` is not defined, the statement `from sound.effects import *` does not import all submodules from the package `sound.effects` into the current namespace; it only ensures that the package `sound.effects` has been imported (possibly running any initialization code in `__init__.py`) and then imports whatever names are defined in the package. This includes any names defined (and
submodules explicitly loaded) by `__init__.py`. It also includes any submodules of the package that were explicitly loaded by previous `import` statements. Consider this code:

```python
import sound.effects.echo
import sound.effects.surround
from sound.effects import *
```

In this example, the echo and surround modules are imported in the current namespace because they are defined in the `sound.effects` package when the `from...import` statement is executed. (This also works when `__all__` is defined.)

Although certain modules are designed to export only names that follow certain patterns when you use `import *`, it is still considered bad practice in production code.

Remember, there is nothing wrong with using `from Package import specific_submodule`! In fact, this is the recommended notation unless the importing module needs to use submodules with the same name from different packages.

### 6.4.2. Intra-package References

When packages are structured into subpackages (as with the `sound` package in the example), you can use absolute imports to refer to submodules of siblings packages. For example, if the module `sound.filters.vocoder` needs to use the echo module in the `sound.effects` package, it can use `from sound.effects import echo`.

You can also write relative imports, with the `from module import`
name form of import statement. These imports use leading dots to indicate the current and parent packages involved in the relative import. From the surrounding module for example, you might use:

```python
from . import echo
from .. import formats
from ..filters import equalizer
```

Note that relative imports are based on the name of the current module. Since the name of the main module is always "__main__", modules intended for use as the main module of a Python application must always use absolute imports.

### 6.4.3. Packages in Multiple Directories

Packages support one more special attribute, `__path__`. This is initialized to be a list containing the name of the directory holding the package's `__init__.py` before the code in that file is executed. This variable can be modified; doing so affects future searches for modules and subpackages contained in the package.

While this feature is not often needed, it can be used to extend the set of modules found in a package.

### Footnotes

[1] In fact function definitions are also 'statements' that are 'executed'; the execution of a module-level function definition enters the function name in the module's global symbol table.

7. Input and Output

There are several ways to present the output of a program; data can be printed in a human-readable form, or written to a file for future use. This chapter will discuss some of the possibilities.
7.1. Fancier Output Formatting

So far we've encountered two ways of writing values: expression statements and the `print()` function. (A third way is using the `write()` method of file objects; the standard output file can be referenced as `sys.stdout`. See the Library Reference for more information on this.)

Often you'll want more control over the formatting of your output than simply printing space-separated values. There are two ways to format your output; the first way is to do all the string handling yourself; using string slicing and concatenation operations you can create any layout you can imagine. The string type has some methods that perform useful operations for padding strings to a given column width; these will be discussed shortly. The second way is to use formatted string literals, or the `str.format()` method.

The `string` module contains a `Template` class which offers yet another way to substitute values into strings.

One question remains, of course: how do you convert values to strings? Luckily, Python has ways to convert any value to a string: pass it to the `repr()` or `str()` functions.

The `str()` function is meant to return representations of values which are fairly human-readable, while `repr()` is meant to generate representations which can be read by the interpreter (or will force a `SyntaxError` if there is no equivalent syntax). For objects which don't have a particular representation for human consumption, `str()` will return the same value as `repr()`. Many values, such as numbers or structures like lists and dictionaries, have the same representation
using either function. Strings, in particular, have two distinct representations.

Some examples:

```python
>>> s = 'Hello, world.'
>>> str(s)
'Hello, world.'
>>> repr(s)
"'Hello, world.'"
>>> str(1/7)
'0.14285714285714285'
>>> x = 10 * 3.25
>>> y = 200 * 200
>>> s = 'The value of x is ' + repr(x) + ', and y is ' + repr(y) + '.
>>> print(s)
The value of x is 32.5, and y is 40000...
>>> # The repr() of a string adds string quotes and \n
... hello = 'hello, world\n'
>>> hellos = repr(hello)
>>> print(hellos)
'hello, world\n'
>>> # The argument to repr() may be any Python object
... repr((x, y, ('spam', 'eggs')))
'(32.5, 40000, ('spam', 'eggs'))'
```

Here are two ways to write a table of squares and cubes:

```python
>>> for x in range(1, 11):
...     print(repr(x).rjust(2), repr(x*x).rjust(3),
...            # Note use of 'end' on previous line
...     print(repr(x**x).rjust(4))
...
1  1  1
2  4  8
3  9 27
```
(Note that in the first example, one space between each column was added by the way print() works: it always adds spaces between its arguments.)

This example demonstrates the str.rjust() method of string objects, which right-justifies a string in a field of a given width by padding it with spaces on the left. There are similar methods str.ljust() and str.center(). These methods do not write anything, they just return a new string. If the input string is too long, they don’t truncate it, but return it unchanged; this will mess up your column lay-out but that’s usually better than the alternative, which would be lying about a value. (If you really want truncation you can
always add a slice operation, as in \texttt{x.ljust(n)[:n].}

There is another method, \texttt{str.zfill()}, which pads a numeric string on the left with zeros. It understands about plus and minus signs:

```python
>>> '12'.zfill(5)
'00012'
>>> '-3.14'.zfill(7)
'-003.14'
>>> '3.14159265359'.zfill(5)
'3.14159265359'
```

Basic usage of the \texttt{str.format()} method looks like this:

```python
>>> print('We are the {} who say "{}!"'.format('knights', 'Ni!'))
We are the knights who say "Ni!"
```

The brackets and characters within them (called format fields) are replaced with the objects passed into the \texttt{str.format()} method. A number in the brackets can be used to refer to the position of the object passed into the \texttt{str.format()} method.

```python
>>> print('{0} and {1}'.format('spam', 'eggs'))
spam and eggs
>>> print('{1} and {0}'.format('spam', 'eggs'))
eggs and spam
```

If keyword arguments are used in the \texttt{str.format()} method, their values are referred to by using the name of the argument.

```python
>>> print('This {food} is {adjective}.'.format(...
  food='spam', adjective='absolutely horrible'))
This spam is absolutely horrible.
```
Positional and keyword arguments can be arbitrarily combined:

```python
>>> print('The story of {0}, {1}, and {other}.').format(Bill, Manfred, other=Georg)
The story of Bill, Manfred, and Georg.
```

'!a' (apply `ascii()`), '!s' (apply `str()`) and '!r' (apply `repr()`) can be used to convert the value before it is formatted:

```python
>>> contents = 'eels'
>>> print('My hovercraft is full of {}'.format(contents))
My hovercraft is full of eels.
>>> print('My hovercraft is full of {!r}'.format(contents))
My hovercraft is full of 'eels'.
```

An optional `:' and format specifier can follow the field name. This allows greater control over how the value is formatted. The following example rounds Pi to three places after the decimal.

```python
>>> import math
>>> print('The value of PI is approximately {0:.3f}'.format(math.pi))
The value of PI is approximately 3.142.
```

Passing an integer after the `:' will cause that field to be a minimum number of characters wide. This is useful for making tables pretty.

```python
>>> table = {'Sjoerd': 4127, 'Jack': 4098, 'Dcab': 7678}
>>> for name, phone in table.items():
...     print('{0:10} ==> {1:10d}'.format(name, phone))
... Jack ==> 4098
... Dcab ==> 7678
... Sjoerd ==> 4127
```
If you have a really long format string that you don’t want to split up, it would be nice if you could reference the variables to be formatted by name instead of by position. This can be done by simply passing the dict and using square brackets `[[]]` to access the keys

```python
>>> table = {'Sjoerd': 4127, 'Jack': 4098, 'Dcab': 8637678}
... print('Jack: {0[Jack]:d}; Sjoerd: {0[Sjoerd]:d}; Dcab: {0[Dcab]:d}'.format(table))
Jack: 4098; Sjoerd: 4127; Dcab: 8637678
```

This could also be done by passing the table as keyword arguments with the `**` notation.

```python
>>> table = {'Sjoerd': 4127, 'Jack': 4098, 'Dcab': 8637678}
... print('Jack: {Jack:d}; Sjoerd: {Sjoerd:d}; Dcab: {Dcab:d}'.format(**table))
Jack: 4098; Sjoerd: 4127; Dcab: 8637678
```

This is particularly useful in combination with the built-in function `vars()`, which returns a dictionary containing all local variables.

For a complete overview of string formatting with `str.format()`, see [Format String Syntax](https://docs.python.org/3/library/string.html#formatstrings).

### 7.1.1. Old string formatting

The `%` operator can also be used for string formatting. It interprets the left argument much like a `sprintf()`-style format string to be applied to the right argument, and returns the string resulting from this formatting operation. For example:

```python
>>> table = {'Sjoerd': 4127, 'Jack': 4098, 'Dcab': 8637678}
... print('Jack: %d; Sjoerd: %d; Dcab: %d'.format(**table))
Jack: 4098; Sjoerd: 4127; Dcab: 8637678
```
```python
>>> import math
>>> print('The value of PI is approximately %5.3f.'
The value of PI is approximately 3.142.
```

More information can be found in the `printf-style String Formatting` section.
7.2. Reading and Writing Files

`open()` returns a file object, and is most commonly used with two arguments: `open(filename, mode)`.

```python
>>> f = open('workfile', 'w')
```

The first argument is a string containing the filename. The second argument is another string containing a few characters describing the way in which the file will be used. `mode` can be `'r'` when the file will only be read, `'w'` for only writing (an existing file with the same name will be erased), and `'a'` opens the file for appending; any data written to the file is automatically added to the end. `'r+'` opens the file for both reading and writing. The `mode` argument is optional; `'r'` will be assumed if it’s omitted.

Normally, files are opened in text mode, that means, you read and write strings from and to the file, which are encoded in a specific encoding. If encoding is not specified, the default is platform dependent (see `open()`). `'b'` appended to the mode opens the file in binary mode: now the data is read and written in the form of bytes objects. This mode should be used for all files that don’t contain text.

In text mode, the default when reading is to convert platform-specific line endings (`\n` on Unix, `\r\n` on Windows) to just `\n`. When writing in text mode, the default is to convert occurrences of `\n` back to platform-specific line endings. This behind-the-scenes modification to file data is fine for text files, but will corrupt binary data like that in JPEG or EXE files. Be very careful to use binary mode when reading and writing such files.
It is good practice to use the `with` keyword when dealing with file objects. The advantage is that the file is properly closed after its suite finishes, even if an exception is raised at some point. Using `with` is also much shorter than writing equivalent `try-finally` blocks:

```python
>>> with open('workfile') as f:
...     read_data = f.read()
>>> f.closed
True
```

If you’re not using the `with` keyword, then you should call `f.close()` to close the file and immediately free up any system resources used by it. If you don’t explicitly close a file, Python’s garbage collector will eventually destroy the object and close the open file for you, but the file may stay open for a while. Another risk is that different Python implementations will do this clean-up at different times.

After a file object is closed, either by a `with` statement or by calling `f.close()`, attempts to use the file object will automatically fail.

```python
>>> f.close()
>>> f.read()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: I/O operation on closed file
```

### 7.2.1. Methods of File Objects

The rest of the examples in this section will assume that a file object called `f` has already been created.

To read a file's contents, call `f.read(size)`, which reads some
quantity of data and returns it as a string (in text mode) or bytes object (in binary mode). size is an optional numeric argument. When size is omitted or negative, the entire contents of the file will be read and returned; it’s your problem if the file is twice as large as your machine’s memory. Otherwise, at most size bytes are read and returned. If the end of the file has been reached, f.read() will return an empty string ('').

```python
>>> f.read()
'This is the entire file.
' >>> f.read()
''
```

f.readline() reads a single line from the file; a newline character (\n) is left at the end of the string, and is only omitted on the last line of the file if the file doesn’t end in a newline. This makes the return value unambiguous; if f.readline() returns an empty string, the end of the file has been reached, while a blank line is represented by '\n', a string containing only a single newline.

```python
>>> f.readline()
'This is the first line of the file.
' >>> f.readline()
'Second line of the file
' >>> f.readline()
''
```

For reading lines from a file, you can loop over the file object. This is memory efficient, fast, and leads to simple code:

```python
>>> for line in f:
...     print(line, end='')
...
This is the first line of the file.
```
If you want to read all the lines of a file in a list you can also use `list(f)` or `f.readlines()`.

`f.write(string)` writes the contents of `string` to the file, returning the number of characters written.

```python
>>> f.write('This is a test\n')
15
```

Other types of objects need to be converted – either to a string (in text mode) or a bytes object (in binary mode) – before writing them:

```python
>>> value = ('the answer', 42)
>>> s = str(value)  # convert the tuple to string
>>> f.write(s)
18
```

`f.tell()` returns an integer giving the file object’s current position in the file represented as number of bytes from the beginning of the file when in binary mode and an opaque number when in text mode.

To change the file object’s position, use `f.seek(offset, from_what)`. The position is computed from adding `offset` to a reference point; the reference point is selected by the `from_what` argument. A `from_what` value of 0 measures from the beginning of the file, 1 uses the current file position, and 2 uses the end of the file as the reference point. `from_what` can be omitted and defaults to 0, using the beginning of the file as the reference point.

```python
>>> f = open('workfile', 'rb+')
>>> f.write(b'0123456789abcdef')
16
```
>>> f.seek(5)  # Go to the 6th byte in the file
5
>>> f.read(1)
b'5'
>>> f.seek(-3, 2)  # Go to the 3rd byte before the end
13
>>> f.read(1)
b'd'

In text files (those opened without a b in the mode string), only seeks relative to the beginning of the file are allowed (the exception being seeking to the very file end with seek(0, 2)) and the only valid offset values are those returned from the f.tell(), or zero. Any other offset value produces undefined behaviour.

File objects have some additional methods, such as isatty() and truncate() which are less frequently used; consult the Library Reference for a complete guide to file objects.

7.2.2. Saving structured data with json

Strings can easily be written to and read from a file. Numbers take a bit more effort, since the read() method only returns strings, which will have to be passed to a function like int(), which takes a string like '123' and returns its numeric value 123. When you want to save more complex data types like nested lists and dictionaries, parsing and serializing by hand becomes complicated.

Rather than having users constantly writing and debugging code to save complicated data types to files, Python allows you to use the popular data interchange format called JSON (JavaScript Object Notation). The standard module called json can take Python data
hierarchies, and convert them to string representations; this process is called **serializing**. Reconstructing the data from the string representation is called **deserializing**. Between serializing and deserializing, the string representing the object may have been stored in a file or data, or sent over a network connection to some distant machine.

**Note:** The JSON format is commonly used by modern applications to allow for data exchange. Many programmers are already familiar with it, which makes it a good choice for interoperability.

If you have an object `x`, you can view its JSON string representation with a simple line of code:

```python
>>> import json
>>> json.dumps([1, 'simple', 'list'])
'[1, "simple", "list"]'
```

Another variant of the `dumps()` function, called `dump()`, simply serializes the object to a text file. So if `f` is a text file object opened for writing, we can do this:

```python
json.dump(x, f)
```

To decode the object again, if `f` is a text file object which has been opened for reading:

```python
x = json.load(f)
```

This simple serialization technique can handle lists and dictionaries, but serializing arbitrary class instances in JSON requires a bit of extra effort. The reference for the `json` module contains an explanation of
See also: pickle - the pickle module

Contrary to JSON, pickle is a protocol which allows the serialization of arbitrarily complex Python objects. As such, it is specific to Python and cannot be used to communicate with applications written in other languages. It is also insecure by default: deserializing pickle data coming from an untrusted source can execute arbitrary code, if the data was crafted by a skilled attacker.
8. Errors and Exceptions

Until now error messages haven’t been more than mentioned, but if you have tried out the examples you have probably seen some. There are (at least) two distinguishable kinds of errors: syntax errors and exceptions.
8.1. Syntax Errors

Syntax errors, also known as parsing errors, are perhaps the most common kind of complaint you get while you are still learning Python:

```python
>>> while True print('Hello world')
File "<stdin>", line 1
    while True print('Hello world')
^  
SyntaxError: invalid syntax
```

The parser repeats the offending line and displays a little ‘arrow’ pointing at the earliest point in the line where the error was detected. The error is caused by (or at least detected at) the token preceding the arrow: in the example, the error is detected at the function `print()`, since a colon (':') is missing before it. File name and line number are printed so you know where to look in case the input came from a script.
8.2. Exceptions

Even if a statement or expression is syntactically correct, it may cause an error when an attempt is made to execute it. Errors detected during execution are called *exceptions* and are not unconditionally fatal: you will soon learn how to handle them in Python programs. Most exceptions are not handled by programs, however, and result in error messages as shown here:

```python
>>> 10 * (1/0)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ZeroDivisionError: division by zero
>>> 4 + spam*3
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
NameError: name 'spam' is not defined
>>> '2' + 2
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: Can't convert 'int' object to str implicitly
```

The last line of the error message indicates what happened. Exceptions come in different types, and the type is printed as part of the message: the types in the example are `ZeroDivisionError`, `NameError` and `TypeError`. The string printed as the exception type is the name of the built-in exception that occurred. This is true for all built-in exceptions, but need not be true for user-defined exceptions (although it is a useful convention). Standard exception names are built-in identifiers (not reserved keywords).

The rest of the line provides detail based on the type of exception and
what caused it.

The preceding part of the error message shows the context where the exception happened, in the form of a stack traceback. In general it contains a stack traceback listing source lines; however, it will not display lines read from standard input.

**Built-in Exceptions** lists the built-in exceptions and their meanings.
8.3. Handling Exceptions

It is possible to write programs that handle selected exceptions. Look at the following example, which asks the user for input until a valid integer has been entered, but allows the user to interrupt the program (using Control-C or whatever the operating system supports); note that a user-generated interruption is signalled by raising the `KeyboardInterrupt` exception.

```python
>>> while True:
    try:
    ...
        x = int(input("Please enter a number: "))
    ...
        break
    ...
    except ValueError:
    ...
        print("Oops! That was no valid number.")
```

The `try` statement works as follows.

- First, the `try clause` (the statement(s) between the `try` and `except` keywords) is executed.
- If no exception occurs, the `except clause` is skipped and execution of the `try` statement is finished.
- If an exception occurs during execution of the try clause, the rest of the clause is skipped. Then if its type matches the exception named after the `except` keyword, the except clause is executed, and then execution continues after the `try` statement.
- If an exception occurs which does not match the exception named in the except clause, it is passed on to outer `try` statements; if no handler is found, it is an `unhandled exception` and execution stops with a message as shown above.
A `try` statement may have more than one except clause, to specify handlers for different exceptions. At most one handler will be executed. Handlers only handle exceptions that occur in the corresponding try clause, not in other handlers of the same `try` statement. An except clause may name multiple exceptions as a parenthesized tuple, for example:

```python
... except (RuntimeError, TypeError, NameError):
    pass
```

A class in an `except` clause is compatible with an exception if it is the same class or a base class thereof (but not the other way around — an except clause listing a derived class is not compatible with a base class). For example, the following code will print B, C, D in that order:

```python
class B(Exception):
    pass

class C(B):
    pass

class D(C):
    pass

for cls in [B, C, D]:
    try:
        raise cls()
    except D:
        print("D")
    except C:
        print("C")
    except B:
        print("B")
```

Note that if the except clauses were reversed (with `except B` first), it
would have printed B, B, B — the first matching except clause is triggered.

The last except clause may omit the exception name(s), to serve as a wildcard. Use this with extreme caution, since it is easy to mask a real programming error in this way! It can also be used to print an error message and then re-raise the exception (allowing a caller to handle the exception as well):

```python
import sys

try:
    f = open('myfile.txt')
    s = f.readline()
    i = int(s.strip())
except OSError as err:
    print("OS error: {0}".format(err))
except ValueError:
    print("Could not convert data to an integer.")
except:
    print("Unexpected error:", sys.exc_info()[0])
raise
```

The `try ... except` statement has an optional `else` clause, which, when present, must follow all except clauses. It is useful for code that must be executed if the try clause does not raise an exception. For example:

```python
for arg in sys.argv[1:]:
    try:
        f = open(arg, 'r')
    except OSError:
        print('cannot open', arg)
    else:
        print(arg, 'has', len(f.readlines()), 'lines')
```
The use of the `else` clause is better than adding additional code to the `try` clause because it avoids accidentally catching an exception that wasn’t raised by the code being protected by the `try ... except` statement.

When an exception occurs, it may have an associated value, also known as the exception’s `argument`. The presence and type of the argument depend on the exception type.

The except clause may specify a variable after the exception name. The variable is bound to an exception instance with the arguments stored in `instance.args`. For convenience, the exception instance defines `__str__()` so the arguments can be printed directly without having to reference `.args`. One may also instantiate an exception first before raising it and add any attributes to it as desired.

```python
>>> try:
...     raise Exception('spam', 'eggs')
... except Exception as inst:
...     print(type(inst))  # the exception instance
...     print(inst.args)   # arguments stored in .args
...     print(inst)        # __str__ allows args to be printed directly
...     x, y = inst.args   # unpack args
...     print('x =', x)    # but may be overridden
...     print('y =', y)
...<class 'Exception'>
('spam', 'eggs')
('spam', 'eggs')
x = spam
y = eggs
```
If an exception has arguments, they are printed as the last part ('detail') of the message for unhandled exceptions.

Exception handlers don't just handle exceptions if they occur immediately in the try clause, but also if they occur inside functions that are called (even indirectly) in the try clause. For example:

```python
>>> def this_fails():
    ...     x = 1/0
    ...     print('Handling run-time error: division by zero')

>>> try:
    ...     this_fails()
    ... except ZeroDivisionError as err:
    ...     print('Handling run-time error:', err)
```

```
Handling run-time error: division by zero
```
8.4. Raising Exceptions

The `raise` statement allows the programmer to force a specified exception to occur. For example:

```python
>>> raise NameError('HiThere')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
NameError: HiThere
```

The sole argument to `raise` indicates the exception to be raised. This must be either an exception instance or an exception class (a class that derives from `Exception`). If an exception class is passed, it will be implicitly instantiated by calling its constructor with no arguments:

```python
raise ValueError  # shorthand for 'raise ValueError()
```

If you need to determine whether an exception was raised but don't intend to handle it, a simpler form of the `raise` statement allows you to re-raise the exception:

```python
>>> try:
...   raise NameError('HiThere')
... except NameError:
...   print('An exception flew by!')
... raise

An exception flew by!
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
NameError: HiThere
```
8.5. User-defined Exceptions

Programs may name their own exceptions by creating a new exception class (see Classes for more about Python classes). Exceptions should typically be derived from the Exception class, either directly or indirectly.

Exception classes can be defined which do anything any other class can do, but are usually kept simple, often only offering a number of attributes that allow information about the error to be extracted by handlers for the exception. When creating a module that can raise several distinct errors, a common practice is to create a base class for exceptions defined by that module, and subclass that to create specific exception classes for different error conditions:

```python
class Error(Exception):
    """Base class for exceptions in this module.""
    pass

class InputError(Error):
    """Exception raised for errors in the input.
    Attributes:
    expression -- input expression in which the error occurred
    message -- explanation of the error"

def __init__(self, expression, message):
    self.expression = expression
    self.message = message

class TransitionError(Error):
    """Raised when an operation attempts a state transition that is not allowed.""
```
Most exceptions are defined with names that end in “Error,” similar to the naming of the standard exceptions.

Many standard modules define their own exceptions to report errors that may occur in functions they define. More information on classes is presented in chapter **Classes**.
8.6. Defining Clean-up Actions

The `try` statement has another optional clause which is intended to define clean-up actions that must be executed under all circumstances. For example:

```python
>>> try:
...     raise KeyboardInterrupt
... finally:
...     print('Goodbye, world!')
...
Goodbye, world!
KeyboardInterrupt
Traceback (most recent call last):
  File "<stdin>", line 2, in <module>
```

A *finally clause* is always executed before leaving the `try` statement, whether an exception has occurred or not. When an exception has occurred in the `try` clause and has not been handled by an `except` clause (or it has occurred in an `except` or `else` clause), it is re-raised after the `finally` clause has been executed. The `finally` clause is also executed “on the way out” when any other clause of the `try` statement is left via a `break`, `continue` or `return` statement.

A more complicated example:

```python
>>> def divide(x, y):
...     try:
...         result = x / y
...     except ZeroDivisionError:
...         print("division by zero!")
...     else:
...         print("result is", result)
... finally:
```
As you can see, the `finally` clause is executed in any event. The `TypeError` raised by dividing two strings is not handled by the `except` clause and therefore re-raised after the `finally` clause has been executed.

In real world applications, the `finally` clause is useful for releasing external resources (such as files or network connections), regardless of whether the use of the resource was successful.
8.7. Predefined Clean-up Actions

Some objects define standard clean-up actions to be undertaken when the object is no longer needed, regardless of whether or not the operation using the object succeeded or failed. Look at the following example, which tries to open a file and print its contents to the screen.

```python
for line in open("myfile.txt"):
    print(line, end="")
```

The problem with this code is that it leaves the file open for an indeterminate amount of time after this part of the code has finished executing. This is not an issue in simple scripts, but can be a problem for larger applications. The `with` statement allows objects like files to be used in a way that ensures they are always cleaned up promptly and correctly.

```python
with open("myfile.txt") as f:
    for line in f:
        print(line, end="")
```

After the statement is executed, the file `f` is always closed, even if a problem was encountered while processing the lines. Objects which, like files, provide predefined clean-up actions will indicate this in their documentation.
9. Classes

Classes provide a means of bundling data and functionality together. Creating a new class creates a new type of object, allowing new instances of that type to be made. Each class instance can have attributes attached to it for maintaining its state. Class instances can also have methods (defined by its class) for modifying its state.

Compared with other programming languages, Python’s class mechanism adds classes with a minimum of new syntax and semantics. It is a mixture of the class mechanisms found in C++ and Modula-3. Python classes provide all the standard features of Object Oriented Programming: the class inheritance mechanism allows multiple base classes, a derived class can override any methods of its base class or classes, and a method can call the method of a base class with the same name. Objects can contain arbitrary amounts and kinds of data. As is true for modules, classes partake of the dynamic nature of Python: they are created at runtime, and can be modified further after creation.

In C++ terminology, normally class members (including the data members) are public (except see below Private Variables), and all member functions are virtual. As in Modula-3, there are no shorthands for referencing the object’s members from its methods: the method function is declared with an explicit first argument representing the object, which is provided implicitly by the call. As in Smalltalk, classes themselves are objects. This provides semantics for importing and renaming. Unlike C++ and Modula-3, built-in types can be used as base classes for extension by the user. Also, like in C++, most built-in operators with special syntax (arithmetic operators, subscripting etc.) can be redefined for class instances.
(Lacking universally accepted terminology to talk about classes, I will make occasional use of Smalltalk and C++ terms. I would use Modula-3 terms, since its object-oriented semantics are closer to those of Python than C++, but I expect that few readers have heard of it.)
Objects have individuality, and multiple names (in multiple scopes) can be bound to the same object. This is known as aliasing in other languages. This is usually not appreciated on a first glance at Python, and can be safely ignored when dealing with immutable basic types (numbers, strings, tuples). However, aliasing has a possibly surprising effect on the semantics of Python code involving mutable objects such as lists, dictionaries, and most other types. This is usually used to the benefit of the program, since aliases behave like pointers in some respects. For example, passing an object is cheap since only a pointer is passed by the implementation; and if a function modifies an object passed as an argument, the caller will see the change — this eliminates the need for two different argument passing mechanisms as in Pascal.
9.2. Python Scopes and Namespaces

Before introducing classes, I first have to tell you something about Python’s scope rules. Class definitions play some neat tricks with namespaces, and you need to know how scopes and namespaces work to fully understand what’s going on. Incidentally, knowledge about this subject is useful for any advanced Python programmer.

Let’s begin with some definitions.

A namespace is a mapping from names to objects. Most namespaces are currently implemented as Python dictionaries, but that’s normally not noticeable in any way (except for performance), and it may change in the future. Examples of namespaces are: the set of built-in names (containing functions such as `abs()`), and built-in exception names; the global names in a module; and the local names in a function invocation. In a sense the set of attributes of an object also form a namespace. The important thing to know about namespaces is that there is absolutely no relation between names in different namespaces; for instance, two different modules may both define a function `maximize` without confusion — users of the modules must prefix it with the module name.

By the way, I use the word attribute for any name following a dot — for example, in the expression `z.real`, `real` is an attribute of the object `z`. Strictly speaking, references to names in modules are attribute references: in the expression `modname.funcname`, `modname` is a module object and `funcname` is an attribute of it. In this case there happens to be a straightforward mapping between the module’s attributes and the global names defined in the module: they share the same namespace! [1]
Attributes may be read-only or writable. In the latter case, assignment to attributes is possible. Module attributes are writable: you can write `modname.the_answer = 42`. Writable attributes may also be deleted with the `del` statement. For example, `del modname.the_answer` will remove the attribute `the_answer` from the object named by `modname`.

Namespaces are created at different moments and have different lifetimes. The namespace containing the built-in names is created when the Python interpreter starts up, and is never deleted. The global namespace for a module is created when the module definition is read in; normally, module namespaces also last until the interpreter quits. The statements executed by the top-level invocation of the interpreter, either read from a script file or interactively, are considered part of a module called `__main__`, so they have their own global namespace. (The built-in names actually also live in a module; this is called `builtins`.)

The local namespace for a function is created when the function is called, and deleted when the function returns or raises an exception that is not handled within the function. (Actually, forgetting would be a better way to describe what actually happens.) Of course, recursive invocations each have their own local namespace.

A **scope** is a textual region of a Python program where a namespace is directly accessible. “Directly accessible” here means that an unqualified reference to a name attempts to find the name in the namespace.

Although scopes are determined statically, they are used dynamically. At any time during execution, there are at least three nested scopes whose namespaces are directly accessible:
• the innermost scope, which is searched first, contains the local names
• the scopes of any enclosing functions, which are searched starting with the nearest enclosing scope, contains non-local, but also non-global names
• the next-to-last scope contains the current module’s global names
• the outermost scope (searched last) is the namespace containing built-in names

If a name is declared global, then all references and assignments go directly to the middle scope containing the module’s global names. To rebind variables found outside of the innermost scope, the nonlocal statement can be used; if not declared nonlocal, those variables are read-only (an attempt to write to such a variable will simply create a new local variable in the innermost scope, leaving the identically named outer variable unchanged).

Usually, the local scope references the local names of the (textually) current function. Outside functions, the local scope references the same namespace as the global scope: the module’s namespace. Class definitions place yet another namespace in the local scope.

It is important to realize that scopes are determined textually: the global scope of a function defined in a module is that module’s namespace, no matter from where or by what alias the function is called. On the other hand, the actual search for names is done dynamically, at run time — however, the language definition is evolving towards static name resolution, at “compile” time, so don’t rely on dynamic name resolution! (In fact, local variables are already determined statically.)

A special quirk of Python is that – if no global statement is in effect – assignments to names always go into the innermost scope.
Assignments do not copy data — they just bind names to objects. The same is true for deletions: the statement `del x` removes the binding of `x` from the namespace referenced by the local scope. In fact, all operations that introduce new names use the local scope: in particular, `import` statements and function definitions bind the module or function name in the local scope.

The `global` statement can be used to indicate that particular variables live in the global scope and should be rebound there; the `nonlocal` statement indicates that particular variables live in an enclosing scope and should be rebound there.

### 9.2.1. Scopes and Namespaces Example

This is an example demonstrating how to reference the different scopes and namespaces, and how `global` and `nonlocal` affect variable binding:

```python
def scope_test():
    def do_local():
        spam = "local spam"

    def do_nonlocal():
        nonlocal spam
        spam = "nonlocal spam"

    def do_global():
        global spam
        spam = "global spam"

    spam = "test spam"
    do_local()
    print("After local assignment:", spam)
    do_nonlocal()
```

```
```python
print("After nonlocal assignment:", spam)
do_global()  
print("After global assignment:", spam)

scope_test()  
print("In global scope:", spam)
```

The output of the example code is:

```
After local assignment: test spam  
After nonlocal assignment: nonlocal spam  
After global assignment: nonlocal spam  
In global scope: global spam
```

Note how the `local` assignment (which is default) didn’t change `scope_test`'s binding of `spam`. The `nonlocal` assignment changed `scope_test`'s binding of `spam`, and the `global` assignment changed the module-level binding.

You can also see that there was no previous binding for `spam` before the `global` assignment.
9.3. A First Look at Classes

Classes introduce a little bit of new syntax, three new object types, and some new semantics.

9.3.1. Class Definition Syntax

The simplest form of class definition looks like this:

```python
class ClassName:
    <statement-1>
    ...
    ...
    <statement-N>
```

Class definitions, like function definitions (def statements) must be executed before they have any effect. (You could conceivably place a class definition in a branch of an if statement, or inside a function.)

In practice, the statements inside a class definition will usually be function definitions, but other statements are allowed, and sometimes useful — we’ll come back to this later. The function definitions inside a class normally have a peculiar form of argument list, dictated by the calling conventions for methods — again, this is explained later.

When a class definition is entered, a new namespace is created, and used as the local scope — thus, all assignments to local variables go into this new namespace. In particular, function definitions bind the name of the new function here.

When a class definition is left normally (via the end), a class object is
created. This is basically a wrapper around the contents of the namespace created by the class definition; we'll learn more about class objects in the next section. The original local scope (the one in effect just before the class definition was entered) is reinstated, and the class object is bound here to the class name given in the class definition header (ClassName in the example).

9.3.2. Class Objects

Class objects support two kinds of operations: attribute references and instantiation.

Attribute references use the standard syntax used for all attribute references in Python: `obj.name`. Valid attribute names are all the names that were in the class's namespace when the class object was created. So, if the class definition looked like this:

```python
class MyClass:
    """A simple example class""
    i = 12345

def f(self):
    return 'hello world'
```

then `MyClass.i` and `MyClass.f` are valid attribute references, returning an integer and a function object, respectively. Class attributes can also be assigned to, so you can change the value of `MyClass.i` by assignment. `__doc__` is also a valid attribute, returning the docstring belonging to the class: "A simple example class".

Class instantiation uses function notation. Just pretend that the class object is a parameterless function that returns a new instance of the
class. For example (assuming the above class):

```
x = MyClass()
```

creates a new `instance` of the class and assigns this object to the local variable `x`.

The instantiation operation (“calling” a class object) creates an empty object. Many classes like to create objects with instances customized to a specific initial state. Therefore a class may define a special method named `__init__()`, like this:

```
def __init__(self):
    self.data = []
```

When a class defines an `__init__()` method, class instantiation automatically invokes `__init__()` for the newly-created class instance. So in this example, a new, initialized instance can be obtained by:

```
x = MyClass()
```

Of course, the `__init__()` method may have arguments for greater flexibility. In that case, arguments given to the class instantiation operator are passed on to `__init__()`. For example,

```
>>> class Complex:
...     def __init__(self, realpart, imagpart):
...         self.r = realpart
...         self.i = imagpart
...
>>> x = Complex(3.0, -4.5)
>>> x.r, x.i
(3.0, -4.5)
```
9.3.3. Instance Objects

Now what can we do with instance objects? The only operations understood by instance objects are attribute references. There are two kinds of valid attribute names, data attributes and methods.

*Data attributes* correspond to “instance variables” in Smalltalk, and to “data members” in C++. Data attributes need not be declared; like local variables, they spring into existence when they are first assigned to. For example, if \( x \) is the instance of `MyClass` created above, the following piece of code will print the value 16, without leaving a trace:

```python
x.counter = 1
while x.counter < 10:
    x.counter = x.counter * 2
print(x.counter)
```

The other kind of instance attribute reference is a *method*. A method is a function that “belongs to” an object. (In Python, the term method is not unique to class instances: other object types can have methods as well. For example, list objects have methods called append, insert, remove, sort, and so on. However, in the following discussion, we’ll use the term method exclusively to mean methods of class instance objects, unless explicitly stated otherwise.)

Valid method names of an instance object depend on its class. By definition, all attributes of a class that are function objects define corresponding methods of its instances. So in our example, \( x.f \) is a valid method reference, since `MyClass.f` is a function, but \( x.i \) is not, since `MyClass.i` is not. But \( x.f \) is not the same thing as
MyClass.f — it is a method object, not a function object.

9.3.4. Method Objects

Usually, a method is called right after it is bound:

```
x.f()
```

In the MyClass example, this will return the string 'hello world'. However, it is not necessary to call a method right away: x.f is a method object, and can be stored away and called at a later time. For example:

```
xf = x.f
while True:
    print(xf())
```

will continue to print hello world until the end of time.

What exactly happens when a method is called? You may have noticed that x.f() was called without an argument above, even though the function definition for f() specified an argument. What happened to the argument? Surely Python raises an exception when a function that requires an argument is called without any — even if the argument isn’t actually used…

Actually, you may have guessed the answer: the special thing about methods is that the instance object is passed as the first argument of the function. In our example, the call x.f() is exactly equivalent to MyClass.f(x). In general, calling a method with a list of n arguments is equivalent to calling the corresponding function with an argument list that is created by inserting the method’s instance object...
before the first argument.

If you still don’t understand how methods work, a look at the implementation can perhaps clarify matters. When an instance attribute is referenced that isn’t a data attribute, its class is searched. If the name denotes a valid class attribute that is a function object, a method object is created by packing (pointers to) the instance object and the function object just found together in an abstract object: this is the method object. When the method object is called with an argument list, a new argument list is constructed from the instance object and the argument list, and the function object is called with this new argument list.

9.3.5. Class and Instance Variables

Generally speaking, instance variables are for data unique to each instance and class variables are for attributes and methods shared by all instances of the class:

```python
class Dog:
    kind = 'canine'  # class variable shared by all instances
    def __init__(self, name):
        self.name = name  # instance variable unique to each instance

>>> d = Dog('Fido')
>>> e = Dog('Buddy')
>>> d.kind  # shared by all dogs
'canine'
>>> e.kind  # shared by all dogs
'canine'
>>> d.name  # unique to d
'Fido'
```
As discussed in *A Word About Names and Objects*, shared data can have possibly surprising effects with involving *mutable* objects such as lists and dictionaries. For example, the *tricks* list in the following code should not be used as a class variable because just a single list would be shared by all *Dog* instances:

```python
class Dog:
    tricks = []  # mistaken use of a class variable

    def __init__(self, name):
        self.name = name
    
    def add_trick(self, trick):
        self.tricks.append(trick)

>>> d = Dog('Fido')
>>> e = Dog('Buddy')
>>> d.add_trick('roll over')
>>> e.add_trick('play dead')
>>> d.tricks  # unexpectedly shared by all Dog instances
['roll over', 'play dead']
```

Correct design of the class should use an instance variable instead:

```python
class Dog:

    def __init__(self, name):
        self.name = name
        self.tricks = []  # creates a new empty list for each dog
```
def add_trick(self, trick):
    self.tricks.append(trick)

>>> d = Dog('Fido')
>>> e = Dog('Buddy')
>>> d.add_trick('roll over')
>>> e.add_trick('play dead')
>>> d.tricks
['roll over']
>>> e.tricks
['play dead']
9.4. Random Remarks

Data attributes override method attributes with the same name; to avoid accidental name conflicts, which may cause hard-to-find bugs in large programs, it is wise to use some kind of convention that minimizes the chance of conflicts. Possible conventions include capitalizing method names, prefixing data attribute names with a small unique string (perhaps just an underscore), or using verbs for methods and nouns for data attributes.

Data attributes may be referenced by methods as well as by ordinary users (“clients”) of an object. In other words, classes are not usable to implement pure abstract data types. In fact, nothing in Python makes it possible to enforce data hiding — it is all based upon convention. (On the other hand, the Python implementation, written in C, can completely hide implementation details and control access to an object if necessary; this can be used by extensions to Python written in C.)

Clients should use data attributes with care — clients may mess up invariants maintained by the methods by stamping on their data attributes. Note that clients may add data attributes of their own to an instance object without affecting the validity of the methods, as long as name conflicts are avoided — again, a naming convention can save a lot of headaches here.

There is no shorthand for referencing data attributes (or other methods!) from within methods. I find that this actually increases the readability of methods: there is no chance of confusing local variables and instance variables when glancing through a method.

Often, the first argument of a method is called self. This is nothing more than a convention: the name self has absolutely no special
meaning to Python. Note, however, that by not following the convention your code may be less readable to other Python programmers, and it is also conceivable that a class browser program might be written that relies upon such a convention.

Any function object that is a class attribute defines a method for instances of that class. It is not necessary that the function definition is textually enclosed in the class definition: assigning a function object to a local variable in the class is also ok. For example:

```python
# Function defined outside the class
def f1(self, x, y):
    return min(x, x+y)

class C:
    f = f1

    def g(self):
        return 'hello world'

    h = g
```

Now `f`, `g` and `h` are all attributes of class `C` that refer to function objects, and consequently they are all methods of instances of `C` — `h` being exactly equivalent to `g`. Note that this practice usually only serves to confuse the reader of a program.

Methods may call other methods by using method attributes of the `self` argument:

```python
class Bag:
    def __init__(self):
        self.data = []
```
def add(self, x):
    self.data.append(x)

def addtwice(self, x):
    self.add(x)
    self.add(x)

Methods may reference global names in the same way as ordinary functions. The global scope associated with a method is the module containing its definition. (A class is never used as a global scope.) While one rarely encounters a good reason for using global data in a method, there are many legitimate uses of the global scope: for one thing, functions and modules imported into the global scope can be used by methods, as well as functions and classes defined in it. Usually, the class containing the method is itself defined in this global scope, and in the next section we'll find some good reasons why a method would want to reference its own class.

Each value is an object, and therefore has a class (also called its type). It is stored as object.__class__.
9.5. Inheritance

Of course, a language feature would not be worthy of the name “class” without supporting inheritance. The syntax for a derived class definition looks like this:

```python
class DerivedClassName(BaseClassName):
    <statement-1>
    ...
    ...
    <statement-N>
```

The name BaseClassName must be defined in a scope containing the derived class definition. In place of a base class name, other arbitrary expressions are also allowed. This can be useful, for example, when the base class is defined in another module:

```python
class DerivedClassName(modname.BaseClassName):
```

Execution of a derived class definition proceeds the same as for a base class. When the class object is constructed, the base class is remembered. This is used for resolving attribute references: if a requested attribute is not found in the class, the search proceeds to look in the base class. This rule is applied recursively if the base class itself is derived from some other class.

There's nothing special about instantiation of derived classes: DerivedClassName() creates a new instance of the class. Method references are resolved as follows: the corresponding class attribute is searched, descending down the chain of base classes if necessary, and the method reference is valid if this yields a function object.
Derived classes may override methods of their base classes. Because methods have no special privileges when calling other methods of the same object, a method of a base class that calls another method defined in the same base class may end up calling a method of a derived class that overrides it. (For C++ programmers: all methods in Python are effectively virtual.)

An overriding method in a derived class may in fact want to extend rather than simply replace the base class method of the same name. There is a simple way to call the base class method directly: just call BaseClassName.methodname(self, arguments). This is occasionally useful to clients as well. (Note that this only works if the base class is accessible as BaseClassName in the global scope.)

Python has two built-in functions that work with inheritance:

- Use `isinstance()` to check an instance's type: `isinstance(obj, int)` will be True only if `obj.__class__` is `int` or some class derived from `int`.
- Use `issubclass()` to check class inheritance: `issubclass(bool, int)` is True since `bool` is a subclass of `int`. However, `issubclass(float, int)` is False since `float` is not a subclass of `int`.

### 9.5.1. Multiple Inheritance

Python supports a form of multiple inheritance as well. A class definition with multiple base classes looks like this:

```python
class DerivedClassName(Base1, Base2, Base3):
    <statement-1>
    
    .
    .
```
For most purposes, in the simplest cases, you can think of the search for attributes inherited from a parent class as depth-first, left-to-right, not searching twice in the same class where there is an overlap in the hierarchy. Thus, if an attribute is not found in DerivedClassName, it is searched for in Base1, then (recursively) in the base classes of Base1, and if it was not found there, it was searched for in Base2, and so on.

In fact, it is slightly more complex than that; the method resolution order changes dynamically to support cooperative calls to `super()`. This approach is known in some other multiple-inheritance languages as call-next-method and is more powerful than the super call found in single-inheritance languages.

Dynamic ordering is necessary because all cases of multiple inheritance exhibit one or more diamond relationships (where at least one of the parent classes can be accessed through multiple paths from the bottommost class). For example, all classes inherit from `object`, so any case of multiple inheritance provides more than one path to reach `object`. To keep the base classes from being accessed more than once, the dynamic algorithm linearizes the search order in a way that preserves the left-to-right ordering specified in each class, that calls each parent only once, and that is monotonic (meaning that a class can be subclassed without affecting the precedence order of its parents). Taken together, these properties make it possible to design reliable and extensible classes with multiple inheritance. For more detail, see [https://www.python.org/download/releases/2.3/mro/](https://www.python.org/download/releases/2.3/mro/).
9.6. Private Variables

“Private” instance variables that cannot be accessed except from inside an object don’t exist in Python. However, there is a convention that is followed by most Python code: a name prefixed with an underscore (e.g. _spam) should be treated as a non-public part of the API (whether it is a function, a method or a data member). It should be considered an implementation detail and subject to change without notice.

Since there is a valid use-case for class-private members (namely to avoid name clashes of names with names defined by subclasses), there is limited support for such a mechanism, called name mangling. Any identifier of the form __spam (at least two leading underscores, at most one trailing underscore) is textually replaced with _classname__spam, where classname is the current class name with leading underscore(s) stripped. This mangling is done without regard to the syntactic position of the identifier, as long as it occurs within the definition of a class.

Name mangling is helpful for letting subclasses override methods without breaking intraclass method calls. For example:

```python
class Mapping:
    def __init__(self, iterable):
        self.items_list = []
        self.__update(iterable)

    def update(self, iterable):
        for item in iterable:
            self.items_list.append(item)

    __update = update  # private copy of original update
```
```python
class MappingSubclass(Mapping):

    def update(self, keys, values):
        # provides new signature for update()
        # but does not break __init__()
        for item in zip(keys, values):
            self.items_list.append(item)
```

Note that the mangling rules are designed mostly to avoid accidents; it still is possible to access or modify a variable that is considered private. This can even be useful in special circumstances, such as in the debugger.

Notice that code passed to `exec()` or `eval()` does not consider the classname of the invoking class to be the current class; this is similar to the effect of the `global` statement, the effect of which is likewise restricted to code that is byte-compiled together. The same restriction applies to `getattr()`, `setattr()` and `delattr()`, as well as when referencing `__dict__` directly.
9.7. Odds and Ends

Sometimes it is useful to have a data type similar to the Pascal “record” or C “struct”, bundling together a few named data items. An empty class definition will do nicely:

```python
class Employee:
    pass
```

```python
john = Employee()  # Create an empty employee record

# Fill the fields of the record
john.name = 'John Doe'
john.dept = 'computer lab'
john.salary = 1000
```

A piece of Python code that expects a particular abstract data type can often be passed a class that emulates the methods of that data type instead. For instance, if you have a function that formats some data from a file object, you can define a class with methods read() and readline() that get the data from a string buffer instead, and pass it as an argument.

Instance method objects have attributes, too: `m.__self__` is the instance object with the method `m()`, and `m.__func__` is the function object corresponding to the method.
9.8. Iterators

By now you have probably noticed that most container objects can be looped over using a `for` statement:

```python
for element in [1, 2, 3]:
    print(element)
for element in (1, 2, 3):
    print(element)
for key in {'one':1, 'two':2}:
    print(key)
for char in "123":
    print(char)
for line in open("myfile.txt"):
    print(line, end=''
```

This style of access is clear, concise, and convenient. The use of iterators pervades and unifies Python. Behind the scenes, the `for` statement calls `iter()` on the container object. The function returns an iterator object that defines the method `__next__()` which accesses elements in the container one at a time. When there are no more elements, `__next__()` raises a `StopIteration` exception which tells the `for` loop to terminate. You can call the `__next__()` method using the `next()` built-in function; this example shows how it all works:

```python
>>> s = 'abc'
>>> it = iter(s)
>>> it
<iterator object at 0x00A1DB50>
>>> next(it)
'a'
>>> next(it)
```
Having seen the mechanics behind the iterator protocol, it is easy to add iterator behavior to your classes. Define an `__iter__()` method which returns an object with a `__next__()` method. If the class defines `__next__()`, then `__iter__()` can just return `self`:

```python
class Reverse:
    """Iterator for looping over a sequence backwards."""
    def __init__(self, data):
        self.data = data
        self.index = len(data)

    def __iter__(self):
        return self

    def __next__(self):
        if self.index == 0:
            raise StopIteration
        self.index = self.index - 1
        return self.data[self.index]
```

```python
>>> rev = Reverse('spam')
>>> iter(rev)
<_main__.Reverse object at 0x00A1DB50>
>>> for char in rev:
    ...   print(char)
..."""
m
a
p
s
9.9. Generators

Generators are a simple and powerful tool for creating iterators. They are written like regular functions but use the `yield` statement whenever they want to return data. Each time `next()` is called on it, the generator resumes where it left off (it remembers all the data values and which statement was last executed). An example shows that generators can be trivially easy to create:

```python
def reverse(data):
    for index in range(len(data)-1, -1, -1):
        yield data[index]
```

```python
>>> for char in reverse('golf '):
...     print(char)
...
f
l
o
g
```

Anything that can be done with generators can also be done with class-based iterators as described in the previous section. What makes generators so compact is that the `__iter__()` and `__next__()` methods are created automatically.

Another key feature is that the local variables and execution state are automatically saved between calls. This made the function easier to write and much more clear than an approach using instance variables like `self.index` and `self.data`.

In addition to automatic method creation and saving program state,
when generators terminate, they automatically raise `StopIteration`. In combination, these features make it easy to create iterators with no more effort than writing a regular function.
9.10. Generator Expressions

Some simple generators can be coded succinctly as expressions using a syntax similar to list comprehensions but with parentheses instead of brackets. These expressions are designed for situations where the generator is used right away by an enclosing function. Generator expressions are more compact but less versatile than full generator definitions and tend to be more memory friendly than equivalent list comprehensions.

Examples:

```python
>>> sum(i*i for i in range(10))  # sum of squares
285

>>> xvec = [10, 20, 30]
>>> yvec = [7, 5, 3]
>>> sum(x*y for x,y in zip(xvec, yvec))  # dot product
260

>>> from math import pi, sin
>>> sine_table = {x: sin(x*pi/180) for x in range(0, 361)}

>>> unique_words = set(word for line in page for word
...                      in line.split())

>>> valedictorian = max((student.gpa, student.name) for student in students)

>>> data = 'golf'
>>> list(data[i] for i in range(len(data)-1, -1, -1))
['f', 'l', 'o', 'g']
```

Footnotes
Except for one thing. Module objects have a secret read-only attribute called __dict__ which returns the dictionary used to implement the module's namespace; the name __dict__ is an attribute but not a global name. Obviously, using this violates the abstraction of namespace implementation, and should be restricted to things like post-mortem debuggers.
10. Brief Tour of the Standard Library
10.1. Operating System Interface

The `os` module provides dozens of functions for interacting with the operating system:

```python
>>> import os
>>> os.getcwd()  # Return the current working directory
'C:\Python36'
```

Be sure to use the `import os` style instead of `from os import *`. This will keep `os.open()` from shadowing the built-in `open()` function which operates much differently.

The built-in `dir()` and `help()` functions are useful as interactive aids for working with large modules like `os`:

```python
>>> import os
>>> dir(os)
<returns a list of all module functions>
>>> help(os)
<returns an extensive manual page created from the module's docstrings>
```

For daily file and directory management tasks, the `shutil` module provides a higher level interface that is easier to use:

```python
>>> import shutil
>>> shutil.copyfile('data.db', 'archive.db')
'archive.db'
>>> shutil.move('/build/executables', 'installdir')
```
'installdir'
10.2. File Wildcards

The `glob` module provides a function for making file lists from directory wildcard searches:

```python
>>> import glob
>>> glob.glob('*.py')
['primes.py', 'random.py', 'quote.py']
```
10.3. Command Line Arguments

Common utility scripts often need to process command line arguments. These arguments are stored in the `sys` module's `argv` attribute as a list. For instance the following output results from running `python demo.py one two three` at the command line:

```python
>>> import sys
>>> print(sys.argv)
['demo.py', 'one', 'two', 'three']
```

The `getopt` module processes `sys.argv` using the conventions of the Unix `getopt()` function. More powerful and flexible command line processing is provided by the `argparse` module.
10.4. Error Output Redirection and Program Termination

The `sys` module also has attributes for `stdin`, `stdout`, and `stderr`. The latter is useful for emitting warnings and error messages to make them visible even when `stdout` has been redirected:

```python
>>> sys.stderr.write('Warning, log file not found starting a new one
Warning, log file not found starting a new one
```

The most direct way to terminate a script is to use `sys.exit()`.
10.5. String Pattern Matching

The `re` module provides regular expression tools for advanced string processing. For complex matching and manipulation, regular expressions offer succinct, optimized solutions:

```python
>>> import re
>>> re.findall(r'\bf[a-z]*', 'which foot or hand fell fastest')
['foot', 'fell', 'fastest']
>>> re.sub(r'\b[a-z]+\b', r'\1', 'cat in the the cat in the hat')
'cat in the the cat in the hat'
```

When only simple capabilities are needed, string methods are preferred because they are easier to read and debug:

```python
>>> 'tea for too'.replace('too', 'two')
'tea for two'
```
# 10.6. Mathematics

The `math` module gives access to the underlying C library functions for floating point math:

```python
>>> import math
>>> math.cos(math.pi / 4)
0.70710678118654757
>>> math.log(1024, 2)
10.0
```

The `random` module provides tools for making random selections:

```python
>>> import random
>>> random.choice(['apple', 'pear', 'banana'])
'apple'
>>> random.sample(range(100), 10)  # sampling without replacement
[30, 83, 16, 4, 8, 81, 41, 50, 18, 33]
>>> random.random()  # random float
0.17970987693706186
>>> random.randrange(6)  # random integer chosen from range(6)
4
```

The `statistics` module calculates basic statistical properties (the mean, median, variance, etc.) of numeric data:

```python
>>> import statistics
>>> data = [2.75, 1.75, 1.25, 0.25, 0.5, 1.25, 3.5]
>>> statistics.mean(data)
1.6071428571428572
>>> statistics.median(data)
1.25
>>> statistics.variance(data)
1.3720238095238095
```
The SciPy project <https://scipy.org> has many other modules for numerical computations.
10.7. Internet Access

There are a number of modules for accessing the internet and processing internet protocols. Two of the simplest are `urllib.request` for retrieving data from URLs and `smtplib` for sending mail:

```python
>>> from urllib.request import urlopen
>>> with urlopen('http://tycho.usno.navy.mil/cgi-bin/timer.pl') as response:
...     for line in response:
...         line = line.decode('utf-8')  # Decoding
...         if 'EST' in line or 'EDT' in line:  # Look for Eastern Time
...             print(line)

<BR>Nov. 25, 09:43:32 PM EST

>>> import smtplib
>>> server = smtplib.SMTP('localhost')
>>> server.sendmail('soothsayer@example.org', 'jcaesar@example.org',
...                  '''To: jcaesar@example.org
...                  From: soothsayer@example.org
...                  Beware the Ides of March.
...                  '''
...                  )
>>> server.quit()
```

(Note that the second example needs a mailserver running on localhost.)
10.8. Dates and Times

The `datetime` module supplies classes for manipulating dates and times in both simple and complex ways. While date and time arithmetic is supported, the focus of the implementation is on efficient member extraction for output formatting and manipulation. The module also supports objects that are timezone aware.

```python
>>> # dates are easily constructed and formatted
>>> from datetime import date
>>> now = date.today()
>>> now
datetime.date(2003, 12, 2)
>>> now.strftime("%m-%d-%y. %d %b %Y is a %A on the '12-02-03. 02 Dec 2003 is a Tuesday on the 02 day of

>>> # dates support calendar arithmetic
>>> birthday = date(1964, 7, 31)
>>> age = now - birthday
>>> age.days
14368
```
10.9. Data Compression

Common data archiving and compression formats are directly supported by modules including: **zlib**, **gzip**, **bz2**, **lzma**, **zipfile** and **tarfile**.

```python
>>> import zlib
>>> s = b'witch which has which witchers wrist watch'
>>> len(s)
41
>>> t = zlib.compress(s)
>>> len(t)
37
>>> zlib.decompress(t)
b'witch which has which witches wrist watch'
>>> zlib.crc32(s)
226805979
```
10.10. Performance Measurement

Some Python users develop a deep interest in knowing the relative performance of different approaches to the same problem. Python provides a measurement tool that answers those questions immediately.

For example, it may be tempting to use the tuple packing and unpacking feature instead of the traditional approach to swapping arguments. The `timeit` module quickly demonstrates a modest performance advantage:

```python
>>> from timeit import Timer
>>> Timer('t=a; a=b; b=t', 'a=1; b=2').timeit()
0.57535828626024577
>>> Timer('a,b = b,a', 'a=1; b=2').timeit()
0.54962537085770791
```

In contrast to `timeit`'s fine level of granularity, the `profile` and `pstats` modules provide tools for identifying time critical sections in larger blocks of code.
10.11. Quality Control

One approach for developing high quality software is to write tests for each function as it is developed and to run those tests frequently during the development process.

The doctest module provides a tool for scanning a module and validating tests embedded in a program’s docstrings. Test construction is as simple as cutting-and-pasting a typical call along with its results into the docstring. This improves the documentation by providing the user with an example and it allows the doctest module to make sure the code remains true to the documentation:

```python
def average(values):
    """Computes the arithmetic mean of a list of numbers."
    return sum(values) / len(values)

import doctest
doctest.testmod()  # automatically validate the embedded tests
```

The unittest module is not as effortless as the doctest module, but it allows a more comprehensive set of tests to be maintained in a separate file:

```python
import unittest
class TestStatisticalFunctions(unittest.TestCase):
    def test_average(self):
```
```python
self.assertEqual(average([20, 30, 70]), 40.0)
self.assertEqual(round(average([1, 5, 7]), 1)

with self.assertRaises(ZeroDivisionError):
    average([])

with self.assertRaises(TypeError):
    average(20, 30, 70)
```

`unittest.main()  # Calling from the command line invocation`
10.12. Batteries Included

Python has a “batteries included” philosophy. This is best seen through the sophisticated and robust capabilities of its larger packages. For example:

- The `xmlrpc.client` and `xmlrpc.server` modules make implementing remote procedure calls into an almost trivial task. Despite the modules names, no direct knowledge or handling of XML is needed.
- The `email` package is a library for managing email messages, including MIME and other RFC 2822-based message documents. Unlike `smtplib` and `poplib` which actually send and receive messages, the email package has a complete toolset for building or decoding complex message structures (including attachments) and for implementing internet encoding and header protocols.
- The `json` package provides robust support for parsing this popular data interchange format. The `csv` module supports direct reading and writing of files in Comma-Separated Value format, commonly supported by databases and spreadsheets. XML processing is supported by the `xml.etree.ElementTree`, `xml.dom` and `xml.sax` packages. Together, these modules and packages greatly simplify data interchange between Python applications and other tools.
- The `sqlite3` module is a wrapper for the SQLite database library, providing a persistent database that can be updated and accessed using slightly nonstandard SQL syntax.
- Internationalization is supported by a number of modules including `gettext`, `locale`, and the `codecs` package.
The Python Software Foundation is a non-profit corporation. Please donate.

Created using Sphinx 1.6.3.
11. Brief Tour of the Standard Library — Part II

This second tour covers more advanced modules that support professional programming needs. These modules rarely occur in small scripts.
11.1. Output Formatting

The `reprlib` module provides a version of `repr()` customized for abbreviated displays of large or deeply nested containers:

```python
>>> import reprlib
>>> reprlib.repr(set('supercalifragilisticexpialidocious
"{a', 'c', 'd', 'e', 'f', 'g', ...}
```

The `pprint` module offers more sophisticated control over printing both built-in and user defined objects in a way that is readable by the interpreter. When the result is longer than one line, the “pretty printer” adds line breaks and indentation to more clearly reveal data structure:

```python
>>> import pprint
>>> t = [[[['black', 'cyan'], 'white'], ['green', 'red',
... 'yellow'], 'blue']]
... >>> pprint.pprint(t, width=30)
[[[['black', 'cyan'],
  'white',
  ['green', 'red']],
  [['magenta', 'yellow'],
   'blue']]]
```

The `textwrap` module formats paragraphs of text to fit a given screen width:

```python
>>> import textwrap
>>> doc = """The wrap() method is just like fill() except that it returns a list of strings instead of one big string with the wrapped lines."""
```
The `textwrap` module provides a `fill()` method to wrap text. The `wrap()` method is similar to `fill()` except that it returns a list of strings instead of a single string with newlines to separate the wrapped lines:

```python
>>> print(textwrap.fill(doc, width=40))
The wrap() method is just like fill() except that it returns a list of strings instead of one big string with newlines to separate the wrapped lines.
```

The `locale` module accesses a database of culture-specific data formats. The grouping attribute of `locale`’s `format` function provides a direct way of formatting numbers with group separators:

```python
>>> import locale
>>> locale.setlocale(locale.LC_ALL, 'English_United States.1252')
>>> conv = locale.localeconv()    # get a mapping
>>> x = 1234567.8
>>> locale.format("%d", x, grouping=True)
'1,234,567'
>>> locale.format_string("%s.%*f", (conv['currency_symbol'], conv['frac_digits']), x), grouping=True)
'$1,234,567.80'
```
11.2. Templating

The string module includes a versatile Template class with a simplified syntax suitable for editing by end-users. This allows users to customize their applications without having to alter the application.

The format uses placeholder names formed by $ with valid Python identifiers (alphanumeric characters and underscores). Surrounding the placeholder with braces allows it to be followed by more alphanumeric letters with no intervening spaces. Writing $$ creates a single escaped $:

```python
>>> from string import Template
>>> t = Template('${village}folk send $$10 to $cause.
'Nottinghamfolk send $10 to the ditch fund.
```

The substitute() method raises a KeyError when a placeholder is not supplied in a dictionary or a keyword argument. For mail-merge style applications, user supplied data may be incomplete and the safe_substitute() method may be more appropriate — it will leave placeholders unchanged if data is missing:

```python
>>> t = Template('Return the $item to $owner.')
>>> d = dict(item='unladen swallow')
>>> t.substitute(d)
Traceback (most recent call last):
  ... KeyError: 'owner'
>>> t.safe_substitute(d)
'Return the unladen swallow to $owner.'
```
Template subclasses can specify a custom delimiter. For example, a batch renaming utility for a photo browser may elect to use percent signs for placeholders such as the current date, image sequence number, or file format:

```python
>>> import time, os.path
>>> photofiles = ['img_1074.jpg', 'img_1076.jpg', 'img_1077.jpg']
>>> class BatchRename(Template):
...     delimiter = '%'
>>> fmt = input('Enter rename style (%d-date %n-seqnum %f-format): 
Enter rename style (%d-date %n-seqnum %f-format): Ashley_%n%f
>>> t = BatchRename(fmt)
>>> date = time.strftime('%d%b%y')
>>> for i, filename in enumerate(photofiles):
...     base, ext = os.path.splitext(filename)
...     newname = t.substitute(d=date, n=i, f=ext)
...     print('{0} --> {1}'.format(filename, newname))
img_1074.jpg --> Ashley_0.jpg
img_1076.jpg --> Ashley_1.jpg
img_1077.jpg --> Ashley_2.jpg
```

Another application for templating is separating program logic from the details of multiple output formats. This makes it possible to substitute custom templates for XML files, plain text reports, and HTML web reports.
11.3. Working with Binary Data Record Layouts

The `struct` module provides `pack()` and `unpack()` functions for working with variable length binary record formats. The following example shows how to loop through header information in a ZIP file without using the `zipfile` module. Pack codes "H" and "I" represent two and four byte unsigned numbers respectively. The "<" indicates that they are standard size and in little-endian byte order:

```python
import struct

with open('myfile.zip', 'rb') as f:
    data = f.read()

start = 0
for i in range(3):  # show the first 3 file headers
    start += 14
    fields = struct.unpack('<IIIHH', data[start:start+14])
    crc32, comp_size, uncomp_size, filenamesize, extra_size = fields
    start += 16
    filename = data[start:start+filenamesize]
    start += filenamesize
    extra = data[start:start+extra_size]
    print(filename, hex(crc32), comp_size, uncomp_size)
    start += extra_size + comp_size  # skip to the next header
```
11.4. Multi-threading

Threading is a technique for decoupling tasks which are not sequentially dependent. Threads can be used to improve the responsiveness of applications that accept user input while other tasks run in the background. A related use case is running I/O in parallel with computations in another thread.

The following code shows how the high level threading module can run tasks in background while the main program continues to run:

```python
import threading, zipfile

class AsyncZip(threading.Thread):
    def __init__(self, infile, outfile):
        threading.Thread.__init__(self)
        self.infile = infile
        self.outfile = outfile

    def run(self):
        f = zipfile.ZipFile(self.outfile, 'w', zipfile.ZIP_DEFLATED)
        f.write(self.infile)
        f.close()
        print('Finished background zip of:', self.infile)

background = AsyncZip('mydata.txt', 'myarchive.zip')
background.start()
print('The main program continues to run in foreground.')

background.join()  # Wait for the background task
print('Main program waited until background was done.')
```

The principal challenge of multi-threaded applications is coordinating
threads that share data or other resources. To that end, the threading module provides a number of synchronization primitives including locks, events, condition variables, and semaphores.

While those tools are powerful, minor design errors can result in problems that are difficult to reproduce. So, the preferred approach to task coordination is to concentrate all access to a resource in a single thread and then use the queue module to feed that thread with requests from other threads. Applications using Queue objects for inter-thread communication and coordination are easier to design, more readable, and more reliable.
11.5. Logging

The `logging` module offers a full featured and flexible logging system. At its simplest, log messages are sent to a file or to `sys.stderr`:

```python
import logging
logging.debug('Debugging information')
logging.info('Informational message')
logging.warning('Warning: config file %s not found',
logging.error('Error occurred')
logging.critical('Critical error -- shutting down')
```

This produces the following output:

```
WARNING:root:Warning:config file server.conf not found
ERROR:root:Error occurred
CRITICAL:root:Critical error -- shutting down
```

By default, informational and debugging messages are suppressed and the output is sent to standard error. Other output options include routing messages through email, datagrams, sockets, or to an HTTP Server. New filters can select different routing based on message priority: DEBUG, INFO, WARNING, ERROR, and CRITICAL.

The logging system can be configured directly from Python or can be loaded from a user editable configuration file for customized logging without altering the application.
11.6. Weak References

Python does automatic memory management (reference counting for most objects and garbage collection to eliminate cycles). The memory is freed shortly after the last reference to it has been eliminated.

This approach works fine for most applications but occasionally there is a need to track objects only as long as they are being used by something else. Unfortunately, just tracking them creates a reference that makes them permanent. The weakref module provides tools for tracking objects without creating a reference. When the object is no longer needed, it is automatically removed from a weakref table and a callback is triggered for weakref objects. Typical applications include caching objects that are expensive to create:

```python
>>> import weakref, gc
>>> class A:
...     def __init__(self, value):
...         self.value = value
...     def __repr__(self):
...         return str(self.value)

>>> a = A(10)  # create a reference
>>> d = weakref.WeakValueDictionary()
>>> d['primary'] = a  # does not create a
>>> d['primary']   # fetch the object if it is still alive
10
>>> del a         # remove the one ref
>>> gc.collect()  # run garbage collection
0
>>> d['primary']  # entry was automatically removed
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
    d['primary']  # entry was automatically
```

File "C:/python36/lib/weakref.py", line 46, in __get__
o = self.data[key]()
KeyError: 'primary'
11.7. Tools for Working with Lists

Many data structure needs can be met with the built-in list type. However, sometimes there is a need for alternative implementations with different performance trade-offs.

The `array` module provides an `array()` object that is like a list that stores only homogeneous data and stores it more compactly. The following example shows an array of numbers stored as two byte unsigned binary numbers (typecode "H") rather than the usual 16 bytes per entry for regular lists of Python int objects:

```python
>>> from array import array
>>> a = array('H', [4000, 10, 700, 22222])
>>> sum(a)
26932
>>> a[1:3]
array('H', [10, 700])
```

The `collections` module provides a `deque()` object that is like a list with faster appends and pops from the left side but slower lookups in the middle. These objects are well suited for implementing queues and breadth first tree searches:

```python
>>> from collections import deque
>>> d = deque(['task1', 'task2', 'task3'])
>>> d.append('task4')
>>> print('Handling', d.popleft())
Handling task1

unsearched = deque([starting_node])
def breadth_first_search(unsearched):
    node = unsearched.popleft()
```
for m in gen_moves(node):
  if is_goal(m):
    return m
unsearched.append(m)

In addition to alternative list implementations, the library also offers other tools such as the bisect module with functions for manipulating sorted lists:

```python
>>> import bisect
>>> scores = [(100, 'perl'), (200, 'tcl'), (400, 'lua')]
>>> bisect.insort(scores, (300, 'ruby'))
>>> scores
[(100, 'perl'), (200, 'tcl'), (300, 'ruby'), (400, 'lua')]
```

The heapq module provides functions for implementing heaps based on regular lists. The lowest valued entry is always kept at position zero. This is useful for applications which repeatedly access the smallest element but do not want to run a full list sort:

```python
>>> from heapq import heapify, heappop, heappush
>>> data = [1, 3, 5, 7, 9, 2, 4, 6, 8, 0]
>>> heapify(data)  # rearrange to heap order
>>> heappush(data, -5)  # add a new element
>>> [heappop(data) for i in range(3)]  # fetch the three smallest
[-5, 0, 1]
```
11.8. Decimal Floating Point Arithmetic

The `decimal` module offers a `Decimal` datatype for decimal floating point arithmetic. Compared to the built-in `float` implementation of binary floating point, the class is especially helpful for

- financial applications and other uses which require exact decimal representation,
- control over precision,
- control over rounding to meet legal or regulatory requirements,
- tracking of significant decimal places, or
- applications where the user expects the results to match calculations done by hand.

For example, calculating a 5% tax on a 70 cent phone charge gives different results in decimal floating point and binary floating point. The difference becomes significant if the results are rounded to the nearest cent:

```python
>>> from decimal import *
>>> round(Decimal('0.70') * Decimal('1.05'), 2)
Decimal('0.74')
>>> round(.70 * 1.05, 2)
0.73
```

The `Decimal` result keeps a trailing zero, automatically inferring four place significance from multiplicands with two place significance. Decimal reproduces mathematics as done by hand and avoids issues that can arise when binary floating point cannot exactly represent decimal quantities.

Exact representation enables the `Decimal` class to perform modulo calculations and equality tests that are unsuitable for binary floating
point:

```python
>>> Decimal('1.00') % Decimal('.10')
Decimal('0.00')
>>> 1.00 % 0.10
0.09999999999999995

>>> sum([Decimal('0.1')] * 10) == Decimal('1.0')
True
>>> sum([0.1] * 10) == 1.0
False
```

The `decimal` module provides arithmetic with as much precision as needed:

```python
>>> getcontext().prec = 36
>>> Decimal(1) / Decimal(7)
Decimal('0.142857142857142857142857142857142857')
```
12. Virtual Environments and Packages
12.1. Introduction

Python applications will often use packages and modules that don’t come as part of the standard library. Applications will sometimes need a specific version of a library, because the application may require that a particular bug has been fixed or the application may be written using an obsolete version of the library’s interface.

This means it may not be possible for one Python installation to meet the requirements of every application. If application A needs version 1.0 of a particular module but application B needs version 2.0, then the requirements are in conflict and installing either version 1.0 or 2.0 will leave one application unable to run.

The solution for this problem is to create a virtual environment, a self-contained directory tree that contains a Python installation for a particular version of Python, plus a number of additional packages.

Different applications can then use different virtual environments. To resolve the earlier example of conflicting requirements, application A can have its own virtual environment with version 1.0 installed while application B has another virtual environment with version 2.0. If application B requires a library be upgraded to version 3.0, this will not affect application A’s environment.
# 12.2. Creating Virtual Environments

The module used to create and manage virtual environments is called *venv*. *venv* will usually install the most recent version of Python that you have available. If you have multiple versions of Python on your system, you can select a specific Python version by running `python3` or whichever version you want.

To create a virtual environment, decide upon a directory where you want to place it, and run the *venv* module as a script with the directory path:

```
python3 -m venv tutorial-env
```

This will create the `tutorial-env` directory if it doesn't exist, and also create directories inside it containing a copy of the Python interpreter, the standard library, and various supporting files.

Once you've created a virtual environment, you may activate it.

On Windows, run:

```
tutorial-env\Scripts\activate.bat
```

On Unix or MacOS, run:

```
source tutorial-env/bin/activate
```

(This script is written for the bash shell. If you use the *csh* or *fish* shells, there are alternate `activate.csh` and `activate.fish` scripts you should use instead.)
Activating the virtual environment will change your shell's prompt to show what virtual environment you're using, and modify the environment so that running `python` will get you that particular version and installation of Python. For example:

```bash
$ source ~/envs/tutorial-env/bin/activate
(tutorial-env) $ python
Python 3.5.1 (default, May 6 2016, 10:59:36)
...  
>>> import sys
>>> sys.path
['', '/usr/local/lib/python35.zip', ..., '~/envs/tutorial-env/lib/python3.5/site-packages']
>>> 
```
12.3. Managing Packages with pip

You can install, upgrade, and remove packages using a program called **pip**. By default **pip** will install packages from the Python Package Index, [https://pypi.python.org/pypi](https://pypi.python.org/pypi). You can browse the Python Package Index by going to it in your web browser, or you can use **pip**'s limited search feature:

```
(tutorial-env) $ pip search astronomy
skyfield - Elegant astronomy for Python
gary - Galactic astronomy and gravitational
novas - The United States Naval Observatory NOVAS astronomy library
astroobs - Provides astronomy ephemerides
PyAstronomy - A collection of astronomy related tools
...
```

**pip** has a number of subcommands: “search”, “install”, “uninstall”, “freeze”, etc. (Consult the Installing Python Modules guide for complete documentation for **pip**.)

You can install the latest version of a package by specifying a package's name:

```
(tutorial-env) $ pip install novas
Collecting novas
  Downloading novas-3.1.1.3.tar.gz (136kB)
Installing collected packages: novas
  Running setup.py install for novas
Successfully installed novas-3.1.1.3
```

You can also install a specific version of a package by giving the package name followed by **==** and the version number:
(tutorial-env) $ pip install requests==2.6.0
Collecting requests==2.6.0
  Using cached requests-2.6.0-py2.py3-none-any.whl
Installing collected packages: requests
Successfully installed requests-2.6.0

If you re-run this command, pip will notice that the requested version is already installed and do nothing. You can supply a different version number to get that version, or you can run pip install --upgrade to upgrade the package to the latest version:

(tutorial-env) $ pip install --upgrade requests
Collecting requests
Installing collected packages: requests
  Found existing installation: requests 2.6.0
    Uninstalling requests-2.6.0:
      Successfully uninstalled requests-2.6.0
Successfully installed requests-2.7.0

pip uninstall followed by one or more package names will remove the packages from the virtual environment.

pip show will display information about a particular package:

(tutorial-env) $ pip show requests
---
Metadata-Version: 2.0
Name: requests
Version: 2.7.0
Summary: Python HTTP for Humans.
Home-page: http://python-requests.org
Author: Kenneth Reitz
Author-email: me@kennethreitz.com
License: Apache 2.0
Location: /Users/akuchling/envs/tutorial-env/lib/pyt
pip list will display all of the packages installed in the virtual environment:

```
(tutorial-env) $ pip list
novas (3.1.1.3)
numpy (1.9.2)
pip (7.0.3)
requests (2.7.0)
setuptools (16.0)
```

pip freeze will produce a similar list of the installed packages, but the output uses the format that pip install expects. A common convention is to put this list in a requirements.txt file:

```
(tutorial-env) $ pip freeze > requirements.txt
(tutorial-env) $ cat requirements.txt.txt
novas==3.1.1.3
numpy==1.9.2
requests==2.7.0
```

The requirements.txt can then be committed to version control and shipped as part of an application. Users can then install all the necessary packages with install -r:

```
(tutorial-env) $ pip install -r requirements.txt.txt
Collecting novas==3.1.1.3 (from -r requirements.txt.txt
 ... Collecting numpy==1.9.2 (from -r requirements.txt.txt (l
 ... Collecting requests==2.7.0 (from -r requirements.txt.txt (l
 ... Installing collected packages: novas, numpy, request
```
Running setup.py install for novas
Successfully installed novas-3.1.1.3 numpy-1.9.2 requests-2.7.0

pip has many more options. Consult the Installing Python Modules guide for complete documentation for pip. When you've written a package and want to make it available on the Python Package Index, consult the Distributing Python Modules guide.
13. What Now?

Reading this tutorial has probably reinforced your interest in using Python — you should be eager to apply Python to solving your real-world problems. Where should you go to learn more?

This tutorial is part of Python’s documentation set. Some other documents in the set are:

- **The Python Standard Library**:
  You should browse through this manual, which gives complete (though terse) reference material about types, functions, and the modules in the standard library. The standard Python distribution includes a lot of additional code. There are modules to read Unix mailboxes, retrieve documents via HTTP, generate random numbers, parse command-line options, write CGI programs, compress data, and many other tasks. Skimming through the Library Reference will give you an idea of what’s available.

- **Installing Python Modules** explains how to install additional modules written by other Python users.

- **The Python Language Reference**: A detailed explanation of Python’s syntax and semantics. It’s heavy reading, but is useful as a complete guide to the language itself.

More Python resources:

- **https://www.python.org**: The major Python Web site. It contains code, documentation, and pointers to Python-related pages around the Web. This Web site is mirrored in various places around the world, such as Europe, Japan, and Australia; a mirror
may be faster than the main site, depending on your geographical location.

- **https://docs.python.org**: Fast access to Python’s documentation.
- **https://pypi.python.org/pypi**: The Python Package Index, previously also nicknamed the Cheese Shop, is an index of user-created Python modules that are available for download. Once you begin releasing code, you can register it here so that others can find it.
- **https://code.activestate.com/recipes/langs/python/**: The Python Cookbook is a sizable collection of code examples, larger modules, and useful scripts. Particularly notable contributions are collected in a book also titled Python Cookbook (O'Reilly & Associates, ISBN 0-596-00797-3.)
- **http://www.pyvideo.org** collects links to Python-related videos from conferences and user-group meetings.
- **https://scipy.org**: The Scientific Python project includes modules for fast array computations and manipulations plus a host of packages for such things as linear algebra, Fourier transforms, non-linear solvers, random number distributions, statistical analysis and the like.

For Python-related questions and problem reports, you can post to the newsgroup *comp.lang.python*, or send them to the mailing list at *python-list@python.org*. The newsgroup and mailing list are gatewayed, so messages posted to one will automatically be forwarded to the other. There are hundreds of postings a day, asking (and answering) questions, suggesting new features, and announcing new modules. Mailing list archives are available at *https://mail.python.org/pipermail/**.

Before posting, be sure to check the list of *Frequently Asked Questions* (also called the FAQ). The FAQ answers many of the questions that come up again and again, and may already contain the solution for your problem.
14. Interactive Input Editing and History Substitution

Some versions of the Python interpreter support editing of the current input line and history substitution, similar to facilities found in the Korn shell and the GNU Bash shell. This is implemented using the GNU Readline library, which supports various styles of editing. This library has its own documentation which we won’t duplicate here.
14.1. Tab Completion and History Editing

Completion of variable and module names is automatically enabled at interpreter startup so that the Tab key invokes the completion function; it looks at Python statement names, the current local variables, and the available module names. For dotted expressions such as `string.a`, it will evaluate the expression up to the final `.' and then suggest completions from the attributes of the resulting object. Note that this may execute application-defined code if an object with a `__getattr__()` method is part of the expression. The default configuration also saves your history into a file named `.python_history` in your user directory. The history will be available again during the next interactive interpreter session.
14.2. Alternatives to the Interactive Interpreter

This facility is an enormous step forward compared to earlier versions of the interpreter; however, some wishes are left: It would be nice if the proper indentation were suggested on continuation lines (the parser knows if an indent token is required next). The completion mechanism might use the interpreter’s symbol table. A command to check (or even suggest) matching parentheses, quotes, etc., would also be useful.

One alternative enhanced interactive interpreter that has been around for quite some time is IPython, which features tab completion, object exploration and advanced history management. It can also be thoroughly customized and embedded into other applications. Another similar enhanced interactive environment is bpython.
15. Floating Point Arithmetic: Issues and Limitations

Floating-point numbers are represented in computer hardware as base 2 (binary) fractions. For example, the decimal fraction

\[0.125\]

has value \(1/10 + 2/100 + 5/1000\), and in the same way the binary fraction

\[0.001\]

has value \(0/2 + 0/4 + 1/8\). These two fractions have identical values, the only real difference being that the first is written in base 10 fractional notation, and the second in base 2.

Unfortunately, most decimal fractions cannot be represented exactly as binary fractions. A consequence is that, in general, the decimal floating-point numbers you enter are only approximated by the binary floating-point numbers actually stored in the machine.

The problem is easier to understand at first in base 10. Consider the fraction \(1/3\). You can approximate that as a base 10 fraction:

\[0.3\]

or, better,

\[0.33\]
or, better,

0.333

and so on. No matter how many digits you’re willing to write down, the result will never be exactly 1/3, but will be an increasingly better approximation of 1/3.

In the same way, no matter how many base 2 digits you’re willing to use, the decimal value 0.1 cannot be represented exactly as a base 2 fraction. In base 2, 1/10 is the infinitely repeating fraction

0.00011001100110011001100110011001100110011001100110011...

Stop at any finite number of bits, and you get an approximation. On most machines today, floats are approximated using a binary fraction with the numerator using the first 53 bits starting with the most significant bit and with the denominator as a power of two. In the case of 1/10, the binary fraction is $3602879701896397 / 2^{55}$ which is close to but not exactly equal to the true value of 1/10.

Many users are not aware of the approximation because of the way values are displayed. Python only prints a decimal approximation to the true decimal value of the binary approximation stored by the machine. On most machines, if Python were to print the true decimal value of the binary approximation stored for 0.1, it would have to display

```python
>>> 0.1
0.10000000000000000000555111512312578270211815834045410
```

That is more digits than most people find useful, so Python keeps the
number of digits manageable by displaying a rounded value instead

```python
>>> 1 / 10
0.1
```

Just remember, even though the printed result looks like the exact value of 1/10, the actual stored value is the nearest representable binary fraction.

Interestingly, there are many different decimal numbers that share the same nearest approximate binary fraction. For example, the numbers 0.1 and 0.100000000000000001 and 0.10000000000000000555111512312578270211815834045410 are all approximated by 3602879701896397 / 2 ** 55. Since all of these decimal values share the same approximation, any one of them could be displayed while still preserving the invariant `eval(repr(x)) == x`.

Historically, the Python prompt and built-in `repr()` function would choose the one with 17 significant digits, 0.10000000000000001. Starting with Python 3.1, Python (on most systems) is now able to choose the shortest of these and simply display 0.1.

Note that this is in the very nature of binary floating-point: this is not a bug in Python, and it is not a bug in your code either. You’ll see the same kind of thing in all languages that support your hardware’s floating-point arithmetic (although some languages may not display the difference by default, or in all output modes).

For more pleasant output, you may wish to use string formatting to produce a limited number of significant digits:

```python
>>> format(math.pi, '.12g')  # give 12 significant digits
```
It's important to realize that this is, in a real sense, an illusion: you're simply rounding the display of the true machine value.

One illusion may beget another. For example, since 0.1 is not exactly 1/10, summing three values of 0.1 may not yield exactly 0.3, either:

```python
>>> .1 + .1 + .1 == .3
False
```

Also, since the 0.1 cannot get any closer to the exact value of 1/10 and 0.3 cannot get any closer to the exact value of 3/10, then pre-rounding with `round()` function cannot help:

```python
>>> round(.1, 1) + round(.1, 1) + round(.1, 1) == round(.3, 1)
False
```

Though the numbers cannot be made closer to their intended exact values, the `round()` function can be useful for post-rounding so that results with inexact values become comparable to one another:

```python
>>> round(.1 + .1 + .1, 10) == round(.3, 10)
True
```

Binary floating-point arithmetic holds many surprises like this. The problem with “0.1” is explained in precise detail below, in the
“Representation Error” section. See The Perils of Floating Point for a more complete account of other common surprises.

As that says near the end, “there are no easy answers.” Still, don’t be unduly wary of floating-point! The errors in Python float operations are inherited from the floating-point hardware, and on most machines are on the order of no more than 1 part in 2**53 per operation. That’s more than adequate for most tasks, but you do need to keep in mind that it’s not decimal arithmetic and that every float operation can suffer a new rounding error.

While pathological cases do exist, for most casual use of floating-point arithmetic you’ll see the result you expect in the end if you simply round the display of your final results to the number of decimal digits you expect. `str()` usually suffices, and for finer control see the `str.format()` method's format specifiers in Format String Syntax.

For use cases which require exact decimal representation, try using the `decimal` module which implements decimal arithmetic suitable for accounting applications and high-precision applications.

Another form of exact arithmetic is supported by the `fractions` module which implements arithmetic based on rational numbers (so the numbers like 1/3 can be represented exactly).

If you are a heavy user of floating point operations you should take a look at the Numerical Python package and many other packages for mathematical and statistical operations supplied by the SciPy project. See <https://scipy.org>.

Python provides tools that may help on those rare occasions when you really do want to know the exact value of a float. The `float.as_integer_ratio()` method expresses the value of a
float as a fraction:

```python
>>> x = 3.14159
>>> x.as_integer_ratio()
(3537115888337719, 1125899906842624)
```

Since the ratio is exact, it can be used to losslessly recreate the original value:

```python
>>> x == 3537115888337719 / 1125899906842624
True
```

The `float.hex()` method expresses a float in hexadecimal (base 16), again giving the exact value stored by your computer:

```python
>>> x.hex()
'0x1.921f9f01b866ep+1'
```

This precise hexadecimal representation can be used to reconstruct the float value exactly:

```python
>>> x == float.fromhex('0x1.921f9f01b866ep+1')
True
```

Since the representation is exact, it is useful for reliably porting values across different versions of Python (platform independence) and exchanging data with other languages that support the same format (such as Java and C99).

Another helpful tool is the `math.fsum()` function which helps mitigate loss-of-precision during summation. It tracks “lost digits” as values are added onto a running total. That can make a difference in overall accuracy so that the errors do not accumulate to the point where they affect the final total:
>>> sum([0.1] * 10) == 1.0
False
>>> math.fsum([0.1] * 10) == 1.0
True
15.1. Representation Error

This section explains the “0.1” example in detail, and shows how you can perform an exact analysis of cases like this yourself. Basic familiarity with binary floating-point representation is assumed.

*Representation error* refers to the fact that some (most, actually) decimal fractions cannot be represented exactly as binary (base 2) fractions. This is the chief reason why Python (or Perl, C, C++, Java, Fortran, and many others) often won’t display the exact decimal number you expect.

Why is that? 1/10 is not exactly representable as a binary fraction. Almost all machines today (November 2000) use IEEE-754 floating point arithmetic, and almost all platforms map Python floats to IEEE-754 “double precision”. 754 doubles contain 53 bits of precision, so on input the computer strives to convert 0.1 to the closest fraction it can of the form \( J/2^{**}N \) where \( J \) is an integer containing exactly 53 bits. Rewriting

\[
1 / 10 \sim J / (2^{**}N)
\]

as

\[
J \sim 2^{**}N / 10
\]

and recalling that \( J \) has exactly 53 bits (is \( \geq 2^{52} \) but \( < 2^{53} \)), the best value for \( N \) is 56:

\[
>>> 2^{**}52 \leq 2^{**}56 // 10 < 2^{**}53
\]

True
That is, 56 is the only value for $N$ that leaves $J$ with exactly 53 bits. The best possible value for $J$ is then that quotient rounded:

```python
>>> q, r = divmod(2**56, 10)
>>> r
6
```

Since the remainder is more than half of 10, the best approximation is obtained by rounding up:

```python
>>> q+1
7205759403792794
```

Therefore the best possible approximation to $1/10$ in 754 double precision is:

```
7205759403792794 / 2 ** 56
```

Dividing both the numerator and denominator by two reduces the fraction to:

```
3602879701896397 / 2 ** 55
```

Note that since we rounded up, this is actually a little bit larger than $1/10$; if we had not rounded up, the quotient would have been a little bit smaller than $1/10$. But in no case can it be exactly $1/10$!

So the computer never “sees” $1/10$: what it sees is the exact fraction given above, the best 754 double approximation it can get:

```python
>>> 0.1 * 2 ** 55
3602879701896397.0
```

If we multiply that fraction by $10^{55}$, we can see the value out to 55
decimal digits:

```
>>> 3602879701896397 * 10 ** 55 // 2 ** 55
1000000000000000055511151231257827021181583404541015625
```

meaning that the exact number stored in the computer is equal to the decimal value 0.1000000000000000055511151231257827021181583404541015625. Instead of displaying the full decimal value, many languages (including older versions of Python), round the result to 17 significant digits:

```
>>> format(0.1, '.17f')
'0.10000000000000001'
```

The fractions and decimal modules make these calculations easy:

```
>>> from decimal import Decimal
>>> from fractions import Fraction

>>> Fraction.from_float(0.1)
Fraction(3602879701896397, 36028797018963968)

>>> (0.1).as_integer_ratio()
(3602879701896397, 36028797018963968)

>>> Decimal.from_float(0.1)
Decimal('0.1000000000000000055511151231257827021181583404541015625')

>>> format(Decimal.from_float(0.1), '.17f')
'0.10000000000000001'
```
16. Appendix
16.1. Interactive Mode

16.1.1. Error Handling

When an error occurs, the interpreter prints an error message and a stack trace. In interactive mode, it then returns to the primary prompt; when input came from a file, it exits with a nonzero exit status after printing the stack trace. (Exceptions handled by an `except` clause in a `try` statement are not errors in this context.) Some errors are unconditionally fatal and cause an exit with a nonzero exit; this applies to internal inconsistencies and some cases of running out of memory. All error messages are written to the standard error stream; normal output from executed commands is written to standard output.

Typing the interrupt character (usually Control-C or Delete) to the primary or secondary prompt cancels the input and returns to the primary prompt. [1] Typing an interrupt while a command is executing raises the `KeyboardInterrupt` exception, which may be handled by a `try` statement.

16.1.2. Executable Python Scripts

On BSD’ish Unix systems, Python scripts can be made directly executable, like shell scripts, by putting the line

```
#!/usr/bin/env python3.5
```

(assuming that the interpreter is on the user’s PATH) at the beginning of the script and giving the file an executable mode. The `#!` must be the first two characters of the file. On some platforms, this first line must end with a Unix-style line ending (`\n`), not a Windows
The script can be given an executable mode, or permission, using the `chmod` command.

```
$ chmod +x myscript.py
```

On Windows systems, there is no notion of an “executable mode”. The Python installer automatically associates `.py` files with `python.exe` so that a double-click on a Python file will run it as a script. The extension can also be `.pyw`, in that case, the console window that normally appears is suppressed.

## 16.1.3. The Interactive Startup File

When you use Python interactively, it is frequently handy to have some standard commands executed every time the interpreter is started. You can do this by setting an environment variable named `PYTHONSTARTUP` to the name of a file containing your start-up commands. This is similar to the `.profile` feature of the Unix shells.

This file is only read in interactive sessions, not when Python reads commands from a script, and not when `/dev/tty` is given as the explicit source of commands (which otherwise behaves like an interactive session). It is executed in the same namespace where interactive commands are executed, so that objects that it defines or imports can be used without qualification in the interactive session. You can also change the prompts `sys.ps1` and `sys.ps2` in this file.

If you want to read an additional start-up file from the current directory, you can program this in the global start-up file using code like `if`
os.path.isfile('.pythonrc.py'): 
exec(open('.pythonrc.py').read()). If you want to use the startup file in a script, you must do this explicitly in the script:

```python
import os
filename = os.environ.get('PYTHONSTARTUP')
if filename and os.path.isfile(filename):
    with open(filename) as fobj:
        startup_file = fobj.read()
    exec(startup_file)
```

16.1.4. The Customization Modules

Python provides two hooks to let you customize it: sitecustomize and usercustomize. To see how it works, you need first to find the location of your user site-packages directory. Start Python and run this code:

```python
>>> import site
>>> site.getusersitepackages()
'/home/user/.local/lib/python3.5/site-packages'
```

Now you can create a file named `usercustomize.py` in that directory and put anything you want in it. It will affect every invocation of Python, unless it is started with the `-s` option to disable the automatic import.

`sitecustomize` works in the same way, but is typically created by an administrator of the computer in the global site-packages directory, and is imported before `usercustomize`. See the documentation of the `site` module for more details.
Footnotes

[1] A problem with the GNU Readline package may prevent this.
1. Command line and environment

The CPython interpreter scans the command line and the environment for various settings.

**CPython implementation detail**: Other implementations’ command line schemes may differ. See [Alternate Implementations](#) for further resources.
1.1. Command line

When invoking Python, you may specify any of these options:

```
python [-bBdEhiIOqsSuvVwx?] [-c command | -m module-name]
```

The most common use case is, of course, a simple invocation of a script:

```
python myscript.py
```

1.1.1. Interface options

The interpreter interface resembles that of the UNIX shell, but provides some additional methods of invocation:

- When called with standard input connected to a tty device, it prompts for commands and executes them until an EOF (an end-of-file character, you can produce that with Ctrl-D on UNIX or Ctrl-Z, Enter on Windows) is read.
- When called with a file name argument or with a file as standard input, it reads and executes a script from that file.
- When called with a directory name argument, it reads and executes an appropriately named script from that directory.
- When called with `-c command`, it executes the Python statement(s) given as command. Here command may contain multiple statements separated by newlines. Leading whitespace is significant in Python statements!
- When called with `-m module-name`, the given module is located on the Python module path and executed as a script.

In non-interactive mode, the entire input is parsed before it is
executed.

An interface option terminates the list of options consumed by the interpreter, all consecutive arguments will end up in sys.argv – note that the first element, subscript zero (sys.argv[0]), is a string reflecting the program’s source.

-\texttt{c}  <command>

Execute the Python code in \texttt{command}. \texttt{command} can be one or more statements separated by newlines, with significant leading whitespace as in normal module code.

If this option is given, the first element of \texttt{sys.argv} will be "-c" and the current directory will be added to the start of \texttt{sys.path} (allowing modules in that directory to be imported as top level modules).

-\texttt{m}  <module-name>

Search \texttt{sys.path} for the named module and execute its contents as the \texttt{__main__} module.

Since the argument is a \texttt{module} name, you must not give a file extension (.py). The module name should be a valid absolute Python module name, but the implementation may not always enforce this (e.g. it may allow you to use a name that includes a hyphen).

Package names (including namespace packages) are also permitted. When a package name is supplied instead of a normal module, the interpreter will execute <pkg>.__main__ as the main module. This behaviour is deliberately similar to the handling of directories and zipfiles that are passed to the interpreter as the script argument.
**Note:** This option cannot be used with built-in modules and extension modules written in C, since they do not have Python module files. However, it can still be used for precompiled modules, even if the original source file is not available.

If this option is given, the first element of `sys.argv` will be the full path to the module file (while the module file is being located, the first element will be set to "-m"). As with the `-c` option, the current directory will be added to the start of `sys.path`.

Many standard library modules contain code that is invoked on their execution as a script. An example is the `timeit` module:

```
python -mtimeit -s 'setup here' 'benchmarked code
python -mtimeit -h # for details
```

**See also:**
`runpy.run_module()`
Equivalent functionality directly available to Python code

**PEP 338** – Executing modules as scripts

*Changed in version 3.1:* Supply the package name to run a `__main__` submodule.

*Changed in version 3.4:* namespace packages are also supported -

Read commands from standard input (`sys.stdin`). If standard input is a terminal, `-i` is implied.

If this option is given, the first element of `sys.argv` will be "-" and the current directory will be added to the start of `sys.path`.
Execute the Python code contained in `script`, which must be a filesystem path (absolute or relative) referring to either a Python file, a directory containing a `__main__.py` file, or a zipfile containing a `__main__.py` file.

If this option is given, the first element of `sys.argv` will be the script name as given on the command line.

If the script name refers directly to a Python file, the directory containing that file is added to the start of `sys.path`, and the file is executed as the `__main__` module.

If the script name refers to a directory or zipfile, the script name is added to the start of `sys.path` and the `__main__.py` file in that location is executed as the `__main__` module.

**See also:**

```python
runpy.run_path()
```

Equivalent functionality directly available to Python code

If no interface option is given, `-i` is implied, `sys.argv[0]` is an empty string ("""), and the current directory will be added to the start of `sys.path`. Also, tab-completion and history editing is automatically enabled, if available on your platform (see Readline configuration).

**See also:** Invoking the Interpreter

*Changed in version 3.4:* Automatic enabling of tab-completion and history editing.
1.1.2. Generic options

-?
-h
--help

Print a short description of all command line options.

-V
--version

Print the Python version number and exit. Example output could be:

Python 3.6.0b2+

When given twice, print more information about the build, like:

Python 3.6.0b2+ (3.6:84a3c5003510+, Oct 26 2016, [GCC 6.2.0 20161005]

*New in version 3.6:* The -VV option.

1.1.3. Miscellaneous options

-b

Issue a warning when comparing bytes or bytearray with str or bytes with int. Issue an error when the option is given twice (-bb).

*Changed in version 3.5:* Affects comparisons of bytes with int.

-B
If given, Python won’t try to write .pyc files on the import of source modules. See also `PYTHONDONOTWRITEBYTECODE`.

-`d`

Turn on parser debugging output (for wizards only, depending on compilation options). See also `PYTHONDEBUG`.

-`E`

Ignore all PYTHON* environment variables, e.g. PYTHONPATH and PYTHONHOME, that might be set.

-`i`

When a script is passed as first argument or the -`c` option is used, enter interactive mode after executing the script or the command, even when `sys.stdin` does not appear to be a terminal. The PYTHONSTARTUP file is not read.

This can be useful to inspect global variables or a stack trace when a script raises an exception. See also `PYTHONINSPECT`.

-`I`

Run Python in isolated mode. This also implies -`E` and -`s`. In isolated mode `sys.path` contains neither the script’s directory nor the user’s site-packages directory. All PYTHON* environment variables are ignored, too. Further restrictions may be imposed to prevent the user from injecting malicious code.

*New in version 3.4.*

-`O`

Turn on basic optimizations. See also `PYTHONOPTIMIZE`.

-`OOo`
Discard docstrings in addition to the -O optimizations.

-q
Don’t display the copyright and version messages even in interactive mode.

New in version 3.2.

-R
Kept for compatibility. On Python 3.3 and greater, hash randomization is turned on by default.

On previous versions of Python, this option turns on hash randomization, so that the __hash__() values of str, bytes and datetime are “salted” with an unpredictable random value. Although they remain constant within an individual Python process, they are not predictable between repeated invocations of Python.

Hash randomization is intended to provide protection against a denial-of-service caused by carefully-chosen inputs that exploit the worst case performance of a dict construction, O(n^2) complexity. See http://www.ocert.org/advisories/ocert-2011-003.html for details.

PYTHONHASHSEED allows you to set a fixed value for the hash seed secret.

New in version 3.2.3.

-s
Don’t add the user site-packages directory to sys.path.

See also: PEP 370 – Per user site-packages directory
-S
Disable the import of the module `site` and the site-dependent manipulations of `sys.path` that it entails. Also disable these manipulations if `site` is explicitly imported later (call `site.main()` if you want them to be triggered).

-u
Force the binary layer of the stdout and stderr streams (which is available as their `buffer` attribute) to be unbuffered. The text I/O layer will still be line-buffered if writing to the console, or block-buffered if redirected to a non-interactive file.

See also `PYTHONUNBUFFERED`.

-v
Print a message each time a module is initialized, showing the place (filename or built-in module) from which it is loaded. When given twice (`-vv`), print a message for each file that is checked for when searching for a module. Also provides information on module cleanup at exit. See also `PYTHONVERBOSE`.

-W arg
Warning control. Python’s warning machinery by default prints warning messages to `sys.stderr`. A typical warning message has the following form:

```
file:line: category: message
```

By default, each warning is printed once for each source line where it occurs. This option controls how often warnings are printed.

Multiple `-W` options may be given; when a warning matches more
than one option, the action for the last matching option is performed. Invalid -W options are ignored (though, a warning message is printed about invalid options when the first warning is issued).

Warnings can also be controlled from within a Python program using the warnings module.

The simplest form of argument is one of the following action strings (or a unique abbreviation):

**ignore**
- Ignore all warnings.

**default**
- Explicitly request the default behavior (printing each warning once per source line).

**all**
- Print a warning each time it occurs (this may generate many messages if a warning is triggered repeatedly for the same source line, such as inside a loop).

**module**
- Print each warning only the first time it occurs in each module.

**once**
- Print each warning only the first time it occurs in the program.

**error**
- Raise an exception instead of printing a warning message.

The full form of argument is:

```
action:message:category:module:line
```

Here, *action* is as explained above but only applies to messages
that match the remaining fields. Empty fields match all values; trailing empty fields may be omitted. The message field matches the start of the warning message printed; this match is case-insensitive. The category field matches the warning category. This must be a class name; the match tests whether the actual warning category of the message is a subclass of the specified warning category. The full class name must be given. The module field matches the (fully-qualified) module name; this match is case-sensitive. The line field matches the line number, where zero matches all line numbers and is thus equivalent to an omitted line number.

See also:  
warnings – the warnings module
PEP 230 – Warning framework
PYTHONWARNINGS

-X

Skip the first line of the source, allowing use of non-Unix forms of 
#!cmd. This is intended for a DOS specific hack only.

Note:  The line numbers in error messages will be off by one.

-X

Reserved for various implementation-specific options. CPython 
currently defines the following possible values:

- -X fault_handler to enable fault_handler;
- -X showrefcount to output the total reference count and 
number of used memory blocks when the program finishes or 
after each statement in the interactive interpreter. This only 
works on debug builds.
- -X tracemalloc to start tracing Python memory allocations
using the `tracemalloc` module. By default, only the most recent frame is stored in a traceback of a trace. Use `-X tracemalloc=NFRAME` to start tracing with a traceback limit of `NFRAME` frames. See the `tracemalloc.start()` for more information.

- `-X showalloccount` to output the total count of allocated objects for each type when the program finishes. This only works when Python was built with `COUNT_ALLOCS` defined.

It also allows passing arbitrary values and retrieving them through the `sys._xoptions` dictionary.

*Changed in version 3.2:* The `-X` option was added.

*New in version 3.3:* The `-X faulthandler` option.

*New in version 3.4:* The `-X showrefcount` and `-X tracemalloc` options.

*New in version 3.6:* The `-X showalloccount` option.

## 1.1.4. Options you shouldn’t use

- `-J`

  Reserved for use by *Jython*. 
1.2. Environment variables

These environment variables influence Python’s behavior, they are processed before the command-line switches other than -E or -l. It is customary that command-line switches override environmental variables where there is a conflict.

**PYTHONHOME**

Change the location of the standard Python libraries. By default, the libraries are searched in `prefix/lib/pythonversion` and `exec_prefix/lib/pythonversion`, where `prefix` and `exec_prefix` are installation-dependent directories, both defaulting to `/usr/local`.

When **PYTHONHOME** is set to a single directory, its value replaces both `prefix` and `exec_prefix`. To specify different values for these, set **PYTHONHOME** to `prefix:exec_prefix`.

**PYTHONPATH**

Augment the default search path for module files. The format is the same as the shell's PATH: one or more directory pathnames separated by `os.pathsep` (e.g. colons on Unix or semicolons on Windows). Non-existent directories are silently ignored.

In addition to normal directories, individual **PYTHONPATH** entries may refer to zipfiles containing pure Python modules (in either source or compiled form). Extension modules cannot be imported from zipfiles.

The default search path is installation dependent, but generally begins with `prefix/lib/pythonversion` (see **PYTHONHOME**).
above). It is always appended to PYTHONPATH.

An additional directory will be inserted in the search path in front of PYTHONPATH as described above under Interface options. The search path can be manipulated from within a Python program as the variable sys.path.

**PYTHONSTARTUP**

If this is the name of a readable file, the Python commands in that file are executed before the first prompt is displayed in interactive mode. The file is executed in the same namespace where interactive commands are executed so that objects defined or imported in it can be used without qualification in the interactive session. You can also change the prompts sys.ps1 and sys.ps2 and the hook sys.__interactivehook__ in this file.

**PYTHONOPTIMIZE**

If this is set to a non-empty string it is equivalent to specifying the -O option. If set to an integer, it is equivalent to specifying -O multiple times.

**PYTHONDEBUG**

If this is set to a non-empty string it is equivalent to specifying the -d option. If set to an integer, it is equivalent to specifying -d multiple times.

**PYTHONINSPECT**

If this is set to a non-empty string it is equivalent to specifying the -i option.

This variable can also be modified by Python code using os.environ to force inspect mode on program termination.
**PYTHONUNBUFFERED**
If this is set to a non-empty string it is equivalent to specifying the `-u` option.

**PYTHONVERBOSE**
If this is set to a non-empty string it is equivalent to specifying the `-v` option. If set to an integer, it is equivalent to specifying `-v` multiple times.

**PYTHONCASEOK**
If this is set, Python ignores case in `import` statements. This only works on Windows and OS X.

**PYTHONDONTWRITEBYTECODE**
If this is set to a non-empty string, Python won’t try to write `.pyc` files on the import of source modules. This is equivalent to specifying the `-B` option.

**PYTHONHASHSEED**
If this variable is not set or set to `random`, a random value is used to seed the hashes of `str`, `bytes` and `datetime` objects.

If `PYTHONHASHSEED` is set to an integer value, it is used as a fixed seed for generating the `hash()` of the types covered by the hash randomization.

Its purpose is to allow repeatable hashing, such as for selftests for the interpreter itself, or to allow a cluster of python processes to share hash values.

The integer must be a decimal number in the range `[0,4294967295]`. Specifying the value 0 will disable hash randomization.
New in version 3.2.3.

**PYTHONIOENCODING**

If this is set before running the interpreter, it overrides the encoding used for stdin/stdout/stderr, in the syntax `encodingname:errordhandler`. Both the `encodingname` and the `:errordhandler` parts are optional and have the same meaning as in `str.encode()`.

For stderr, the `:errordhandler` part is ignored; the handler will always be 'backslashreplace'.

*Changed in version 3.4:* The `encodingname` part is now optional.

*Changed in version 3.6:* On Windows, the encoding specified by this variable is ignored for interactive console buffers unless `PYTHONLEGACYWINDOWSSTDIO` is also specified. Files and pipes redirected through the standard streams are not affected.

**PYTHONNOUSERSITE**

If this is set, Python won’t add the user site-packages directory to `sys.path`.

See also:  [PEP 370](https://www.python.org/dev/peps/pep-0370/) – Per user site-packages directory

**PYTHONUSERBASE**

Defines the user base directory, which is used to compute the path of the user site-packages directory and Distutils installation paths for `python setup.py install --user`.

See also:  [PEP 370](https://www.python.org/dev/peps/pep-0370/) – Per user site-packages directory
**PYTHONEXECUTABLE**

If this environment variable is set, `sys.argv[0]` will be set to its value instead of the value got through the C runtime. Only works on Mac OS X.

**PYTHONWARNINGS**

This is equivalent to the `-W` option. If set to a comma separated string, it is equivalent to specifying `-W` multiple times.

**PYTHONFAULTHANDLER**

If this environment variable is set to a non-empty string, `faulthandler.enable()` is called at startup: install a handler for SIGSEGV, SIGFPE, SIGABRT, SIGBUS and SIGILL signals to dump the Python traceback. This is equivalent to `-X faulthandler` option.

*New in version 3.3.*

**PYTHONTRACEMALLOC**

If this environment variable is set to a non-empty string, start tracing Python memory allocations using the `tracemalloc` module. The value of the variable is the maximum number of frames stored in a traceback of a trace. For example, `PYTHONTRACEMALLOC=1` stores only the most recent frame. See the `tracemalloc.start()` for more information.

*New in version 3.4.*

**PYTHONASYNCIODEBUG**

If this environment variable is set to a non-empty string, enable the debug mode of the `asyncio` module.

*New in version 3.4.*
**PYTHONMALLOC**

Set the Python memory allocators and/or install debug hooks.

Set the family of memory allocators used by Python:

- **malloc**: use the `malloc()` function of the C library for all domains (PYMEM DOMAIN RAW, PYMEM DOMAIN MEM, PYMEM DOMAIN OBJ).
- **pymalloc**: use the pymalloc allocator for PYMEM DOMAIN MEM and PYMEM DOMAIN OBJ domains and use the `malloc()` function for the PYMEM DOMAIN RAW domain.

Install debug hooks:

- **debug**: install debug hooks on top of the default memory allocator
- **malloc_debug**: same as `malloc` but also install debug hooks
- **pymalloc_debug**: same as `pymalloc` but also install debug hooks

When Python is compiled in release mode, the default is pymalloc. When compiled in debug mode, the default is pymalloc_debug and the debug hooks are used automatically.

If Python is configured without `pymalloc` support, pymalloc and `pymalloc_debug` are not available, the default is `malloc` in release mode and `malloc_debug` in debug mode.

See the `PyMem_SetupDebugHooks()` function for debug hooks on Python memory allocators.

*New in version 3.6.*
**PYTHONMALLOCSTATS**

If set to a non-empty string, Python will print statistics of the pymalloc memory allocator every time a new pymalloc object arena is created, and on shutdown.

This variable is ignored if the PYTHONMALLOC environment variable is used to force the malloc() allocator of the C library, or if Python is configured without pymalloc support.

*Changed in version 3.6:* This variable can now also be used on Python compiled in release mode. It now has no effect if set to an empty string.

**PYTHONLEGACYWINDOWSFSENCODING**

If set to a non-empty string, the default filesystem encoding and errors mode will revert to their pre-3.6 values of ‘mbcs’ and ‘replace’, respectively. Otherwise, the new defaults ‘utf-8’ and ‘surrogatepass’ are used.

This may also be enabled at runtime with `sys._enablelegacywindowsfsencoding()`.

*Availability:* Windows

*New in version 3.6:* See PEP 529 for more details.

**PYTHONLEGACYWINDOWSSSTUDIO**

If set to a non-empty string, does not use the new console reader and writer. This means that Unicode characters will be encoded according to the active console code page, rather than using utf-8.

This variable is ignored if the standard streams are redirected (to files or pipes) rather than referring to console buffers.
Availability: Windows

New in version 3.6.

1.2.1. Debug-mode variables

Setting these variables only has an effect in a debug build of Python, that is, if Python was configured with the `--with-pydebug` build option.

**PYTHONTHREADDEBUG**

If set, Python will print threading debug info.

**PYTHONDUMPREFS**

If set, Python will dump objects and reference counts still alive after shutting down the interpreter.
2. Using Python on Unix platforms
2.1. Getting and installing the latest version of Python

2.1.1. On Linux

Python comes preinstalled on most Linux distributions, and is available as a package on all others. However there are certain features you might want to use that are not available on your distro's package. You can easily compile the latest version of Python from source.

In the event that Python doesn't come preinstalled and isn't in the repositories as well, you can easily make packages for your own distro. Have a look at the following links:

See also:

for Debian users

https://en.opensuse.org/Portal:Packaging
for OpenSuse users

for Fedora users

for Slackware users

2.1.2. On FreeBSD and OpenBSD

- FreeBSD users, to add the package use:
OpenBSD users use:

```
pkg_add -r python
```

For example i386 users get the 2.5.1 version of Python using:

```
pkg_add ftp://ftp.openbsd.org/pub/OpenBSD/4.2/packages/i386/python-2.5.1p2.tgz
```

2.1.3. On OpenSolaris

You can get Python from OpenCSW. Various versions of Python are available and can be installed with e.g. `pkgutil -i python27`. 
2.2. Building Python

If you want to compile CPython yourself, first thing you should do is get the source. You can download either the latest release’s source or just grab a fresh clone. (If you want to contribute patches, you will need a clone.)

The build process consists in the usual

```
./configure
make
make install
```

invocations. Configuration options and caveats for specific Unix platforms are extensively documented in the README.rst file in the root of the Python source tree.

**Warning:** make install can overwrite or masquerade the python3 binary. make altinstall is therefore recommended instead of make install since it only installs

```
exec_prefix/bin/pythonversion.
```
2.3. Python-related paths and files

These are subject to difference depending on local installation conventions; prefix (${prefix}) and exec_prefix (${exec_prefix}) are installation-dependent and should be interpreted as for GNU software; they may be the same.

For example, on most Linux systems, the default for both is /usr.

<table>
<thead>
<tr>
<th>File/directory</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>exec_prefix/bin/python3</td>
<td>Recommended location of the interpreter.</td>
</tr>
<tr>
<td>prefix/lib/pythonversion, exec_prefix/lib/pythonversion</td>
<td>Recommended locations of the directories containing the standard modules.</td>
</tr>
<tr>
<td>prefix/include/pythonversion, exec_prefix/include/pythonversion</td>
<td>Recommended locations of the directories containing the include files needed for developing Python extensions and embedding the interpreter.</td>
</tr>
</tbody>
</table>
2.4. Miscellaneous

To easily use Python scripts on Unix, you need to make them executable, e.g. with

```bash
$ chmod +x script
```

and put an appropriate Shebang line at the top of the script. A good choice is usually

```
#!/usr/bin/env python3
```

which searches for the Python interpreter in the whole PATH. However, some Unices may not have the `env` command, so you may need to hardcode `/usr/bin/python3` as the interpreter path.

To use shell commands in your Python scripts, look at the `subprocess` module.
2.5. Editors and IDEs

There are a number of IDEs that support Python programming language. Many editors and IDEs provide syntax highlighting, debugging tools, and PEP-8 checks.

Please go to Python Editors and Integrated Development Environments for a comprehensive list.
3. Using Python on Windows

This document aims to give an overview of Windows-specific behaviour you should know about when using Python on Microsoft Windows.
3.1. Installing Python

Unlike most Unix systems and services, Windows does not include a system supported installation of Python. To make Python available, the CPython team has compiled Windows installers (MSI packages) with every release for many years. These installers are primarily intended to add a per-user installation of Python, with the core interpreter and library being used by a single user. The installer is also able to install for all users of a single machine, and a separate ZIP file is available for application-local distributions.

3.1.1. Supported Versions

As specified in PEP 11, a Python release only supports a Windows platform while Microsoft considers the platform under extended support. This means that Python 3.6 supports Windows Vista and newer. If you require Windows XP support then please install Python 3.4.

3.1.2. Installation Steps

Four Python 3.6 installers are available for download - two each for the 32-bit and 64-bit versions of the interpreter. The web installer is a small initial download, and it will automatically download the required components as necessary. The offline installer includes the components necessary for a default installation and only requires an internet connection for optional features. See Installing Without Downloading for other ways to avoid downloading during installation.

After starting the installer, one of two options may be selected:
If you select “Install Now”:

- You will not need to be an administrator (unless a system update for the C Runtime Library is required or you install the Python Launcher for Windows for all users)
- Python will be installed into your user directory
- The Python Launcher for Windows will be installed according to the option at the bottom of the first page
- The standard library, test suite, launcher and pip will be installed
- If selected, the install directory will be added to your PATH
- Shortcuts will only be visible for the current user

Selecting “Customize installation” will allow you to select the features to install, the installation location and other options or post-install actions. To install debugging symbols or binaries, you will need to use this option.

To perform an all-users installation, you should select “Customize installation”. In this case:
You may be required to provide administrative credentials or approval
Python will be installed into the Program Files directory
The Python Launcher for Windows will be installed into the Windows directory
Optional features may be selected during installation
The standard library can be pre-compiled to bytecode
If selected, the install directory will be added to the system PATH
Shortcuts are available for all users

3.1.3. Removing the MAX_PATH Limitation

Windows historically has limited path lengths to 260 characters. This meant that paths longer than this would not resolve and errors would result.

In the latest versions of Windows, this limitation can be expanded to approximately 32,000 characters. Your administrator will need to activate the “Enable Win32 long paths” group policy, or set the registry value
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\
to 1.

This allows the open() function, the os module and most other path functionality to accept and return paths longer than 260 characters when using strings. (Use of bytes as paths is deprecated on Windows, and this feature is not available when using bytes.)

After changing the above option, no further configuration is required.

Changed in version 3.6: Support for long paths was enabled in Python.

3.1.4. Installing Without UI
All of the options available in the installer UI can also be specified from the command line, allowing scripted installers to replicate an installation on many machines without user interaction. These options may also be set without suppressing the UI in order to change some of the defaults.

To completely hide the installer UI and install Python silently, pass the `/quiet` option. To skip past the user interaction but still display progress and errors, pass the `/passive` option. The `/uninstall` option may be passed to immediately begin removing Python - no prompt will be displayed.

All other options are passed as name=value, where the value is usually 0 to disable a feature, 1 to enable a feature, or a path. The full list of available options is shown below.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<td>1</td>
</tr>
<tr>
<td>Include_test</td>
<td>Install standard library test suite</td>
<td>1</td>
</tr>
<tr>
<td>Include_tools</td>
<td>Install utility scripts</td>
<td>1</td>
</tr>
</tbody>
</table>

- Only installs the launcher.
<table>
<thead>
<tr>
<th>LauncherOnly</th>
<th>This will override most other options.</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>SimpleInstall</td>
<td>Disable most install UI</td>
<td>0</td>
</tr>
<tr>
<td>SimpleInstallDescription</td>
<td>A custom message to display when the simplified install UI is used.</td>
<td>(empty)</td>
</tr>
</tbody>
</table>

For example, to silently install a default, system-wide Python installation, you could use the following command (from an elevated command prompt):

```bash
python-3.6.0.exe /quiet InstallAllUsers=1 PrependPath=1 Include_test=0
```

To allow users to easily install a personal copy of Python without the test suite, you could provide a shortcut with the following command. This will display a simplified initial page and disallow customization:

```bash
python-3.6.0.exe InstallAllUsers=0 Include_launcher=0 SimpleInstall=1 SimpleInstallDescription="Just for me, no test suite."
```

(Note that omitting the launcher also omits file associations, and is only recommended for per-user installs when there is also a system-wide installation that included the launcher.)

The options listed above can also be provided in a file named `unattend.xml` alongside the executable. This file specifies a list of options and values. When a value is provided as an attribute, it will be converted to a number if possible. Values provided as element text are
always left as strings. This example file sets the same options and the previous example:

```xml
<Options>
    <Option Name="InstallAllUsers" Value="no"/>
    <Option Name="Include_launcher" Value="0"/>
    <Option Name="Include_test" Value="no"/>
    <Option Name="SimpleInstall" Value="yes"/>
    <Option Name="SimpleInstallDescription">Just for me, no test suite</Option>
</Options>
```

### 3.1.5. Installing Without Downloading

As some features of Python are not included in the initial installer download, selecting those features may require an internet connection. To avoid this need, all possible components may be downloaded on-demand to create a complete *layout* that will no longer require an internet connection regardless of the selected features. Note that this download may be bigger than required, but where a large number of installations are going to be performed it is very useful to have a locally cached copy.

Execute the following command from Command Prompt to download all possible required files. Remember to substitute `python-3.6.0.exe` for the actual name of your installer, and to create layouts in their own directories to avoid collisions between files with the same name.

```
python-3.6.0.exe /layout [optional target directory]
```

You may also specify the `/quiet` option to hide the progress display.
3.1.6. Modifying an install

Once Python has been installed, you can add or remove features through the Programs and Features tool that is part of Windows. Select the Python entry and choose “Uninstall/Change” to open the installer in maintenance mode.

“Modify” allows you to add or remove features by modifying the checkboxes - unchanged checkboxes will not install or remove anything. Some options cannot be changed in this mode, such as the install directory; to modify these, you will need to remove and then reinstall Python completely.

“Repair” will verify all the files that should be installed using the current settings and replace any that have been removed or modified.

“Uninstall” will remove Python entirely, with the exception of the Python Launcher for Windows, which has its own entry in Programs and Features.

3.1.7. Other Platforms

With ongoing development of Python, some platforms that used to be supported earlier are no longer supported (due to the lack of users or developers). Check PEP 11 for details on all unsupported platforms.

- Windows CE is still supported.
- The Cygwin installer offers to install the Python interpreter as well (cf. Cygwin package source, Maintainer releases)

See Python for Windows for detailed information about platforms with pre-compiled installers.

**Python on XP**
“7 Minutes to “Hello World!”” by Richard Dooling, 2006

**Installing on Windows**

**For Windows users**
3.2. Alternative bundles

Besides the standard CPython distribution, there are modified packages including additional functionality. The following is a list of popular versions and their key features:

**ActivePython**
- Installer with multi-platform compatibility, documentation, PyWin32

**Anaconda**
- Popular scientific modules (such as numpy, scipy and pandas) and the `conda` package manager.

**Canopy**
- A “comprehensive Python analysis environment” with editors and other development tools.

**WinPython**
- Windows-specific distribution with prebuilt scientific packages and tools for building packages.

Note that these packages may not include the latest versions of Python or other libraries, and are not maintained or supported by the core Python team.
3.3. Configuring Python

To run Python conveniently from a command prompt, you might consider changing some default environment variables in Windows. While the installer provides an option to configure the PATH and PATHEXT variables for you, this is only reliable for a single, system-wide installation. If you regularly use multiple versions of Python, consider using the Python Launcher for Windows.

3.3.1. Excursus: Setting environment variables

Windows allows environment variables to be configured permanently at both the User level and the System level, or temporarily in a command prompt.

To temporarily set environment variables, open Command Prompt and use the `set` command:

```bash
C:\>set PATH=C:\Program Files\Python 3.6;%PATH%
C:\>set PYTHONPATH=%PYTHONPATH%;C:\My_python_lib
C:\>python
```

These changes will apply to any further commands executed in that console, and will be inherited by any applications started from the console.

Including the variable name within percent signs will expand to the existing value, allowing you to add your new value at either the start or the end. Modifying PATH by adding the directory containing `python.exe` to the start is a common way to ensure the correct version of Python is launched.
To permanently modify the default environment variables, click Start and search for ‘edit environment variables’, or open System properties, Advanced system settings and click the Environment Variables button. In this dialog, you can add or modify User and System variables. To change System variables, you need non-restricted access to your machine (i.e. Administrator rights).

**Note:** Windows will concatenate User variables after System variables, which may cause unexpected results when modifying PATH.

The `PYTHONPATH` variable is used by all versions of Python 2 and Python 3, so you should not permanently configure this variable unless it only includes code that is compatible with all of your installed Python versions.

3.3.2. Finding the Python executable

*Changed in version 3.5.*

Besides using the automatically created start menu entry for the Python interpreter, you might want to start Python in the command prompt. The installer has an option to set that up for you.

On the first page of the installer, an option labelled “Add Python to PATH” may be selected to have the installer add the install location into the PATH. The location of the `Scripts\` folder is also added. This allows you to type `python` to run the interpreter, and `pip` for the package installer. Thus, you can also execute your scripts with command line options, see *Command line* documentation.

If you don’t enable this option at install time, you can always re-run the installer, select Modify, and enable it. Alternatively, you can manually modify the PATH using the directions in *Excursus: Setting environment variables*. You need to set your PATH environment variable to include the directory of your Python installation, delimited by a semicolon from other entries. An example variable could look like this (assuming the first two entries already existed):

```
C:\WINDOWS\system32;C:\WINDOWS;C:\Program Files\Python
```
3.4. Python Launcher for Windows

New in version 3.3.

The Python launcher for Windows is a utility which aids in locating and executing of different Python versions. It allows scripts (or the command-line) to indicate a preference for a specific Python version, and will locate and execute that version.

Unlike the PATH variable, the launcher will correctly select the most appropriate version of Python. It will prefer per-user installations over system-wide ones, and orders by language version rather than using the most recently installed version.

3.4.1. Getting started

3.4.1.1. From the command-line

Changed in version 3.6.

System-wide installations of Python 3.3 and later will put the launcher on your PATH. The launcher is compatible with all available versions of Python, so it does not matter which version is installed. To check that the launcher is available, execute the following command in Command Prompt:

```
py
```

You should find that the latest version of Python you have installed is started - it can be exited as normal, and any additional command-line arguments specified will be sent directly to Python.
If you have multiple versions of Python installed (e.g., 2.7 and 3.6) you will have noticed that Python 3.6 was started - to launch Python 2.7, try the command:

```
py -2.7
```

If you want the latest version of Python 2.x you have installed, try the command:

```
py -2
```

You should find the latest version of Python 2.x starts.

If you see the following error, you do not have the launcher installed:

```
'py' is not recognized as an internal or external command, operable program or batch file.
```

Per-user installations of Python do not add the launcher to PATH unless the option was selected on installation.

### 3.4.1.2. Virtual environments

*New in version 3.5.*

If the launcher is run with no explicit Python version specification, and a virtual environment (created with the standard library `venv` module or the external `virtualenv` tool) active, the launcher will run the virtual environment’s interpreter rather than the global one. To run the global interpreter, either deactivate the virtual environment, or explicitly specify the global Python version.

### 3.4.1.3. From a script
Let's create a test Python script - create a file called `hello.py` with the following contents

```
#!/python
import sys
sys.stdout.write("hello from Python %s\n" % (sys.version,))
```

From the directory in which `hello.py` lives, execute the command:

```
py hello.py
```

You should notice the version number of your latest Python 2.x installation is printed. Now try changing the first line to be:

```
#!/python3
```

Re-executing the command should now print the latest Python 3.x information. As with the above command-line examples, you can specify a more explicit version qualifier. Assuming you have Python 2.6 installed, try changing the first line to `#!/python2.6` and you should find the 2.6 version information printed.

Note that unlike interactive use, a bare “python” will use the latest version of Python 2.x that you have installed. This is for backward compatibility and for compatibility with Unix, where the command `python` typically refers to Python 2.

3.4.1.4. From file associations

The launcher should have been associated with Python files (i.e. `.py`, `.pyw`, `.pyc` files) when it was installed. This means that when you
double-click on one of these files from Windows explorer the launcher will be used, and therefore you can use the same facilities described above to have the script specify the version which should be used.

The key benefit of this is that a single launcher can support multiple Python versions at the same time depending on the contents of the first line.

### 3.4.2. Shebang Lines

If the first line of a script file starts with `#!`, it is known as a “shebang” line. Linux and other Unix like operating systems have native support for such lines and they are commonly used on such systems to indicate how a script should be executed. This launcher allows the same facilities to be used with Python scripts on Windows and the examples above demonstrate their use.

To allow shebang lines in Python scripts to be portable between Unix and Windows, this launcher supports a number of ‘virtual’ commands to specify which interpreter to use. The supported virtual commands are:

- `#/usr/bin/env python`
- `#/usr/bin/python`
- `#/usr/local/bin/python`
- `python`

For example, if the first line of your script starts with

```
#!/usr/bin/python
```

The default Python will be located and used. As many Python scripts written to work on Unix will already have this line, you should find
these scripts can be used by the launcher without modification. If you are writing a new script on Windows which you hope will be useful on Unix, you should use one of the shebang lines starting with `#/usr`.

Any of the above virtual commands can be suffixed with an explicit version (either just the major version, or the major and minor version) - for example `/usr/bin/python2.7` - which will cause that specific version to be located and used.

The `/usr/bin/env` form of shebang line has one further special property. Before looking for installed Python interpreters, this form will search the executable PATH for a Python executable. This corresponds to the behaviour of the Unix `env` program, which performs a PATH search.

### 3.4.3. Arguments in shebang lines

The shebang lines can also specify additional options to be passed to the Python interpreter. For example, if you have a shebang line:

```bash
#!/usr/bin/python -v
```

Then Python will be started with the `-v` option

### 3.4.4. Customization

#### 3.4.4.1. Customization via INI files

Two .ini files will be searched by the launcher - `py.ini` in the current user’s “application data” directory (i.e. the directory returned by calling the Windows function `SHGetFolderPath` with `CSIDL_LOCAL_APPDATA`) and `py.ini` in the same directory as the
launcher. The same .ini files are used for both the ‘console’ version of the launcher (i.e. py.exe) and for the ‘windows’ version (i.e. pyw.exe)

Customization specified in the “application directory” will have precedence over the one next to the executable, so a user, who may not have write access to the .ini file next to the launcher, can override commands in that global .ini file)

3.4.4.2. Customizing default Python versions

In some cases, a version qualifier can be included in a command to dictate which version of Python will be used by the command. A version qualifier starts with a major version number and can optionally be followed by a period (‘.’) and a minor version specifier. If the minor qualifier is specified, it may optionally be followed by “-32” to indicate the 32-bit implementation of that version be used.

For example, a shebang line of #!python has no version qualifier, while #!python3 has a version qualifier which specifies only a major version.

If no version qualifiers are found in a command, the environment variable PY_PYTHON can be set to specify the default version qualifier - the default value is “2”. Note this value could specify just a major version (e.g. “2”) or a major.minor qualifier (e.g. “2.6”), or even major.minor-32.

If no minor version qualifiers are found, the environment variable PY_PYTHON{major} (where {major} is the current major version qualifier as determined above) can be set to specify the full version. If no such option is found, the launcher will enumerate the installed Python versions and use the latest minor release found for the major version, which is likely, although not guaranteed, to be the most
recently installed version in that family.

On 64-bit Windows with both 32-bit and 64-bit implementations of the same (major.minor) Python version installed, the 64-bit version will always be preferred. This will be true for both 32-bit and 64-bit implementations of the launcher - a 32-bit launcher will prefer to execute a 64-bit Python installation of the specified version if available. This is so the behavior of the launcher can be predicted knowing only what versions are installed on the PC and without regard to the order in which they were installed (i.e., without knowing whether a 32 or 64-bit version of Python and corresponding launcher was installed last). As noted above, an optional “-32” suffix can be used on a version specifier to change this behaviour.

Examples:

- If no relevant options are set, the commands `python` and `python2` will use the latest Python 2.x version installed and the command `python3` will use the latest Python 3.x installed.
- The commands `python3.1` and `python2.7` will not consult any options at all as the versions are fully specified.
- If PY_PYTHON=3, the commands `python` and `python3` will both use the latest installed Python 3 version.
- If PY_PYTHON=3.1-32, the command `python` will use the 32-bit implementation of 3.1 whereas the command `python3` will use the latest installed Python (PY_PYTHON was not considered at all as a major version was specified.)
- If PY_PYTHON=3 and PY_PYTHON3=3.1, the commands `python` and `python3` will both use specifically 3.1

In addition to environment variables, the same settings can be configured in the .INI file used by the launcher. The section in the INI file is called `[defaults]` and the key name will be the same as the
environment variables without the leading PY_ prefix (and note that the key names in the INI file are case insensitive.) The contents of an environment variable will override things specified in the INI file.

For example:

- Setting PY_PYTHON=3.1 is equivalent to the INI file containing:

  [defaults]
  python=3.1

- Setting PY_PYTHON=3 and PY_PYTHON3=3.1 is equivalent to the INI file containing:

  [defaults]
  python=3
  python3=3.1

3.4.5. Diagnostics

If an environment variable PYLAUNCH_DEBUG is set (to any value), the launcher will print diagnostic information to stderr (i.e. to the console). While this information manages to be simultaneously verbose and terse, it should allow you to see what versions of Python were located, why a particular version was chosen and the exact command-line used to execute the target Python.
3.5. Finding modules

Python usually stores its library (and thereby your site-packages folder) in the installation directory. So, if you had installed Python to C:\Python, the default library would reside in C:\Python\Lib and third-party modules should be stored in C:\Python\Lib\site-packages.

To completely override sys.path, create a .pth file with the same name as the DLL (python36.pth) or the executable (python.pth) and specify one line for each path to add to sys.path. The file based on the DLL name overrides the one based on the executable, which allows paths to be restricted for any program loading the runtime if desired.

When the file exists, all registry and environment variables are ignored, isolated mode is enabled, and site is not imported unless one line in the file specifies import site. Blank paths and lines starting with # are ignored. Each path may be absolute or relative to the location of the file. Import statements other than to site are not permitted, and arbitrary code cannot be specified.

Note that .pth files (without leading underscore) will be processed normally by the site module.

When no .pth file is found, this is how sys.path is populated on Windows:

- An empty entry is added at the start, which corresponds to the current directory.
- If the environment variable PYTHONPATH exists, as described in
Environment variables, its entries are added next. Note that on Windows, paths in this variable must be separated by semicolons, to distinguish them from the colon used in drive identifiers (C:\ etc.).

- Additional “application paths” can be added in the registry as subkeys of \SOFTWARE\Python\PythonCore\version\PythonPath under both the HKEY_CURRENT_USER and HKEY_LOCAL_MACHINE hives. Subkeys which have semicolon-delimited path strings as their default value will cause each path to be added to sys.path. (Note that all known installers only use HKLM, so HKCU is typically empty.)

- If the environment variable PYTHONHOME is set, it is assumed as “Python Home”. Otherwise, the path of the main Python executable is used to locate a “landmark file” (either Lib\os.py or pythonXY.zip) to deduce the “Python Home”. If a Python home is found, the relevant sub-directories added to sys.path (Lib, plat-win, etc) are based on that folder. Otherwise, the core Python path is constructed from the PythonPath stored in the registry.

- If the Python Home cannot be located, no PYTHONPATH is specified in the environment, and no registry entries can be found, a default path with relative entries is used (e.g. .\Lib;.\plat-win, etc).

If a pyvenv.cfg file is found alongside the main executable or in the directory one level above the executable, the following variations apply:

- If home is an absolute path and PYTHONHOME is not set, this path is used instead of the path to the main executable when deducing the home location.
The end result of all this is:

- When running `python.exe`, or any other `.exe` in the main Python directory (either an installed version, or directly from the PCbuild directory), the core path is deduced, and the core paths in the registry are ignored. Other “application paths” in the registry are always read.
- When Python is hosted in another `.exe` (different directory, embedded via COM, etc), the “Python Home” will not be deduced, so the core path from the registry is used. Other “application paths” in the registry are always read.
- If Python can’t find its home and there are no registry value (frozen `.exe`, some very strange installation setup) you get a path with some default, but relative, paths.

For those who want to bundle Python into their application or distribution, the following advice will prevent conflicts with other installations:

- Include a `_pth` file alongside your executable containing the directories to include. This will ignore paths listed in the registry and environment variables, and also ignore `site` unless `import site` is listed.
- If you are loading `python3.dll` or `python36.dll` in your own executable, explicitly call `Py_SetPath()` or (at least) `Py_SetProgramName()` before `Py_Initialize()`.
- Clear and/or overwrite `PYTHONPATH` and set `PYTHONHOME` before launching `python.exe` from your application.
- If you cannot use the previous suggestions (for example, you are a distribution that allows people to run `python.exe` directly), ensure that the landmark file (`Lib\os.py`) exists in your install directory. (Note that it will not be detected inside a ZIP file, but a correctly named ZIP file will be detected instead.)
These will ensure that the files in a system-wide installation will not take precedence over the copy of the standard library bundled with your application. Otherwise, your users may experience problems using your application. Note that the first suggestion is the best, as the other may still be susceptible to non-standard paths in the registry and user site-packages.

*Changed in version 3.6:*

- Adds `_pth` file support and removes `applocal` option from `pyvenv.cfg`.
- Adds `pythonXX.zip` as a potential landmark when directly adjacent to the executable.

*Deprecated since version 3.6:*

Modules specified in the registry under `Modules` (not `PythonPath`) may be imported by `importlib.machinery.WindowsRegistryFinder`. This finder is enabled on Windows in 3.6.0 and earlier, but may need to be explicitly added to `sys.meta_path` in the future.
3.6. Additional modules

Even though Python aims to be portable among all platforms, there are features that are unique to Windows. A couple of modules, both in the standard library and external, and snippets exist to use these features.

The Windows-specific standard modules are documented in MS Windows Specific Services.

3.6.1. PyWin32

The PyWin32 module by Mark Hammond is a collection of modules for advanced Windows-specific support. This includes utilities for:

- Component Object Model (COM)
- Win32 API calls
- Registry
- Event log
- Microsoft Foundation Classes (MFC) user interfaces

PythonWin is a sample MFC application shipped with PyWin32. It is an embeddable IDE with a built-in debugger.

See also:

Win32 How Do I…?
by Tim Golden

Python and COM
by David and Paul Boddie

3.6.2. cx_Freeze
cx_Freeze is a distutils extension (see Extending Distutils) which wraps Python scripts into executable Windows programs (*.exe files). When you have done this, you can distribute your application without requiring your users to install Python.

### 3.6.3. WConio

Since Python's advanced terminal handling layer, curses, is restricted to Unix-like systems, there is a library exclusive to Windows as well: Windows Console I/O for Python.

**WConio** is a wrapper for Turbo-C's CONIO.H, used to create text user interfaces.
3.7. Compiling Python on Windows

If you want to compile CPython yourself, first thing you should do is get the source. You can download either the latest release’s source or just grab a fresh checkout.

The source tree contains a build solution and project files for Microsoft Visual Studio 2015, which is the compiler used to build the official Python releases. These files are in the PCbuild directory.

Check PCbuild/readme.txt for general information on the build process.

For extension modules, consult Building C and C++ Extensions on Windows.

3.8. Embedded Distribution

*New in version 3.5.*

The embedded distribution is a ZIP file containing a minimal Python environment. It is intended for acting as part of another application, rather than being directly accessed by end-users.

When extracted, the embedded distribution is (almost) fully isolated from the user’s system, including environment variables, system registry settings, and installed packages. The standard library is included as pre-compiled and optimized `.pyc` files in a ZIP, and `python3.dll`, `python36.dll`, `python.exe` and `pythonw.exe` are all provided. Tcl/tk (including all dependants, such as Idle), pip and the Python documentation are not included.

**Note:** The embedded distribution does not include the [Microsoft C Runtime](https://docs.microsoft.com/en-us/cpp/build/microsoft-runtime-library) and it is the responsibility of the application installer to provide this. The runtime may have already been installed on a user’s system previously or automatically via Windows Update, and can be detected by finding `ucrtbase.dll` in the system directory.

Third-party packages should be installed by the application installer alongside the embedded distribution. Using pip to manage dependencies as for a regular Python installation is not supported with this distribution, though with some care it may be possible to include and use pip for automatic updates. In general, third-party packages should be treated as part of the application (“vendoring”) so that the developer can ensure compatibility with newer versions before providing updates to users.
The two recommended use cases for this distribution are described below.

3.8.1. Python Application

An application written in Python does not necessarily require users to be aware of that fact. The embedded distribution may be used in this case to include a private version of Python in an install package. Depending on how transparent it should be (or conversely, how professional it should appear), there are two options.

Using a specialized executable as a launcher requires some coding, but provides the most transparent experience for users. With a customized launcher, there are no obvious indications that the program is running on Python: icons can be customized, company and version information can be specified, and file associations behave properly. In most cases, a custom launcher should simply be able to call `Py_Main` with a hard-coded command line.

The simpler approach is to provide a batch file or generated shortcut that directly calls the `python.exe` or `pythonw.exe` with the required command-line arguments. In this case, the application will appear to be Python and not its actual name, and users may have trouble distinguishing it from other running Python processes or file associations.

With the latter approach, packages should be installed as directories alongside the Python executable to ensure they are available on the path. With the specialized launcher, packages can be located in other locations as there is an opportunity to specify the search path before launching the application.
3.8.2. Embedding Python

Applications written in native code often require some form of scripting language, and the embedded Python distribution can be used for this purpose. In general, the majority of the application is in native code, and some part will either invoke `python.exe` or directly use `python3.dll`. For either case, extracting the embedded distribution to a subdirectory of the application installation is sufficient to provide a loadable Python interpreter.

As with the application use, packages can be installed to any location as there is an opportunity to specify search paths before initializing the interpreter. Otherwise, there is no fundamental differences between using the embedded distribution and a regular installation.

4. Using Python on a Macintosh

Author: Bob Savage <bobsavage@mac.com>

Python on a Macintosh running Mac OS X is in principle very similar to Python on any other Unix platform, but there are a number of additional features such as the IDE and the Package Manager that are worth pointing out.
4.1. Getting and Installing MacPython

Mac OS X 10.8 comes with Python 2.7 pre-installed by Apple. If you wish, you are invited to install the most recent version of Python 3 from the Python website (https://www.python.org). A current “universal binary” build of Python, which runs natively on the Mac’s new Intel and legacy PPC CPU’s, is available there.

What you get after installing is a number of things:

- A MacPython 3.6 folder in your Applications folder. In here you find IDLE, the development environment that is a standard part of official Python distributions; PythonLauncher, which handles double-clicking Python scripts from the Finder; and the “Build Applet” tool, which allows you to package Python scripts as standalone applications on your system.

- A framework /Library/Frameworks/Python.framework, which includes the Python executable and libraries. The installer adds this location to your shell path. To uninstall MacPython, you can simply remove these three things. A symlink to the Python executable is placed in /usr/local/bin/.

The Apple-provided build of Python is installed in /System/Library/Frameworks/Python.framework and /usr/bin/python, respectively. You should never modify or delete these, as they are Apple-controlled and are used by Apple- or third-party software. Remember that if you choose to install a newer Python version from python.org, you will have two different but functional Python installations on your computer, so it will be important that your paths and usages are consistent with what you want to do.

IDLE includes a help menu that allows you to access Python
documentation. If you are completely new to Python you should start reading the tutorial introduction in that document.

If you are familiar with Python on other Unix platforms you should read the section on running Python scripts from the Unix shell.

4.1.1. How to run a Python script

Your best way to get started with Python on Mac OS X is through the IDLE integrated development environment, see section The IDE and use the Help menu when the IDE is running.

If you want to run Python scripts from the Terminal window command line or from the Finder you first need an editor to create your script. Mac OS X comes with a number of standard Unix command line editors, vim and emacs among them. If you want a more Mac-like editor, BBEdit or TextWrangler from Bare Bones Software (see http://www.barebones.com/products/bbedit/index.html) are good choices, as is TextMate (see https://macromates.com/). Other editors include Gvim (http://macvim.org) and Aquamacs (http://aquamacs.org/).

To run your script from the Terminal window you must make sure that /usr/local/bin is in your shell search path.

To run your script from the Finder you have two options:

- Drag it to PythonLauncher
- Select PythonLauncher as the default application to open your script (or any .py script) through the finder Info window and double-click it. PythonLauncher has various preferences to control how your script is launched. Option-dragging allows you to change these for one invocation, or use its Preferences menu to
change things globally.

4.1.2. Running scripts with a GUI

With older versions of Python, there is one Mac OS X quirk that you need to be aware of: programs that talk to the Aqua window manager (in other words, anything that has a GUI) need to be run in a special way. Use `pythonw` instead of `python` to start such scripts.

With Python 3.6, you can use either `python` or `pythonw`.

4.1.3. Configuration

Python on OS X honors all standard Unix environment variables such as `PYTHONPATH`, but setting these variables for programs started from the Finder is non-standard as the Finder does not read your `.profile` or `.cshrc` at startup. You need to create a file `~/.MacOSX/environment.plist`. See Apple's Technical Document QA1067 for details.

For more information on installation Python packages in MacPython, see section `Installing Additional Python Packages`.
4.2. The IDE

MacPython ships with the standard IDLE development environment. A good introduction to using IDLE can be found at https://hkn.eecs.berkeley.edu/~dyoo/python/idle_intro/index.html.
4.3. Installing Additional Python Packages

There are several methods to install additional Python packages:

- Packages can be installed via the standard Python distutils mode (python setup.py install).
- Many packages can also be installed via the setuptools extension or pip wrapper, see https://pip.pypa.io/.
4.4. GUI Programming on the Mac

There are several options for building GUI applications on the Mac with Python.

*PyObjC* is a Python binding to Apple’s Objective-C/Cocoa framework, which is the foundation of most modern Mac development. Information on PyObjC is available from [https://pythonhosted.org/pyobjc/](https://pythonhosted.org/pyobjc/).

The standard Python GUI toolkit is *tkinter*, based on the cross-platform Tk toolkit ([https://www.tcl.tk](https://www.tcl.tk)). An Aqua-native version of Tk is bundled with OS X by Apple, and the latest version can be downloaded and installed from [https://www.activestate.com](https://www.activestate.com); it can also be built from source.

*wxPython* is another popular cross-platform GUI toolkit that runs natively on Mac OS X. Packages and documentation are available from [http://www.wxpython.org](http://www.wxpython.org).

*PyQt* is another popular cross-platform GUI toolkit that runs natively on Mac OS X. More information can be found at [https://riverbankcomputing.com/software/pyqt/intro](https://riverbankcomputing.com/software/pyqt/intro).
4.5. Distributing Python Applications on the Mac

The “Build Applet” tool that is placed in the MacPython 3.6 folder is fine for packaging small Python scripts on your own machine to run as a standard Mac application. This tool, however, is not robust enough to distribute Python applications to other users.

The standard tool for deploying standalone Python applications on the Mac is **py2app**. More information on installing and using py2app can be found at [http://undefined.org/python/#py2app](http://undefined.org/python/#py2app).
4.6. Other Resources

The MacPython mailing list is an excellent support resource for Python users and developers on the Mac:

https://www.python.org/community/sigs/current/pythonmac-sig/

Another useful resource is the MacPython wiki:

https://wiki.python.org/moin/MacPython
1. Introduction

This reference manual describes the Python programming language. It is not intended as a tutorial.

While I am trying to be as precise as possible, I chose to use English rather than formal specifications for everything except syntax and lexical analysis. This should make the document more understandable to the average reader, but will leave room for ambiguities. Consequently, if you were coming from Mars and tried to re-implement Python from this document alone, you might have to guess things and in fact you would probably end up implementing quite a different language. On the other hand, if you are using Python and wonder what the precise rules about a particular area of the language are, you should definitely be able to find them here. If you would like to see a more formal definition of the language, maybe you could volunteer your time — or invent a cloning machine :-).

It is dangerous to add too many implementation details to a language reference document — the implementation may change, and other implementations of the same language may work differently. On the other hand, CPython is the one Python implementation in widespread use (although alternate implementations continue to gain support), and its particular quirks are sometimes worth being mentioned, especially where the implementation imposes additional limitations. Therefore, you’ll find short “implementation notes” sprinkled throughout the text.

Every Python implementation comes with a number of built-in and standard modules. These are documented in The Python Standard Library. A few built-in modules are mentioned when they interact in a significant way with the language definition.
1.1. Alternate Implementations

Though there is one Python implementation which is by far the most popular, there are some alternate implementations which are of particular interest to different audiences.

Known implementations include:

CPython
This is the original and most-maintained implementation of Python, written in C. New language features generally appear here first.

Jython
Python implemented in Java. This implementation can be used as a scripting language for Java applications, or can be used to create applications using the Java class libraries. It is also often used to create tests for Java libraries. More information can be found at the Jython website.

Python for .NET
This implementation actually uses the CPython implementation, but is a managed .NET application and makes .NET libraries available. It was created by Brian Lloyd. For more information, see the Python for .NET home page.

IronPython
An alternate Python for .NET. Unlike Python.NET, this is a complete Python implementation that generates IL, and compiles Python code directly to .NET assemblies. It was created by Jim Hugunin, the original creator of Jython. For more information, see the IronPython website.

PyPy
An implementation of Python written completely in Python. It supports several advanced features not found in other implementations like stackless support and a Just in Time compiler.
One of the goals of the project is to encourage experimentation with the language itself by making it easier to modify the interpreter (since it is written in Python). Additional information is available on the PyPy project’s home page.

Each of these implementations varies in some way from the language as documented in this manual, or introduces specific information beyond what’s covered in the standard Python documentation. Please refer to the implementation-specific documentation to determine what else you need to know about the specific implementation you’re using.
1.2. Notation

The descriptions of lexical analysis and syntax use a modified BNF grammar notation. This uses the following style of definition:

```
name ::= lc_letter (lc_letter | "_")*
lc_letter ::= "a"..."z"
```

The first line says that a `name` is an `lc_letter` followed by a sequence of zero or more `lc_letter`s and underscores. An `lc_letter` in turn is any of the single characters 'a' through 'z'. (This rule is actually adhered to for the names defined in lexical and grammar rules in this document.)

Each rule begins with a name (which is the name defined by the rule) and ::= . A vertical bar (|) is used to separate alternatives; it is the least binding operator in this notation. A star (*) means zero or more repetitions of the preceding item; likewise, a plus (+) means one or more repetitions, and a phrase enclosed in square brackets ([ ] ) means zero or one occurrences (in other words, the enclosed phrase is optional). The * and + operators bind as tightly as possible; parentheses are used for grouping. Literal strings are enclosed in quotes. White space is only meaningful to separate tokens. Rules are normally contained on a single line; rules with many alternatives may be formatted alternatively with each line after the first beginning with a vertical bar.

In lexical definitions (as the example above), two more conventions are used: Two literal characters separated by three dots mean a choice of any single character in the given (inclusive) range of ASCII characters. A phrase between angular brackets (<...>) gives an
informal description of the symbol defined; e.g., this could be used to describe the notion of ‘control character’ if needed.

Even though the notation used is almost the same, there is a big difference between the meaning of lexical and syntactic definitions: a lexical definition operates on the individual characters of the input source, while a syntax definition operates on the stream of tokens generated by the lexical analysis. All uses of BNF in the next chapter (“Lexical Analysis”) are lexical definitions; uses in subsequent chapters are syntactic definitions.
2. Lexical analysis

A Python program is read by a parser. Input to the parser is a stream of tokens, generated by the lexical analyzer. This chapter describes how the lexical analyzer breaks a file into tokens.

Python reads program text as Unicode code points; the encoding of a source file can be given by an encoding declaration and defaults to UTF-8, see PEP 3120 for details. If the source file cannot be decoded, a SyntaxError is raised.
2.1. Line structure

A Python program is divided into a number of *logical lines*.

2.1.1. Logical lines

The end of a logical line is represented by the token NEWLINE. Statements cannot cross logical line boundaries except where NEWLINE is allowed by the syntax (e.g., between statements in compound statements). A logical line is constructed from one or more *physical lines* by following the explicit or implicit *line joining* rules.

2.1.2. Physical lines

A physical line is a sequence of characters terminated by an end-of-line sequence. In source files, any of the standard platform line termination sequences can be used - the Unix form using ASCII LF (linefeed), the Windows form using the ASCII sequence CR LF (return followed by linefeed), or the old Macintosh form using the ASCII CR (return) character. All of these forms can be used equally, regardless of platform.

When embedding Python, source code strings should be passed to Python APIs using the standard C conventions for newline characters (the `\n` character, representing ASCII LF, is the line terminator).

2.1.3. Comments

A comment starts with a hash character (`#`) that is not part of a string literal, and ends at the end of the physical line. A comment signifies
the end of the logical line unless the implicit line joining rules are invoked. Comments are ignored by the syntax; they are not tokens.

2.1.4. Encoding declarations

If a comment in the first or second line of the Python script matches the regular expression `coding[=:]\s*([-\w.]+)`, this comment is processed as an encoding declaration; the first group of this expression names the encoding of the source code file. The encoding declaration must appear on a line of its own. If it is the second line, the first line must also be a comment-only line. The recommended forms of an encoding expression are

```
# -*- coding: <encoding-name> -*-
```

which is recognized also by GNU Emacs, and

```
# vim:fileencoding=<encoding-name>
```

which is recognized by Bram Moolenaar’s VIM.

If no encoding declaration is found, the default encoding is UTF-8. In addition, if the first bytes of the file are the UTF-8 byte-order mark (b'\xef\xbb\xbf'), the declared file encoding is UTF-8 (this is supported, among others, by Microsoft’s `notepad`).

If an encoding is declared, the encoding name must be recognized by Python. The encoding is used for all lexical analysis, including string literals, comments and identifiers.

2.1.5. Explicit line joining
Two or more physical lines may be joined into logical lines using backslash characters (\), as follows: when a physical line ends in a backslash that is not part of a string literal or comment, it is joined with the following forming a single logical line, deleting the backslash and the following end-of-line character. For example:

```python
if 1900 < year < 2100 and 1 <= month <= 12 \ 
    and 1 <= day <= 31 and 0 <= hour < 24 \ 
    and 0 <= minute < 60 and 0 <= second < 60: # Looks like a valid date
    return 1
```

A line ending in a backslash cannot carry a comment. A backslash does not continue a comment. A backslash does not continue a token except for string literals (i.e., tokens other than string literals cannot be split across physical lines using a backslash). A backslash is illegal elsewhere on a line outside a string literal.

### 2.1.6. Implicit line joining

Expressions in parentheses, square brackets or curly braces can be split over more than one physical line without using backslashes. For example:

```python
month_names = ['Januari', 'Februari', 'Maart', 'April', 'Mei', 'Juni', 'Juli', 'Augustus', 'September', 'Oktober', 'November', 'December']
```

Implicitly continued lines can carry comments. The indentation of the continuation lines is not important. Blank continuation lines are allowed. There is no NEWLINE token between implicit continuation lines. Implicitly continued lines can also occur within triple-quoted
strings (see below); in that case they cannot carry comments.

2.1.7. Blank lines

A logical line that contains only spaces, tabs, formfeeds and possibly a comment, is ignored (i.e., no NEWLINE token is generated). During interactive input of statements, handling of a blank line may differ depending on the implementation of the read-eval-print loop. In the standard interactive interpreter, an entirely blank logical line (i.e. one containing not even whitespace or a comment) terminates a multi-line statement.

2.1.8. Indentation

Leading whitespace (spaces and tabs) at the beginning of a logical line is used to compute the indentation level of the line, which in turn is used to determine the grouping of statements.

Tabs are replaced (from left to right) by one to eight spaces such that the total number of characters up to and including the replacement is a multiple of eight (this is intended to be the same rule as used by Unix). The total number of spaces preceding the first non-blank character then determines the line’s indentation. Indentation cannot be split over multiple physical lines using backslashes; the whitespace up to the first backslash determines the indentation.

Indentation is rejected as inconsistent if a source file mixes tabs and spaces in a way that makes the meaning dependent on the worth of a tab in spaces; a TabError is raised in that case.

**Cross-platform compatibility note:** because of the nature of text editors on non-UNIX platforms, it is unwise to use a mixture of spaces
and tabs for the indentation in a single source file. It should also be noted that different platforms may explicitly limit the maximum indentation level.

A formfeed character may be present at the start of the line; it will be ignored for the indentation calculations above. Formfeed characters occurring elsewhere in the leading whitespace have an undefined effect (for instance, they may reset the space count to zero).

The indentation levels of consecutive lines are used to generate INDENT and DEDENT tokens, using a stack, as follows.

Before the first line of the file is read, a single zero is pushed on the stack; this will never be popped off again. The numbers pushed on the stack will always be strictly increasing from bottom to top. At the beginning of each logical line, the line’s indentation level is compared to the top of the stack. If it is equal, nothing happens. If it is larger, it is pushed on the stack, and one INDENT token is generated. If it is smaller, it must be one of the numbers occurring on the stack; all numbers on the stack that are larger are popped off, and for each number popped off a DEDENT token is generated. At the end of the file, a DEDENT token is generated for each number remaining on the stack that is larger than zero.

Here is an example of a correctly (though confusingly) indented piece of Python code:

```python
def perm(l):
    # Compute the list of all permutations of l
    if len(l) <= 1:
        return [l]
    r = []
    for i in range(len(l)):
        s = l[:i] + l[i+1:]
```
\[
p = \text{perm}(s) \\
\textbf{for } x \textbf{ in } p: \\
\quad r.\text{append}(l[i:i+1] + x) \\
\textbf{return } r
\]

The following example shows various indentation errors:

```python
def perm(l):
    # error: first line indented
    for i in range(len(l)):
        s = l[:i] + l[i+1:] 
        p = \text{perm}(l[:i] + l[i+1:]) 
        # error: unexpected indent
        for x in p:
            r.\text{append}(l[i:i+1] + x)
    \textbf{return } r  
    # error: inconsistent dedent
```

(Actually, the first three errors are detected by the parser; only the last error is found by the lexical analyzer — the indentation of `return` does not match a level popped off the stack.)

2.1.9. Whitespace between tokens

Except at the beginning of a logical line or in string literals, the whitespace characters space, tab and formfeed can be used interchangeably to separate tokens. Whitespace is needed between two tokens only if their concatenation could otherwise be interpreted as a different token (e.g., `ab` is one token, but `a b` is two tokens).
2.2. Other tokens

Besides NEWLINE, INDENT and DEDENT, the following categories of tokens exist: *identifiers*, *keywords*, *literals*, *operators*, and *delimiters*. Whitespace characters (other than line terminators, discussed earlier) are not tokens, but serve to delimit tokens. Where ambiguity exists, a token comprises the longest possible string that forms a legal token, when read from left to right.
2.3. Identifiers and keywords

Identifiers (also referred to as *names*) are described by the following lexical definitions.

The syntax of identifiers in Python is based on the Unicode standard annex UAX-31, with elaboration and changes as defined below; see also [PEP 3131](https://www.python.org/dev/peps/pep-03131/) for further details.

Within the ASCII range (U+0001..U+007F), the valid characters for identifiers are the same as in Python 2.x: the uppercase and lowercase letters `A` through `Z`, the underscore `_` and, except for the first character, the digits `0` through `9`.

Python 3.0 introduces additional characters from outside the ASCII range (see [PEP 3131](https://www.python.org/dev/peps/pep-03131/)). For these characters, the classification uses the version of the Unicode Character Database as included in the `unicodedata` module.

Identifiers are unlimited in length. Case is significant.

```plaintext
identifier ::= xid_start xid_continue*
id_start ::= <all characters in general categories Lu, Ll, Lt, Lm, Lo, Nl, the underscore, and characters with the Other_ID_Start property>
id_continue ::= <all characters in id_start, plus characters in the categories Mn, Mc, Nd, Pc and others with the Other_ID_Continue property>
xid_start ::= <all characters in id_start whose NFKC normalization is in id_start xid_continue*> xid_continue ::= <all characters in id_continue whose NFKC normalization is in id_continue*>
```

The Unicode category codes mentioned above stand for:

- *Lu* - uppercase letters
- *Ll* - lowercase letters
- *Lt* - titlecase letters
- *Lm* - modifier letters
• *Lo* - other letters  
• *Nl* - letter numbers  
• *Mn* - nonspacing marks  
• *Mc* - spacing combining marks  
• *Nd* - decimal numbers  
• *Pc* - connector punctuations  
• *Other_ID_Start* - explicit list of characters in PropList.txt to support backwards compatibility  
• *Other_ID_Continue* - likewise

All identifiers are converted into the normal form NFKC while parsing; comparison of identifiers is based on NFKC.

A non-normative HTML file listing all valid identifier characters for Unicode 4.1 can be found at [https://www.dcl.hpi.uni-potsdam.de/home/loewis/table-3131.html](https://www.dcl.hpi.uni-potsdam.de/home/loewis/table-3131.html).

2.3.1. Keywords

The following identifiers are used as reserved words, or *keywords* of the language, and cannot be used as ordinary identifiers. They must be spelled exactly as written here:

<table>
<thead>
<tr>
<th>False</th>
<th>class</th>
<th>finally</th>
<th>is</th>
<th>return</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>continue</td>
<td>for</td>
<td>lambda</td>
<td>try</td>
</tr>
<tr>
<td>True</td>
<td>def</td>
<td>from</td>
<td>nonlocal</td>
<td>while</td>
</tr>
<tr>
<td>and</td>
<td>del</td>
<td>global</td>
<td>not</td>
<td>with</td>
</tr>
<tr>
<td>as</td>
<td>elif</td>
<td>if</td>
<td>or</td>
<td>yield</td>
</tr>
<tr>
<td>assert</td>
<td>else</td>
<td>import</td>
<td>pass</td>
<td></td>
</tr>
<tr>
<td>break</td>
<td>except</td>
<td>in</td>
<td>raise</td>
<td></td>
</tr>
</tbody>
</table>

2.3.2. Reserved classes of identifiers
Certain classes of identifiers (besides keywords) have special meanings. These classes are identified by the patterns of leading and trailing underscore characters:

_ *

Not imported by `from module import *`. The special identifier `_` is used in the interactive interpreter to store the result of the last evaluation; it is stored in the `builtins` module. When not in interactive mode, `_` has no special meaning and is not defined. See section *The import statement*.

**Note:** The name `_` is often used in conjunction with internationalization; refer to the documentation for the `gettext` module for more information on this convention.

__*__

System-defined names. These names are defined by the interpreter and its implementation (including the standard library). Current system names are discussed in the *Special method names* section and elsewhere. More will likely be defined in future versions of Python. Any use of __*__ names, in any context, that does not follow explicitly documented use, is subject to breakage without warning.

___*

Class-private names. Names in this category, when used within the context of a class definition, are re-written to use a mangled form to help avoid name clashes between “private” attributes of base and derived classes. See section *Identifiers (Names)*.
2.4. Literals

Literals are notations for constant values of some built-in types.

2.4.1. String and Bytes literals

String literals are described by the following lexical definitions:

```
stringliteral ::= [stringprefix](shortstring | longstring)
stringprefix ::= "r" | "u" | "R" | "U" | "f" | "F" |
                | "fr" | "Fr" | "fR" | "FR" |
shortstring ::= "'" shortstringitem* "'" | "'
longstring ::= "'''" longstringitem* "'''" | '''
shortstringitem ::= shortstringchar | stringescapeseq
longstringitem ::= longstringchar | stringescapeseq
shortstringchar ::= <any source character except "\" or newline or the quote>
longstringchar ::= <any ASCII character except "\">
stringescapeseq ::= "\" <any source character>
```

```
bytesliteral ::= bytesprefix(shortbytes | longbytes)
bytesprefix ::= "b" | "B" | "br" | "Br" | "bR" |
shortbytes ::= "'" shortbytesitem* "'" | "'
longbytes ::= "'''" longbytesitem* "'''" | '''
shortbytesitem ::= shortbyteschar | bytesescapeseq
longbytesitem ::= longbyteschar | bytesescapeseq
shortbyteschar ::= <any ASCII character except "\" or newline or the quote>
longbyteschar ::= <any ASCII character except "\">
bytesescapeseq ::= "\" <any ASCII character>
```

One syntactic restriction not indicated by these productions is that whitespace is not allowed between the stringprefix or bytesprefix and the rest of the literal. The source character set is
defined by the encoding declaration; it is UTF-8 if no encoding declaration is given in the source file; see section Encoding declarations.

In plain English: Both types of literals can be enclosed in matching single quotes ('') or double quotes ("'). They can also be enclosed in matching groups of three single or double quotes (these are generally referred to as triple-quoted strings). The backslash (\) character is used to escape characters that otherwise have a special meaning, such as newline, backslash itself, or the quote character.

Bytes literals are always prefixed with 'b' or 'B'; they produce an instance of the bytes type instead of the str type. They may only contain ASCII characters; bytes with a numeric value of 128 or greater must be expressed with escapes.

As of Python 3.3 it is possible again to prefix string literals with a u prefix to simplify maintenance of dual 2.x and 3.x codebases.

Both string and bytes literals may optionally be prefixed with a letter 'r' or 'R'; such strings are called raw strings and treat backslashes as literal characters. As a result, in string literals, '\U' and '\u' escapes in raw strings are not treated specially. Given that Python 2.x's raw unicode literals behave differently than Python 3.x's the 'ur' syntax is not supported.

New in version 3.3: The 'rb' prefix of raw bytes literals has been added as a synonym of 'br'.

New in version 3.3: Support for the unicode legacy literal (u'value') was reintroduced to simplify the maintenance of dual Python 2.x and 3.x codebases. See PEP 414 for more information.
A string literal with 'f' or 'F' in its prefix is a formatted string literal; see Formatted string literals. The 'f' may be combined with 'r', but not with 'b' or 'u', therefore raw formatted strings are possible, but formatted bytes literals are not.

In triple-quoted literals, unescaped newlines and quotes are allowed (and are retained), except that three unescaped quotes in a row terminate the literal. (A “quote” is the character used to open the literal, i.e. either ' or ".)

Unless an 'r' or 'R' prefix is present, escape sequences in string and bytes literals are interpreted according to rules similar to those used by Standard C. The recognized escape sequences are:

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Meaning</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>\newline</td>
<td>Backslash and newline ignored</td>
<td></td>
</tr>
<tr>
<td>\</td>
<td>Backslash ()</td>
<td></td>
</tr>
<tr>
<td>'</td>
<td>Single quote (')</td>
<td></td>
</tr>
<tr>
<td>&quot;</td>
<td>Double quote (&quot;)</td>
<td></td>
</tr>
<tr>
<td>\a</td>
<td>ASCII Bell (BEL)</td>
<td></td>
</tr>
<tr>
<td>\b</td>
<td>ASCII Backspace (BS)</td>
<td></td>
</tr>
<tr>
<td>\f</td>
<td>ASCII Formfeed (FF)</td>
<td></td>
</tr>
<tr>
<td>\n</td>
<td>ASCII Linefeed (LF)</td>
<td></td>
</tr>
<tr>
<td>\r</td>
<td>ASCII Carriage Return (CR)</td>
<td></td>
</tr>
<tr>
<td>\t</td>
<td>ASCII Horizontal Tab (TAB)</td>
<td></td>
</tr>
<tr>
<td>\v</td>
<td>ASCII Vertical Tab (VT)</td>
<td></td>
</tr>
<tr>
<td>\ooo</td>
<td>Character with octal value \ooo</td>
<td>(1,3)</td>
</tr>
</tbody>
</table>
Escape sequences only recognized in string literals are:

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Meaning</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>\N{name}</td>
<td>Character named name in the Unicode database</td>
<td>(4)</td>
</tr>
<tr>
<td>\uxxxx</td>
<td>Character with 16-bit hex value xxxx</td>
<td>(5)</td>
</tr>
<tr>
<td>\Uxxxxxxxxxxxx</td>
<td>Character with 32-bit hex value xxxxxxxxxx</td>
<td>(6)</td>
</tr>
</tbody>
</table>

Notes:

1. As in Standard C, up to three octal digits are accepted.
2. Unlike in Standard C, exactly two hex digits are required.
3. In a bytes literal, hexadecimal and octal escapes denote the byte with the given value. In a string literal, these escapes denote a Unicode character with the given value.
4. Changed in version 3.3: Support for name aliases [1] has been added.
5. Exactly four hex digits are required.
6. Any Unicode character can be encoded this way. Exactly eight hex digits are required.

Unlike Standard C, all unrecognized escape sequences are left in the string unchanged, i.e., the backslash is left in the result. (This behavior is useful when debugging: if an escape sequence is mistyped, the resulting output is more easily recognized as broken.) It is also
important to note that the escape sequences only recognized in string literals fall into the category of unrecognized escapes for bytes literals.

*Changed in version 3.6:* Unrecognized escape sequences produce a DeprecationWarning. In some future version of Python they will be a SyntaxError.

Even in a raw literal, quotes can be escaped with a backslash, but the backslash remains in the result; for example, `r"\""` is a valid string literal consisting of two characters: a backslash and a double quote; `r"\"` is not a valid string literal (even a raw string cannot end in an odd number of backslashes). Specifically, a *raw literal cannot end in a single backslash* (since the backslash would escape the following quote character). Note also that a single backslash followed by a newline is interpreted as those two characters as part of the literal, *not* as a line continuation.

### 2.4.2. String literal concatenation

Multiple adjacent string or bytes literals (delimited by whitespace), possibly using different quoting conventions, are allowed, and their meaning is the same as their concatenation. Thus, "hello
'world' is equivalent to "helloworld". This feature can be used to reduce the number of backslashes needed, to split long strings conveniently across long lines, or even to add comments to parts of strings, for example:

```python
re.compile("[A-Za-z_]" # letter or underscore
"[A-Za-z0-9_]" # letter, digit or underscore
)
```

Note that this feature is defined at the syntactical level, but
implemented at compile time. The ‘+’ operator must be used to concatenate string expressions at run time. Also note that literal concatenation can use different quoting styles for each component (even mixing raw strings and triple quoted strings), and formatted string literals may be concatenated with plain string literals.

2.4.3. Formatted string literals

New in version 3.6.

A **formatted string literal** or *f-string* is a string literal that is prefixed with 'f' or 'F'. These strings may contain replacement fields, which are expressions delimited by curly braces `{}`. While other string literals always have a constant value, formatted strings are really expressions evaluated at run time.

Escape sequences are decoded like in ordinary string literals (except when a literal is also marked as a raw string). After decoding, the grammar for the contents of the string is:

```
f_string ::= (literal_char | "{{" | "}")" |
replacement_field ::= "{" f_expression ["!"!] conversion |
| f_expression ::= (conditional_expression | "*"
| conditional_expression |
| yield_expression |
| conversion ::= "s" | "r" | "a"
| format_spec ::= (literal_char | NULL | replacement_field |
| literal_char ::= <any code point except "{", " |
```

The parts of the string outside curly braces are treated literally, except that any doubled curly braces '{{' or '}}' are replaced with the corresponding single curly brace. A single opening curly bracket '{'
marks a replacement field, which starts with a Python expression. After the expression, there may be a conversion field, introduced by an exclamation point `'!'`. A format specifier may also be appended, introduced by a colon `':'`. A replacement field ends with a closing curly bracket `'}'`.

Expressions in formatted string literals are treated like regular Python expressions surrounded by parentheses, with a few exceptions. An empty expression is not allowed, and a `lambda` expression must be surrounded by explicit parentheses. Replacement expressions can contain line breaks (e.g. in triple-quoted strings), but they cannot contain comments. Each expression is evaluated in the context where the formatted string literal appears, in order from left to right.

If a conversion is specified, the result of evaluating the expression is converted before formatting. Conversion `'!s'` calls `str()` on the result, `'!r'` calls `repr()`, and `'!a'` calls `ascii()`.

The result is then formatted using the `format()` protocol. The format specifier is passed to the `__format__()` method of the expression or conversion result. An empty string is passed when the format specifier is omitted. The formatted result is then included in the final value of the whole string.

Top-level format specifiers may include nested replacement fields. These nested fields may include their own conversion fields and format specifiers, but may not include more deeply-nested replacement fields.

Formatted string literals may be concatenated, but replacement fields cannot be split across literals.

Some examples of formatted string literals:
A consequence of sharing the same syntax as regular string literals is that characters in the replacement fields must not conflict with the quoting used in the outer formatted string literal:

```
f"abc {a['x']} def"  # error: outer string literal ended prematurely
f"abc {a['x']} def"  # workaround: use different quoting
```

Backslashes are not allowed in format expressions and will raise an error:

```
f"newline: {ord('\n')}"  # raises SyntaxError
```

To include a value in which a backslash escape is required, create a temporary variable.

```
>>> newline = ord('\n')
>>> f"newline: {newline}"
Formatted string literals cannot be used as docstrings, even if they do not include expressions.

```python
>>> def foo():
...    f"Not a docstring"
...>>> foo.__doc__ is None
True
```

See also PEP 498 for the proposal that added formatted string literals, and `str.format()`, which uses a related format string mechanism.

### 2.4.4. Numeric literals

There are three types of numeric literals: integers, floating point numbers, and imaginary numbers. There are no complex literals (complex numbers can be formed by adding a real number and an imaginary number).

Note that numeric literals do not include a sign; a phrase like `-1` is actually an expression composed of the unary operator `-' and the literal `1`.

### 2.4.5. Integer literals

Integer literals are described by the following lexical definitions:

```plaintext
integer ::= decinteger | bininteger | octinteger

decinteger ::= nonzerodigit (["_" ] digit)* | "0"-

bininteger ::= "0" ("b" | "B") (["_" ] bindigit)+

octinteger ::= "0" ("o" | "O") (["_" ] octdigit)+
```
There is no limit for the length of integer literals apart from what can be stored in available memory.

Underscores are ignored for determining the numeric value of the literal. They can be used to group digits for enhanced readability. One underscore can occur between digits, and after base specifiers like 0x.

Note that leading zeros in a non-zero decimal number are not allowed. This is for disambiguation with C-style octal literals, which Python used before version 3.0.

Some examples of integer literals:

<table>
<thead>
<tr>
<th>Integer</th>
<th>Hexadecimal</th>
<th>Octal</th>
<th>Binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>0x177</td>
<td>0o177</td>
<td>0b1111</td>
</tr>
<tr>
<td>3</td>
<td>0x177</td>
<td>0o377</td>
<td>0b1111</td>
</tr>
<tr>
<td>100_000_000_000</td>
<td>0o177</td>
<td>0o377</td>
<td>0b1111_0101</td>
</tr>
</tbody>
</table>

*Changed in version 3.6:* Underscores are now allowed for grouping purposes in literals.

## 2.4.6. Floating point literals

Floating point literals are described by the following lexical definitions:
Note that the integer and exponent parts are always interpreted using radix 10. For example, 077e010 is legal, and denotes the same number as 77e10. The allowed range of floating point literals is implementation-dependent. As in integer literals, underscores are supported for digit grouping.

Some examples of floating point literals:

```
3.14  10.  .001  1e100  3.14e-10  0e0
```

Note that numeric literals do not include a sign; a phrase like -1 is actually an expression composed of the unary operator - and the literal 1.

*Changed in version* 3.6: Underscores are now allowed for grouping purposes in literals.

### 2.4.7. Imaginary literals

Imaginary literals are described by the following lexical definitions:

```
imagnumber ::= (floatnumber | digitpart) ("j" | "J")
```

An imaginary literal yields a complex number with a real part of 0.0. Complex numbers are represented as a pair of floating point numbers
and have the same restrictions on their range. To create a complex number with a nonzero real part, add a floating point number to it, e.g., \((3+4j)\). Some examples of imaginary literals:

<table>
<thead>
<tr>
<th>3.14j</th>
<th>10.j</th>
<th>10j</th>
<th>.001j</th>
<th>1e100j</th>
<th>3.14e-10j</th>
</tr>
</thead>
</table>

2.5. Operators

The following tokens are operators:

<table>
<thead>
<tr>
<th>+</th>
<th>-</th>
<th>*</th>
<th>**</th>
<th>/</th>
<th>//</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;&lt;</td>
<td>&gt;&gt;</td>
<td>&amp;</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>&lt;</td>
<td>&gt;</td>
<td>&lt;=</td>
<td>&gt;=</td>
<td>==</td>
<td>!=</td>
<td></td>
</tr>
</tbody>
</table>
2.6. Delimiters

The following tokens serve as delimiters in the grammar:

<table>
<thead>
<tr>
<th>,</th>
<th>:</th>
<th>.</th>
<th>;</th>
<th>@</th>
<th>=</th>
<th>-&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>+=</td>
<td>-=</td>
<td>*=</td>
<td>/=</td>
<td>//=</td>
<td>%=</td>
<td>@=</td>
</tr>
<tr>
<td>&amp;=</td>
<td></td>
<td>=</td>
<td>^=</td>
<td>&gt;&gt;=</td>
<td>&lt;&lt;=</td>
<td>**=</td>
</tr>
</tbody>
</table>

The period can also occur in floating-point and imaginary literals. A sequence of three periods has a special meaning as an ellipsis literal.

The second half of the list, the augmented assignment operators, serve lexically as delimiters, but also perform an operation.

The following printing ASCII characters have special meaning as part of other tokens or are otherwise significant to the lexical analyzer:

| ' | " | # | \ |

The following printing ASCII characters are not used in Python. Their occurrence outside string literals and comments is an unconditional error:

| $ | ? | ` | \ |

3. Data model
3.1. Objects, values and types

*Objects* are Python’s abstraction for data. All data in a Python program is represented by objects or by relations between objects. (In a sense, and in conformance to Von Neumann’s model of a “stored program computer,” code is also represented by objects.)

Every object has an identity, a type and a value. An object’s *identity* never changes once it has been created; you may think of it as the object’s address in memory. The ‘*is*’ operator compares the identity of two objects; the `id()` function returns an integer representing its identity.

**CPython implementation detail:** For CPython, `id(x)` is the memory address where `x` is stored.

An object’s *type* determines the operations that the object supports (e.g., “does it have a length?”) and also defines the possible values for objects of that type. The `type()` function returns an object’s type (which is an object itself). Like its identity, an object’s *type* is also unchangeable. [1]

The *value* of some objects can change. Objects whose value can change are said to be *mutable*; objects whose value is unchangeable once they are created are called *immutable*. (The value of an immutable container object that contains a reference to a mutable object can change when the latter’s value is changed; however the container is still considered immutable, because the collection of objects it contains cannot be changed. So, immutability is not strictly the same as having an unchangeable value, it is more subtle.) An object’s mutability is determined by its type; for instance, numbers, strings and tuples are immutable, while dictionaries and lists are
mutable.

Objects are never explicitly destroyed; however, when they become unreachable they may be garbage-collected. An implementation is allowed to postpone garbage collection or omit it altogether — it is a matter of implementation quality how garbage collection is implemented, as long as no objects are collected that are still reachable.

**CPython implementation detail:** CPython currently uses a reference-counting scheme with (optional) delayed detection of cyclically linked garbage, which collects most objects as soon as they become unreachable, but is not guaranteed to collect garbage containing circular references. See the documentation of the `gc` module for information on controlling the collection of cyclic garbage. Other implementations act differently and CPython may change. Do not depend on immediate finalization of objects when they become unreachable (so you should always close files explicitly).

Note that the use of the implementation’s tracing or debugging facilities may keep objects alive that would normally be collectable. Also note that catching an exception with a `try...except` statement may keep objects alive.

Some objects contain references to “external” resources such as open files or windows. It is understood that these resources are freed when the object is garbage-collected, but since garbage collection is not guaranteed to happen, such objects also provide an explicit way to release the external resource, usually a `close()` method. Programs are strongly recommended to explicitly close such objects. The `try...finally` statement and the `with` statement provide convenient ways to do this.
Some objects contain references to other objects; these are called containers. Examples of containers are tuples, lists and dictionaries. The references are part of a container’s value. In most cases, when we talk about the value of a container, we imply the values, not the identities of the contained objects; however, when we talk about the mutability of a container, only the identities of the immediately contained objects are implied. So, if an immutable container (like a tuple) contains a reference to a mutable object, its value changes if that mutable object is changed.

Types affect almost all aspects of object behavior. Even the importance of object identity is affected in some sense: for immutable types, operations that compute new values may actually return a reference to any existing object with the same type and value, while for mutable objects this is not allowed. E.g., after `a = 1; b = 1`, `a` and `b` may or may not refer to the same object with the value one, depending on the implementation, but after `c = []; d = []`, `c` and `d` are guaranteed to refer to two different, unique, newly created empty lists. (Note that `c = d = []` assigns the same object to both `c` and `d`.)
3.2. The standard type hierarchy

Below is a list of the types that are built into Python. Extension modules (written in C, Java, or other languages, depending on the implementation) can define additional types. Future versions of Python may add types to the type hierarchy (e.g., rational numbers, efficiently stored arrays of integers, etc.), although such additions will often be provided via the standard library instead.

Some of the type descriptions below contain a paragraph listing ‘special attributes.’ These are attributes that provide access to the implementation and are not intended for general use. Their definition may change in the future.

None
This type has a single value. There is a single object with this value. This object is accessed through the built-in name `None`. It is used to signify the absence of a value in many situations, e.g., it is returned from functions that don’t explicitly return anything. Its truth value is false.

NotImplemented
This type has a single value. There is a single object with this value. This object is accessed through the built-in name `NotImplemented`. Numeric methods and rich comparison methods should return this value if they do not implement the operation for the operands provided. (The interpreter will then try the reflected operation, or some other fallback, depending on the operator.) Its truth value is true.

See Implementing the arithmetic operations for more details.
Ellipsis

This type has a single value. There is a single object with this value. This object is accessed through the literal \ldots or the built-in name \texttt{Ellipsis}. Its truth value is true.

\texttt{numbers.Number}

These are created by numeric literals and returned as results by arithmetic operators and arithmetic built-in functions. Numeric objects are immutable; once created their value never changes. Python numbers are of course strongly related to mathematical numbers, but subject to the limitations of numerical representation in computers.

Python distinguishes between integers, floating point numbers, and complex numbers:

\texttt{numbers.Integral}

These represent elements from the mathematical set of integers (positive and negative).

There are two types of integers:

Integers (\texttt{int})

These represent numbers in an unlimited range, subject to available (virtual) memory only. For the purpose of shift and mask operations, a binary representation is assumed, and negative numbers are represented in a variant of 2’s complement which gives the illusion of an infinite string of sign bits extending to the left.

Booleans (\texttt{bool})

These represent the truth values False and True. The two objects representing the values \texttt{False} and \texttt{True} are the
only Boolean objects. The Boolean type is a subtype of the integer type, and Boolean values behave like the values 0 and 1, respectively, in almost all contexts, the exception being that when converted to a string, the strings "False" or "True" are returned, respectively.

The rules for integer representation are intended to give the most meaningful interpretation of shift and mask operations involving negative integers.

numbers.Real (float)
These represent machine-level double precision floating point numbers. You are at the mercy of the underlying machine architecture (and C or Java implementation) for the accepted range and handling of overflow. Python does not support single-precision floating point numbers; the savings in processor and memory usage that are usually the reason for using these are dwarfed by the overhead of using objects in Python, so there is no reason to complicate the language with two kinds of floating point numbers.

numbers.Complex (complex)
These represent complex numbers as a pair of machine-level double precision floating point numbers. The same caveats apply as for floating point numbers. The real and imaginary parts of a complex number $z$ can be retrieved through the read-only attributes $z.real$ and $z.imag$.

Sequences
These represent finite ordered sets indexed by non-negative numbers. The built-in function $\text{len()}$ returns the number of items of a sequence. When the length of a sequence is $n$, the index set
contains the numbers 0, 1, ..., n-1. Item i of sequence a is selected by \( a[i] \).

Sequences also support slicing: \( a[i:j] \) selects all items with index \( k \) such that \( i \leq k < j \). When used as an expression, a slice is a sequence of the same type. This implies that the index set is renumbered so that it starts at 0.

Some sequences also support “extended slicing” with a third “step” parameter: \( a[i:j:k] \) selects all items of a with index \( x \) where \( x = i + n*k \), \( n \geq 0 \) and \( i \leq x < j \).

Sequences are distinguished according to their mutability:

Immutable sequences

An object of an immutable sequence type cannot change once it is created. (If the object contains references to other objects, these other objects may be mutable and may be changed; however, the collection of objects directly referenced by an immutable object cannot change.)

The following types are immutable sequences:

Strings

A string is a sequence of values that represent Unicode code points. All the code points in the range \( \text{U+0000} - \text{U+10FFFF} \) can be represented in a string. Python doesn't have a char type; instead, every code point in the string is represented as a string object with length 1. The built-in function \( \text{ord()} \) converts a code point from its string form to an integer in the range \( 0 - 10FFFF \); \( \text{chr()} \) converts an integer in the range \( 0 - 10FFFF \) to the corresponding
length 1 string object. \texttt{str.encode()} can be used to convert a \texttt{str} to \texttt{bytes} using the given text encoding, and \texttt{bytes.decode()} can be used to achieve the opposite.

Tuples
The items of a tuple are arbitrary Python objects. Tuples of two or more items are formed by comma-separated lists of expressions. A tuple of one item (a ‘singleton’) can be formed by affixing a comma to an expression (an expression by itself does not create a tuple, since parentheses must be usable for grouping of expressions). An empty tuple can be formed by an empty pair of parentheses.

Bytes
A bytes object is an immutable array. The items are 8-bit bytes, represented by integers in the range $0 \leq x < 256$. Bytes literals (like \texttt{b'abc'}) and the built-in \texttt{bytes()} constructor can be used to create bytes objects. Also, bytes objects can be decoded to strings via the \texttt{decode()} method.

Mutable sequences
Mutable sequences can be changed after they are created. The subscription and slicing notations can be used as the target of assignment and \texttt{del} (delete) statements.

There are currently two intrinsic mutable sequence types:

Lists
The items of a list are arbitrary Python objects. Lists are formed by placing a comma-separated list of expressions in square brackets. (Note that there are no special cases needed to form lists of length 0 or 1.)
Byte Arrays

A bytearray object is a mutable array. They are created by the built-in `bytearray()` constructor. Aside from being mutable (and hence unhashable), byte arrays otherwise provide the same interface and functionality as immutable `bytes` objects.

The extension module `array` provides an additional example of a mutable sequence type, as does the `collections` module.

Set types

These represent unordered, finite sets of unique, immutable objects. As such, they cannot be indexed by any subscript. However, they can be iterated over, and the built-in function `len()` returns the number of items in a set. Common uses for sets are fast membership testing, removing duplicates from a sequence, and computing mathematical operations such as intersection, union, difference, and symmetric difference.

For set elements, the same immutability rules apply as for dictionary keys. Note that numeric types obey the normal rules for numeric comparison: if two numbers compare equal (e.g., 1 and 1.0), only one of them can be contained in a set.

There are currently two intrinsic set types:

Sets

These represent a mutable set. They are created by the built-in `set()` constructor and can be modified afterwards by several methods, such as `add()`.
Frozen sets
These represent an immutable set. They are created by the built-in `frozenset()` constructor. As a frozenset is immutable and hashable, it can be used again as an element of another set, or as a dictionary key.

Mappings
These represent finite sets of objects indexed by arbitrary index sets. The subscript notation `a[k]` selects the item indexed by `k` from the mapping `a`; this can be used in expressions and as the target of assignments or `del` statements. The built-in function `len()` returns the number of items in a mapping.

There is currently a single intrinsic mapping type:

Dictionaries
These represent finite sets of objects indexed by nearly arbitrary values. The only types of values not acceptable as keys are values containing lists or dictionaries or other mutable types that are compared by value rather than by object identity, the reason being that the efficient implementation of dictionaries requires a key's hash value to remain constant. Numeric types used for keys obey the normal rules for numeric comparison: if two numbers compare equal (e.g., `1` and `1.0`) then they can be used interchangeably to index the same dictionary entry.

Dictionaries are mutable; they can be created by the `{...}` notation (see section Dictionary displays).

The extension modules `dbm.ndbm` and `dbm.gnu` provide additional examples of mapping types, as does the `collections` module.
Callable types

These are the types to which the function call operation (see section Calls) can be applied:

User-defined functions

A user-defined function object is created by a function definition (see section Function definitions). It should be called with an argument list containing the same number of items as the function’s formal parameter list.

Special attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Meaning</th>
<th>Writable</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>doc</strong></td>
<td>The function’s documentation string, or None if unavailable; not inherited by subclasses</td>
<td>Writable</td>
</tr>
<tr>
<td><strong>name</strong></td>
<td>The function’s name</td>
<td>Writable</td>
</tr>
<tr>
<td><strong>qualname</strong></td>
<td>The function’s qualified name</td>
<td>Writable</td>
</tr>
<tr>
<td><strong>module</strong></td>
<td>The name of the module the function was defined in, or None if unavailable.</td>
<td>Writable</td>
</tr>
<tr>
<td><strong>defaults</strong></td>
<td>A tuple containing default argument values for those arguments that have defaults, or None if no arguments have a default value</td>
<td>Writable</td>
</tr>
<tr>
<td></td>
<td>The code object</td>
<td></td>
</tr>
<tr>
<td><strong>code</strong></td>
<td>representing the compiled function body.</td>
<td>Writable</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td><strong>globals</strong></td>
<td>A reference to the dictionary that holds the function’s global variables — the global namespace of the module in which the function was defined.</td>
<td>Read-only</td>
</tr>
<tr>
<td><strong>dict</strong></td>
<td>The namespace supporting arbitrary function attributes.</td>
<td>Writable</td>
</tr>
<tr>
<td><strong>closure</strong></td>
<td>None or a tuple of cells that contain bindings for the function’s free variables.</td>
<td>Read-only</td>
</tr>
<tr>
<td><strong>annotations</strong></td>
<td>A dict containing annotations of parameters. The keys of the dict are the parameter names, and 'return' for the return annotation, if provided.</td>
<td>Writable</td>
</tr>
<tr>
<td><strong>kwdefaults</strong></td>
<td>A dict containing defaults for keyword-only parameters.</td>
<td>Writable</td>
</tr>
</tbody>
</table>

Most of the attributes labelled “Writable” check the type of the assigned value.

Function objects also support getting and setting arbitrary attributes, which can be used, for example, to attach metadata to functions. Regular attribute dot-notation is used to get and set such attributes. Note that the current implementation only supports function attributes on user-defined functions. Function attributes on built-in functions may be supported in the future.
Additional information about a function’s definition can be retrieved from its code object; see the description of internal types below.

Instance methods
An instance method object combines a class, a class instance and any callable object (normally a user-defined function).

Special read-only attributes: __self__ is the class instance object, __func__ is the function object; __doc__ is the method’s documentation (same as __func__.__doc__); __name__ is the method name (same as __func__.__name__); __module__ is the name of the module the method was defined in, or None if unavailable.

Methods also support accessing (but not setting) the arbitrary function attributes on the underlying function object.

User-defined method objects may be created when getting an attribute of a class (perhaps via an instance of that class), if that attribute is a user-defined function object or a class method object.

When an instance method object is created by retrieving a user-defined function object from a class via one of its instances, its __self__ attribute is the instance, and the method object is said to be bound. The new method’s __func__ attribute is the original function object.

When a user-defined method object is created by retrieving another method object from a class or instance, the behaviour is the same as for a function object, except that the __func__ attribute of the new instance is not the original method object
but its __func__ attribute.

When an instance method object is created by retrieving a class method object from a class or instance, its __self__ attribute is the class itself, and its __func__ attribute is the function object underlying the class method.

When an instance method object is called, the underlying function (__func__) is called, inserting the class instance (__self__) in front of the argument list. For instance, when C is a class which contains a definition for a function f(), and x is an instance of C, calling x.f(1) is equivalent to calling C.f(x, 1).

When an instance method object is derived from a class method object, the “class instance” stored in __self__ will actually be the class itself, so that calling either x.f(1) or C.f(1) is equivalent to calling f(C,1) where f is the underlying function.

Note that the transformation from function object to instance method object happens each time the attribute is retrieved from the instance. In some cases, a fruitful optimization is to assign the attribute to a local variable and call that local variable. Also notice that this transformation only happens for user-defined functions; other callable objects (and all non-callable objects) are retrieved without transformation. It is also important to note that user-defined functions which are attributes of a class instance are not converted to bound methods; this only happens when the function is an attribute of the class.

Generator functions
A function or method which uses the `yield` statement (see section The `yield` statement) is called a **generator function**. Such a function, when called, always returns an iterator object which can be used to execute the body of the function: calling the iterator's `__next__()` method will cause the function to execute until it provides a value using the `yield` statement. When the function executes a `return` statement or falls off the end, a **StopIteration** exception is raised and the iterator will have reached the end of the set of values to be returned.

**Coroutine functions**

A function or method which is defined using `async def` is called a **coroutine function**. Such a function, when called, returns a coroutine object. It may contain `await` expressions, as well as `async with` and `async for` statements. See also the Coroutine Objects section.

**Asynchronous generator functions**

A function or method which is defined using `async def` and which uses the `yield` statement is called a **asynchronous generator function**. Such a function, when called, returns an asynchronous iterator object which can be used in an `async for` statement to execute the body of the function.

Calling the asynchronous iterator's `__anext__()` method will return an `awaitable` which when awaited will execute until it provides a value using the `yield` expression. When the function executes an empty `return` statement or falls off the end, a **StopAsyncIteration** exception is raised and the
asynchronous iterator will have reached the end of the set of values to be yielded.

Built-in functions
A built-in function object is a wrapper around a C function. Examples of built-in functions are `len()` and `math.sin()` (`math` is a standard built-in module). The number and type of the arguments are determined by the C function. Special read-only attributes: `__doc__` is the function’s documentation string, or `None` if unavailable; `__name__` is the function’s name; `__self__` is set to `None` (but see the next item); `__module__` is the name of the module the function was defined in or `None` if unavailable.

Built-in methods
This is really a different disguise of a built-in function, this time containing an object passed to the C function as an implicit extra argument. An example of a built-in method is `alist.append()`, assuming `alist` is a list object. In this case, the special read-only attribute `__self__` is set to the object denoted by `alist`.

Classes
Classes are callable. These objects normally act as factories for new instances of themselves, but variations are possible for class types that override `__new__()`. The arguments of the call are passed to `__new__()` and, in the typical case, to `__init__()` to initialize the new instance.

Class Instances
Instances of arbitrary classes can be made callable by defining a `__call__()` method in their class.
Modules

Modules are a basic organizational unit of Python code, and are created by the `import system` as invoked either by the `import` statement (see `import`), or by calling functions such as `importlib.import_module()` and built-in `__import__()`. A module object has a namespace implemented by a dictionary object (this is the dictionary referenced by the `__globals__` attribute of functions defined in the module). Attribute references are translated to lookups in this dictionary, e.g., `m.x` is equivalent to `m.__dict__['x']`. A module object does not contain the code object used to initialize the module (since it isn’t needed once the initialization is done).

Attribute assignment updates the module’s namespace dictionary, e.g., `m.x = 1` is equivalent to `m.__dict__['x'] = 1`.

Predefined (writable) attributes: `__name__` is the module’s name; `__doc__` is the module’s documentation string, or `None` if unavailable; `__annotations__` (optional) is a dictionary containing `variable annotations` collected during module body execution; `__file__` is the pathname of the file from which the module was loaded, if it was loaded from a file. The `__file__` attribute may be missing for certain types of modules, such as C modules that are statically linked into the interpreter; for extension modules loaded dynamically from a shared library, it is the pathname of the shared library file.

Special read-only attribute: `__dict__` is the module’s namespace as a dictionary object.

**CPython implementation detail:** Because of the way CPython clears module dictionaries, the module dictionary will be cleared
when the module falls out of scope even if the dictionary still has live references. To avoid this, copy the dictionary or keep the module around while using its dictionary directly.

Custom classes

Custom class types are typically created by class definitions (see section Class definitions). A class has a namespace implemented by a dictionary object. Class attribute references are translated to lookups in this dictionary, e.g., \texttt{C.x} is translated to \texttt{C.__dict__["x"]} (although there are a number of hooks which allow for other means of locating attributes). When the attribute name is not found there, the attribute search continues in the base classes. This search of the base classes uses the C3 method resolution order which behaves correctly even in the presence of ‘diamond’ inheritance structures where there are multiple inheritance paths leading back to a common ancestor. Additional details on the C3 MRO used by Python can be found in the documentation accompanying the 2.3 release at \url{https://www.python.org/download/releases/2.3/mro/}.

When a class attribute reference (for class C, say) would yield a class method object, it is transformed into an instance method object whose \texttt{__self__} attributes is C. When it would yield a static method object, it is transformed into the object wrapped by the static method object. See section Implementing Descriptors for another way in which attributes retrieved from a class may differ from those actually contained in its \texttt{__dict__}.

Class attribute assignments update the class's dictionary, never the dictionary of a base class.

A class object can be called (see above) to yield a class instance (see below).
Special attributes: __name__ is the class name; __module__ is the module name in which the class was defined; __dict__ is the dictionary containing the class's namespace; __bases__ is a tuple containing the base classes, in the order of their occurrence in the base class list; __doc__ is the class's documentation string, or None if undefined; __annotations__ (optional) is a dictionary containing variable annotations collected during class body execution.

Class instances
A class instance is created by calling a class object (see above). A class instance has a namespace implemented as a dictionary which is the first place in which attribute references are searched. When an attribute is not found there, and the instance's class has an attribute by that name, the search continues with the class attributes. If a class attribute is found that is a user-defined function object, it is transformed into an instance method object whose __self__ attribute is the instance. Static method and class method objects are also transformed; see above under “Classes”. See section Implementing Descriptors for another way in which attributes of a class retrieved via its instances may differ from the objects actually stored in the class's __dict__. If no class attribute is found, and the object's class has a __getattr__() method, that is called to satisfy the lookup.

Attribute assignments and deletions update the instance's dictionary, never a class's dictionary. If the class has a __setattr__() or __delattr__() method, this is called instead of updating the instance dictionary directly.

Class instances can pretend to be numbers, sequences, or mappings if they have methods with certain special names. See
section Special method names.

Special attributes: \_\_dict\_ is the attribute dictionary; \_\_class\_ is the instance's class.

I/O objects (also known as file objects)
A file object represents an open file. Various shortcuts are available to create file objects: the open() built-in function, and also os.popen(), os.fdopen(), and the makefile() method of socket objects (and perhaps by other functions or methods provided by extension modules).

The objects sys.stdin, sys.stdout and sys.stderr are initialized to file objects corresponding to the interpreter's standard input, output and error streams; they are all open in text mode and therefore follow the interface defined by the io.TextIOBase abstract class.

Internal types
A few types used internally by the interpreter are exposed to the user. Their definitions may change with future versions of the interpreter, but they are mentioned here for completeness.

Code objects
Code objects represent byte-compiled executable Python code, or bytecode. The difference between a code object and a function object is that the function object contains an explicit reference to the function's globals (the module in which it was defined), while a code object contains no context; also the default argument values are stored in the function object, not in the code object (because they represent values calculated at run-time). Unlike function objects, code objects are immutable and contain no references (directly or indirectly) to mutable
objects.

Special read-only attributes: co_name gives the function name; co_argcount is the number of positional arguments (including arguments with default values); co_nlocals is the number of local variables used by the function (including arguments); co_varnames is a tuple containing the names of the local variables (starting with the argument names); co_cellvars is a tuple containing the names of local variables that are referenced by nested functions; co_freevars is a tuple containing the names of free variables; co_code is a string representing the sequence of bytecode instructions; co_consts is a tuple containing the literals used by the bytecode; co_names is a tuple containing the names used by the bytecode; co_filename is the filename from which the code was compiled; co_firstlineno is the first line number of the function; co_lnotab is a string encoding the mapping from bytecode offsets to line numbers (for details see the source code of the interpreter); co_stacksize is the required stack size (including local variables); co_flags is an integer encoding a number of flags for the interpreter.

The following flag bits are defined for co_flags: bit 0x04 is set if the function uses the *arguments syntax to accept an arbitrary number of positional arguments; bit 0x08 is set if the function uses the **keywords syntax to accept arbitrary keyword arguments; bit 0x20 is set if the function is a generator.

Future feature declarations (from __future__ import division) also use bits in co_flags to indicate whether a
code object was compiled with a particular feature enabled: bit \(0x2000\) is set if the function was compiled with future division enabled; bits \(0x10\) and \(0x1000\) were used in earlier versions of Python.

Other bits in \texttt{co\_flags} are reserved for internal use.

If a code object represents a function, the first item in \texttt{co\_consts} is the documentation string of the function, or None if undefined.

**Frame objects**

Frame objects represent execution frames. They may occur in traceback objects (see below).

Special read-only attributes: \texttt{f\_back} is to the previous stack frame (towards the caller), or None if this is the bottom stack frame; \texttt{f\_code} is the code object being executed in this frame; \texttt{f\_locals} is the dictionary used to look up local variables; \texttt{f\_globals} is used for global variables; \texttt{f\_builtins} is used for built-in (intrinsic) names; \texttt{f\_lasti} gives the precise instruction (this is an index into the bytecode string of the code object).

Special writable attributes: \texttt{f\_trace}, if not None, is a function called at the start of each source code line (this is used by the debugger); \texttt{f\_lineno} is the current line number of the frame — writing to this from within a trace function jumps to the given line (only for the bottom-most frame). A debugger can implement a Jump command (aka Set Next Statement) by writing to \texttt{f\_lineno}. 
Frame objects support one method:

```python
frame.clear()
```

This method clears all references to local variables held by the frame. Also, if the frame belonged to a generator, the generator is finalized. This helps break reference cycles involving frame objects (for example when catching an exception and storing its traceback for later use).

```
RuntimeError` is raised if the frame is currently executing.
```

New in version 3.4.

Traceback objects

Traceback objects represent a stack trace of an exception. A traceback object is created when an exception occurs. When the search for an exception handler unwinds the execution stack, at each unwound level a traceback object is inserted in front of the current traceback. When an exception handler is entered, the stack trace is made available to the program. (See section `The try statement`.) It is accessible as the third item of the tuple returned by `sys.exc_info()`. When the program contains no suitable handler, the stack trace is written (nicely formatted) to the standard error stream; if the interpreter is interactive, it is also made available to the user as `sys.last_traceback`.

Special read-only attributes: `tb_next` is the next level in the stack trace (towards the frame where the exception occurred), or `None` if there is no next level; `tb_frame` points to the execution frame of the current level; `tb_lineno` gives the line number where the exception occurred; `tb_lasti` indicates the
precise instruction. The line number and last instruction in the traceback may differ from the line number of its frame object if the exception occurred in a try statement with no matching except clause or with a finally clause.

Slice objects
Slice objects are used to represent slices for \_getitem\_() methods. They are also created by the built-in slice() function.

Special read-only attributes: start is the lower bound; stop is the upper bound; step is the step value; each is None if omitted. These attributes can have any type.

Slice objects support one method:

slice.\textbf{indices}(self, length)
This method takes a single integer argument length and computes information about the slice that the slice object would describe if applied to a sequence of length items. It returns a tuple of three integers; respectively these are the start and stop indices and the step or stride length of the slice. Missing or out-of-bounds indices are handled in a manner consistent with regular slices.

Static method objects
Static method objects provide a way of defeating the transformation of function objects to method objects described above. A static method object is a wrapper around any other object, usually a user-defined method object. When a static method object is retrieved from a class or a class instance, the object actually returned is the wrapped object, which is not subject to any further transformation. Static method objects are
not themselves callable, although the objects they wrap usually are. Static method objects are created by the built-in `staticmethod()` constructor.

Class method objects

A class method object, like a static method object, is a wrapper around another object that alters the way in which that object is retrieved from classes and class instances. The behaviour of class method objects upon such retrieval is described above, under “User-defined methods”. Class method objects are created by the built-in `classmethod()` constructor.
3.3. Special method names

A class can implement certain operations that are invoked by special syntax (such as arithmetic operations or subscripting and slicing) by defining methods with special names. This is Python's approach to operator overloading, allowing classes to define their own behavior with respect to language operators. For instance, if a class defines a method named `__getitem__()`, and `x` is an instance of this class, then `x[i]` is roughly equivalent to `type(x).__getitem__(x, i)`. Except where mentioned, attempts to execute an operation raise an exception when no appropriate method is defined (typically `AttributeError` or `TypeError`).

Setting a special method to `None` indicates that the corresponding operation is not available. For example, if a class sets `__iter__()` to `None`, the class is not iterable, so calling `iter()` on its instances will raise a `TypeError` (without falling back to `__getitem__()`).[2]

When implementing a class that emulates any built-in type, it is important that the emulation only be implemented to the degree that it makes sense for the object being modelled. For example, some sequences may work well with retrieval of individual elements, but extracting a slice may not make sense. (One example of this is the `NodeList` interface in the W3C’s Document Object Model.)

3.3.1. Basic customization

```
object.__new__(cls[, ...])
```

Called to create a new instance of class `cls`. `__new__()` is a static method (special-cased so you need not declare it as such) that
takes the class of which an instance was requested as its first argument. The remaining arguments are those passed to the object constructor expression (the call to the class). The return value of `__new__()` should be the new object instance (usually an instance of `cls`).

Typical implementations create a new instance of the class by invoking the superclass's `__new__()` method using `super().__new__(cls[, ...])` with appropriate arguments and then modifying the newly-created instance as necessary before returning it.

If `__new__()` returns an instance of `cls`, then the new instance's `__init__()` method will be invoked like `__init__(self[, ...])`, where `self` is the new instance and the remaining arguments are the same as were passed to `__new__()`. If `__new__()` does not return an instance of `cls`, then the new instance's `__init__()` method will not be invoked.

`__new__()` is intended mainly to allow subclasses of immutable types (like `int`, `str`, or `tuple`) to customize instance creation. It is also commonly overridden in custom metaclasses in order to customize class creation.

`object.__init__(self[, ...])`

Called after the instance has been created (by `__new__()`), but before it is returned to the caller. The arguments are those passed to the class constructor expression. If a base class has an `__init__()` method, the derived class's `__init__()` method, if any, must explicitly call it to ensure proper initialization of the base class part of the instance; for example:
super().__init__(args...).

Because `__new__()` and `__init__()` work together in constructing objects (`__new__()` to create it, and `__init__()` to customize it), no non-None value may be returned by `__init__()`; doing so will cause a `TypeError` to be raised at runtime.

```python
object.__del__(self)
```

Called when the instance is about to be destroyed. This is also called a destructor. If a base class has a `__del__()` method, the derived class’s `__del__()` method, if any, must explicitly call it to ensure proper deletion of the base class part of the instance. Note that it is possible (though not recommended!) for the `__del__()` method to postpone destruction of the instance by creating a new reference to it. It may then be called at a later time when this new reference is deleted. It is not guaranteed that `__del__()` methods are called for objects that still exist when the interpreter exits.

**Note:** `del x` doesn’t directly call `x.__del__()` — the former decrements the reference count for `x` by one, and the latter is only called when `x`’s reference count reaches zero. Some common situations that may prevent the reference count of an object from going to zero include: circular references between objects (e.g., a doubly-linked list or a tree data structure with parent and child pointers); a reference to the object on the stack frame of a function that caught an exception (the traceback stored in `sys.exc_info()[2]` keeps the stack frame alive); or a reference to the object on the stack frame that raised an unhandled exception in interactive mode (the traceback stored in `sys.last_traceback` keeps the stack frame alive). The first
situation can only be remedied by explicitly breaking the cycles; the second can be resolved by freeing the reference to the traceback object when it is no longer useful, and the third can be resolved by storing None in `sys.last_traceback`. Circular references which are garbage are detected and cleaned up when the cyclic garbage collector is enabled (it's on by default). Refer to the documentation for the `gc` module for more information about this topic.

**Warning:** Due to the precarious circumstances under which `__del__()` methods are invoked, exceptions that occur during their execution are ignored, and a warning is printed to `sys.stderr` instead. Also, when `__del__()` is invoked in response to a module being deleted (e.g., when execution of the program is done), other globals referenced by the `__del__()` method may already have been deleted or in the process of being torn down (e.g. the import machinery shutting down). For this reason, `__del__()` methods should do the absolute minimum needed to maintain external invariants. Starting with version 1.5, Python guarantees that globals whose name begins with a single underscore are deleted from their module before other globals are deleted; if no other references to such globals exist, this may help in assuring that imported modules are still available at the time when the `__del__()` method is called.

```python
object.__repr__(self)
```

Called by the `repr()` built-in function to compute the “official” string representation of an object. If at all possible, this should look like a valid Python expression that could be used to recreate an object with the same value (given an appropriate environment). If this is not possible, a string of the form `<...some useful...`
description...> should be returned. The return value must be a string object. If a class defines __repr__() but not __str__(), then __repr__() is also used when an “informal” string representation of instances of that class is required.

This is typically used for debugging, so it is important that the representation is information-rich and unambiguous.

object.__str__(self)
Called by str(object) and the built-in functions format() and print() to compute the “informal” or nicely printable string representation of an object. The return value must be a string object.

This method differs from object.__repr__() in that there is no expectation that __str__() return a valid Python expression: a more convenient or concise representation can be used.

The default implementation defined by the built-in type object calls object.__repr__().

object.__bytes__(self)
Called by bytes to compute a byte-string representation of an object. This should return a bytes object.

object.__format__(self, format_spec)
Called by the format() built-in function, and by extension, evaluation of formatted string literals and the str.format() method, to produce a “formatted” string representation of an object. The format_spec argument is a string that contains a description of the formatting options desired. The interpretation of the format_spec argument is up to the type implementing
__format__(), however most classes will either delegate formatting to one of the built-in types, or use a similar formatting option syntax.

The return value must be a string object.

*Changed in version 3.4:* The __format__ method of object itself raises a TypeError if passed any non-empty string.

object.__lt__(self, other)
oobject.__le__(self, other)
oobject.__gt__(self, other)
oobject.__le__(self, other)
oobject.__gt__(self, other)
oobject.__ge__(self, other)

These are the so-called “rich comparison” methods. The correspondence between operator symbols and method names is as follows: x<y calls x.__lt__(y), x<=y calls x.__le__(y), x==y calls x.__eq__(y), x!=y calls x.__ne__(y), x>y calls x.__gt__(y), and x>=y calls x.__ge__(y).

A rich comparison method may return the singleton NotImplemented if it does not implement the operation for a given pair of arguments. By convention, False and True are returned for a successful comparison. However, these methods can return any value, so if the comparison operator is used in a Boolean context (e.g., in the condition of an if statement), Python will call bool() on the value to determine if the result is true or false.
By default, `__ne__()` delegates to `__eq__()` and inverts the result unless it is `NotImplemented`. There are no other implied relationships among the comparison operators, for example, the truth of `(x<y or x==y)` does not imply `x<=y`. To automatically generate ordering operations from a single root operation, see `functools.total_ordering()`.

See the paragraph on `__hash__()` for some important notes on creating hashable objects which support custom comparison operations and are usable as dictionary keys.

There are no swapped-argument versions of these methods (to be used when the left argument does not support the operation but the right argument does); rather, `__lt__()` and `__gt__()` are each other’s reflection, `__le__()` and `__ge__()` are each other’s reflection, and `__eq__()` and `__ne__()` are their own reflection. If the operands are of different types, and right operand's type is a direct or indirect subclass of the left operand's type, the reflected method of the right operand has priority, otherwise the left operand's method has priority. Virtual subclassing is not considered.

object.__hash__(self)

 Called by built-in function `hash()` and for operations on members of hashed collections including `set`, `frozenset`, and `dict`. `__hash__() should return an integer. The only required property is that objects which compare equal have the same hash value; it is advised to mix together the hash values of the components of the object that also play a part in comparison of objects by packing them into a tuple and hashing the tuple. Example:

```python
def __hash__(self):
```
Note: hash() truncates the value returned from an object's custom __hash__() method to the size of a Py_ssize_t. This is typically 8 bytes on 64-bit builds and 4 bytes on 32-bit builds. If an object's __hash__() must interoperate on builds of different bit sizes, be sure to check the width on all supported builds. An easy way to do this is with python -c "import sys; print(sys.hash_info.width)".

If a class does not define an __eq__() method it should not define a __hash__() operation either; if it defines __eq__() but not __hash__(), its instances will not be usable as items in hashable collections. If a class defines mutable objects and implements an __eq__() method, it should not implement __hash__(), since the implementation of hashable collections requires that a key's hash value is immutable (if the object's hash value changes, it will be in the wrong hash bucket).

User-defined classes have __eq__() and __hash__() methods by default; with them, all objects compare unequal (except with themselves) and x.__hash__() returns an appropriate value such that x == y implies both that x is y and hash(x) == hash(y).

A class that overrides __eq__() and does not define __hash__() will have its __hash__() implicitly set to None. When the __hash__() method of a class is None, instances of the class will raise an appropriate TypeError when a program attempts to retrieve their hash value, and will also be correctly identified as unhashable when checking isinstance(obj,
collections.Hashable).

If a class that overrides \_\_eq\_\_() needs to retain the implementation of \_\_hash\_\_() from a parent class, the interpreter must be told this explicitly by setting \_\_hash\_\_ = \_\_<ParentClass>\_\_.\_\_hash\_\_.

If a class that does not override \_\_eq\_\_() wishes to suppress hash support, it should include \_\_hash\_\_ = None in the class definition. A class which defines its own \_\_hash\_\_() that explicitly raises a TypeError would be incorrectly identified as hashable by an isinstance(obj, collections.Hashable) call.

**Note:** By default, the \_\_hash\_\_() values of str, bytes and datetime objects are “salted” with an unpredictable random value. Although they remain constant within an individual Python process, they are not predictable between repeated invocations of Python.

This is intended to provide protection against a denial-of-service caused by carefully-chosen inputs that exploit the worst case performance of a dict insertion, \(O(n^2)\) complexity. See [http://www.ocert.org/advisories/ocert-2011-003.html](http://www.ocert.org/advisories/ocert-2011-003.html) for details.

Changing hash values affects the iteration order of dicts, sets and other mappings. Python has never made guarantees about this ordering (and it typically varies between 32-bit and 64-bit builds).

See also PYTHONHASHSEED.

*Changed in version 3.3:* Hash randomization is enabled by default.

object.\_\_bool\_\_(self)
Called to implement truth value testing and the built-in operation `bool()`; should return `False` or `True`. When this method is not defined, `__len__()` is called, if it is defined, and the object is considered true if its result is nonzero. If a class defines neither `__len__()` nor `__bool__()`, all its instances are considered true.

3.3.2. Customizing attribute access

The following methods can be defined to customize the meaning of attribute access (use of, assignment to, or deletion of `x.name`) for class instances.

```python
object.__getattr__(self, name)
```

Called when an attribute lookup has not found the attribute in the usual places (i.e. it is not an instance attribute nor is it found in the class tree for `self`). `name` is the attribute name. This method should return the (computed) attribute value or raise an `AttributeError` exception.

Note that if the attribute is found through the normal mechanism, `__getattr__()` is not called. (This is an intentional asymmetry between `__getattr__()` and `__setattr__()`. This is done both for efficiency reasons and because otherwise `__getattr__()` would have no way to access other attributes of the instance. Note that at least for instance variables, you can fake total control by not inserting any values in the instance attribute dictionary (but instead inserting them in another object). See the `__getattribute__()` method below for a way to actually get total control over attribute access.
object.__getattr__(self, name)

Called unconditionally to implement attribute accesses for instances of the class. If the class also defines __getattribute__(), the latter will not be called unless __getattribute__() either calls it explicitly or raises an AttributeError. This method should return the (computed) attribute value or raise an AttributeError exception. In order to avoid infinite recursion in this method, its implementation should always call the base class method with the same name to access any attributes it needs, for example, object.__getattribute__(self, name).

**Note:** This method may still be bypassed when looking up special methods as the result of implicit invocation via language syntax or built-in functions. See [Special method lookup](#).

object.__setattr__(self, name, value)

Called when an attribute assignment is attempted. This is called instead of the normal mechanism (i.e. store the value in the instance dictionary). name is the attribute name, value is the value to be assigned to it.

If __setattr__() wants to assign to an instance attribute, it should call the base class method with the same name, for example, object.__setattr__(self, name, value).

object.__delattr__(self, name)

Like __setattr__() but for attribute deletion instead of assignment. This should only be implemented if del obj.name is meaningful for the object.

object.__dir__(self)
Called when \texttt{dir()} is called on the object. A sequence must be returned. \texttt{dir()} converts the returned sequence to a list and sorts it.

3.3.2.1. Implementing Descriptors

The following methods only apply when an instance of the class containing the method (a so-called \textit{descriptor} class) appears in an \textit{owner} class (the descriptor must be in either the owner’s class dictionary or in the class dictionary for one of its parents). In the examples below, “the attribute” refers to the attribute whose name is the key of the property in the owner class’ \texttt{__dict__}.

\begin{verbatim}
object.__get__(self, instance, owner)
\end{verbatim}

Called to get the attribute of the owner class (class attribute access) or of an instance of that class (instance attribute access). \textit{owner} is always the owner class, while \textit{instance} is the instance that the attribute was accessed through, or \texttt{None} when the attribute is accessed through the \textit{owner}. This method should return the (computed) attribute value or raise an \texttt{AttributeError} exception.

\begin{verbatim}
object.__set__(self, instance, value)
\end{verbatim}

Called to set the attribute on an instance \textit{instance} of the owner class to a new value, \textit{value}.

\begin{verbatim}
object.__delete__(self, instance)
\end{verbatim}

Called to delete the attribute on an instance \textit{instance} of the owner class.

\begin{verbatim}
object.__set_name__(self, owner, name)
\end{verbatim}

Called at the time the owning class \textit{owner} is created. The
The attribute __objclass__ is interpreted by the inspect module as specifying the class where this object was defined (setting this appropriately can assist in runtime introspection of dynamic class attributes). For callables, it may indicate that an instance of the given type (or a subclass) is expected or required as the first positional argument (for example, CPython sets this attribute for unbound methods that are implemented in C).

3.3.2.2. Invoking Descriptors

In general, a descriptor is an object attribute with “binding behavior”, one whose attribute access has been overridden by methods in the descriptor protocol: __get__(), __set__(), and __delete__(). If any of those methods are defined for an object, it is said to be a descriptor.

The default behavior for attribute access is to get, set, or delete the attribute from an object’s dictionary. For instance, a.x has a lookup chain starting with a.__dict__['x'], then type(a).__dict__['x'], and continuing through the base classes of type(a) excluding metaclasses.

However, if the looked-up value is an object defining one of the descriptor methods, then Python may override the default behavior and invoke the descriptor method instead. Where this occurs in the precedence chain depends on which descriptor methods were defined and how they were called.

The starting point for descriptor invocation is a binding, a.x. How the
arguments are assembled depends on a:

Direct Call
The simplest and least common call is when user code directly invokes a descriptor method: `x.__get__(a)`.

Instance Binding
If binding to an object instance, `a.x` is transformed into the call: `type(a).__dict__['x'].__get__(a, type(a))`.

Class Binding
If binding to a class, `A.x` is transformed into the call: `A.__dict__['x'].__get__(None, A)`.

Super Binding
If `a` is an instance of `super`, then the binding `super(B, obj).m()` searches `obj.__class__.__mro__` for the base class `A` immediately preceding `B` and then invokes the descriptor with the call: `A.__dict__['m'].__get__(obj, obj.__class__)`.

For instance bindings, the precedence of descriptor invocation depends on the which descriptor methods are defined. A descriptor can define any combination of `__get__()`, `__set__()` and `__delete__()`. If it does not define `__get__()`, then accessing the attribute will return the descriptor object itself unless there is a value in the object's instance dictionary. If the descriptor defines `__set__()` and/or `__delete__()`, it is a data descriptor; if it defines neither, it is a non-data descriptor. Normally, data descriptors define both `__get__()` and `__set__()`, while non-data descriptors have just the `__get__()` method. Data descriptors with `__set__()` and `__get__()` defined always override a redefinition in an instance dictionary. In contrast, non-data descriptors can be overridden by instances.
Python methods (including `staticmethod()` and `classmethod()`)
are implemented as non-data descriptors. Accordingly, instances can
redefine and override methods. This allows individual instances to
acquire behaviors that differ from other instances of the same class.

The `property()` function is implemented as a data descriptor.
Accordingly, instances cannot override the behavior of a property.

3.3.2.3. __slots__

By default, instances of classes have a dictionary for attribute storage.
This wastes space for objects having very few instance variables. The
space consumption can become acute when creating large numbers
of instances.

The default can be overridden by defining `__slots__` in a class
definition. The `__slots__` declaration takes a sequence of instance
variables and reserves just enough space in each instance to hold a
value for each variable. Space is saved because `__dict__` is not
created for each instance.

`object.__slots__`

This class variable can be assigned a string, iterable, or sequence
of strings with variable names used by instances. `__slots__` reserves space for the declared variables and prevents the
automatic creation of `__dict__` and `__weakref__` for each instance.

3.3.2.3.1. Notes on using `__slots__`

- When inheriting from a class without `__slots__`, the `__dict__`
  attribute of that class will always be accessible, so a `__slots__`
definition in the subclass is meaningless.
- Without a `__dict__` variable, instances cannot be assigned new
variables not listed in the __slots__ definition. Attempts to assign to an unlisted variable name raises AttributeError. If dynamic assignment of new variables is desired, then add '__dict__' to the sequence of strings in the __slots__ declaration.

- Without a __weakref__ variable for each instance, classes defining __slots__ do not support weak references to its instances. If weak reference support is needed, then add '__weakref__' to the sequence of strings in the __slots__ declaration.

- __slots__ are implemented at the class level by creating descriptors (Implementing Descriptors) for each variable name. As a result, class attributes cannot be used to set default values for instance variables defined by __slots__; otherwise, the class attribute would overwrite the descriptor assignment.

- The action of a __slots__ declaration is limited to the class where it is defined. As a result, subclasses will have a __dict__ unless they also define __slots__ (which must only contain names of any additional slots).

- If a class defines a slot also defined in a base class, the instance variable defined by the base class slot is inaccessible (except by retrieving its descriptor directly from the base class). This renders the meaning of the program undefined. In the future, a check may be added to prevent this.

- Nonempty __slots__ does not work for classes derived from “variable-length” built-in types such as int, bytes and tuple.

- Any non-string iterable may be assigned to __slots__. Mappings may also be used; however, in the future, special meaning may be assigned to the values corresponding to each key.

- __class__ assignment works only if both classes have the same __slots__.

3.3.3. Customizing class creation
Whenever a class inherits from another class, `__init_subclass__` is called on that class. This way, it is possible to write classes which change the behavior of subclasses. This is closely related to class decorators, but where class decorators only affect the specific class they're applied to, `__init_subclass__` solely applies to future subclasses of the class defining the method.

`classmethod` object. `__init_subclass__`(cls)

This method is called whenever the containing class is subclassed. `cls` is then the new subclass. If defined as a normal instance method, this method is implicitly converted to a class method.

Keyword arguments which are given to a new class are passed to the parent's class `__init_subclass__`. For compatibility with other classes using `__init_subclass__`, one should take out the needed keyword arguments and pass the others over to the base class, as in:

```python
class Philosopher:
    def __init_subclass__(cls, default_name, **kwargs):
        super().__init_subclass__(**kwargs)
        cls.default_name = default_name

class AustralianPhilosopher(Philosopher, default_
pass
```

The default implementation `object.__init_subclass__` does nothing, but raises an error if it is called with any arguments.

**Note:** The metaclass hint `metaclass` is consumed by the rest of the type machinery, and is never passed to `__init_subclass__` implementations. The actual metaclass
(rather than the explicit hint) can be accessed as `type(cls)`.

New in version 3.6.

3.3.3.1. Metaclasses

By default, classes are constructed using `type()`. The class body is executed in a new namespace and the class name is bound locally to the result of `type(name, bases, namespace)`.

The class creation process can be customized by passing the `metaclass` keyword argument in the class definition line, or by inheriting from an existing class that included such an argument. In the following example, both `MyClass` and `MySubclass` are instances of `Meta`:

```python
class Meta(type):
    pass

class MyClass(metaclass=Meta):
    pass

class MySubclass(MyClass):
    pass
```

Any other keyword arguments that are specified in the class definition are passed through to all metaclass operations described below.

When a class definition is executed, the following steps occur:

- the appropriate metaclass is determined
- the class namespace is prepared
- the class body is executed
- the class object is created
3.3.3.2. Determining the appropriate metaclass

The appropriate metaclass for a class definition is determined as follows:

- if no bases and no explicit metaclass are given, then `type()` is used
- if an explicit metaclass is given and it is *not* an instance of `type()`, then it is used directly as the metaclass
- if an instance of `type()` is given as the explicit metaclass, or bases are defined, then the most derived metaclass is used

The most derived metaclass is selected from the explicitly specified metaclass (if any) and the metaclasses (i.e. `type(cls)`) of all specified base classes. The most derived metaclass is one which is a subtype of *all* of these candidate metaclasses. If none of the candidate metaclasses meets that criterion, then the class definition will fail with `TypeError`.

3.3.3.3. Preparing the class namespace

Once the appropriate metaclass has been identified, then the class namespace is prepared. If the metaclass has a `__prepare__` attribute, it is called as `namespace = metaclass.__prepare__(name, bases, **kwds)` (where the additional keyword arguments, if any, come from the class definition).

If the metaclass has no `__prepare__` attribute, then the class namespace is initialised as an empty ordered mapping.

See also:

**PEP 3115 - Metaclasses in Python 3000**
3.3.3.4. Executing the class body

The class body is executed (approximately) as `exec(body, globals(), namespace)`. The key difference from a normal call to `exec()` is that lexical scoping allows the class body (including any methods) to reference names from the current and outer scopes when the class definition occurs inside a function.

However, even when the class definition occurs inside the function, methods defined inside the class still cannot see names defined at the class scope. Class variables must be accessed through the first parameter of instance or class methods, or through the implicit lexically scoped `__class__` reference described in the next section.

3.3.3.5. Creating the class object

Once the class namespace has been populated by executing the class body, the class object is created by calling `metaclass(name, bases, namespace, **kwds)` (the additional keywords passed here are the same as those passed to `__prepare__`).

This class object is the one that will be referenced by the zero-argument form of `super()`. `__class__` is an implicit closure reference created by the compiler if any methods in a class body refer to either `__class__` or `super`. This allows the zero argument form of `super()` to correctly identify the class being defined based on lexical scoping, while the class or instance that was used to make the current call is identified based on the first argument passed to the method.

**CPython implementation detail:** In CPython 3.6 and later, the
__class__ cell is passed to the metaclass as a __classcell__ entry in the class namespace. If present, this must be propagated up to the type.__new__ call in order for the class to be initialised correctly. Failing to do so will result in a DeprecationWarning in Python 3.6, and a RuntimeWarning in the future.

When using the default metaclass type, or any metaclass that ultimately calls type.__new__, the following additional customisation steps are invoked after creating the class object:

- first, type.__new__ collects all of the descriptors in the class namespace that define a __set_name__() method;
- second, all of these __set_name__ methods are called with the class being defined and the assigned name of that particular descriptor; and
- finally, the __init_subclass__() hook is called on the immediate parent of the new class in its method resolution order.

After the class object is created, it is passed to the class decorators included in the class definition (if any) and the resulting object is bound in the local namespace as the defined class.

When a new class is created by type.__new__, the object provided as the namespace parameter is copied to a new ordered mapping and the original object is discarded. The new copy is wrapped in a read-only proxy, which becomes the __dict__ attribute of the class object.

See also:

**PEP 3135 - New super**

Describes the implicit __class__ closure reference

3.3.3.6. Metaclass example
The potential uses for metaclasses are boundless. Some ideas that have been explored include enum, logging, interface checking, automatic delegation, automatic property creation, proxies, frameworks, and automatic resource locking/synchronization.

Here is an example of a metaclass that uses an `collections.OrderedDict` to remember the order that class variables are defined:

```python
class OrderedClass(type):
    @classmethod
    def __prepare__(metacls, name, bases, **kwds):
        return collections.OrderedDict()

    def __new__(cls, name, bases, namespace, **kwds):
        result = type.__new__(cls, name, bases, dict(result.members)
        result.members = tuple(namespace)
        return result

class A(metaclass=OrderedClass):
    def one(self): pass
    def two(self): pass
    def three(self): pass
    def four(self): pass

>>> A.members
('__module__', 'one', 'two', 'three', 'four')
```

When the class definition for A gets executed, the process begins with calling the metaclass's `__prepare__()` method which returns an empty `collections.OrderedDict`. That mapping records the methods and attributes of A as they are defined within the body of the
class statement. Once those definitions are executed, the ordered dictionary is fully populated and the metaclass’s `__new__() method gets invoked. That method builds the new type and it saves the ordered dictionary keys in an attribute called `members`.

### 3.3.4. Customizing instance and subclass checks

The following methods are used to override the default behavior of the `isinstance()` and `issubclass()` built-in functions.

In particular, the metaclass `abc.ABCMeta` implements these methods in order to allow the addition of Abstract Base Classes (ABCs) as “virtual base classes” to any class or type (including built-in types), including other ABCs.

```python
class.__instancecheck__(self, instance)

Return true if `instance` should be considered a (direct or indirect) instance of `class`. If defined, called to implement `isinstance(instance, class)`.
```

```python
class.__subclasscheck__(self, subclass)

Return true if `subclass` should be considered a (direct or indirect) subclass of `class`. If defined, called to implement `issubclass(subclass, class)`.
```

Note that these methods are looked up on the type (metaclass) of a class. They cannot be defined as class methods in the actual class. This is consistent with the lookup of special methods that are called on instances, only in this case the instance is itself a class.

**See also:**
3.3.5. Emulating callable objects

\texttt{object.\_\_call\_\_(self[, \ args...])}

Called when the instance is “called” as a function; if this method is
defined, \texttt{x(arg1, arg2, ...)} is a shorthand for
\texttt{x.\_\_call\_\_(arg1, arg2, ...)}. 

3.3.6. Emulating container types

The following methods can be defined to implement container objects.
Containers usually are sequences (such as lists or tuples) or
mappings (like dictionaries), but can represent other containers as
well. The first set of methods is used either to emulate a sequence or
to emulate a mapping; the difference is that for a sequence, the
allowable keys should be the integers \( k \) for which \( 0 \leq k < N \) where
\( N \) is the length of the sequence, or slice objects, which define a range
of items. It is also recommended that mappings provide the methods
\texttt{keys()}, \texttt{values()}, \texttt{items()}, \texttt{get()}, \texttt{clear()}, \texttt{setdefault()},
\texttt{pop()}, \texttt{popitem()}, \texttt{copy()}, and \texttt{update()} behaving similar to
those for Python’s standard dictionary objects. The \texttt{collections}
module provides a \texttt{MutableMapping} abstract base class to help
create those methods from a base set of \texttt{\_\_getitem\_\_()},
\texttt{\_\_setitem\_\_()}, \texttt{\_\_delitem\_\_()}, and \texttt{keys()}. Mutual
sequences should provide methods `append()`, `count()`, `index()`, `extend()`, `insert()`, `pop()`, `remove()`, `reverse()` and `sort()`, like Python standard list objects. Finally, sequence types should implement addition (meaning concatenation) and multiplication (meaning repetition) by defining the methods `__add__()`, `__radd__()`, `__iadd__()`, `__mul__()`, `__rmul__()` and `__imul__()` described below; they should not define other numerical operators. It is recommended that both mappings and sequences implement the `__contains__()` method to allow efficient use of the `in` operator; for mappings, `in` should search the mapping’s keys; for sequences, it should search through the values. It is further recommended that both mappings and sequences implement the `__iter__()` method to allow efficient iteration through the container; for mappings, `__iter__()` should be the same as `keys()`; for sequences, it should iterate through the values.

```
object.__len__(self)
```

Called to implement the built-in function `len()`. Should return the length of the object, an integer \( \geq 0 \). Also, an object that doesn’t define a `__bool__()` method and whose `__len__()` method returns zero is considered to be false in a Boolean context.

**CPython implementation detail:** In CPython, the length is required to be at most `sys.maxsize`. If the length is larger than `sys.maxsize` some features (such as `len()`) may raise `OverflowError`. To prevent raising `OverflowError` by truth value testing, an object must define a `__bool__()` method.

```
object.__length_hint__(self)
```

Called to implement `operator.length_hint()`. Should return an estimated length for the object (which may be greater or less
than the actual length). The length must be an integer \( \geq 0 \). This method is purely an optimization and is never required for correctness.

*New in version 3.4.*

**Note:** Slicing is done exclusively with the following three methods. A call like

```
a[1:2] = b
```

is translated to

```
a[slice(1, 2, None)] = b
```

and so forth. Missing slice items are always filled in with None.

```python
object.__getitem__(self, key)
```

Called to implement evaluation of `self[key]`. For sequence types, the accepted keys should be integers and slice objects. Note that the special interpretation of negative indexes (if the class wishes to emulate a sequence type) is up to the `__getitem__()` method. If `key` is of an inappropriate type, `TypeError` may be raised; if of a value outside the set of indexes for the sequence (after any special interpretation of negative values), `IndexError` should be raised. For mapping types, if `key` is missing (not in the container), `KeyError` should be raised.

**Note:** for loops expect that an `IndexError` will be raised for illegal indexes to allow proper detection of the end of the sequence.
object.__missing__(self, key)
    Called by dict.__getitem__() to implement self[key] for dict subclasses when key is not in the dictionary.

object.__setitem__(self, key, value)
    Called to implement assignment to self[key]. Same note as for __getitem__(). This should only be implemented for mappings if the objects support changes to the values for keys, or if new keys can be added, or for sequences if elements can be replaced. The same exceptions should be raised for improper key values as for the __getitem__() method.

object.__delitem__(self, key)
    Called to implement deletion of self[key]. Same note as for __getitem__(). This should only be implemented for mappings if the objects support removal of keys, or for sequences if elements can be removed from the sequence. The same exceptions should be raised for improper key values as for the __getitem__() method.

object.__iter__(self)
    This method is called when an iterator is required for a container. This method should return a new iterator object that can iterate over all the objects in the container. For mappings, it should iterate over the keys of the container.

    Iterator objects also need to implement this method; they are required to return themselves. For more information on iterator objects, see Iterator Types.

object.__reversed__(self)
    Called (if present) by the reversed() built-in to implement
reverse iteration. It should return a new iterator object that iterates over all the objects in the container in reverse order.

If the \_\_reversed\_\_(\) method is not provided, the \texttt{reversed()} built-in will fall back to using the sequence protocol (\_\_len\_\_(\) and \_\_getitem\_\_(\)). Objects that support the sequence protocol should only provide \_\_reversed\_\_(\) if they can provide an implementation that is more efficient than the one provided by \texttt{reversed()}.

The membership test operators (\texttt{in} and \texttt{not in}) are normally implemented as an iteration through a sequence. However, container objects can supply the following special method with a more efficient implementation, which also does not require the object be a sequence.

\texttt{object.\_\_contains\_\_(self, item)}

Called to implement membership test operators. Should return true if \texttt{item} is in \texttt{self}, false otherwise. For mapping objects, this should consider the keys of the mapping rather than the values or the key-item pairs.

For objects that don’t define \_\_contains\_\_(\), the membership test first tries iteration via \_\_iter\_\_(\), then the old sequence iteration protocol via \_\_getitem\_\_(\), see this section in the language reference.

3.3.7. Emulating numeric types

The following methods can be defined to emulate numeric objects. Methods corresponding to operations that are not supported by the particular kind of number implemented (e.g., bitwise operations for non-integral numbers) should be left undefined.
object.__add__(self, other)
object.__sub__(self, other)
object.__mul__(self, other)
object.__matmul__(self, other)
object.__truediv__(self, other)
object.__floordiv__(self, other)
object.__mod__(self, other)
object.__divmod__(self, other)
object.__pow__(self, other[, modulo])
object.__lshift__(self, other)
object.__rshift__(self, other)
object.__and__(self, other)
object.__xor__(self, other)
object.__or__(self, other)

These methods are called to implement the binary arithmetic operations (+, -, *, @, /, //, %, divmod(), pow(), **, <<, >>, & and ^). For instance, to evaluate the expression \(x + y\), where \(x\) is an instance of a class that has an \(\texttt{__add__}\) method, \(x.__add__(y)\) is called. The \(\texttt{__divmod__}\) method should be the equivalent to using \(\texttt{__floordiv__}\) and \(\texttt{__mod__}\); it should not be related to \(\texttt{__truediv__}\). Note that \(\texttt{__pow__}\) should be defined to accept an optional third argument if the ternary version of the built-in \(\texttt{pow}\) function is to be supported.

If one of those methods does not support the operation with the supplied arguments, it should return \texttt{NotImplemented}.

object.__radd__(self, other)
object.__rsub__(self, other)
object.__rmul__(self, other)
object.__rmatmul__(self, other)
object.__rtruediv__(self, other)
object.__rfloordiv__(self, other)
object.__rmod__(self, other)
object.__rdivmod__(self, other)
object.__rpow__(self, other)
object.__rlshift__(self, other)
object.__rrshift__(self, other)
object.__rand__(self, other)
object.__rxor__(self, other)
object.__ror__(self, other)

These methods are called to implement the binary arithmetic operations (+, -, *, @, /, //, %, divmod(), pow(), **, <<, >>, &, ^, |) with reflected (swapped) operands. These functions are only called if the left operand does not support the corresponding operation [3] and the operands are of different types. [4] For instance, to evaluate the expression x - y, where y is an instance of a class that has an __rsub__() method, y.__rsub__(x) is called if x.__sub__(y) returns NotImplemented.

Note that ternary pow() will not try calling __rpow__() (the coercion rules would become too complicated).

Note: If the right operand's type is a subclass of the left operand's type and that subclass provides the reflected method for the operation, this method will be called before the left operand's non-reflected method. This behavior allows subclasses to override their ancestors' operations.

object.__iadd__(self, other)
object.__isub__(self, other)
object.__imul__(self, other)
object.__imatmul__(self, other)
object.__itruediv__(self, other)
object.__ifloordiv__(self, other)
object.__imod__(self, other)
object.__ipow__(self, other[, modulo])
object.__ilshift__(self, other)
object.__irshift__(self, other)
object.__iand__(self, other)
object.__ixor__(self, other)
object.__ior__(self, other)

These methods are called to implement the augmented arithmetic assignments (+=, -=, *=, @=, /=, //=, %=, **=, <<=, >>=, &=, ^=, |=). These methods should attempt to do the operation in-place (modifying self) and return the result (which could be, but does not have to be, self). If a specific method is not defined, the augmented assignment falls back to the normal methods. For instance, if x is an instance of a class with an __iadd__() method, x += y is equivalent to x = x.__iadd__(y) . Otherwise, x.__add__(y) and y.__radd__(x) are considered, as with the evaluation of x + y. In certain situations, augmented assignment can result in unexpected errors (see Why does a_tuple[i] += ['item'] raise an exception when the addition works?), but this behavior is in fact part of the data model.

object.__neg__(self)
object.__pos__(self)
object.__abs__(self)
object.__invert__(self)

Called to implement the unary arithmetic operations (−, +, abs() and ~).
object.__complex__(self)
object.__int__(self)
object.__float__(self)
object.__round__(self[n])

Called to implement the built-in functions `complex()`, `int()`, `float()` and `round()`. Should return a value of the appropriate type.

object.__index__(self)

Called to implement `operator.index()`, and whenever Python needs to losslessly convert the numeric object to an integer object (such as in slicing, or in the built-in `bin()`, `hex()` and `oct()` functions). Presence of this method indicates that the numeric object is an integer type. Must return an integer.

**Note:** In order to have a coherent integer type class, when `__index__()` is defined `__int__() should also be defined, and both should return the same value.

### 3.3.8. With Statement Context Managers

A **context manager** is an object that defines the runtime context to be established when executing a `with` statement. The context manager handles the entry into, and the exit from, the desired runtime context for the execution of the block of code. Context managers are normally invoked using the `with` statement (described in section The with statement), but can also be used by directly invoking their methods.

Typical uses of context managers include saving and restoring various kinds of global state, locking and unlocking resources, closing opened files, etc.
For more information on context managers, see **Context Manager Types**.

**object.__enter__(self)**

Enter the runtime context related to this object. The *with* statement will bind this method’s return value to the target(s) specified in the *as* clause of the statement, if any.

**object.__exit__(self, exc_type, exc_value, traceback)**

Exit the runtime context related to this object. The parameters describe the exception that caused the context to be exited. If the context was exited without an exception, all three arguments will be *None*.

If an exception is supplied, and the method wishes to suppress the exception (i.e., prevent it from being propagated), it should return a true value. Otherwise, the exception will be processed normally upon exit from this method.

Note that **__exit__()** methods should not reraise the passed-in exception; this is the caller’s responsibility.

**See also:**

**PEP 343 - The “with” statement**

The specification, background, and examples for the Python *with* statement.

### 3.3.9. Special method lookup

For custom classes, implicit invocations of special methods are only guaranteed to work correctly if defined on an object’s type, not in the
object’s instance dictionary. That behaviour is the reason why the following code raises an exception:

```python
class C:
...
    pass
...
c = C()
c.__len__ = lambda: 5
len(c)
```

```
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: object of type 'C' has no len()
```

The rationale behind this behaviour lies with a number of special methods such as `__hash__()` and `__repr__()` that are implemented by all objects, including type objects. If the implicit lookup of these methods used the conventional lookup process, they would fail when invoked on the type object itself:

```python
1.__hash__() == hash(1)
int.__hash__() == hash(int)
```

```
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: descriptor '__hash__' of 'int' object needs an argument
```

Incorrectly attempting to invoke an unbound method of a class in this way is sometimes referred to as ‘metaclass confusion’, and is avoided by bypassing the instance when looking up special methods:

```python
type(1).__hash__(1) == hash(1)
type(int).__hash__(int) == hash(int)
```
In addition to bypassing any instance attributes in the interest of correctness, implicit special method lookup generally also bypasses the `__getattribute__()` method even of the object's metaclass:

```python
>>> class Meta(type):
...     def __getattribute__(*args):
...         print("Metaclass getattribute invoked")
...         return type.__getattribute__(*args)
...
>>> class C(object, metaclass=Meta):
...     def __len__(self):
...         return 10
...     def __getattribute__(*args):
...         print("Class getattribute invoked")
...         return object.__getattribute__(*args)
...
>>> c = C()
>>> c.__len__()                        # Explicit lookup via class
Class getattribute invoked
10
>>> type(c).__len__(c)                # Explicit lookup via type
Metaclass getattribute invoked
10
>>> len(c)                            # Implicit lookup
10
```

Bypassing the `__getattribute__()` machinery in this fashion provides significant scope for speed optimisations within the interpreter, at the cost of some flexibility in the handling of special methods (the special method must be set on the class object itself in order to be consistently invoked by the interpreter).
3.4. Coroutines

3.4.1. Awaitable Objects

An **awaitable** object generally implements an `__await__()` method. **Coroutine** objects returned from `async def` functions are awaitable.

**Note:** The **generator iterator** objects returned from generators decorated with `types.coroutine()` or `asyncio.coroutine()` are also awaitable, but they do not implement `__await__()`. `object.__await__(self)`

Must return an **iterator**. Should be used to implement **awaitable** objects. For instance, `asyncio.Future` implements this method to be compatible with the `await` expression.

*New in version 3.5.*

**See also:** PEP 492 for additional information about awaitable objects.

3.4.2. Coroutine Objects

**Coroutine** objects are **awaitable** objects. A coroutine’s execution can be controlled by calling `__await__()` and iterating over the result. When the coroutine has finished executing and returns, the iterator raises `StopIteration`, and the exception’s value attribute holds the return value. If the coroutine raises an exception, it is propagated by the iterator. Coroutines should not directly raise unhandled `StopIteration` exceptions.
Coroutines also have the methods listed below, which are analogous to those of generators (see Generator-iterator methods). However, unlike generators, coroutines do not directly support iteration.

*Changed in version 3.5.2:* It is a `RuntimeError` to await on a coroutine more than once.

**coroutine.**`send(value)`

Starts or resumes execution of the coroutine. If `value` is `None`, this is equivalent to advancing the iterator returned by `__await__()`. If `value` is not `None`, this method delegates to the `send()` method of the iterator that caused the coroutine to suspend. The result (return value, `StopIteration`, or other exception) is the same as when iterating over the `__await__()` return value, described above.

**coroutine.**`throw(type[, value[, traceback]])`

Raises the specified exception in the coroutine. This method delegates to the `throw()` method of the iterator that caused the coroutine to suspend, if it has such a method. Otherwise, the exception is raised at the suspension point. The result (return value, `StopIteration`, or other exception) is the same as when iterating over the `__await__()` return value, described above. If the exception is not caught in the coroutine, it propagates back to the caller.

**coroutine.**`close()`

Causes the coroutine to clean itself up and exit. If the coroutine is suspended, this method first delegates to the `close()` method of the iterator that caused the coroutine to suspend, if it has such a method. Then it raises `GeneratorExit` at the suspension point,
causing the coroutine to immediately clean itself up. Finally, the coroutine is marked as having finished executing, even if it was never started.

Coroutine objects are automatically closed using the above process when they are about to be destroyed.

### 3.4.3. Asynchronous Iterators

An *asynchronous iterable* is able to call asynchronous code in its `__aiter__` implementation, and an *asynchronous iterator* can call asynchronous code in its `__anext__` method.

Asynchronous iterators can be used in an `async for` statement.

```python
object.__aiter__(self)

Must return an *asynchronous iterator* object.
```

```python
object.__anext__(self)

Must return an *awaitable* resulting in a next value of the iterator. Should raise a `StopAsyncIteration` error when the iteration is over.
```

An example of an asynchronous iterable object:

```python
class Reader:
    async def readline(self):
        ...

    def __aiter__(self):
        return self

    async def __anext__(self):
        val = await self.readline()
```
if val == b'':
    raise StopAsyncIteration
return val

New in version 3.5.

Note:

*Changed in version 3.5.2:* Starting with CPython 3.5.2, `__aiter__` can directly return asynchronous iterators. Returning an `awaitable` object will result in a `PendingDeprecationWarning`.

The recommended way of writing backwards compatible code in CPython 3.5.x is to continue returning awaitables from `__aiter__`. If you want to avoid the PendingDeprecationWarning and keep the code backwards compatible, the following decorator can be used:

```python
import functools
import sys

if sys.version_info < (3, 5, 2):
    def aiter_compat(func):
        @functools.wraps(func)
        async def wrapper(self):
            return func(self)
        return wrapper
else:
    def aiter_compat(func):
        return func

Example:

class AsyncIterator:
    @aiter_compat
```
Starting with CPython 3.6, the `PendingDeprecationWarning` will be replaced with the `DeprecationWarning`. In CPython 3.7, returning an awaitable from `__aiter__` will result in a `RuntimeError`.

3.4.4. Asynchronous Context Managers

An asynchronous context manager is a context manager that is able to suspend execution in its `__aenter__` and `__aexit__` methods.

Asynchronous context managers can be used in an `async with` statement.

```python
object.__aenter__(self)
```

This method is semantically similar to the `__enter__()`, with only difference that it must return an `awaitable`.

```python
object.__aexit__(self, exc_type, exc_value, traceback)
```

This method is semantically similar to the `__exit__()` , with only difference that it must return an `awaitable`.

An example of an asynchronous context manager class:

```python
class AsyncContextManager:
    async def __aenter__(self):
        await log('entering context')
```
async def __aexit__(self, exc_type, exc, tb):
    await log('exiting context')

New in version 3.5.

Footnotes

[1] It is possible in some cases to change an object’s type, under certain controlled conditions. It generally isn’t a good idea though, since it can lead to some very strange behaviour if it is handled incorrectly.

The __hash__(), __iter__(), __reversed__(), and __contains__() methods have special handling for this; others will still raise a TypeError, but may do so by relying on the behavior that None is not callable.

“Does not support” here means that the class has no such method, or the method returns NotImplemented. Do not set the method to None if you want to force fallback to the right operand's reflected method—that will instead have the opposite effect of explicitly blocking such fallback.

[3] For operands of the same type, it is assumed that if the non-reflected method (such as __add__() ) fails the operation is not supported, which is why the reflected method is not called.
4. Execution model
4.1. Structure of a program

A Python program is constructed from code blocks. A block is a piece of Python program text that is executed as a unit. The following are blocks: a module, a function body, and a class definition. Each command typed interactively is a block. A script file (a file given as standard input to the interpreter or specified as a command line argument to the interpreter) is a code block. A script command (a command specified on the interpreter command line with the `-c` option) is a code block. The string argument passed to the built-in functions `eval()` and `exec()` is a code block.

A code block is executed in an execution frame. A frame contains some administrative information (used for debugging) and determines where and how execution continues after the code block’s execution has completed.
4.2. Naming and binding

4.2.1. Binding of names

Names refer to objects. Names are introduced by name binding operations.

The following constructs bind names: formal parameters to functions, import statements, class and function definitions (these bind the class or function name in the defining block), and targets that are identifiers if occurring in an assignment, for loop header, or after as in a with statement or except clause. The import statement of the form from ... import * binds all names defined in the imported module, except those beginning with an underscore. This form may only be used at the module level.

A target occurring in a del statement is also considered bound for this purpose (though the actual semantics are to unbind the name).

Each assignment or import statement occurs within a block defined by a class or function definition or at the module level (the top-level code block).

If a name is bound in a block, it is a local variable of that block, unless declared as nonlocal or global. If a name is bound at the module level, it is a global variable. (The variables of the module code block are local and global.) If a variable is used in a code block but not defined there, it is a free variable.

Each occurrence of a name in the program text refers to the binding of that name established by the following name resolution rules.
4.2.2. Resolution of names

A scope defines the visibility of a name within a block. If a local variable is defined in a block, its scope includes that block. If the definition occurs in a function block, the scope extends to any blocks contained within the defining one, unless a contained block introduces a different binding for the name.

When a name is used in a code block, it is resolved using the nearest enclosing scope. The set of all such scopes visible to a code block is called the block's *environment*.

When a name is not found at all, a `NameError` exception is raised. If the current scope is a function scope, and the name refers to a local variable that has not yet been bound to a value at the point where the name is used, an `UnboundLocalError` exception is raised. `UnboundLocalError` is a subclass of `NameError`.

If a name binding operation occurs anywhere within a code block, all uses of the name within the block are treated as references to the current block. This can lead to errors when a name is used within a block before it is bound. This rule is subtle. Python lacks declarations and allows name binding operations to occur anywhere within a code block. The local variables of a code block can be determined by scanning the entire text of the block for name binding operations.

If the `global` statement occurs within a block, all uses of the name specified in the statement refer to the binding of that name in the top-level namespace. Names are resolved in the top-level namespace by searching the global namespace, i.e. the namespace of the module containing the code block, and the `builtins` namespace, the namespace of the module `builtins`. The global namespace is
searched first. If the name is not found there, the builtins namespace is searched. The `global` statement must precede all uses of the name.

The `global` statement has the same scope as a name binding operation in the same block. If the nearest enclosing scope for a free variable contains a global statement, the free variable is treated as a global.

The `nonlocal` statement causes corresponding names to refer to previously bound variables in the nearest enclosing function scope. `SyntaxError` is raised at compile time if the given name does not exist in any enclosing function scope.

The namespace for a module is automatically created the first time a module is imported. The main module for a script is always called `__main__`.

Class definition blocks and arguments to `exec()` and `eval()` are special in the context of name resolution. A class definition is an executable statement that may use and define names. These references follow the normal rules for name resolution with an exception that unbound local variables are looked up in the global namespace. The namespace of the class definition becomes the attribute dictionary of the class. The scope of names defined in a class block is limited to the class block; it does not extend to the code blocks of methods – this includes comprehensions and generator expressions since they are implemented using a function scope. This means that the following will fail:

```python
class A:
    a = 42
    b = list(a + i for i in range(10))
```
4.2.3. Builtins and restricted execution

**CPython implementation detail:** Users should not touch `__builtins__`; it is strictly an implementation detail. Users wanting to override values in the builtins namespace should import the `builtins` module and modify its attributes appropriately.

The builtins namespace associated with the execution of a code block is actually found by looking up the name `__builtins__` in its global namespace; this should be a dictionary or a module (in the latter case the module’s dictionary is used). By default, when in the `__main__` module, `__builtins__` is the built-in module `builtins`; when in any other module, `__builtins__` is an alias for the dictionary of the `builtins` module itself.

4.2.4. Interaction with dynamic features

Name resolution of free variables occurs at runtime, not at compile time. This means that the following code will print 42:

```python
i = 10
def f():
    print(i)
i = 42
f()
```

The `eval()` and `exec()` functions do not have access to the full environment for resolving names. Names may be resolved in the local and global namespaces of the caller. Free variables are not resolved in the nearest enclosing namespace, but in the global namespace. [1] The `exec()` and `eval()` functions have optional arguments to override the global and local namespace. If only one namespace is
specified, it is used for both.
4.3. Exceptions

Exceptions are a means of breaking out of the normal flow of control of a code block in order to handle errors or other exceptional conditions. An exception is raised at the point where the error is detected; it may be handled by the surrounding code block or by any code block that directly or indirectly invoked the code block where the error occurred.

The Python interpreter raises an exception when it detects a run-time error (such as division by zero). A Python program can also explicitly raise an exception with the `raise` statement. Exception handlers are specified with the `try ... except` statement. The `finally` clause of such a statement can be used to specify cleanup code which does not handle the exception, but is executed whether an exception occurred or not in the preceding code.

Python uses the “termination” model of error handling: an exception handler can find out what happened and continue execution at an outer level, but it cannot repair the cause of the error and retry the failing operation (except by re-entering the offending piece of code from the top).

When an exception is not handled at all, the interpreter terminates execution of the program, or returns to its interactive main loop. In either case, it prints a stack backtrace, except when the exception is `SystemExit`.

Exceptions are identified by class instances. The `except` clause is selected depending on the class of the instance: it must reference the class of the instance or a base class thereof. The instance can be received by the handler and can carry additional information about the exceptional condition.
Note: Exception messages are not part of the Python API. Their contents may change from one version of Python to the next without warning and should not be relied on by code which will run under multiple versions of the interpreter.

See also the description of the try statement in section The try statement and raise statement in section The raise statement.

Footnotes

[1] This limitation occurs because the code that is executed by these operations is not available at the time the module is compiled.
5. The import system

Python code in one module gains access to the code in another module by the process of importing it. The import statement is the most common way of invoking the import machinery, but it is not the only way. Functions such as importlib.import_module() and built-in __import__() can also be used to invoke the import machinery.

The import statement combines two operations; it searches for the named module, then it binds the results of that search to a name in the local scope. The search operation of the import statement is defined as a call to the __import__() function, with the appropriate arguments. The return value of __import__() is used to perform the name binding operation of the import statement. See the import statement for the exact details of that name binding operation.

A direct call to __import__() performs only the module search and, if found, the module creation operation. While certain side-effects may occur, such as the importing of parent packages, and the updating of various caches (including sys.modules), only the import statement performs a name binding operation.

When calling __import__() as part of an import statement, the standard builtin __import__() is called. Other mechanisms for invoking the import system (such as importlib.import_module()) may choose to subvert __import__() and use its own solution to implement import semantics.

When a module is first imported, Python searches for the module and
if found, it creates a module object [1], initializing it. If the named module cannot be found, a `ModuleNotFoundError` is raised. Python implements various strategies to search for the named module when the import machinery is invoked. These strategies can be modified and extended by using various hooks described in the sections below.

*Changed in version 3.3:* The import system has been updated to fully implement the second phase of PEP 302. There is no longer any implicit import machinery - the full import system is exposed through `sys.meta_path`. In addition, native namespace package support has been implemented (see PEP 420).
5.1. **importlib**

The *importlib* module provides a rich API for interacting with the import system. For example, *importlib.import_module()* provides a recommended, simpler API than built-in *__import__()* for invoking the import machinery. Refer to the *importlib* library documentation for additional detail.
5.2. Packages

Python has only one type of module object, and all modules are of this type, regardless of whether the module is implemented in Python, C, or something else. To help organize modules and provide a naming hierarchy, Python has a concept of packages.

You can think of packages as the directories on a file system and modules as files within directories, but don’t take this analogy too literally since packages and modules need not originate from the file system. For the purposes of this documentation, we’ll use this convenient analogy of directories and files. Like file system directories, packages are organized hierarchically, and packages may themselves contain subpackages, as well as regular modules.

It’s important to keep in mind that all packages are modules, but not all modules are packages. Or put another way, packages are just a special kind of module. Specifically, any module that contains a \_\_path\_ attribute is considered a package.

All modules have a name. Subpackage names are separated from their parent package name by dots, akin to Python’s standard attribute access syntax. Thus you might have a module called \texttt{sys} and a package called \texttt{email}, which in turn has a subpackage called \texttt{email.mime} and a module within that subpackage called \texttt{email.mime.text}.

5.2.1. Regular packages

Python defines two types of packages, regular packages and namespace packages. Regular packages are traditional packages as
they existed in Python 3.2 and earlier. A regular package is typically implemented as a directory containing an `__init__.py` file. When a regular package is imported, this `__init__.py` file is implicitly executed, and the objects it defines are bound to names in the package's namespace. The `__init__.py` file can contain the same Python code that any other module can contain, and Python will add some additional attributes to the module when it is imported.

For example, the following file system layout defines a top level `parent` package with three subpackages:

```
parent/
   __init__.py
one/
   __init__.py
two/
   __init__.py
three/
   __init__.py
```

Importing `parent.one` will implicitly execute `parent/__init__.py` and `parent/one/__init__.py`. Subsequent imports of `parent.two` or `parent.three` will execute `parent/two/__init__.py` and `parent/three/__init__.py` respectively.

### 5.2.2. Namespace packages

A namespace package is a composite of various `portions`, where each portion contributes a subpackage to the parent package. Portions may reside in different locations on the file system. Portions may also be found in zip files, on the network, or anywhere else that Python
searches during import. Namespace packages may or may not correspond directly to objects on the file system; they may be virtual modules that have no concrete representation.

Namespace packages do not use an ordinary list for their __path__ attribute. They instead use a custom iterable type which will automatically perform a new search for package portions on the next import attempt within that package if the path of their parent package (or sys.path for a top level package) changes.

With namespace packages, there is no parent/__init__.py file. In fact, there may be multiple parent directories found during import search, where each one is provided by a different portion. Thus parent/one may not be physically located next to parent/two. In this case, Python will create a namespace package for the top-level parent package whenever it or one of its subpackages is imported.

See also PEP 420 for the namespace package specification.
5.3. Searching

To begin the search, Python needs the fully qualified name of the module (or package, but for the purposes of this discussion, the difference is immaterial) being imported. This name may come from various arguments to the `import` statement, or from the parameters to the `importlib.import_module()` or `__import__()` functions.

This name will be used in various phases of the import search, and it may be the dotted path to a submodule, e.g. `foo.bar.baz`. In this case, Python first tries to import `foo`, then `foo.bar`, and finally `foo.bar.baz`. If any of the intermediate imports fail, a `ModuleNotFoundError` is raised.

5.3.1. The module cache

The first place checked during import search is `sys.modules`. This mapping serves as a cache of all modules that have been previously imported, including the intermediate paths. So if `foo.bar.baz` was previously imported, `sys.modules` will contain entries for `foo`, `foo.bar`, and `foo.bar.baz`. Each key will have as its value the corresponding module object.

During import, the module name is looked up in `sys.modules` and if present, the associated value is the module satisfying the import, and the process completes. However, if the value is `None`, then a `ModuleNotFoundError` is raised. If the module name is missing, Python will continue searching for the module.

`sys.modules` is writable. Deleting a key may not destroy the
associated module (as other modules may hold references to it), but it will invalidate the cache entry for the named module, causing Python to search anew for the named module upon its next import. The key can also be assigned to `None`, forcing the next import of the module to result in a `ModuleNotFoundError`.

Beware though, as if you keep a reference to the module object, invalidate its cache entry in `sys.modules`, and then re-import the named module, the two module objects will not be the same. By contrast, `importlib.reload()` will reuse the same module object, and simply reinitialise the module contents by rerunning the module's code.

### 5.3.2. Finders and loaders

If the named module is not found in `sys.modules`, then Python's import protocol is invoked to find and load the module. This protocol consists of two conceptual objects, finders and loaders. A finder’s job is to determine whether it can find the named module using whatever strategy it knows about. Objects that implement both of these interfaces are referred to as importers - they return themselves when they find that they can load the requested module.

Python includes a number of default finders and importers. The first one knows how to locate built-in modules, and the second knows how to locate frozen modules. A third default finder searches an import path for modules. The import path is a list of locations that may name file system paths or zip files. It can also be extended to search for any locatable resource, such as those identified by URLs.

The import machinery is extensible, so new finders can be added to extend the range and scope of module searching.
Finders do not actually load modules. If they can find the named module, they return a *module spec*, an encapsulation of the module's import-related information, which the import machinery then uses when loading the module.

The following sections describe the protocol for finders and loaders in more detail, including how you can create and register new ones to extend the import machinery.

*Changed in version 3.4:* In previous versions of Python, finders returned *loaders* directly, whereas now they return module specs which *contain* loaders. Loaders are still used during import but have fewer responsibilities.

### 5.3.3. Import hooks

The import machinery is designed to be extensible; the primary mechanism for this are the *import hooks*. There are two types of import hooks: *meta hooks* and *import path hooks*.

Meta hooks are called at the start of import processing, before any other import processing has occurred, other than `sys.modules` cache look up. This allows meta hooks to override `sys.path` processing, frozen modules, or even built-in modules. Meta hooks are registered by adding new finder objects to `sys.meta_path`, as described below.

Import path hooks are called as part of `sys.path` (or `package.__path__`) processing, at the point where their associated path item is encountered. Import path hooks are registered by adding new callables to `sys.path_hooks` as described below.
5.3.4. The meta path

When the named module is not found in `sys.modules`, Python next searches `sys.meta_path`, which contains a list of meta path finder objects. These finders are queried in order to see if they know how to handle the named module. Meta path finders must implement a method called `find_spec()` which takes three arguments: a name, an import path, and (optionally) a target module. The meta path finder can use any strategy it wants to determine whether it can handle the named module or not.

If the meta path finder knows how to handle the named module, it returns a spec object. If it cannot handle the named module, it returns `None`. If `sys.meta_path` processing reaches the end of its list without returning a spec, then a `ModuleNotFoundError` is raised. Any other exceptions raised are simply propagated up, aborting the import process.

The `find_spec()` method of meta path finders is called with two or three arguments. The first is the fully qualified name of the module being imported, for example `foo.bar.baz`. The second argument is the path entries to use for the module search. For top-level modules, the second argument is `None`, but for submodules or subpackages, the second argument is the value of the parent package's `__path__` attribute. If the appropriate `__path__` attribute cannot be accessed, a `ModuleNotFoundError` is raised. The third argument is an existing module object that will be the target of loading later. The import system passes in a target module only during reload.

The meta path may be traversed multiple times for a single import request. For example, assuming none of the modules involved has
already been cached, importing foo.bar.baz will first perform a top level import, calling `mpf.find_spec("foo", None, None)` on each meta path finder (mpf). After foo has been imported, foo.bar will be imported by traversing the meta path a second time, calling `mpf.find_spec("foo.bar", foo.__path__, None)`. Once foo.bar has been imported, the final traversal will call `mpf.find_spec("foo.bar.baz", foo.bar.__path__, None)`.

Some meta path finders only support top level imports. These importers will always return `None` when anything other than `None` is passed as the second argument.

Python's default `sys.meta_path` has three meta path finders, one that knows how to import built-in modules, one that knows how to import frozen modules, and one that knows how to import modules from an import path (i.e. the path based finder).

*Changed in version 3.4:* The `find_spec()` method of meta path finders replaced `find_module()`, which is now deprecated. While it will continue to work without change, the import machinery will try it only if the finder does not implement `find_spec()`.
5.4. Loading

If and when a module spec is found, the import machinery will use it (and the loader it contains) when loading the module. Here is an approximation of what happens during the loading portion of import:

```python
module = None
if spec.loader is not None and hasattr(spec.loader, # It is assumed 'exec_module' will also be defined
    module = spec.loader.create_module(spec)
    module = None:
        module = ModuleType(spec.name)
    # The import-related module attributes get set here:
    _init_module_attrs(spec, module)

if spec.loader is None:
    if spec.submodule_search_locations is not None:
        # namespace package
        sys.modules[spec.name] = module
    else:
        # unsupported
        raise ImportError
elif not hasattr(spec.loader, 'exec_module'):
    module = spec.loader.load_module(spec.name)
    # Set __loader__ and __package__ if missing.
else:
    sys.modules[spec.name] = module
    try:
        spec.loader.exec_module(module)
    except BaseException:
        try:
            del sys.modules[spec.name]
        except KeyError:
            pass
    raise
```
Note the following details:

- If there is an existing module object with the given name in `sys.modules`, import will have already returned it.
- The module will exist in `sys.modules` before the loader executes the module code. This is crucial because the module code may (directly or indirectly) import itself; adding it to `sys.modules` beforehand prevents unbounded recursion in the worst case and multiple loading in the best.
- If loading fails, the failing module – and only the failing module – gets removed from `sys.modules`. Any module already in the `sys.modules` cache, and any module that was successfully loaded as a side-effect, must remain in the cache. This contrasts with reloading where even the failing module is left in `sys.modules`.
- After the module is created but before execution, the import machinery sets the import-related module attributes (“_init_module_attrs” in the pseudo-code example above), as summarized in a later section.
- Module execution is the key moment of loading in which the module's namespace gets populated. Execution is entirely delegated to the loader, which gets to decide what gets populated and how.
- The module created during loading and passed to `exec_module()` may not be the one returned at the end of import [2].

Changed in version 3.4: The import system has taken over the boilerplate responsibilities of loaders. These were previously performed by the `importlib.abc.Loader.load_module()` method.
5.4.1. Loaders

Module loaders provide the critical function of loading: module execution. The import machinery calls the `importlib.abc.Loader.exec_module()` method with a single argument, the module object to execute. Any value returned from `exec_module()` is ignored.

Loaders must satisfy the following requirements:

- If the module is a Python module (as opposed to a built-in module or a dynamically loaded extension), the loader should execute the module’s code in the module’s global name space (`module.__dict__`).
- If the loader cannot execute the module, it should raise an `ImportError`, although any other exception raised during `exec_module()` will be propagated.

In many cases, the finder and loader can be the same object; in such cases the `find_spec()` method would just return a spec with the loader set to `self`.

Module loaders may opt in to creating the module object during loading by implementing a `create_module()` method. It takes one argument, the module spec, and returns the new module object to use during loading. `create_module()` does not need to set any attributes on the module object. If the method returns `None`, the import machinery will create the new module itself.

*New in version 3.4*: The `create_module()` method of loaders.

*Changed in version 3.4*: The `load_module()` method was replaced
by `exec_module()` and the import machinery assumed all the boilerplate responsibilities of loading.

For compatibility with existing loaders, the import machinery will use the `load_module()` method of loaders if it exists and the loader does not also implement `exec_module()`. However, `load_module()` has been deprecated and loaders should implement `exec_module()` instead.

The `load_module()` method must implement all the boilerplate loading functionality described above in addition to executing the module. All the same constraints apply, with some additional clarification:

- If there is an existing module object with the given name in `sys.modules`, the loader must use that existing module. (Otherwise, `importlib.reload()` will not work correctly.)
- If the named module does not exist in `sys.modules`, the loader must create a new module object and add it to `sys.modules`.
- The module must exist in `sys.modules` before the loader executes the module code, to prevent unbounded recursion or multiple loading.
- If loading fails, the loader must remove any modules it has inserted into `sys.modules`, but it must remove only the failing module(s), and only if the loader itself has loaded the module(s) explicitly.

*Changed in version 3.5:* A `DeprecationWarning` is raised when `exec_module()` is defined but `create_module()` is not.

*Changed in version 3.6:* An `ImportError` is raised when `exec_module()` is defined but `create_module()` is not.
5.4.2. Submodules

When a submodule is loaded using any mechanism (e.g. `importlib` APIs, the `import` or `import-from` statements, or built-in `__import__()`) a binding is placed in the parent module's namespace to the submodule object. For example, if package `spam` has a submodule `foo`, after importing `spam.foo`, `spam` will have an attribute `foo` which is bound to the submodule. Let's say you have the following directory structure:

```
spam/
  __init__.py
  foo.py
  bar.py
```

and `spam/__init__.py` has the following lines in it:

```
from .foo import Foo
from .bar import Bar
```

then executing the following puts a name binding to `foo` and `bar` in the `spam` module:

```
>>> import spam
>>> spam.foo
<module 'spam.foo' from '/tmp/imports/spam/foo.py'>
>>> spam.bar
<module 'spam.bar' from '/tmp/imports/spam/bar.py'>
```

Given Python’s familiar name binding rules this might seem surprising, but it’s actually a fundamental feature of the import system. The invariant holding is that if you have `sys.modules['spam']` and
sys.modules['spam.foo'] (as you would after the above import), the latter must appear as the `foo` attribute of the former.

5.4.3. Module spec

The import machinery uses a variety of information about each module during import, especially before loading. Most of the information is common to all modules. The purpose of a module's spec is to encapsulate this import-related information on a per-module basis.

Using a spec during import allows state to be transferred between import system components, e.g. between the finder that creates the module spec and the loader that executes it. Most importantly, it allows the import machinery to perform the boilerplate operations of loading, whereas without a module spec the loader had that responsibility.

See `ModuleSpec` for more specifics on what information a module's spec may hold.

*New in version 3.4.*

5.4.4. Import-related module attributes

The import machinery fills in these attributes on each module object during loading, based on the module's spec, before the loader executes the module.

`__name__`

The `__name__` attribute must be set to the fully-qualified name of the module. This name is used to uniquely identify the module in the import system.
**__loader__**

The __loader__ attribute must be set to the loader object that the import machinery used when loading the module. This is mostly for introspection, but can be used for additional loader-specific functionality, for example getting data associated with a loader.

**__package__**

The module's __package__ attribute must be set. Its value must be a string, but it can be the same value as its __name__. When the module is a package, its __package__ value should be set to its __name__. When the module is not a package, __package__ should be set to the empty string for top-level modules, or for submodules, to the parent package’s name. See PEP 366 for further details.

This attribute is used instead of __name__ to calculate explicit relative imports for main modules, as defined in PEP 366. It is expected to have the same value as __spec__.parent.

*Changed in version 3.6:* The value of __package__ is expected to be the same as __spec__.parent.

**__spec__**

The __spec__ attribute must be set to the module spec that was used when importing the module. Setting __spec__ appropriately applies equally to modules initialized during interpreter startup. The one exception is __main__, where __spec__ is set to None in some cases.

When __package__ is not defined, __spec__.parent is used as a fallback.
New in version 3.4.

Changed in version 3.6: `__spec__.parent` is used as a fallback when `__package__` is not defined.

`__path__`
If the module is a package (either regular or namespace), the module object's `__path__` attribute must be set. The value must be iterable, but may be empty if `__path__` has no further significance. If `__path__` is not empty, it must produce strings when iterated over. More details on the semantics of `__path__` are given below.

Non-package modules should not have a `__path__` attribute.

`__file__`  
`__cached__`  
`__file__` is optional. If set, this attribute's value must be a string. The import system may opt to leave `__file__` unset if it has no semantic meaning (e.g. a module loaded from a database).

If `__file__` is set, it may also be appropriate to set the `__cached__` attribute which is the path to any compiled version of the code (e.g. byte-compiled file). The file does not need to exist to set this attribute; the path can simply point to where the compiled file would exist (see PEP 3147).

It is also appropriate to set `__cached__` when `__file__` is not set. However, that scenario is quite atypical. Ultimately, the loader is what makes use of `__file__` and/or `__cached__`. So if a loader can load from a cached module but otherwise does not load from a file, that atypical scenario may be appropriate.
5.4.5. module.__path__

By definition, if a module has a __path__ attribute, it is a package, regardless of its value.

A package's __path__ attribute is used during imports of its subpackages. Within the import machinery, it functions much the same as sys.path, i.e. providing a list of locations to search for modules during import. However, __path__ is typically much more constrained than sys.path.

__path__ must be an iterable of strings, but it may be empty. The same rules used for sys.path also apply to a package's __path__, and sys.path_hooks (described below) are consulted when traversing a package's __path__.

A package's __init__.py file may set or alter the package's __path__ attribute, and this was typically the way namespace packages were implemented prior to PEP 420. With the adoption of PEP 420, namespace packages no longer need to supply __init__.py files containing only __path__ manipulation code; the import machinery automatically sets __path__ correctly for the namespace package.

5.4.6. Module reprs

By default, all modules have a usable repr, however depending on the attributes set above, and in the module's spec, you can more explicitly control the repr of module objects.

If the module has a spec (__spec__), the import machinery will try to
generate a repr from it. If that fails or there is no spec, the import system will craft a default repr using whatever information is available on the module. It will try to use the `module.__name__`, `module.__file__`, and `module.__loader__` as input into the repr, with defaults for whatever information is missing.

Here are the exact rules used:

- If the module has a `__spec__` attribute, the information in the spec is used to generate the repr. The “name”, “loader”, “origin”, and “has_location” attributes are consulted.
- If the module has a `__file__` attribute, this is used as part of the module’s repr.
- If the module has no `__file__` but does have a `__loader__` that is not None, then the loader’s repr is used as part of the module’s repr.
- Otherwise, just use the module’s `__name__` in the repr.

*Changed in version 3.4:* Use of `loader.module_repr()` has been deprecated and the module spec is now used by the import machinery to generate a module repr.

For backward compatibility with Python 3.3, the module repr will be generated by calling the loader’s `module_repr()` method, if defined, before trying either approach described above. However, the method is deprecated.
5.5. The Path Based Finder

As mentioned previously, Python comes with several default meta path finders. One of these, called the path based finder (PathFinder), searches an import path, which contains a list of path entries. Each path entry names a location to search for modules.

The path based finder itself doesn't know how to import anything. Instead, it traverses the individual path entries, associating each of them with a path entry finder that knows how to handle that particular kind of path.

The default set of path entry finders implement all the semantics for finding modules on the file system, handling special file types such as Python source code (.py files), Python byte code (.pyc files) and shared libraries (e.g. .so files). When supported by the zipimport module in the standard library, the default path entry finders also handle loading all of these file types (other than shared libraries) from zipfiles.

Path entries need not be limited to file system locations. They can refer to URLs, database queries, or any other location that can be specified as a string.

The path based finder provides additional hooks and protocols so that you can extend and customize the types of searchable path entries. For example, if you wanted to support path entries as network URLs, you could write a hook that implements HTTP semantics to find modules on the web. This hook (a callable) would return a path entry finder supporting the protocol described below, which was then used to get a loader for the module from the web.
A word of warning: this section and the previous both use the term *finder*, distinguishing between them by using the terms *meta path finder* and *path entry finder*. These two types of finders are very similar, support similar protocols, and function in similar ways during the import process, but it's important to keep in mind that they are subtly different. In particular, meta path finders operate at the beginning of the import process, as keyed off the `sys.meta_path` traversal.

By contrast, path entry finders are in a sense an implementation detail of the path based finder, and in fact, if the path based finder were to be removed from `sys.meta_path`, none of the path entry finder semantics would be invoked.

### 5.5.1. Path entry finders

The *path based finder* is responsible for finding and loading Python modules and packages whose location is specified with a string *path entry*. Most path entries name locations in the file system, but they need not be limited to this.

As a meta path finder, the *path based finder* implements the `find_spec()` protocol previously described, however it exposes additional hooks that can be used to customize how modules are found and loaded from the *import path*.

Three variables are used by the *path based finder*, `sys.path`, `sys.path_hooks` and `sys.path_importer_cache`. The `__path__` attributes on package objects are also used. These provide additional ways that the import machinery can be customized.

`sys.path` contains a list of strings providing search locations for
modules and packages. It is initialized from the PYTHONPATH environment variable and various other installation- and implementation-specific defaults. Entries in `sys.path` can name directories on the file system, zip files, and potentially other “locations” (see the `site` module) that should be searched for modules, such as URLs, or database queries. Only strings and bytes should be present on `sys.path`; all other data types are ignored. The encoding of bytes entries is determined by the individual path entry finders.

The path based finder is a meta path finder, so the import machinery begins the import path search by calling the path based finder's `find_spec()` method as described previously. When the `path` argument to `find_spec()` is given, it will be a list of string paths to traverse - typically a package's `__path__` attribute for an import within that package. If the `path` argument is `None`, this indicates a top level import and `sys.path` is used.

The path based finder iterates over every entry in the search path, and for each of these, looks for an appropriate path entry finder (`PathEntryFinder`) for the path entry. Because this can be an expensive operation (e.g. there may be `stat()` call overheads for this search), the path based finder maintains a cache mapping path entries to path entry finders. This cache is maintained in `sys.path_importer_cache` (despite the name, this cache actually stores finder objects rather than being limited to importer objects). In this way, the expensive search for a particular path entry location's path entry finder need only be done once. User code is free to remove cache entries from `sys.path_importer_cache` forcing the path based finder to perform the path entry search again [3].

If the path entry is not present in the cache, the path based finder iterates over every callable in `sys.path_hooks`. Each of the path
entry hooks in this list is called with a single argument, the path entry to be searched. This callable may either return a path entry finder that can handle the path entry, or it may raise ImportError. An ImportError is used by the path based finder to signal that the hook cannot find a path entry finder for that path entry. The exception is ignored and import path iteration continues. The hook should expect either a string or bytes object; the encoding of bytes objects is up to the hook (e.g. it may be a file system encoding, UTF-8, or something else), and if the hook cannot decode the argument, it should raise ImportError.

If sys.path_hooks iteration ends with no path entry finder being returned, then the path based finder’s find_spec() method will store None in sys.path_importer_cache (to indicate that there is no finder for this path entry) and return None, indicating that this meta path finder could not find the module.

If a path entry finder is returned by one of the path entry hook callables on sys.path_hooks, then the following protocol is used to ask the finder for a module spec, which is then used when loading the module.

The current working directory – denoted by an empty string – is handled slightly differently from other entries on sys.path. First, if the current working directory is found to not exist, no value is stored in sys.path_importer_cache. Second, the value for the current working directory is looked up fresh for each module lookup. Third, the path used for sys.path_importer_cache and returned by importlib.machinery.PathFinder.find_spec() will be the actual current working directory and not the empty string.

5.5.2. Path entry finder protocol
In order to support imports of modules and initialized packages and also to contribute portions to namespace packages, path entry finders must implement the `find_spec()` method.

`find_spec()` takes two argument, the fully qualified name of the module being imported, and the (optional) target module. `find_spec()` returns a fully populated spec for the module. This spec will always have “loader” set (with one exception).

To indicate to the import machinery that the spec represents a namespace portion, the path entry finder sets “loader” on the spec to `None` and “submodule_search_locations” to a list containing the portion.

*Changed in version 3.4:* `find_spec()` replaced `find_loader()` and `find_module()`, both of which are now deprecated, but will be used if `find_spec()` is not defined.

Older path entry finders may implement one of these two deprecated methods instead of `find_spec()`. The methods are still respected for the sake of backward compatibility. However, if `find_spec()` is implemented on the path entry finder, the legacy methods are ignored.

`find_loader()` takes one argument, the fully qualified name of the module being imported. `find_loader()` returns a 2-tuple where the first item is the loader and the second item is a namespace portion. When the first item (i.e. the loader) is `None`, this means that while the path entry finder does not have a loader for the named module, it knows that the path entry contributes to a namespace portion for the named module. This will almost always be the case where Python is asked to import a namespace package that has no physical presence on the file system. When a path entry finder returns `None` for the
loader, the second item of the 2-tuple return value must be a sequence, although it can be empty.

If \texttt{find\_loader()} returns a non-None loader value, the portion is ignored and the loader is returned from the path based finder, terminating the search through the path entries.

For backwards compatibility with other implementations of the import protocol, many path entry finders also support the same, traditional \texttt{find\_module()} method that meta path finders support. However, path entry finder \texttt{find\_module()} methods are never called with a path argument (they are expected to record the appropriate path information from the initial call to the path hook).

The \texttt{find\_module()} method on path entry finders is deprecated, as it does not allow the path entry finder to contribute portions to namespace packages. If both \texttt{find\_loader()} and \texttt{find\_module()} exist on a path entry finder, the import system will always call \texttt{find\_loader()} in preference to \texttt{find\_module()}. 
5.6. Replacing the standard import system

The most reliable mechanism for replacing the entire import system is to delete the default contents of `sys.meta_path`, replacing them entirely with a custom meta path hook.

If it is acceptable to only alter the behaviour of import statements without affecting other APIs that access the import system, then replacing the builtin `__import__()` function may be sufficient. This technique may also be employed at the module level to only alter the behaviour of import statements within that module.

To selectively prevent import of some modules from a hook early on the meta path (rather than disabling the standard import system entirely), it is sufficient to raise `ModuleNotFoundError` directly from `find_spec()` instead of returning `None`. The latter indicates that the meta path search should continue, while raising an exception terminates it immediately.
5.7. Special considerations for __main__

The __main__ module is a special case relative to Python’s import system. As noted elsewhere, the __main__ module is directly initialized at interpreter startup, much like sys and builtins. However, unlike those two, it doesn’t strictly qualify as a built-in module. This is because the manner in which __main__ is initialized depends on the flags and other options with which the interpreter is invoked.

5.7.1. __main__.__spec__

Depending on how __main__ is initialized, __main__.__spec__ gets set appropriately or to None.

When Python is started with the -m option, __spec__ is set to the module spec of the corresponding module or package. __spec__ is also populated when the __main__ module is loaded as part of executing a directory, zipfile or other sys.path entry.

In the remaining cases __main__.__spec__ is set to None, as the code used to populate the __main__ does not correspond directly with an importable module:

- interactive prompt
- -c switch
- running from stdin
- running directly from a source or bytecode file

Note that __main__.__spec__ is always None in the last case, even if the file could technically be imported directly as a module
instead. Use the `-m` switch if valid module metadata is desired in `__main__`.

Note also that even when `__main__` corresponds with an importable module and `__main__.__spec__` is set accordingly, they're still considered `distinct` modules. This is due to the fact that blocks guarded by `if __name__ == "__main__":` checks only execute when the module is used to populate the `__main__` namespace, and not during normal import.
5.8. Open issues

XXX It would be really nice to have a diagram.

XXX * (import_machinery.rst) how about a section devoted just to the attributes of modules and packages, perhaps expanding upon or supplanting the related entries in the data model reference page?

XXX runpy, pkgutil, et al in the library manual should all get “See Also” links at the top pointing to the new import system section.

XXX Add more explanation regarding the different ways in which __main__ is initialized?

XXX Add more info on __main__ quirks/pitfalls (i.e. copy from PEP 395).
5.9. References

The import machinery has evolved considerably since Python's early days. The original specification for packages is still available to read, although some details have changed since the writing of that document.

The original specification for `sys.meta_path` was **PEP 302**, with subsequent extension in **PEP 420**.

**PEP 420** introduced namespace packages for Python 3.3. **PEP 420** also introduced the `find_loader()` protocol as an alternative to `find_module()`.

**PEP 366** describes the addition of the `__package__` attribute for explicit relative imports in main modules.

**PEP 328** introduced absolute and explicit relative imports and initially proposed `__name__` for semantics **PEP 366** would eventually specify for `__package__`.

**PEP 338** defines executing modules as scripts.

**PEP 451** adds the encapsulation of per-module import state in spec objects. It also off-loads most of the boilerplate responsibilities of loaders back onto the import machinery. These changes allow the deprecation of several APIs in the import system and also addition of new methods to finders and loaders.

Footnotes

The importlib implementation avoids using the return value directly. Instead, it gets the module object by looking the module name up in `sys.modules`. The indirect effect of this is that an imported module may replace itself in `sys.modules`. This is implementation-specific behavior that is not guaranteed to work in other Python implementations.

In legacy code, it is possible to find instances of `imp.NullImporter` in the `sys.path_importer_cache`. It is recommended that code be changed to use `None` instead. See Porting Python code for more details.
6. Expressions

This chapter explains the meaning of the elements of expressions in Python.

**Syntax Notes:** In this and the following chapters, extended BNF notation will be used to describe syntax, not lexical analysis. When (one alternative of) a syntax rule has the form

```
name ::= othername
```

and no semantics are given, the semantics of this form of `name` are the same as for `othername`. 
6.1. Arithmetic conversions

When a description of an arithmetic operator below uses the phrase “the numeric arguments are converted to a common type,” this means that the operator implementation for built-in types works as follows:

- If either argument is a complex number, the other is converted to complex;
- otherwise, if either argument is a floating point number, the other is converted to floating point;
- otherwise, both must be integers and no conversion is necessary.

Some additional rules apply for certain operators (e.g., a string as a left argument to the ‘%’ operator). Extensions must define their own conversion behavior.
6.2. Atoms

Atoms are the most basic elements of expressions. The simplest atoms are identifiers or literals. Forms enclosed in parentheses, brackets or braces are also categorized syntactically as atoms. The syntax for atoms is:

```
tag{atom ::= identifier | literal | enclosure
tag{enclosure ::= parenth_form | list_display | dict_display | generator_expression | yield_atom}
```

6.2.1. Identifiers (Names)

An identifier occurring as an atom is a name. See section Identifiers and keywords for lexical definition and section Naming and binding for documentation of naming and binding.

When the name is bound to an object, evaluation of the atom yields that object. When a name is not bound, an attempt to evaluate it raises a NameError exception.

**Private name mangling:** When an identifier that textually occurs in a class definition begins with two or more underscore characters and does not end in two or more underscores, it is considered a private name of that class. Private names are transformed to a longer form before code is generated for them. The transformation inserts the class name, with leading underscores removed and a single underscore inserted, in front of the name. For example, the identifier __spam occurring in a class named Ham will be transformed to _Ham__spam. This transformation is independent of the syntactical context in which the identifier is used. If the transformed name is
extremely long (longer than 255 characters), implementation defined truncation may happen. If the class name consists only of underscores, no transformation is done.

6.2.2. Literals

Python supports string and bytes literals and various numeric literals:

\[
\text{literal} ::= \text{stringliteral} \mid \text{bytesliteral} \\
\mid \text{integer} \mid \text{floatnumber} \mid \text{imagnumber}
\]

Evaluation of a literal yields an object of the given type (string, bytes, integer, floating point number, complex number) with the given value. The value may be approximated in the case of floating point and imaginary (complex) literals. See section Literals for details.

All literals correspond to immutable data types, and hence the object’s identity is less important than its value. Multiple evaluations of literals with the same value (either the same occurrence in the program text or a different occurrence) may obtain the same object or a different object with the same value.

6.2.3. Parenthesized forms

A parenthesized form is an optional expression list enclosed in parentheses:

\[
\text{parenth form} ::= "(" [\text{starred expression}] ")"
\]

A parenthesized expression list yields whatever that expression list yields: if the list contains at least one comma, it yields a tuple; otherwise, it yields the single expression that makes up the expression
list.

An empty pair of parentheses yields an empty tuple object. Since tuples are immutable, the rules for literals apply (i.e., two occurrences of the empty tuple may or may not yield the same object).

Note that tuples are not formed by the parentheses, but rather by use of the comma operator. The exception is the empty tuple, for which parentheses are required — allowing unparenthesized “nothing” in expressions would cause ambiguities and allow common typos to pass uncaught.

6.2.4. Displays for lists, sets and dictionaries

For constructing a list, a set or a dictionary Python provides special syntax called “displays”, each of them in two flavors:

- either the container contents are listed explicitly, or
- they are computed via a set of looping and filtering instructions, called a *comprehension*.

Common syntax elements for comprehensions are:

```
comprehension ::= expression comp_for
comp_for ::= [ASYNC] "for" target_list "in" or iter
comp_iter ::= comp_for | comp_if
comp_if ::= "if" expression_nocond [comp_iter]
```

The comprehension consists of a single expression followed by at least one *for* clause and zero or more *for* or *if* clauses. In this case, the elements of the new container are those that would be produced by considering each of the *for* or *if* clauses a block, nesting from left to right, and evaluating the expression to produce an
element each time the innermost block is reached.

Note that the comprehension is executed in a separate scope, so names assigned to in the target list don't "leak" into the enclosing scope.

Since Python 3.6, in an async def function, an async for clause may be used to iterate over a asynchronous iterator. A comprehension in an async def function may consist of either a for or async for clause following the leading expression, may contain additional for or async for clauses, and may also use await expressions. If a comprehension contains either async for clauses or await expressions it is called an asynchronous comprehension. An asynchronous comprehension may suspend the execution of the coroutine function in which it appears. See also PEP 530.

6.2.5. List displays

A list display is a possibly empty series of expressions enclosed in square brackets:

\[
\text{list_display} ::= \[ \text{starred_list | comprehension} \]
\]

A list display yields a new list object, the contents being specified by either a list of expressions or a comprehension. When a comma-separated list of expressions is supplied, its elements are evaluated from left to right and placed into the list object in that order. When a comprehension is supplied, the list is constructed from the elements resulting from the comprehension.

6.2.6. Set displays
A set display is denoted by curly braces and distinguishable from dictionary displays by the lack of colons separating keys and values:

\[
\text{set_display} ::= \{ (\text{starred_list} | \text{comprehension}) \}
\]

A set display yields a new mutable set object, the contents being specified by either a sequence of expressions or a comprehension. When a comma-separated list of expressions is supplied, its elements are evaluated from left to right and added to the set object. When a comprehension is supplied, the set is constructed from the elements resulting from the comprehension.

An empty set cannot be constructed with \{\}; this literal constructs an empty dictionary.

6.2.7. Dictionary displays

A dictionary display is a possibly empty series of key/datum pairs enclosed in curly braces:

\[
\text{dict_display} ::= \{ [\text{key_datum_list} | \text{dict_comprehension}] \}
\]

A dictionary display yields a new dictionary object.

If a comma-separated sequence of key/datum pairs is given, they are evaluated from left to right to define the entries of the dictionary: each key object is used as a key into the dictionary to store the corresponding datum. This means that you can specify the same key multiple times in the key/datum list, and the final dictionary’s value for
that key will be the last one given.

A double asterisk ** denotes dictionary unpacking. Its operand must be a mapping. Each mapping item is added to the new dictionary. Later values replace values already set by earlier key/datum pairs and earlier dictionary unpackings.

New in version 3.5: Unpacking into dictionary displays, originally proposed by PEP 448.

A dict comprehension, in contrast to list and set comprehensions, needs two expressions separated with a colon followed by the usual “for” and “if” clauses. When the comprehension is run, the resulting key and value elements are inserted in the new dictionary in the order they are produced.

Restrictions on the types of the key values are listed earlier in section The standard type hierarchy. (To summarize, the key type should be hashable, which excludes all mutable objects.) Clashes between duplicate keys are not detected; the last datum (textually rightmost in the display) stored for a given key value prevails.

6.2.8. Generator expressions

A generator expression is a compact generator notation in parentheses:

```
generator_expression ::= "(" expression comp_for ")"
```

A generator expression yields a new generator object. Its syntax is the same as for comprehensions, except that it is enclosed in parentheses instead of brackets or curly braces.
Variables used in the generator expression are evaluated lazily when the `__next__()` method is called for the generator object (in the same fashion as normal generators). However, the leftmost `for` clause is immediately evaluated, so that an error produced by it can be seen before any other possible error in the code that handles the generator expression. Subsequent `for` clauses cannot be evaluated immediately since they may depend on the previous `for` loop. For example: `(x*y for x in range(10) for y in bar(x))`.

The parentheses can be omitted on calls with only one argument. See section Calls for details.

Since Python 3.6, if the generator appears in an `async def` function, then `async for` clauses and `await` expressions are permitted as with an asynchronous comprehension. If a generator expression contains either `async for` clauses or `await` expressions it is called an asynchronous generator expression. An asynchronous generator expression yields a new asynchronous generator object, which is an asynchronous iterator (see Asynchronous Iterators).

6.2.9. Yield expressions

```
yield_atom ::= "(" yield_expression ")"
yield_expression ::= "yield" [expression_list | "for"]
```

The yield expression is used when defining a generator function or an asynchronous generator function and thus can only be used in the body of a function definition. Using a yield expression in a function's body causes that function to be a generator, and using it in an `async def` function's body causes that coroutine function to be an asynchronous generator. For example:
Generator functions are described below, while asynchronous generator functions are described separately in section Asynchronous generator functions.

When a generator function is called, it returns an iterator known as a generator. That generator then controls the execution of the generator function. The execution starts when one of the generator’s methods is called. At that time, the execution proceeds to the first yield expression, where it is suspended again, returning the value of expression_list to the generator’s caller. By suspended, we mean that all local state is retained, including the current bindings of local variables, the instruction pointer, the internal evaluation stack, and the state of any exception handling. When the execution is resumed by calling one of the generator’s methods, the function can proceed exactly as if the yield expression were just another external call. The value of the yield expression after resuming depends on the method which resumed the execution. If __next__() is used (typically via either a for or the next() builtin) then the result is None. Otherwise, if send() is used, then the result will be the value passed in to that method.

All of this makes generator functions quite similar to coroutines; they yield multiple times, they have more than one entry point and their execution can be suspended. The only difference is that a generator function cannot control where the execution should continue after it yields; the control is always transferred to the generator’s caller.
Yield expressions are allowed anywhere in a try construct. If the generator is not resumed before it is finalized (by reaching a zero reference count or by being garbage collected), the generator-iterator's close() method will be called, allowing any pending finally clauses to execute.

When yield from <expr> is used, it treats the supplied expression as a subiterator. All values produced by that subiterator are passed directly to the caller of the current generator's methods. Any values passed in with send() and any exceptions passed in with throw() are passed to the underlying iterator if it has the appropriate methods. If this is not the case, then send() will raise AttributeError or TypeError, while throw() will just raise the passed in exception immediately.

When the underlying iterator is complete, the value attribute of the raised StopIteration instance becomes the value of the yield expression. It can be either set explicitly when raising StopIteration, or automatically when the sub-iterator is a generator (by returning a value from the sub-generator).

Changed in version 3.3: Added yield from <expr> to delegate control flow to a subiterator.

The parentheses may be omitted when the yield expression is the sole expression on the right hand side of an assignment statement.

PEP 255 - Simple Generators

The proposal for adding generators and the yield statement to Python.

### PEP 342 - Coroutines via Enhanced Generators

The proposal to enhance the API and syntax of generators, making them usable as simple coroutines.

### PEP 380 - Syntax for Delegating to a Subgenerator

The proposal to introduce the `yield_from` syntax, making delegation to sub-generators easy.

6.2.9.1. Generator-iterator methods

This subsection describes the methods of a generator iterator. They can be used to control the execution of a generator function.

Note that calling any of the generator methods below when the generator is already executing raises a `ValueError` exception.

**generator.``next``()**

Starts the execution of a generator function or resumes it at the last executed yield expression. When a generator function is resumed with a `next()` method, the current yield expression always evaluates to `None`. The execution then continues to the next yield expression, where the generator is suspended again, and the value of the `expression_list` is returned to `next()`'s caller. If the generator exits without yielding another value, a `StopIteration` exception is raised.

This method is normally called implicitly, e.g. by a `for` loop, or by the built-in `next()` function.

**generator.``send``(value)**

Resumes the execution and “sends” a value into the generator function. The `value` argument becomes the result of the current yield expression. The `send()` method returns the next value
yielded by the generator, or raises `StopIteration` if the
generator exits without yielding another value. When `send()` is
called to start the generator, it must be called with `None` as the
argument, because there is no yield expression that could receive
the value.

generator. `throw(type[, value[, traceback]])`

Raises an exception of type `type` at the point where the generator
was paused, and returns the next value yielded by the generator
function. If the generator exits without yielding another value, a
`StopIteration` exception is raised. If the generator function
does not catch the passed-in exception, or raises a different
exception, then that exception propagates to the caller.

generator. `close()`

Raises a `GeneratorExit` at the point where the generator
function was paused. If the generator function then exits gracefully,
is already closed, or raises `GeneratorExit` (by not catching the
exception), `close` returns to its caller. If the generator yields a
value, a `RuntimeError` is raised. If the generator raises any other
exception, it is propagated to the caller. `close()` does nothing if
the generator has already exited due to an exception or normal
exit.

6.2.9.2. Examples

Here is a simple example that demonstrates the behavior of
generators and generator functions:

```python
>>> def echo(value=None):
...     print("Execution starts when 'next()' is called.
...     try:
```
... while True:
...
    try:
...
        value = (yield value)
...
    except Exception as e:
...
        value = e
...
    finally:
...
        print("Don't forget to clean up when 'close()' is called."
...
>>> generator = echo(1)
>>> print(next(generator))
Execution starts when 'next()' is called for the first time
1
>>> print(next(generator))
None
>>> print(generator.send(2))
2
>>> generator.throw(TypeError, "spam")
TypeError('spam',)
>>> generator.close()
Don't forget to clean up when 'close()' is called.

For examples using yield from, see PEP 380: Syntax for Delegating to a Subgenerator in “What’s New in Python.”

6.2.9.3. Asynchronous generator functions

The presence of a yield expression in a function or method defined using async def further defines the function as an asynchronous generator function.

When an asynchronous generator function is called, it returns an asynchronous iterator known as an asynchronous generator object. That object then controls the execution of the generator function. An asynchronous generator object is typically used in an async for
statement in a coroutine function analogously to how a generator object would be used in a for statement.

Calling one of the asynchronous generator’s methods returns an awaitable object, and the execution starts when this object is awaited on. At that time, the execution proceeds to the first yield expression, where it is suspended again, returning the value of expression_list to the awaiting coroutine. As with a generator, suspension means that all local state is retained, including the current bindings of local variables, the instruction pointer, the internal evaluation stack, and the state of any exception handling. When the execution is resumed by awaiting on the next object returned by the asynchronous generator’s methods, the function can proceed exactly as if the yield expression were just another external call. The value of the yield expression after resuming depends on the method which resumed the execution. If __anext__() is used then the result is None. Otherwise, if asend() is used, then the result will be the value passed in to that method.

In an asynchronous generator function, yield expressions are allowed anywhere in a try construct. However, if an asynchronous generator is not resumed before it is finalized (by reaching a zero reference count or by being garbage collected), then a yield expression within a try construct could result in a failure to execute pending finally clauses. In this case, it is the responsibility of the event loop or scheduler running the asynchronous generator to call the asynchronous generator-iterator’s aclose() method and run the resulting coroutine object, thus allowing any pending finally clauses to execute.

To take care of finalization, an event loop should define a finalizer function which takes an asynchronous generator-iterator and
presumably calls `aclose()` and executes the coroutine. This finalizer may be registered by calling `sys.set_asyncgen_hooks()`. When first iterated over, an asynchronous generator-iterator will store the registered finalizer to be called upon finalization. For a reference example of a finalizer method see the implementation of `asyncio.Loop.shutdown_asyncgens` in `Lib/asyncio/base_events.py`.

The expression `yield from <expr>` is a syntax error when used in an asynchronous generator function.

### 6.2.9.4. Asynchronous generator-iterator methods

This subsection describes the methods of an asynchronous generator iterator, which are used to control the execution of a generator function.

#### `coroutine agen.__anext__()`

Returns an awaitable which when run starts to execute the asynchronous generator or resumes it at the last executed yield expression. When an asynchronous generator function is resumed with a `__anext__()` method, the current yield expression always evaluates to `None` in the returned awaitable, which when run will continue to the next yield expression. The value of the `expression_list` of the yield expression is the value of the `StopIteration` exception raised by the completing coroutine. If the asynchronous generator exits without yielding another value, the awaitable instead raises an `StopAsyncIteration` exception, signalling that the asynchronous iteration has completed.

This method is normally called implicitly by a `async for` loop.
coroutine agen. `asend(value)`

Returns an awaitable which when run resumes the execution of the asynchronous generator. As with the `send()` method for a generator, this “sends” a value into the asynchronous generator function, and the `value` argument becomes the result of the current yield expression. The awaitable returned by the `asend()` method will return the next value yielded by the generator as the value of the raised `StopIteration`, or raises `StopAsyncIteration` if the asynchronous generator exits without yielding another value. When `asend()` is called to start the asynchronous generator, it must be called with `None` as the argument, because there is no yield expression that could receive the value.

coroutine agen. `athrow(type[, value[, traceback]])`

Returns an awaitable that raises an exception of type `type` at the point where the asynchronous generator was paused, and returns the next value yielded by the generator function as the value of the raised `StopIteration` exception. If the asynchronous generator exits without yielding another value, an `StopAsyncIteration` exception is raised by the awaitable. If the generator function does not catch the passed-in exception, or raises a different exception, then when the awaitable is run that exception propagates to the caller of the awaitable.

coroutine agen. `aclose()`

Returns an awaitable that when run will throw a `GeneratorExit` into the asynchronous generator function at the point where it was paused. If the asynchronous generator function then exits gracefully, is already closed, or raises `GeneratorExit` (by not catching the exception), then the returned awaitable will raise a `StopIteration` exception. Any further awaitables returned by
subsequent calls to the asynchronous generator will raise a \texttt{StopAsyncIteration} exception. If the asynchronous generator yields a value, a \texttt{RuntimeError} is raised by the awaitable. If the asynchronous generator raises any other exception, it is propagated to the caller of the awaitable. If the asynchronous generator has already exited due to an exception or normal exit, then further calls to \texttt{aclose()} will return an awaitable that does nothing.
6.3. Primaries

Primaries represent the most tightly bound operations of the language. Their syntax is:

```
primary ::= atom | attributeref | subscription | slicing
```

6.3.1. Attribute references

An attribute reference is a primary followed by a period and a name:

```
attributeref ::= primary "." identifier
```

The primary must evaluate to an object of a type that supports attribute references, which most objects do. This object is then asked to produce the attribute whose name is the identifier. This production can be customized by overriding the `__getattr__()` method. If this attribute is not available, the exception `AttributeError` is raised. Otherwise, the type and value of the object produced is determined by the object. Multiple evaluations of the same attribute reference may yield different objects.

6.3.2. Subscriptions

A subscription selects an item of a sequence (string, tuple or list) or mapping (dictionary) object:

```
subscription ::= primary "[" expression_list "]"
```

The primary must evaluate to an object that supports subscription (lists
or dictionaries for example). User-defined objects can support subscription by defining a \_\_getitem\_\_() method.

For built-in objects, there are two types of objects that support subscription:

If the primary is a mapping, the expression list must evaluate to an object whose value is one of the keys of the mapping, and the subscription selects the value in the mapping that corresponds to that key. (The expression list is a tuple except if it has exactly one item.)

If the primary is a sequence, the expression (list) must evaluate to an integer or a slice (as discussed in the following section).
