Returns a tuple (release, vendor, vminfo, osinfo) with vminfo being a tuple (vm_name, vm_release, vm_vendor) and osinfo being a tuple (os_name, os_version, os_arch). Values which cannot be determined are set to the defaults given as parameters (which all default to '').
16.14.3. Windows Platform

platform.win32_ver(release='', version='', csd='', ptype='')

Get additional version information from the Windows Registry and return a tuple (release, version, csd, ptype) referring to OS release, version number, CSD level (service pack) and OS type (multi/single processor).

As a hint: ptype is 'Uniprocessor Free' on single processor NT machines and 'Multiprocessor Free' on multi processor machines. The ‘Free’ refers to the OS version being free of debugging code. It could also state ‘Checked’ which means the OS version uses debugging code, i.e. code that checks arguments, ranges, etc.

Note: This function works best with Mark Hammond’s win32all package installed, but also on Python 2.3 and later (support for this was added in Python 2.6). It obviously only runs on Win32 compatible platforms.

16.14.3.1. Win95/98 specific

platform.popen(cmd, mode='r', bufsize=-1)

Portable popen() interface. Find a working popen implementation preferring win32pipe.popen(). On Windows NT, win32pipe.popen() should work; on Windows 9x it hangs due to bugs in the MS C library.

Deprecated since version 3.3: This function is obsolete. Use the subprocess module. Check especially the Replacing Old...
Functions with the subprocess Module section.
16.14.4. Mac OS Platform

platform.macro(release='', versioninfo=(',', ',', ''), machine='')
  Get Mac OS version information and return it as tuple (release, versioninfo, machine) with versioninfo being a tuple (version, dev_stage, non_release_version).

  Entries which cannot be determined are set to ".". All tuple entries are strings.
16.14.5. Unix Platforms

platform.dist(distname='', version='', id='', supported_dists=('SuSE', 'debian', 'redhat', 'mandrake', ...))

This is another name for linux_distribution().

Deprecated since version 3.5, will be removed in version 3.7.

platform.linux_distribution(distname='', version='', id='', supported_dists=('SuSE', 'debian', 'redhat', 'mandrake', ...), full_distribution_name=1)

Tries to determine the name of the Linux OS distribution name.

supported_dists may be given to define the set of Linux distributions to look for. It defaults to a list of currently supported Linux distributions identified by their release file name.

If full_distribution_name is true (default), the full distribution read from the OS is returned. Otherwise the short name taken from supported_dists is used.

Returns a tuple (distname,version,id) which defaults to the args given as parameters. id is the item in parentheses after the version number. It is usually the version codename.

Deprecated since version 3.5, will be removed in version 3.7.

platform.libc_ver(executable=sys.executable, lib='', version='', chunksize=2048)

Tries to determine the libc version against which the file executable (defaults to the Python interpreter) is linked. Returns a tuple of strings (lib, version) which default to the given parameters in
case the lookup fails.

Note that this function has intimate knowledge of how different libc versions add symbols to the executable is probably only usable for executables compiled using gcc.

The file is read and scanned in chunks of chunksize bytes.
16.15. `errno` — Standard errno system symbols

This module makes available standard `errno` system symbols. The value of each symbol is the corresponding integer value. The names and descriptions are borrowed from `linux/include/errno.h`, which should be pretty all-inclusive.

`errno.errorcode`

Dictionary providing a mapping from the `errno` value to the string name in the underlying system. For instance, `errno.errorcode[errno.EPERM]` maps to 'EPERM'.

To translate a numeric error code to an error message, use `os.strerror()`.

Of the following list, symbols that are not used on the current platform are not defined by the module. The specific list of defined symbols is available as `errno.errorcode.keys()`. Symbols available can include:

`errno.EPERM`

Operation not permitted

`errno.ENOENT`

No such file or directory

`errno.ESRCH`

No such process

`errno.EINTR`
Interrupted system call.

See also: This error is mapped to the exception `InterruptedError`.

- **errno. EIO**
  I/O error

- **errno. ENXIO**
  No such device or address

- **errno. E2BIG**
  Arg list too long

- **errno. ENOEXEC**
  Exec format error

- **errno. EBADF**
  Bad file number

- **errno. ECHILD**
  No child processes

- **errno. EAGAIN**
  Try again

- **errno. ENOMEM**
  Out of memory

- **errno. EACCES**
  Permission denied

- **errno. EFAULT**
Bad address

\texttt{errno.\textbf{ENOTBLK}}
Block device required

\texttt{errno.\textbf{EBUSY}}
Device or resource busy

\texttt{errno.\textbf{EEXIST}}
File exists

\texttt{errno.\textbf{EXDEV}}
Cross-device link

\texttt{errno.\textbf{ENODEV}}
No such device

\texttt{errno.\textbf{ENOTDIR}}
Not a directory

\texttt{errno.\textbf{EISDIR}}
Is a directory

\texttt{errno.\textbf{EINVAL}}
Invalid argument

\texttt{errno.\textbf{ENFILE}}
File table overflow

\texttt{errno.\textbf{EMFILE}}
Too many open files

\texttt{errno.\textbf{ENOTTY}}
Not a typewriter
errno. **ETXTBSY**
Text file busy

errno. **EFBIG**
File too large

errno. **ENOSPC**
No space left on device

errno. **ESPIPE**
Illegal seek

errno. **EROFS**
Read-only file system

errno. **EMLINK**
Too many links

errno. **EPIPE**
Broken pipe

errno. **EDOM**
Math argument out of domain of func

errno. **ERANGE**
Math result not representable

errno. **EDEADLK**
Resource deadlock would occur

errno. **ENAMETOOLONG**
File name too long

errno. **ENOLCK**
No record locks available

errno. **ENOSYS**
Function not implemented

errno. **ENOTEMPTY**
Directory not empty

errno. **ELOOP**
Too many symbolic links encountered

errno. **EWOULDBLOCK**
Operation would block

errno. **ENOMSG**
No message of desired type

errno. **EIDRM**
Identifier removed

errno. **ECHANG**
Channel number out of range

errno. **EL2NSYNC**
Level 2 not synchronized

errno. **EL3HLT**
Level 3 halted

errno. **EL3RST**
Level 3 reset

errno. **ELNRNG**
Link number out of range
errno. **EUNATCH**  
Protocol driver not attached

errno. **ENOCSI**  
No CSI structure available

errno. **EL2HLT**  
Level 2 halted

errno. **EBADE**  
Invalid exchange

errno. **EBADR**  
Invalid request descriptor

errno. **EXFULL**  
Exchange full

errno. **ENOANO**  
No anode

errno. **EBADRQC**  
Invalid request code

errno. **EBADSLT**  
Invalid slot

errno. **EDEADLOCK**  
File locking deadlock error

errno. **EBFONT**  
Bad font file format

errno. **ENOSTR**
Device not a stream

errno. **ENODATA**
No data available

errno. **ETIME**
Timer expired

errno. **ENOSR**
Out of streams resources

errno. **ENONET**
Machine is not on the network

errno. **ENOPKG**
Package not installed

errno. **EREMOTE**
Object is remote

errno. **ENOLINK**
Link has been severed

errno. **EADV**
Advertise error

errno. **ESRMNT**
Srmount error

errno. **ECOMM**
Communication error on send

errno. **EPROTO**
Protocol error
errno. **EMULTIHOP**
Multihop attempted

errno. **EDOTDOT**
RFS specific error

errno. **EBADMSG**
Not a data message

errno. **EOVERFLOW**
Value too large for defined data type

errno. **ENOTUNIQ**
Name not unique on network

errno. **EBADFD**
File descriptor in bad state

errno. **EREMCHG**
Remote address changed

errno. **ELIBACC**
Can not access a needed shared library

errno. **ELIBBAD**
Accessing a corrupted shared library

errno. **ELIBSCN**
.lib section in a.out corrupted

errno. **ELIBMAX**
Attempting to link in too many shared libraries

errno. **ELIBEXEC**
Cannot exec a shared library directly

errno. EILSEQ
Illegal byte sequence

errno. ERESTART
Interrupted system call should be restarted

errno. ESTRPIPE
Streams pipe error

errno. EUSERS
Too many users

errno. ENOTSOCK
Socket operation on non-socket

errno. EDESTADDRREQ
Destination address required

errno. EMSGSIZE
Message too long

errno. EPROTOTYPE
Protocol wrong type for socket

errno. ENOPROTOOPT
Protocol not available

errno. EPROTONOSUPPORT
Protocol not supported

errno. ESOCKTNOSUPPORT
Socket type not supported
errno. **EOPNOTSUPP**  
Operation not supported on transport endpoint

errno. **EPFNOSUPPORT**  
Protocol family not supported

errno. **EAFNOSUPPORT**  
Address family not supported by protocol

errno. **EADDRINUSE**  
Address already in use

errno. **EADDRNOTAVAIL**  
Cannot assign requested address

errno. **ENETDOWN**  
Network is down

errno. **ENETUNREACH**  
Network is unreachable

errno. **ENETRESET**  
Network dropped connection because of reset

errno. **ECONNABORTED**  
Software caused connection abort

errno. **ECONNRESET**  
Connection reset by peer

errno. **ENOBUFFS**  
No buffer space available

errno. **EISCONN**
Transport endpoint is already connected

errno. **ENOTCONN**
Transport endpoint is not connected

errno. **ESHUTDOWN**
Cannot send after transport endpoint shutdown

errno. **ETOOMANYREFS**
Too many references: cannot splice

errno. **ETimedOUT**
Connection timed out

errno. **ECONNREFUSED**
Connection refused

errno. **EHOSTDOWN**
Host is down

errno. **EHOSTUNREACH**
No route to host

errno. **EALREADY**
Operation already in progress

errno. **EINPROGRESS**
Operation now in progress

errno. **ESTALE**
Stale NFS file handle

errno. **EUCLEAN**
Structure needs cleaning
errno. **ENOTNAM**
Not a XENIX named type file

errno. **ENAVAIL**
No XENIX semaphores available

errno. **EISNAM**
Is a named type file

errno. **EREMOTEIO**
Remote I/O error

errno. **EDQUOT**
Quota exceeded
16.16. **ctypes** — A foreign function library for Python

**ctypes** is a foreign function library for Python. It provides C compatible data types, and allows calling functions in DLLs or shared libraries. It can be used to wrap these libraries in pure Python.
16.16.1. ctypes tutorial

Note: The code samples in this tutorial use doctest to make sure that they actually work. Since some code samples behave differently under Linux, Windows, or Mac OS X, they contain doctest directives in comments.

Note: Some code samples reference the ctypes c_int type. On platforms where sizeof(long) == sizeof(int) it is an alias to c_long. So, you should not be confused if c_long is printed if you would expect c_int — they are actually the same type.

16.16.1.1. Loading dynamic link libraries

c types exports the cdll, and on Windows windll and oledll objects, for loading dynamic link libraries.

You load libraries by accessing them as attributes of these objects. cdll loads libraries which export functions using the standard cdecl calling convention, while windll libraries call functions using the stdcall calling convention. oledll also uses the stdcall calling convention, and assumes the functions return a Windows HRESULT error code. The error code is used to automatically raise an OSError exception when the function call fails.

Changed in version 3.3: Windows errors used to raise WindowsError, which is now an alias of OSError.

Here are some examples for Windows. Note that msvcrtn is the MS standard C library containing most standard C functions, and uses the cdecl calling convention:
Windows appends the usual `.dll` file suffix automatically.

**Note:** Accessing the standard C library through `cdll.msvcrt` will use an outdated version of the library that may be incompatible with the one being used by Python. Where possible, use native Python functionality, or else import and use the `msvcrt` module.

On Linux, it is required to specify the filename *including* the extension to load a library, so attribute access cannot be used to load libraries. Either the `LoadLibrary()` method of the dll loaders should be used, or you should load the library by creating an instance of `CDLL` by calling the constructor:

```python
>>> cdll.LoadLibrary("libc.so.6")
<CDLL 'libc.so.6', handle ... at ...>
>>> libc = CDLL("libc.so.6")
>>> libc
<CDLL 'libc.so.6', handle ... at ...>
>>> 
```

### 16.16.1.2. Accessing functions from loaded dlls

Functions are accessed as attributes of dll objects:

```python
>>> from ctypes import *
```
>>> libc.printf
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.GetModuleHandleA)
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.MyOwnFunction)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 239, in __getattr__
    func = __stdcallFuncPtr(name, self)
AttributeError: function 'MyOwnFunction' not found

Note that win32 system dlls like kernel32 and user32 often export ANSI as well as UNICODE versions of a function. The UNICODE version is exported with an `W` appended to the name, while the ANSI version is exported with an `A` appended to the name. The win32 GetModuleHandle function, which returns a module handle for a given module name, has the following C prototype, and a macro is used to expose one of them as GetModuleHandle depending on whether UNICODE is defined or not:

```c
/* ANSI version */
HMODULE GetModuleHandleA(LPCSTR lpModuleName);
/* UNICODE version */
HMODULE GetModuleHandleW(LPCWSTR lpModuleName);
```

windll does not try to select one of them by magic, you must access the version you need by specifying GetModuleHandleA or GetModuleHandleW explicitly, and then call it with bytes or string objects respectively.

Sometimes, dlls export functions with names which aren’t valid Python identifiers, like `"??2@YAPAXI@Z"`. In this case you have to use `getattr()` to retrieve the function:
On Windows, some dlls export functions not by name but by ordinal. These functions can be accessed by indexing the dll object with the ordinal number:

```
>>> cdll.kernel32[1]
<FuncPtr object at 0x...>
>>> cdll.kernel32[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 310, in __getitem__
    func = _StdcallFuncPtr(name, self)
  AttributeError: function ordinal 0 not found
```  

### 16.16.1.3. Calling functions

You can call these functions like any other Python callable. This example uses the `time()` function, which returns system time in seconds since the Unix epoch, and the `GetModuleHandleA()` function, which returns a win32 module handle.

This example calls both functions with a NULL pointer (`None` should be used as the NULL pointer):

```
>>> print(libc.time(None))
1150640792
>>> print(hex(windll.kernel32.GetModuleHandleA(None)))
0x1d000000
```
**Note:** `ctypes` may raise a `ValueError` after calling the function, if it detects that an invalid number of arguments were passed. This behavior should not be relied upon. It is deprecated in 3.6.2, and will be removed in 3.7.

`ValueError` is raised when you call an `stdcall` function with the `cdecl` calling convention, or vice versa:

```python
>>> cdll.kernel32.GetModuleHandleA(None)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with not enough arguments

>>> windll.msvcrt.printf(b"spam")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with too many arguments
```

To find out the correct calling convention you have to look into the C header file or the documentation for the function you want to call.

On Windows, `ctypes` uses win32 structured exception handling to prevent crashes from general protection faults when functions are called with invalid argument values:

```python
>>> windll.kernel32.GetModuleHandleA(32)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
OSError: exception: access violation reading 0x00000

>>>```
There are, however, enough ways to crash Python with `ctypes`, so you should be careful anyway. The `faulthandler` module can be helpful in debugging crashes (e.g. from segmentation faults produced by erroneous C library calls).

None, integers, bytes objects and (unicode) strings are the only native Python objects that can directly be used as parameters in these function calls. `None` is passed as a C `NULL` pointer, bytes objects and strings are passed as pointer to the memory block that contains their data (char * or wchar_t *). Python integers are passed as the platforms default C int type, their value is masked to fit into the C type.

Before we move on calling functions with other parameter types, we have to learn more about `ctypes` data types.

16.16.1.4. Fundamental data types

`ctypes` defines a number of primitive C compatible data types:

<table>
<thead>
<tr>
<th>ctypes type</th>
<th>C type</th>
<th>Python type</th>
</tr>
</thead>
<tbody>
<tr>
<td>c_bool</td>
<td>_Bool</td>
<td>bool (1)</td>
</tr>
<tr>
<td>c_char</td>
<td>char</td>
<td>1-character bytes object</td>
</tr>
<tr>
<td>c_wchar</td>
<td>wchar_t</td>
<td>1-character string</td>
</tr>
<tr>
<td>c_byte</td>
<td>char</td>
<td>int</td>
</tr>
<tr>
<td>c_ubyte</td>
<td>unsigned char</td>
<td>int</td>
</tr>
<tr>
<td>c_short</td>
<td>short</td>
<td>int</td>
</tr>
<tr>
<td>c_ushort</td>
<td>unsigned short</td>
<td>int</td>
</tr>
<tr>
<td>c_int</td>
<td>int</td>
<td>int</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td>Value Type</td>
</tr>
<tr>
<td>--------------</td>
<td>--------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td><code>c_uint</code></td>
<td>unsigned int</td>
<td>int</td>
</tr>
<tr>
<td><code>c_long</code></td>
<td>long</td>
<td>int</td>
</tr>
<tr>
<td><code>c_ulong</code></td>
<td>unsigned long</td>
<td>int</td>
</tr>
<tr>
<td><code>c_ulonglong</code></td>
<td>__int64 or long long</td>
<td>int</td>
</tr>
<tr>
<td><code>c_ulonglong</code></td>
<td>unsigned __int64 or unsigned long long</td>
<td>int</td>
</tr>
<tr>
<td><code>c_size_t</code></td>
<td>size_t</td>
<td>int</td>
</tr>
<tr>
<td><code>c_ssize_t</code></td>
<td>ssize_t or Py_ssize_t</td>
<td>int</td>
</tr>
<tr>
<td><code>c_float</code></td>
<td>float</td>
<td>float</td>
</tr>
<tr>
<td><code>c_double</code></td>
<td>double</td>
<td>float</td>
</tr>
<tr>
<td><code>c_longdouble</code></td>
<td>long double</td>
<td>float</td>
</tr>
<tr>
<td><code>c_char_p</code></td>
<td>char *(NUL terminated)</td>
<td>bytes object or None</td>
</tr>
<tr>
<td><code>c_wchar_p</code></td>
<td>wchar_t *(NUL terminated)</td>
<td>string or None</td>
</tr>
<tr>
<td><code>c_void_p</code></td>
<td>void *</td>
<td>int or None</td>
</tr>
</tbody>
</table>

1. The constructor accepts any object with a truth value.

All these types can be created by calling them with an optional initializer of the correct type and value:

```python
>>> c_int()
c_long(0)
>>> c_wchar_p("Hello, World")
c_wchar_p(140018365411392)
>>> c_ushort(-3)
c_ushort(65533)
```
Since these types are mutable, their value can also be changed afterwards:

```python
>>> i = c_int(42)
>>> print(i)
c_long(42)
>>> print(i.value)
42
>>> i.value = -99
>>> print(i.value)
-99
```

Assigning a new value to instances of the pointer types `c_char_p`, `c_wchar_p`, and `c_void_p` changes the memory location they point to, *not the contents* of the memory block (of course not, because Python bytes objects are immutable):

```python
>>> s = "Hello, World"
>>> c_s = c_wchar_p(s)
>>> print(c_s)
c_wchar_p(139966785747344)
>>> print(c_s.value)
Hello World
>>> c_s.value = "Hi, there"
>>> print(c_s)                       # the memory location has changed
    c_wchar_p(139966783348904)
>>> print(c_s.value)
Hi, there
>>> print(s)                        # first object is unchanged
Hello, World
```

You should be careful, however, not to pass them to functions expecting pointers to mutable memory. If you need mutable memory
blocks, ctypes has a `create_string_buffer()` function which creates these in various ways. The current memory block contents can be accessed (or changed) with the `raw` property; if you want to access it as NUL terminated string, use the `value` property:

```python
>>> from ctypes import *
>>> p = create_string_buffer(3)           # create
>>> print(sizeof(p), repr(p.raw))
3 b'\x00\x00\x00'
>>> p = create_string_buffer(b"Hello")   # create
>>> print(sizeof(p), repr(p.raw))
6 b"Hello\x00"
>>> print(repr(p.value))
b"Hello"
>>> p = create_string_buffer(b"Hello", 10) # create
>>> print(sizeof(p), repr(p.raw))
10 b"Hello\x00\x00\x00\x00\x00\x00"
>>> p.value = b"Hi"
>>> print(sizeof(p), repr(p.raw))
10 b"Hi\x00\x00\x00\x00\x00\x00"
>>>
```

The `create_string_buffer()` function replaces the `c_buffer()` function (which is still available as an alias), as well as the `c_string()` function from earlier ctypes releases. To create a mutable memory block containing unicode characters of the C type `wchar_t` use the `create_unicode_buffer()` function.

### 16.16.1.5. Calling functions, continued

Note that `printf` prints to the real standard output channel, *not* to `sys.stdout`, so these examples will only work at the console prompt, not from within `IDLE` or `PythonWin`: 
As has been mentioned before, all Python types except integers, strings, and bytes objects have to be wrapped in their corresponding `ctypes` type, so that they can be converted to the required C data type:

```python
>>> printf = libc.printf
>>> printf(b"Hello, %s\n", b"World!")
Hello, World!
14
>>> printf(b"Hello, %S\n", "World!")
Hello, World!
14
>>> printf(b"%d bottles of beer\n", 42)
42 bottles of beer
19
>>> printf(b"%f bottles of beer\n", 42.5)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: Don
>>>
```

16.16.1.6. Calling functions with your own custom data types

You can also customize `ctypes` argument conversion to allow instances of your own classes be used as function arguments. `ctypes` looks for an `_as_parameter_` attribute and uses this as the
function argument. Of course, it must be one of integer, string, or bytes:

```python
>>> class Bottles:
...    def __init__(self, number):
...        self._as_parameter_ = number
...
>>> bottles = Bottles(42)
>>> printf(b"%d bottles of beer\n", bottles)
42 bottles of beer
19
``` 

If you don't want to store the instance's data in the _as_parameter_ instance variable, you could define a `property` which makes the attribute available on request.

**16.16.1.7. Specifying the required argument types (function prototypes)**

It is possible to specify the required argument types of functions exported from DLLs by setting the `argtypes` attribute.

`argtypes` must be a sequence of C data types (the `printf` function is probably not a good example here, because it takes a variable number and different types of parameters depending on the format string, on the other hand this is quite handy to experiment with this feature):

```python
>>> printf.argtypes = [c_char_p, c_char_p, c_int, c_
>>> printf(b"String '%s', Int %d, Double %f\n", b"Hi
String 'Hi', Int 10, Double 2.200000
37
```
Specifying a format protects against incompatible argument types (just as a prototype for a C function), and tries to convert the arguments to valid types:

```python
>>> printf(b"%d %d %d", 1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: wrong type
>>> printf(b"%s %d %f\n", b"X", 2, 3)
X 2 3.000000
13
>>> 
```

If you have defined your own classes which you pass to function calls, you have to implement a `from_param()` class method for them to be able to use them in the argtypes sequence. The `from_param()` class method receives the Python object passed to the function call, it should do a type check or whatever is needed to make sure this object is acceptable, and then return the object itself, its `_as_parameter_` attribute, or whatever you want to pass as the C function argument in this case. Again, the result should be an integer, string, bytes, a `ctypes` instance, or an object with an `_as_parameter_` attribute.

### 16.16.1.8. Return types

By default functions are assumed to return the C `int` type. Other return types can be specified by setting the `restype` attribute of the function object.

Here is a more advanced example, it uses the `strchr` function, which
expects a string pointer and a char, and returns a pointer to a string:

```python
>>> strchr = libc.strchr
>>> strchr(b"abcdef", ord("d"))
8059983
>>> strchr(b"abcdef", ord("d")) # c_char_p is a pointer to string
b'def'
>>> print(strchr(b"abcdef", ord("x")))
None

If you want to avoid the `ord("x")` calls above, you can set the `argtypes` attribute, and the second argument will be converted from a single character Python bytes object into a C char:

```python
>>> strchr.restype = c_char_p
>>> strchr.argtypes = [c_char_p, c_char]
>>> strchr(b"abcdef", b"d")
'def'
>>> strchr(b"abcdef", b"def")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: one character string expected
>>> print(strchr(b"abcdef", b"x"))
None
>>> strchr(b"abcdef", b"d")
'def'
```
function call. This is useful to check for error return values and automatically raise an exception:

```python
>>> GetModuleHandle = windll.kernel32.GetModuleHandle
>>> def ValidHandle(value):
...     if value == 0:
...         raise WinError()
...     return value
... >>>
>>> GetModuleHandle.restype = ValidHandle
>>> GetModuleHandle(None)
486539264
>>> GetModuleHandle("something silly")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 3, in ValidHandle
OSError: [Errno 126] The specified module could not
>>> WinError is a function which will call Windows FormatMessage() api to get the string representation of an error code, and returns an exception. WinError takes an optional error code parameter, if no one is used, it calls GetLastError() to retrieve it.

Please note that a much more powerful error checking mechanism is available through the errcheck attribute; see the reference manual for details.

16.16.1.9. Passing pointers (or: passing parameters by reference)

Sometimes a C api function expects a pointer to a data type as
parameter, probably to write into the corresponding location, or if the
data is too large to be passed by value. This is also known as passing
parameters by reference.

`ctypes` exports the `byref()` function which is used to pass
parameters by reference. The same effect can be achieved with the
`pointer()` function, although `pointer()` does a lot more work
since it constructs a real pointer object, so it is faster to use `byref()`
if you don’t need the pointer object in Python itself:

```python
>>> i = c_int()
>>> f = c_float()
>>> s = create_string_buffer(b'\000' * 32)
>>> print(i.value, f.value, repr(s.value))
0 0.0 b''
>>> libc sscanf(b'1 3.14 Hello', b'%(d f s)
...    byref(i), byref(f), s)
3
>>> print(i.value, f.value, repr(s.value))
1 3.1400001049 b'Hello'
```  

16.16.1.10. Structures and unions

Structures and unions must derive from the `Structure` and `Union`
base classes which are defined in the `ctypes` module. Each subclass
must define a `_fields_` attribute. `_fields_` must be a list of 2-
tuples, containing a field name and a field type.

The field type must be a `ctypes` type like `c_int`, or any other
derived `ctypes` type: structure, union, array, pointer.

Here is a simple example of a POINT structure, which contains two
integers named x and y, and also shows how to initialize a structure in the constructor:

```python
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = [("x", c_int),
...                 ("y", c_int)]
...     point = POINT(10, 20)
>>> print(point.x, point.y)
10 20
>>> point = POINT(y=5)
>>> print(point.x, point.y)
0 5
>>> POINT(1, 2, 3)
ValueError: too many initializers
>>>```

You can, however, build much more complicated structures. A structure can itself contain other structures by using a structure as a field type.

Here is a RECT structure which contains two POINTs named `upperleft` and `lowerright`:

```python
>>> class RECT(Structure):
...     _fields_ = [("upperleft", POINT),
...                 ("lowerright", POINT)]
...     rc = RECT(point)
>>> print(rc.upperleft.x, rc.upperleft.y)
0 5
>>> print(rc.lowerright.x, rc.lowerright.y)
0 0
```
Nested structures can also be initialized in the constructor in several ways:

```python
>>> r = RECT(POINT(1, 2), POINT(3, 4))
>>> r = RECT((1, 2), (3, 4))
```

Field descriptors can be retrieved from the class, they are useful for debugging because they can provide useful information:

```python
>>> print(POINT.x)
<Field type=c_long, ofs=0, size=4>
>>> print(POINT.y)
<Field type=c_long, ofs=4, size=4>
```

**Warning:** `ctypes` does not support passing unions or structures with bit-fields to functions by value. While this may work on 32-bit x86, it's not guaranteed by the library to work in the general case. Unions and structures with bit-fields should always be passed to functions by pointer.

### 16.16.1.11. Structure/union alignment and byte order

By default, Structure and Union fields are aligned in the same way the C compiler does it. It is possible to override this behavior be specifying a `__pack__` class attribute in the subclass definition. This must be set to a positive integer and specifies the maximum alignment for the fields. This is what `#pragma pack(n)` also does in MSVC.

`ctypes` uses the native byte order for Structures and Unions. To build
structures with non-native byte order, you can use one of the BigEndianStructure, LittleEndianStructure, BigEndianUnion, and LittleEndianUnion base classes. These classes cannot contain pointer fields.

16.16.1.12. Bit fields in structures and unions

It is possible to create structures and unions containing bit fields. Bit fields are only possible for integer fields, the bit width is specified as the third item in the _fields_ tuples:

```python
>>> class Int(Structure):
...     _fields_ = [(
...         "first_16", c_int, 16),
...         ("second_16", c_int, 16)]
... >>> print(Int.first_16)
<Field type=c_long, ofs=0:0, bits=16>
>>> print(Int.second_16)
<Field type=c_long, ofs=0:16, bits=16>
```  

16.16.1.13. Arrays

Arrays are sequences, containing a fixed number of instances of the same type.

The recommended way to create array types is by multiplying a data type with a positive integer:

```python
TenPointsArrayType = POINT * 10
```  

Here is an example of a somewhat artificial data type, a structure containing 4 POINTs among other stuff:
```python
>>> from ctypes import *

>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...            
>>> class MyStruct(Structure):
...     _fields_ = [("a", c_int),
...                 ("b", c_float),
...                 ("point_array", POINT * 4)]

>>> print(len(MyStruct().point_array))
4

>>> Instances are created in the usual way, by calling the class:

 arr = TenPointsArrayType()
 for pt in arr:
     print(pt.x, pt.y)

The above code print a series of 0 0 lines, because the array contents is initialized to zeros.

Initializers of the correct type can also be specified:

```python
>>> from ctypes import *

>>> TenIntegers = c_int * 10
>>> ii = TenIntegers(1, 2, 3, 4, 5, 6, 7, 8, 9, 10)
>>> print(ii)
<c_long_Array_10 object at 0x...>
>>> for i in ii: print(i, end=" ")
...
1 2 3 4 5 6 7 8 9 10
```

Pointer instances are created by calling the `pointer()` function on a `ctypes` type:

```python
>>> from ctypes import *
>>> i = c_int(42)
>>> pi = pointer(i)
```

Pointer instances have a `contents` attribute which returns the object to which the pointer points, the `i` object above:

```python
>>> pi.contents
c_long(42)
```

Note that `ctypes` does not have OOR (original object return), it constructs a new, equivalent object each time you retrieve an attribute:

```python
>>> pi.contents is i
False
>>> pi.contents is pi.contents
False
```

Assigning another `c_int` instance to the pointer’s contents attribute would cause the pointer to point to the memory location where this is stored:

```python
>>> i = c_int(99)
>>> pi.contents = i
>>> pi.contents
c_long(99)
```
Pointer instances can also be indexed with integers:

```python
>>> pi[0]
99
>>> 
```

Assigning to an integer index changes the pointed to value:

```python
>>> print(i)
c_long(99)
>>> pi[0] = 22
>>> print(i)
c_long(22)
>>> 
```

It is also possible to use indexes different from 0, but you must know what you’re doing, just as in C: You can access or change arbitrary memory locations. Generally you only use this feature if you receive a pointer from a C function, and you know that the pointer actually points to an array instead of a single item.

Behind the scenes, the `pointer()` function does more than simply create pointer instances, it has to create pointer types first. This is done with the `POINTER()` function, which accepts any `ctypes` type, and returns a new type:

```python
>>> PI = POINTER(c_int)
>>> PI
<class 'ctypes.LP_c_long'>
>>> PI[42]
Traceback (most recent call last):
  File "<stdin>"", line 1, in <module>
TypeError: expected c_long instead of int
>>> PI(c_int(42))
<ctypes.LP_c_long object at 0x...>
```
Calling the pointer type without an argument creates a `NULL` pointer. `NULL` pointers have a `False` boolean value:

```python
>>> null_ptr = POINTER(c_int)()
>>> print(bool(null_ptr))
False
```

`ctypes` checks for `NULL` when dereferencing pointers (but dereferencing invalid non-`NULL` pointers would crash Python):

```python
>>> null_ptr[0]
Traceback (most recent call last):
  ....
ValueError: NULL pointer access
```

```python
>>> null_ptr[0] = 1234
Traceback (most recent call last):
  ....
ValueError: NULL pointer access
```

16.16.1.15. Type conversions

Usually, `ctypes` does strict type checking. This means, if you have `POINTER(c_int)` in the `argtypes` list of a function or as the type of a member field in a structure definition, only instances of exactly the same type are accepted. There are some exceptions to this rule, where `ctypes` accepts other objects. For example, you can pass compatible array instances instead of pointer types. So, for
POINTER(c_int), ctypes accepts an array of c_int:

```python
>>> class Bar(Structure):
...     _fields_ = [("count", c_int), ("values", POINTER(c_int))]
...
>>> bar = Bar()
>>> bar.values = (c_int * 3)(1, 2, 3)
>>> bar.count = 3
>>> for i in range(bar.count):
...     print(bar.values[i])
...
1
2
3
```

In addition, if a function argument is explicitly declared to be a pointer type (such as POINTER(c_int)) in argtypes, an object of the pointed type (c_int in this case) can be passed to the function. ctypes will apply the required byref() conversion in this case automatically.

To set a POINTER type field to NULL, you can assign None:

```python
>>> bar.values = None
```

Sometimes you have instances of incompatible types. In C, you can cast one type into another type. ctypes provides a cast() function which can be used in the same way. The Bar structure defined above accepts POINTER(c_int) pointers or c_int arrays for its values field, but not instances of other types:
For these cases, the \texttt{cast()} function is handy.

The \texttt{cast()} function can be used to cast a ctypes instance into a pointer to a different ctypes data type. \texttt{cast()} takes two parameters, a ctypes object that is or can be converted to a pointer of some kind, and a ctypes pointer type. It returns an instance of the second argument, which references the same memory block as the first argument:

\begin{verbatim}
>>> a = (c_byte * 4)()
>>> cast(a, POINTER(c_int))
<ctypes.LP_c_long object at ...>
\end{verbatim}

So, \texttt{cast()} can be used to assign to the \texttt{values} field of \texttt{Bar} the structure:

\begin{verbatim}
>>> bar = Bar()
>>> bar.values = cast((c_byte * 4)(), POINTER(c_int))
>>> print(bar.values[0])
0
\end{verbatim}

16.16.1.16. Incomplete Types

\textit{Incomplete Types} are structures, unions or arrays whose members are
not yet specified. In C, they are specified by forward declarations, which are defined later:

```c
struct cell; /* forward declaration */
struct cell {
    char *name;
    struct cell *next;
};
```

The straightforward translation into ctypes code would be this, but it does not work:

```python
>>> class cell(Structure):
...     _fields_ = [('name', c_char_p),
...                 ('next', POINTER(cell))]
...
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 2, in cell
NameError: name 'cell' is not defined
>>> 
```

because the new `class cell` is not available in the class statement itself. In ctypes, we can define the `cell` class and set the `_fields_` attribute later, after the class statement:

```python
>>> from ctypes import *
>>> class cell(Structure):
...     pass
...
>>> cell._fields_ = [('name', c_char_p),
...                   ('next', POINTER(cell))]
>>> 
```
Lets try it. We create two instances of `cell`, and let them point to each other, and finally follow the pointer chain a few times:

```python
>>> c1 = cell()
>>> c1.name = "foo"
>>> c2 = cell()
>>> c2.name = "bar"
>>> c1.next = pointer(c2)
>>> c2.next = pointer(c1)
>>> p = c1
>>> for i in range(8):
    ...    print(p.name, end="
    ...    p = p.next[0]
    ...
foo bar foo bar foo bar foo bar
>>>```

16.16.1.17. Callback functions

`ctypes` allows creating C callable function pointers from Python callables. These are sometimes called *callback functions*.

First, you must create a class for the callback function. The class knows the calling convention, the return type, and the number and types of arguments this function will receive.

The `CFUNCTYPE()` factory function creates types for callback functions using the `cdecl` calling convention. On Windows, the `WINFUNCTYPE()` factory function creates types for callback functions using the `stdcall` calling convention.

Both of these factory functions are called with the result type as first argument, and the callback functions expected argument types as the remaining arguments.
I will present an example here which uses the standard C library’s `qsort()` function, that is used to sort items with the help of a callback function. `qsort()` will be used to sort an array of integers:

```
>>> IntArray5 = c_int * 5
>>> ia = IntArray5(5, 1, 7, 33, 99)
>>> qsort = libc.qsort
>>> qsort.restype = None
```

`qsort()` must be called with a pointer to the data to sort, the number of items in the data array, the size of one item, and a pointer to the comparison function, the callback. The callback will then be called with two pointers to items, and it must return a negative integer if the first item is smaller than the second, a zero if they are equal, and a positive integer otherwise.

So our callback function receives pointers to integers, and must return an integer. First we create the type for the callback function:

```
>>> CMPFUNC = CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
```

To get started, here is a simple callback that shows the values it gets passed:

```
>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return 0
...
>>> cmp_func = CMPFUNC(py_cmp_func)
```
The result:

```python
>>> qsort(ia, len(ia), sizeof(c_int), cmp_func)
py_cmp_func  5 1
py_cmp_func 33 99
py_cmp_func  7 33
py_cmp_func  5 7
py_cmp_func  1 7
```

Now we can actually compare the two items and return a useful result:

```python
>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return a[0] - b[0]
...
>>> qsort(ia, len(ia), sizeof(c_int), CMPFUNC(py_cmp_func))
py_cmp_func  5 1
py_cmp_func 33 99
py_cmp_func  7 33
py_cmp_func  1 7
```

As we can easily check, our array is sorted now:

```python
>>> for i in ia: print(i, end=" ")
...
1 5 7 33 99
```

**Note:** Make sure you keep references to `CFUNCTYPE()` objects as long as they are used from C code. `ctypes` doesn’t, and if you
don't, they may be garbage collected, crashing your program when a callback is made.

Also, note that if the callback function is called in a thread created outside of Python's control (e.g. by the foreign code that calls the callback), ctypes creates a new dummy Python thread on every invocation. This behavior is correct for most purposes, but it means that values stored with `threading.local` will not survive across different callbacks, even when those calls are made from the same C thread.

16.16.1.18. Accessing values exported from dlls

Some shared libraries not only export functions, they also export variables. An example in the Python library itself is the `Py_OptimizeFlag`, an integer set to 0, 1, or 2, depending on the `-O` or `-OO` flag given on startup.

`ctypes` can access values like this with the `in_dll()` class methods of the type. `pythonapi` is a predefined symbol giving access to the Python C api:

```python
global opt_flag
opt_flag = c_int.in_dll(pythonapi, "Py_OptimizeFlag")
print(opt_flag)
```

If the interpreter would have been started with `-O`, the sample would have printed `c_long(1)`, or `c_long(2)` if `-OO` would have been specified.

An extended example which also demonstrates the use of pointers
accesses the \texttt{PyImport\_FrozenModules} pointer exported by Python.

Quoting the docs for that value:

This pointer is initialized to point to an array of \texttt{struct \_frozen} records, terminated by one whose members are all \texttt{NULL} or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.

So manipulating this pointer could even prove useful. To restrict the example size, we show only how this table can be read with \texttt{ctypes}:

```python
>>> from ctypes import *
>>> class struct_frozen(Structure):
...     _fields_ = ["name", c_char_p],
...     ("code", POINTER(c_ubyte)),
...     ("size", c_int]
... >>>
```

We have defined the \texttt{struct \_frozen} data type, so we can get the pointer to the table:

```python
>>> FrozenTable = POINTER(struct_frozen)
>>> table = FrozenTable.in_dll(pythonapi, "PyImport_"
>>> Since \texttt{table} is a pointer to the array of \texttt{struct\_frozen} records, we can iterate over it, but we just have to make sure that our loop terminates, because pointers have no size. Sooner or later it would probably crash with an access violation or whatever, so it's better to
break out of the loop when we hit the NULL entry:

```python
>>> for item in table:
...     if item.name is None:
...         break
...     print(item.name.decode("ascii"), item.size)
...
_frozen_importlib 31764
_frozen_importlib_external 41499
_hello__ 161
__phello__ -161
__phello__.spam 161
>>> 
```

The fact that standard Python has a frozen module and a frozen package (indicated by the negative size member) is not well known, it is only used for testing. Try it out with `import __hello__` for example.

### 16.16.1.19. Surprises

There are some edges in `ctypes` where you might expect something other than what actually happens.

Consider the following example:

```python
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class RECT(Structure):
...     _fields_ = ("a", POINT), ("b", POINT)
...
>>> p1 = POINT(1, 2)
>>> p2 = POINT(3, 4)
```
Hm. We certainly expected the last statement to print 3 4 1 2. What happened? Here are the steps of the `rc.a, rc.b = rc.b, rc.a` line above:

```python
>>> temp0, temp1 = rc.b, rc.a
>>> rc.a = temp0
>>> rc.b = temp1
>>> 
```

Note that `temp0` and `temp1` are objects still using the internal buffer of the `rc` object above. So executing `rc.a = temp0` copies the buffer contents of `temp0` into `rc` ‘s buffer. This, in turn, changes the contents of `temp1`. So, the last assignment `rc.b = temp1`, doesn’t have the expected effect.

Keep in mind that retrieving sub-objects from Structure, Unions, and Arrays doesn’t copy the sub-object, instead it retrieves a wrapper object accessing the root-object’s underlying buffer.

Another example that may behave different from what one would expect is this:

```python
>>> s = c_char_p()
>>> s.value = "abc def ghi"
>>> s.value
```
'abc def ghi'

```python
>>> s.value is s.value
False
```  

Why is it printing `False`? ctypes instances are objects containing a memory block plus some descriptors accessing the contents of the memory. Storing a Python object in the memory block does not store the object itself, instead the contents of the object is stored. Accessing the contents again constructs a new Python object each time!

### 16.16.1.20. Variable-sized data types

**ctypes** provides some support for variable-sized arrays and structures.

The `resize()` function can be used to resize the memory buffer of an existing ctypes object. The function takes the object as first argument, and the requested size in bytes as the second argument. The memory block cannot be made smaller than the natural memory block specified by the objects type, a `ValueError` is raised if this is tried:

```python
>>> short_array = (c_short * 4)()  
>>> print(sizeof(short_array))
8  
>>> resize(short_array, 4)
Traceback (most recent call last):
  ...  
ValueError: minimum size is 8
```
This is nice and fine, but how would one access the additional elements contained in this array? Since the type still only knows about 4 elements, we get errors accessing other elements:

```python
>>> short_array[7]
Traceback (most recent call last):
  ...  
IndexError: invalid index
```

Another way to use variable-sized data types with `ctypes` is to use the dynamic nature of Python, and (re-)define the data type after the required size is already known, on a case by case basis.
16.16.2. ctypes reference

16.16.2.1. Finding shared libraries

When programming in a compiled language, shared libraries are accessed when compiling/linking a program, and when the program is run.

The purpose of the `find_library()` function is to locate a library in a way similar to what the compiler or runtime loader does (on platforms with several versions of a shared library the most recent should be loaded), while the ctypes library loaders act like when a program is run, and call the runtime loader directly.

The `ctypes.util` module provides a function which can help to determine the library to load.

`ctypes.util.find_library(name)`

Try to find a library and return a pathname. `name` is the library name without any prefix like `lib`, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

On Linux, `find_library()` tries to run external programs (`/sbin/ldconfig, gcc, objdump and ld`) to find the library file. It returns the filename of the library file.

*Changed in version 3.6:* On Linux, the value of the environment variable `LD_LIBRARY_PATH` is used when searching for libraries, if a library cannot be found by any other means.
Here are some examples:

```python
>>> from ctypes.util import find_library
>>> find_library("m")
'libm.so.6'
>>> find_library("c")
'libc.so.6'
>>> find_library("bz2")
'libbz2.so.1.0'
>>> 
```

On OS X, `find_library()` tries several predefined naming schemes and paths to locate the library, and returns a full pathname if successful:

```python
>>> from ctypes.util import find_library
>>> find_library("c")
'/usr/lib/libc.dylib'
>>> find_library("m")
'/usr/lib/libm.dylib'
>>> find_library("bz2")
'/usr/lib/libbz2.dylib'
>>> find_library("AGL")
'/System/Library/Frameworks/AGL.framework/AGL'
>>> 
```

On Windows, `find_library()` searches along the system search path, and returns the full pathname, but since there is no predefined naming scheme a call like `find_library("c")` will fail and return `None`.

If wrapping a shared library with `ctypes`, it may be better to determine the shared library name at development time, and hardcode that into the wrapper module instead of using `find_library()` to
locate the library at runtime.

16.16.2.2. Loading shared libraries

There are several ways to load shared libraries into the Python process. One way is to instantiate one of the following classes:

```python
class ctypes.CDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False, use_last_error=False)
```

Instances of this class represent loaded shared libraries. Functions in these libraries use the standard C calling convention, and are assumed to return int.

```python
class ctypes.OleDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False, use_last_error=False)
```

Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the stdcall calling convention, and are assumed to return the windows specific HRESULT code. HRESULT values contain information specifying whether the function call failed or succeeded, together with additional error code. If the return value signals a failure, an OSError is automatically raised.

*Changed in version 3.3:* WindowsError used to be raised.

```python
class ctypes.WinDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False, use_last_error=False)
```

Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the stdcall calling convention, and are assumed to return int by default.

On Windows CE only the standard calling convention is used, for
convenience the WinDLL and OleDLL use the standard calling convention on this platform.

The Python global interpreter lock is released before calling any function exported by these libraries, and reacquired afterwards.

```
class ctypes.PyDLL(name, mode=DEFAULT_MODE, handle=None)
```

Instances of this class behave like CDLL instances, except that the Python GIL is not released during the function call, and after the function execution the Python error flag is checked. If the error flag is set, a Python exception is raised.

Thus, this is only useful to call Python C api functions directly.

All these classes can be instantiated by calling them with at least one argument, the pathname of the shared library. If you have an existing handle to an already loaded shared library, it can be passed as the handle named parameter, otherwise the underlying platforms dlopen or LoadLibrary function is used to load the library into the process, and to get a handle to it.

The `mode` parameter can be used to specify how the library is loaded. For details, consult the `dlopen(3)` manpage. On Windows, `mode` is ignored. On posix systems, RTLD_NOW is always added, and is not configurable.

The `use_errno` parameter, when set to true, enables a ctypes mechanism that allows accessing the system `errno` error number in a safe way. ctypes maintains a thread-local copy of the systems `errno` variable; if you call foreign functions created with `use_errno=True` then the `errno` value before the function call is swapped with the ctypes private copy, the same happens immediately
after the function call.

The function `ctypes.get_errno()` returns the value of the ctypes private copy, and the function `ctypes.set_errno()` changes the ctypes private copy to a new value and returns the former value.

The `use_last_error` parameter, when set to true, enables the same mechanism for the Windows error code which is managed by the `GetLastError()` and `SetLastError()` Windows API functions; `ctypes.get_last_error()` and `ctypes.set_last_error()` are used to request and change the ctypes private copy of the windows error code.

`ctypes.RTLD_GLOBAL`

Flag to use as `mode` parameter. On platforms where this flag is not available, it is defined as the integer zero.

`ctypes.RTLD_LOCAL`

Flag to use as `mode` parameter. On platforms where this is not available, it is the same as `RTLD_GLOBAL`.

`ctypes.DEFAULT_MODE`

The default mode which is used to load shared libraries. On OSX 10.3, this is `RTLD_GLOBAL`, otherwise it is the same as `RTLD_LOCAL`.

Instances of these classes have no public methods. Functions exported by the shared library can be accessed as attributes or by index. Please note that accessing the function through an attribute caches the result and therefore accessing it repeatedly returns the same object each time. On the other hand, accessing it through an index returns a new object each time:
```python
>>> from ctypes import CDLL
>>> libc = CDLL("libc.so.6")  # On Linux
>>> libc.time == libc.time
True
>>> libc[\'time\'] == libc[\'time\']
False
```

The following public attributes are available, their name starts with an underscore to not clash with exported function names:

**PyDLL._handle**

The system handle used to access the library.

**PyDLL._name**

The name of the library passed in the constructor.

Shared libraries can also be loaded by using one of the prefabricated objects, which are instances of the `LibraryLoader` class, either by calling the `LoadLibrary()` method, or by retrieving the library as attribute of the loader instance.

```python
class ctypes.LibraryLoader(dlltype):
    Class which loads shared libraries. `dlltype` should be one of the CDLL, PyDLL, WinDLL, or OleDLL types.

    __getattr__() has special behavior: It allows loading a shared library by accessing it as attribute of a library loader instance. The result is cached, so repeated attribute accesses return the same library each time.

    LoadLibrary(name)
    Load a shared library into the process and return it. This method always returns a new instance of the library.
```
These prefabricated library loaders are available:

```python
ctypes.cdll
    Creates CDLL instances.

ctypes.windll
    Windows only: Creates WinDLL instances.

ctypes.oledll
    Windows only: Creates OleDLL instances.

ctypes.pydll
    Creates PyDLL instances.
```

For accessing the C Python api directly, a ready-to-use Python shared library object is available:

```python
ctypes.pythonapi
    An instance of PyDLL that exposes Python C API functions as attributes. Note that all these functions are assumed to return C int, which is of course not always the truth, so you have to assign the correct restype attribute to use these functions.
```

### 16.16.2.3. Foreign functions

As explained in the previous section, foreign functions can be accessed as attributes of loaded shared libraries. The function objects created in this way by default accept any number of arguments, accept any ctypes data instances as arguments, and return the default result type specified by the library loader. They are instances of a private class:

```python
class ctypes._FuncPtr
```
Base class for C callable foreign functions.

Instances of foreign functions are also C compatible data types; they represent C function pointers.

This behavior can be customized by assigning to special attributes of the foreign function object.

**restype**

Assign a ctypes type to specify the result type of the foreign function. Use None for void, a function not returning anything.

It is possible to assign a callable Python object that is not a ctypes type, in this case the function is assumed to return a C int, and the callable will be called with this integer, allowing further processing or error checking. Using this is deprecated, for more flexible post processing or error checking use a ctypes data type as `restype` and assign a callable to the `errcheck` attribute.

**argtypes**

Assign a tuple of ctypes types to specify the argument types that the function accepts. Functions using the `stdcall` calling convention can only be called with the same number of arguments as the length of this tuple; functions using the C calling convention accept additional, unspecified arguments as well.

When a foreign function is called, each actual argument is passed to the `from_param()` class method of the items in the `argtypes` tuple, this method allows adapting the actual argument to an object that the foreign function accepts. For example, a `c_char_p` item in the `argtypes` tuple will convert
a string passed as argument into a bytes object using ctypes conversion rules.

New: It is now possible to put items in argtypes which are not ctypes types, but each item must have a `from_param()` method which returns a value usable as argument (integer, string, ctypes instance). This allows defining adapters that can adapt custom objects as function parameters.

**errcheck**

Assign a Python function or another callable to this attribute. The callable will be called with three or more arguments:

```python
callable(result, func, arguments)
```

`result` is what the foreign function returns, as specified by the `restype` attribute.

`func` is the foreign function object itself, this allows reusing the same callable object to check or post process the results of several functions.

`arguments` is a tuple containing the parameters originally passed to the function call, this allows specializing the behavior on the arguments used.

The object that this function returns will be returned from the foreign function call, but it can also check the result value and raise an exception if the foreign function call failed.

**exception** `ctypes.ArgumentError`

This exception is raised when a foreign function call cannot convert one of the passed arguments.
16.16.2.4. Function prototypes

Foreign functions can also be created by instantiating function prototypes. Function prototypes are similar to function prototypes in C; they describe a function (return type, argument types, calling convention) without defining an implementation. The factory functions must be called with the desired result type and the argument types of the function.

```python
ctypes.CFUNCTYPE(restype, *argtypes, use_errno=False, use_last_error=False)
```

The returned function prototype creates functions that use the standard C calling convention. The function will release the GIL during the call. If `use_errno` is set to true, the ctypes private copy of the system `errno` variable is exchanged with the real `errno` value before and after the call; `use_last_error` does the same for the Windows error code.

```python
ctypes.WINFUNCTYPE(restype, *argtypes, use_errno=False, use_last_error=False)
```

Windows only: The returned function prototype creates functions that use the `stdcall` calling convention, except on Windows CE where `WINFUNCTYPE()` is the same as `CFUNCTYPE()`. The function will release the GIL during the call. `use_errno` and `use_last_error` have the same meaning as above.

```python
ctypes.PYFUNCTYPE(restype, *argtypes)
```

The returned function prototype creates functions that use the Python calling convention. The function will not release the GIL during the call.

Function prototypes created by these factory functions can be
instantiated in different ways, depending on the type and number of the parameters in the call:

**prototype(address)**

Returns a foreign function at the specified address which must be an integer.

**prototype(callable)**

Create a C callable function (a callback function) from a Python callable.

**prototype(func_spec[, paramflags])**

Returns a foreign function exported by a shared library. `func_spec` must be a 2-tuple `(name_or_ordinal, library)`. The first item is the name of the exported function as string, or the ordinal of the exported function as small integer. The second item is the shared library instance.

**prototype(vtbl_index, name[, paramflags[, iid]])**

Returns a foreign function that will call a COM method. `vtbl_index` is the index into the virtual function table, a small non-negative integer. `name` is name of the COM method. `iid` is an optional pointer to the interface identifier which is used in extended error reporting.

COM methods use a special calling convention: They require a pointer to the COM interface as first argument, in addition to those parameters that are specified in the argtypes tuple.

The optional `paramflags` parameter creates foreign function wrappers with much more functionality than the features described above.
paramflags must be a tuple of the same length as argtypes.

Each item in this tuple contains further information about a parameter, it must be a tuple containing one, two, or three items.

The first item is an integer containing a combination of direction flags for the parameter:

1
   Specifies an input parameter to the function.
2
   Output parameter. The foreign function fills in a value.
4
   Input parameter which defaults to the integer zero.

The optional second item is the parameter name as string. If this is specified, the foreign function can be called with named parameters.

The optional third item is the default value for this parameter.

This example demonstrates how to wrap the Windows MessageBoxW function so that it supports default parameters and named arguments. The C declaration from the windows header file is this:

```
WINUSERAPI int WINAPI MessageBoxW(
    HWND hWnd,
    LPCWSTR lpText,
    LPCWSTR lpCaption,
    UINT uType);
```

Here is the wrapping with ctypes:
The foreign function can now be called in these ways:

```python
>>> MessageBox()
>>> MessageBox(text="Spam, spam, spam")
>>> MessageBox(flags=2, text="foo bar")
```

A second example demonstrates output parameters. The `GetWindowRect` function retrieves the dimensions of a specified window by copying them into `RECT` structure that the caller has to supply. Here is the C declaration:

```c
WINUSERAPI BOOL WINAPI GetWindowRect(
    HWND hWnd,
    LPRECT lpRect);
```

Here is the wrapping with `ctypes`:

```python
>>> from ctypes import POINTER, WINFUNCTYPE, windll
>>> from ctypes.wintypes import BOOL, HWND, RECT
>>> prototype = WINFUNCTYPE(BOOL, HWND, POINTER(RECT))
>>> paramflags = (1, "hwnd"), (2, "lprect")
>>> GetWindowRect = prototype("GetWindowRect", windll.user32)
```
output parameter values when there are more than one, so the GetWindowRect function now returns a RECT instance, when called.

Output parameters can be combined with the errcheck protocol to do further output processing and error checking. The win32 GetWindowRect api function returns a BOOL to signal success or failure, so this function could do the error checking, and raises an exception when the api call failed:

```python
>>> def errcheck(result, func, args):
    ... if not result:
    ...     raise WinError()
    ... return args
...
>>> GetWindowRect.errcheck = errcheck
```

If the errcheck function returns the argument tuple it receives unchanged, ctypes continues the normal processing it does on the output parameters. If you want to return a tuple of window coordinates instead of a RECT instance, you can retrieve the fields in the function and return them instead, the normal processing will no longer take place:

```python
>>> def errcheck(result, func, args):
    ... if not result:
    ...     raise WinError()
    ... rc = args[1]
    ... return rc.left, rc.top, rc.bottom, rc.right
...
>>> GetWindowRect.errcheck = errcheck
```

16.16.2.5. Utility functions
ctypes.**addressof**(obj)

Returns the address of the memory buffer as integer. *obj* must be an instance of a ctypes type.

c ctypes.**alignment**(obj_or_type)

Returns the alignment requirements of a ctypes type. *obj_or_type* must be a ctypes type or instance.

c types.**byref**(obj[, offset])

Returns a light-weight pointer to *obj*, which must be an instance of a ctypes type. *offset* defaults to zero, and must be an integer that will be added to the internal pointer value.

```python
byref(obj, offset)
```
corresponds to this C code:

```c
(((char *)obj) + offset)
```

The returned object can only be used as a foreign function call parameter. It behaves similar to `pointer(obj)`, but the construction is a lot faster.

c types.**cast**(obj, type)

This function is similar to the cast operator in C. It returns a new instance of *type* which points to the same memory block as *obj*. *type* must be a pointer type, and *obj* must be an object that can be interpreted as a pointer.

c types.**create_string_buffer**(init_or_size, size=None)

This function creates a mutable character buffer. The returned object is a ctypes array of **c_char**.

*init_or_size* must be an integer which specifies the size of the
array, or a bytes object which will be used to initialize the array items.

If a bytes object is specified as first argument, the buffer is made one item larger than its length so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the bytes should not be used.

`ctypes.create_unicode_buffer(init_or_size, size=None)`
This function creates a mutable unicode character buffer. The returned object is a ctypes array of `c_wchar`.

`init_or_size` must be an integer which specifies the size of the array, or a string which will be used to initialize the array items.

If a string is specified as first argument, the buffer is made one item larger than the length of the string so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the string should not be used.

`ctypes.DllCanUnloadNow()`
Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the DllCanUnloadNow function that the _ctypes extension dll exports.

`ctypes.DllGetClassObject()`
Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the DllGetClassObject function that the _ctypes extension dll exports.

`ctypes.util.find_library(name)`
Try to find a library and return a pathname. *name* is the library name without any prefix like `lib`, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

**ctypes.util.find_msvcrt()**

Windows only: return the filename of the VC runtime library used by Python, and by the extension modules. If the name of the library cannot be determined, `None` is returned.

If you need to free memory, for example, allocated by an extension module with a call to the `free(void *)`, it is important that you use the function in the same library that allocated the memory.

**ctypes.FormattingError([[code]]**

Windows only: Returns a textual description of the error code *code*. If no error code is specified, the last error code is used by calling the Windows api function `GetLastError`.

**ctypes.GetLastError()**

Windows only: Returns the last error code set by Windows in the calling thread. This function calls the Windows `GetLastError()` function directly, it does not return the ctypes-private copy of the error code.

**ctypes.get_errno()**

Returns the current value of the ctypes-private copy of the system `errno` variable in the calling thread.

**ctypes.get_last_error()**
Windows only: returns the current value of the ctypes-private copy of the system LastError variable in the calling thread.

```python
ctypes.memmove(dst, src, count)
```

Same as the standard C memmove library function: copies `count` bytes from `src` to `dst`. `dst` and `src` must be integers or ctypes instances that can be converted to pointers.

```python
ctypes.memset(dst, c, count)
```

Same as the standard C memset library function: fills the memory block at address `dst` with `count` bytes of value `c`. `dst` must be an integer specifying an address, or a ctypes instance.

```python
c ctypes.POINTER(type)
```

This factory function creates and returns a new ctypes pointer type. Pointer types are cached and reused internally, so calling this function repeatedly is cheap. `type` must be a ctypes type.

```python
c ctypes.pointer(obj)
```

This function creates a new pointer instance, pointing to `obj`. The returned object is of the type `POINTER(type(obj))`.

Note: If you just want to pass a pointer to an object to a foreign function call, you should use `byref(obj)` which is much faster.

```python
c ctypes.resize(obj, size)
```

This function resizes the internal memory buffer of `obj`, which must be an instance of a ctypes type. It is not possible to make the buffer smaller than the native size of the objects type, as given by `sizeof(type(obj))`, but it is possible to enlarge the buffer.

```python
c ctypes.set_errno(value)
```

Set the current value of the ctypes-private copy of the system
errno variable in the calling thread to value and return the previous value.

**ctypes.set_last_error(value)**

Windows only: set the current value of the ctypes-private copy of the system LastError variable in the calling thread to value and return the previous value.

**ctypes.sizeof(obj_or_type)**

Returns the size in bytes of a ctypes type or instance memory buffer. Does the same as the C sizeof operator.

**ctypes.string_at(address, size=-1)**

This function returns the C string starting at memory address address as a bytes object. If size is specified, it is used as size, otherwise the string is assumed to be zero-terminated.

**ctypes.WinError(code=None, descr=None)**

Windows only: this function is probably the worst-named thing in ctypes. It creates an instance of OSError. If code is not specified, GetLastError is called to determine the error code. If descr is not specified, FormatError() is called to get a textual description of the error.

*Changed in version 3.3:* An instance of WindowsError used to be created.

**ctypes.wstring_at(address, size=-1)**

This function returns the wide character string starting at memory address address as a string. If size is specified, it is used as the number of characters of the string, otherwise the string is assumed to be zero-terminated.
16.16.2.6. Data types

*class ctypes._CData*

This non-public class is the common base class of all ctypes data types. Among other things, all ctypes type instances contain a memory block that hold C compatible data; the address of the memory block is returned by the `addressof()` helper function. Another instance variable is exposed as `_objects`; this contains other Python objects that need to be kept alive in case the memory block contains pointers.

Common methods of ctypes data types, these are all class methods (to be exact, they are methods of the *metaclass*):

**from_buffer(source[, offset])**

This method returns a ctypes instance that shares the buffer of the source object. The source object must support the writeable buffer interface. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a *ValueError* is raised.

**from_buffer_copy(source[, offset])**

This method creates a ctypes instance, copying the buffer from the source object buffer which must be readable. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a *ValueError* is raised.

**from_address(address)**

This method returns a ctypes type instance using the memory specified by *address* which must be an integer.
**from_param(obj)**
This method adapts `obj` to a ctypes type. It is called with the actual object used in a foreign function call when the type is present in the foreign function's `argtypes` tuple; it must return an object that can be used as a function call parameter.

All ctypes data types have a default implementation of this classmethod that normally returns `obj` if that is an instance of the type. Some types accept other objects as well.

**in_dll(library, name)**
This method returns a ctypes type instance exported by a shared library. `name` is the name of the symbol that exports the data, `library` is the loaded shared library.

Common instance variables of ctypes data types:

**_b_base_**
Sometimes ctypes data instances do not own the memory block they contain, instead they share part of the memory block of a base object. The `_b_base_` read-only member is the root ctypes object that owns the memory block.

**_b_needsfree_**
This read-only variable is true when the ctypes data instance has allocated the memory block itself, false otherwise.

**_objects**
This member is either `None` or a dictionary containing Python objects that need to be kept alive so that the memory block contents is kept valid. This object is only exposed for debugging; never modify the contents of this dictionary.
16.16.2.7. Fundamental data types

class ctypes._SimpleCData

This non-public class is the base class of all fundamental ctypes data types. It is mentioned here because it contains the common attributes of the fundamental ctypes data types. _SimpleCData is a subclass of _CData, so it inherits their methods and attributes. ctypes data types that are not and do not contain pointers can now be pickled.

Instances have a single attribute:

value

This attribute contains the actual value of the instance. For integer and pointer types, it is an integer, for character types, it is a single character bytes object or string, for character pointer types it is a Python bytes object or string.

When the value attribute is retrieved from a ctypes instance, usually a new object is returned each time. ctypes does not implement original object return, always a new object is constructed. The same is true for all other ctypes object instances.

Fundamental data types, when returned as foreign function call results, or, for example, by retrieving structure field members or array items, are transparently converted to native Python types. In other words, if a foreign function has a restype of c_char_p, you will always receive a Python bytes object, not a c_char_p instance.

Subclasses of fundamental data types do not inherit this behavior. So, if a foreign functions restype is a subclass of c_void_p, you will
receive an instance of this subclass from the function call. Of course, you can get the value of the pointer by accessing the `value` attribute.

These are the fundamental ctypes data types:

```python
class ctypes.c_byte
    Represents the C signed char datatype, and interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_char
    Represents the C char datatype, and interprets the value as a single character. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

class ctypes.c_char_p
    Represents the C char * datatype when it points to a zero-terminated string. For a general character pointer that may also point to binary data, `POINTER(c_char)` must be used. The constructor accepts an integer address, or a bytes object.

class ctypes.c_double
    Represents the C double datatype. The constructor accepts an optional float initializer.

class ctypes.c_longdouble
    Represents the C long double datatype. The constructor accepts an optional float initializer. On platforms where `sizeof(long double) == sizeof(double)` it is an alias to `c_double`.

class ctypes.c_float
    Represents the C float datatype. The constructor accepts an
optional float initializer.

```python
class ctypes.c_int
    Represents the C signed int datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where sizeof(int) == sizeof(long) it is an alias to c_long.
```

```python
class ctypes.c_int8
    Represents the C 8-bit signed int datatype. Usually an alias for c_byte.
```

```python
class ctypes.c_int16
    Represents the C 16-bit signed int datatype. Usually an alias for c_short.
```

```python
class ctypes.c_int32
    Represents the C 32-bit signed int datatype. Usually an alias for c_int.
```

```python
class ctypes.c_int64
    Represents the C 64-bit signed int datatype. Usually an alias for c_longlong.
```

```python
class ctypes.c_long
    Represents the C signed long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.
```

```python
class ctypes.c_longlong
    Represents the C signed long long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.
```

```python
class ctypes.c_short
```
Represents the C signed short datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

`class ctypes.c_size_t`
Represents the C size_t datatype.

`class ctypes.c_ssize_t`
Represents the C ssize_t datatype.

*New in version 3.2.*

`class ctypes.c_ubyte`
Represents the C unsigned char datatype, it interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

`class ctypes.c_uint`
Represents the C unsigned int datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias for `c_ulong`.

`class ctypes.c_uint8`
Represents the C 8-bit unsigned int datatype. Usually an alias for `c_ubyte`.

`class ctypes.c_uint16`
Represents the C 16-bit unsigned int datatype. Usually an alias for `c_ushort`.

`class ctypes.c_uint32`
Represents the C 32-bit unsigned int datatype. Usually an alias for `c_uint`. 
class ctypes.c_uint64
    Represents the C 64-bit unsigned int datatype. Usually an alias for c_ulonglong.

class ctypes.c_ulong
    Represents the C unsigned long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_ulonglong
    Represents the C unsigned long long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_ushort
    Represents the C unsigned short datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_void_p
    Represents the C void * type. The value is represented as integer. The constructor accepts an optional integer initializer.

class ctypes.c_wchar
    Represents the C wchar_t datatype, and interprets the value as a single character unicode string. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

class ctypes.c_wchar_p
    Represents the C wchar_t * datatype, which must be a pointer to a zero-terminated wide character string. The constructor accepts an integer address, or a string.
class ctypes.c_bool
Represent the C bool datatype (more accurately, _Bool from C99). Its value can be True or False, and the constructor accepts any object that has a truth value.

class ctypes HRESULT
Windows only: Represents a HRESULT value, which contains success or error information for a function or method call.

class ctypes.py_object
Represents the C PyObject * datatype. Calling this without an argument creates a NULL PyObject * pointer.

The ctypes.wintypes module provides quite some other Windows specific data types, for example HWND, WPARAM, or DWORD. Some useful structures like MSG or RECT are also defined.

16.16.2.8. Structured data types

class ctypes.Union(*args, **kw)
Abstract base class for unions in native byte order.

class ctypes.BigEndianStructure(*args, **kw)
Abstract base class for structures in big endian byte order.

class ctypes.LittleEndianStructure(*args, **kw)
Abstract base class for structures in little endian byte order.

Structures with non-native byte order cannot contain pointer type fields, or any other data types containing pointer type fields.

class ctypes.Structure(*args, **kw)
Abstract base class for structures in *native* byte order.

Concrete structure and union types must be created by subclassing one of these types, and at least define a `_fields_` class variable. `ctypes` will create descriptors which allow reading and writing the fields by direct attribute accesses. These are the `_fields_`

A sequence defining the structure fields. The items must be 2-tuples or 3-tuples. The first item is the name of the field, the second item specifies the type of the field; it can be any ctypes data type.

For integer type fields like `c_int`, a third optional item can be given. It must be a small positive integer defining the bit width of the field.

Field names must be unique within one structure or union. This is not checked, only one field can be accessed when names are repeated.

It is possible to define the `_fields_` class variable *after* the class statement that defines the Structure subclass, this allows creating data types that directly or indirectly reference themselves:

```python
class List(Structure):
    pass
List._fields_ = ["pnext", POINTER(List)], ...
```

The `_fields_` class variable must, however, be defined before
the type is first used (an instance is created, `sizeof()` is called on it, and so on). Later assignments to the `__fields__` class variable will raise an AttributeError.

It is possible to defined sub-subclasses of structure types, they inherit the fields of the base class plus the `__fields__` defined in the sub-subclass, if any.

```
__pack__
```

An optional small integer that allows overriding the alignment of structure fields in the instance. `__pack__` must already be defined when `__fields__` is assigned, otherwise it will have no effect.

```
__anonymous__
```

An optional sequence that lists the names of unnamed (anonymous) fields. `__anonymous__` must be already defined when `__fields__` is assigned, otherwise it will have no effect.

The fields listed in this variable must be structure or union type fields. `ctypes` will create descriptors in the structure type that allows accessing the nested fields directly, without the need to create the structure or union field.

Here is an example type (Windows):

```python
class _U(Union):
    __fields__ = ["lptdesc", POINTER(TYPEDESC)),
                  "lpadesc", POINTER(ARRAYDESC))
                  "hreftime", HREFTYPE)]

class TYPEDESC(Structure):
    __anonymous__ = ("u",
    __fields__ = ["u", _U),
```
The TYPEDESC structure describes a COM data type, the vt field specifies which one of the union fields is valid. Since the u field is defined as anonymous field, it is now possible to access the members directly off the TYPEDESC instance. td.lptdesc and td.u.lptdesc are equivalent, but the former is faster since it does not need to create a temporary union instance:

```python
td = TYPEDESC()
td.vt = VT_PTR
td.lptdesc = POINTER(some_type)
td.u.lptdesc = POINTER(some_type)
```

It is possible to defined sub-subclasses of structures, they inherit the fields of the base class. If the subclass definition has a separate `_fields_` variable, the fields specified in this are appended to the fields of the base class.

Structure and union constructors accept both positional and keyword arguments. Positional arguments are used to initialize member fields in the same order as they are appear in `_fields_`. Keyword arguments in the constructor are interpreted as attribute assignments, so they will initialize `_fields_` with the same name, or create new attributes for names not present in `_fields_`.

### 16.16.2.9. Arrays and pointers

```python
class ctypes.Array(*args)
```

Abstract base class for arrays.
The recommended way to create concrete array types is by multiplying any `ctypes` data type with a positive integer. Alternatively, you can subclass this type and define `_length_` and `_type_` class variables. Array elements can be read and written using standard subscript and slice accesses; for slice reads, the resulting object is not itself an `Array`.

`_length_`

A positive integer specifying the number of elements in the array. Out-of-range subscripts result in an `IndexError`. Will be returned by `len()`.

`_type_`

Specifies the type of each element in the array.

Array subclass constructors accept positional arguments, used to initialize the elements in order.

class ctypes.__Pointer

Private, abstract base class for pointers.

Concrete pointer types are created by calling `POINTER()` with the type that will be pointed to; this is done automatically by `pointer()`.

If a pointer points to an array, its elements can be read and written using standard subscript and slice accesses. Pointer objects have no size, so `len()` will raise `TypeError`. Negative subscripts will read from the memory before the pointer (as in C), and out-of-range subscripts will probably crash with an access violation (if you're lucky).

`_type_`
Specifies the type pointed to.

**contents**

Returns the object to which the pointer points. Assigning to this attribute changes the pointer to point to the assigned object.
17. Concurrent Execution

The modules described in this chapter provide support for concurrent execution of code. The appropriate choice of tool will depend on the task to be executed (CPU bound vs IO bound) and preferred style of development (event driven cooperative multitasking vs preemptive multitasking). Here's an overview:

- **17.1. threading — Thread-based parallelism**
  - 17.1.1. Thread-Local Data
  - 17.1.2. Thread Objects
  - 17.1.3. Lock Objects
  - 17.1.4. RLock Objects
  - 17.1.5. Condition Objects
  - 17.1.6. Semaphore Objects
    - 17.1.6.1. Semaphore Example
  - 17.1.7. Event Objects
  - 17.1.8. Timer Objects
  - 17.1.9. Barrier Objects
  - 17.1.10. Using locks, conditions, and semaphores in the with statement

- **17.2. multiprocessing — Process-based parallelism**
  - 17.2.1. Introduction

The following are support modules for some of the above services:

- 17.8. _thread — Low-level threading API
- 17.9. _dummy_thread — Drop-in replacement for the _thread module
- 17.10. dummy_threading — Drop-in replacement for the threading module
17.1. threading — Thread-based parallelism

Source code: Lib/threading.py

This module constructs higher-level threading interfaces on top of the lower level _thread module. See also the queue module.

*Changed in version 3.7:* This module used to be optional, it is now always available.

**Note:** While they are not listed below, the camelCase names used for some methods and functions in this module in the Python 2.x series are still supported by this module.

This module defines the following functions:

- **threading.active_count()**
  
  Return the number of `Thread` objects currently alive. The returned count is equal to the length of the list returned by `enumerate()`.

- **threading.current_thread()**
  
  Return the current `Thread` object, corresponding to the caller's thread of control. If the caller's thread of control was not created through the `threading` module, a dummy thread object with limited functionality is returned.

- **threading.get_ident()**
  
  Return the ‘thread identifier’ of the current thread. This is a nonzero
integer. Its value has no direct meaning; it is intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

*New in version 3.3.*

**threading.enumerate()**

Return a list of all *Thread* objects currently alive. The list includes daemonic threads, dummy thread objects created by *current_thread()* , and the main thread. It excludes terminated threads and threads that have not yet been started.

**threading.main_thread()**

Return the main *Thread* object. In normal conditions, the main thread is the thread from which the Python interpreter was started.

*New in version 3.4.*

**threading.settrace(func)**

Set a trace function for all threads started from the *threading* module. The *func* will be passed to *sys.settrace()* for each thread, before its *run()* method is called.

**threading.setprofile(func)**

Set a profile function for all threads started from the *threading* module. The *func* will be passed to *sys.setprofile()* for each thread, before its *run()* method is called.

**threading.stack_size([size])**

Return the thread stack size used when creating new threads. The optional *size* argument specifies the stack size to be used for
subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If size is not specified, 0 is used. If changing the thread stack size is unsupported, a RuntimeError is raised. If the specified stack size is invalid, a ValueError is raised and the stack size is unmodified. 32 KiB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32 KiB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4 KiB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information). Availability: Windows, systems with POSIX threads.

This module also defines the following constant:

```python
threading.TIMEOUT_MAX
```

The maximum value allowed for the `timeout` parameter of blocking functions (`Lock.acquire()`, `RLock.acquire()`, `Condition.wait()`, etc.). Specifying a timeout greater than this value will raise an OverflowError.

*New in version 3.2.*

This module defines a number of classes, which are detailed in the sections below.

The design of this module is loosely based on Java’s threading model. However, where Java makes locks and condition variables basic behavior of every object, they are separate objects in Python. Python’s `Thread` class supports a subset of the behavior of Java’s Thread
class; currently, there are no priorities, no thread groups, and threads cannot be destroyed, stopped, suspended, resumed, or interrupted. The static methods of Java’s Thread class, when implemented, are mapped to module-level functions.

All of the methods described below are executed atomically.
17.1.1. Thread-Local Data

Thread-local data is data whose values are thread specific. To manage thread-local data, just create an instance of `local` (or a subclass) and store attributes on it:

```python
mydata = threading.local()
mydata.x = 1
```

The instance's values will be different for separate threads.

`class threading.local`

A class that represents thread-local data.

For more details and extensive examples, see the documentation string of the `_threading_local` module.
17.1.2. Thread Objects

The `Thread` class represents an activity that is run in a separate thread of control. There are two ways to specify the activity: by passing a callable object to the constructor, or by overriding the `run()` method in a subclass. No other methods (except for the constructor) should be overridden in a subclass. In other words, only override the `__init__()` and `run()` methods of this class.

Once a thread object is created, its activity must be started by calling the thread's `start()` method. This invokes the `run()` method in a separate thread of control.

Once the thread's activity is started, the thread is considered 'alive'. It stops being alive when its `run()` method terminates – either normally, or by raising an unhandled exception. The `is_alive()` method tests whether the thread is alive.

Other threads can call a thread's `join()` method. This blocks the calling thread until the thread whose `join()` method is called is terminated.

A thread has a name. The name can be passed to the constructor, and read or changed through the `name` attribute.

A thread can be flagged as a “daemon thread”. The significance of this flag is that the entire Python program exits when only daemon threads are left. The initial value is inherited from the creating thread. The flag can be set through the `daemon` property or the `daemon` constructor argument.

**Note:** Daemon threads are abruptly stopped at shutdown. Their...
resources (such as open files, database transactions, etc.) may not be released properly. If you want your threads to stop gracefully, make them non-daemonic and use a suitable signalling mechanism such as an Event.

There is a “main thread” object; this corresponds to the initial thread of control in the Python program. It is not a daemon thread.

There is the possibility that “dummy thread objects” are created. These are thread objects corresponding to “alien threads”, which are threads of control started outside the threading module, such as directly from C code. Dummy thread objects have limited functionality; they are always considered alive and daemonic, and cannot be join()ed. They are never deleted, since it is impossible to detect the termination of alien threads.

class threading.Thread(group=None, target=None, name=None, args=(), kwargs={}, *, daemon=None)

This constructor should always be called with keyword arguments. Arguments are:

group should be None; reserved for future extension when a ThreadGroup class is implemented.

target is the callable object to be invoked by the run() method. Defaults to None, meaning nothing is called.

name is the thread name. By default, a unique name is constructed of the form “Thread-N” where N is a small decimal number.

args is the argument tuple for the target invocation. Defaults to ()

kwargs is a dictionary of keyword arguments for the target
invocation. Defaults to {}.

If not None, `daemon` explicitly sets whether the thread is daemonic. If None (the default), the daemonic property is inherited from the current thread.

If the subclass overrides the constructor, it must make sure to invoke the base class constructor (`Thread.__init__()`)) before doing anything else to the thread.

*Changed in version 3.3:* Added the `daemon` argument.

**start()**

Start the thread's activity.

It must be called at most once per thread object. It arranges for the object's `run()` method to be invoked in a separate thread of control.

This method will raise a `RuntimeError` if called more than once on the same thread object.

**run()**

Method representing the thread's activity.

You may override this method in a subclass. The standard `run()` method invokes the callable object passed to the object's constructor as the `target` argument, if any, with sequential and keyword arguments taken from the `args` and `kwargs` arguments, respectively.

**join(timeout=None)**

Wait until the thread terminates. This blocks the calling thread
until the thread whose `join()` method is called terminates – either normally or through an unhandled exception – or until the optional timeout occurs.

When the `timeout` argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof). As `join()` always returns `None`, you must call `is_alive()` after `join()` to decide whether a timeout happened – if the thread is still alive, the `join()` call timed out.

When the `timeout` argument is not present or `None`, the operation will block until the thread terminates.

A thread can be `join()`ed many times.

`join()` raises a `RuntimeError` if an attempt is made to join the current thread as that would cause a deadlock. It is also an error to `join()` a thread before it has been started and attempts to do so raise the same exception.

**name**

A string used for identification purposes only. It has no semantics. Multiple threads may be given the same name. The initial name is set by the constructor.

**getName()**

**setName()**

Old getter/setter API for `name`; use it directly as a property instead.

**ident**

The ‘thread identifier’ of this thread or `None` if the thread has
not been started. This is a nonzero integer. See the get_ident() function. Thread identifiers may be recycled when a thread exits and another thread is created. The identifier is available even after the thread has exited.

**is_alive()**

Return whether the thread is alive.

This method returns True just before the run() method starts until just after the run() method terminates. The module function enumerate() returns a list of all alive threads.

**daemon**

A boolean value indicating whether this thread is a daemon thread (True) or not (False). This must be set before start() is called, otherwise RuntimeError is raised. Its initial value is inherited from the creating thread; the main thread is not a daemon thread and therefore all threads created in the main thread default to daemon = False.

The entire Python program exits when no alive non-daemon threads are left.

**isDaemon()**

**setDaemon()**

Old getter/setter API for daemon; use it directly as a property instead.

**CPython implementation detail:** In CPython, due to the Global Interpreter Lock, only one thread can execute Python code at once (even though certain performance-oriented libraries might overcome this limitation). If you want your application to make better use of the
computational resources of multi-core machines, you are advised to use `multiprocessing` or `concurrent.futures.ProcessPoolExecutor`. However, threading is still an appropriate model if you want to run multiple I/O-bound tasks simultaneously.
17.1.3. Lock Objects

A primitive lock is a synchronization primitive that is not owned by a particular thread when locked. In Python, it is currently the lowest level synchronization primitive available, implemented directly by the `_thread` extension module.

A primitive lock is in one of two states, “locked” or “unlocked”. It is created in the unlocked state. It has two basic methods, `acquire()` and `release()`. When the state is unlocked, `acquire()` changes the state to locked and returns immediately. When the state is locked, `acquire()` blocks until a call to `release()` in another thread changes it to unlocked, then the `acquire()` call resets it to locked and returns. The `release()` method should only be called in the locked state; it changes the state to unlocked and returns immediately. If an attempt is made to release an unlocked lock, a `RuntimeError` will be raised.

Locks also support the context management protocol.

When more than one thread is blocked in `acquire()` waiting for the state to turn to unlocked, only one thread proceeds when a `release()` call resets the state to unlocked; which one of the waiting threads proceeds is not defined, and may vary across implementations.

All methods are executed atomically.

```class` threading. Lock

The class implementing primitive lock objects. Once a thread has acquired a lock, subsequent attempts to acquire it block, until it is released; any thread may release it.`
Note that `Lock` is actually a factory function which returns an instance of the most efficient version of the concrete Lock class that is supported by the platform.

**acquire**(*blocking=True, timeout=-1*)

Acquire a lock, blocking or non-blocking.

When invoked with the `blocking` argument set to `True` (the default), block until the lock is unlocked, then set it to locked and return `True`.

When invoked with the `blocking` argument set to `False`, do not block. If a call with `blocking` set to `True` would block, return `False` immediately; otherwise, set the lock to locked and return `True`.

When invoked with the floating-point `timeout` argument set to a positive value, block for at most the number of seconds specified by `timeout` and as long as the lock cannot be acquired. A `timeout` argument of `-1` specifies an unbounded wait. It is forbidden to specify a `timeout` when `blocking` is false.

The return value is `True` if the lock is acquired successfully, `False` if not (for example if the `timeout` expired).

*Changed in version 3.2:* The `timeout` parameter is new.

*Changed in version 3.2:* Lock acquires can now be interrupted by signals on POSIX.

**release()**

Release a lock. This can be called from any thread, not only the thread which has acquired the lock.
When the lock is locked, reset it to unlocked, and return. If any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

When invoked on an unlocked lock, a `RuntimeError` is raised.

There is no return value.
17.1.4. RLock Objects

A reentrant lock is a synchronization primitive that may be acquired multiple times by the same thread. Internally, it uses the concepts of “owning thread” and “recursion level” in addition to the locked/unlocked state used by primitive locks. In the locked state, some thread owns the lock; in the unlocked state, no thread owns it.

To lock the lock, a thread calls its `acquire()` method; this returns once the thread owns the lock. To unlock the lock, a thread calls its `release()` method. `acquire()/release()` call pairs may be nested; only the final `release()` (the `release()` of the outermost pair) resets the lock to unlocked and allows another thread blocked in `acquire()` to proceed.

Reentrant locks also support the context management protocol.

class threading.RLock

This class implements reentrant lock objects. A reentrant lock must be released by the thread that acquired it. Once a thread has acquired a reentrant lock, the same thread may acquire it again without blocking; the thread must release it once for each time it has acquired it.

Note that RLock is actually a factory function which returns an instance of the most efficient version of the concrete RLock class that is supported by the platform.

`acquire(blocking=True, timeout=-1)`

Acquire a lock, blocking or non-blocking.

When invoked without arguments: if this thread already owns
the lock, increment the recursion level by one, and return immediately. Otherwise, if another thread owns the lock, block until the lock is unlocked. Once the lock is unlocked (not owned by any thread), then grab ownership, set the recursion level to one, and return. If more than one thread is blocked waiting until the lock is unlocked, only one at a time will be able to grab ownership of the lock. There is no return value in this case.

When invoked with the `blocking` argument set to true, do the same thing as when called without arguments, and return true.

When invoked with the `blocking` argument set to false, do not block. If a call without an argument would block, return false immediately; otherwise, do the same thing as when called without arguments, and return true.

When invoked with the floating-point `timeout` argument set to a positive value, block for at most the number of seconds specified by `timeout` and as long as the lock cannot be acquired. Return true if the lock has been acquired, false if the timeout has elapsed.

*Changed in version 3.2:* The `timeout` parameter is new.

**release()**

Release a lock, decrementing the recursion level. If after the decrement it is zero, reset the lock to unlocked (not owned by any thread), and if any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling thread.

Only call this method when the calling thread owns the lock. A
RuntimeError is raised if this method is called when the lock is unlocked.

There is no return value.
17.1.5. Condition Objects

A condition variable is always associated with some kind of lock; this can be passed in or one will be created by default. Passing one in is useful when several condition variables must share the same lock. The lock is part of the condition object: you don’t have to track it separately.

A condition variable obeys the **context management protocol**: using the `with` statement acquires the associated lock for the duration of the enclosed block. The `acquire()` and `release()` methods also call the corresponding methods of the associated lock.

Other methods must be called with the associated lock held. The `wait()` method releases the lock, and then blocks until another thread awakens it by calling `notify()` or `notify_all()`. Once awakened, `wait()` re-acquires the lock and returns. It is also possible to specify a timeout.

The `notify()` method wakes up one of the threads waiting for the condition variable, if any are waiting. The `notify_all()` method wakes up all threads waiting for the condition variable.

Note: the `notify()` and `notify_all()` methods don’t release the lock; this means that the thread or threads awakened will not return from their `wait()` call immediately, but only when the thread that called `notify()` or `notify_all()` finally relinquishes ownership of the lock.

The typical programming style using condition variables uses the lock to synchronize access to some shared state; threads that are
interested in a particular change of state call \texttt{wait()} repeatedly until they see the desired state, while threads that modify the state call \texttt{notify()} or \texttt{notify\_all()} when they change the state in such a way that it could possibly be a desired state for one of the waiters. For example, the following code is a generic producer-consumer situation with unlimited buffer capacity:

\begin{verbatim}
# Consume one item
with cv:
    while not an_item_is_available():
        cv.wait()
        get_an_available_item()

# Produce one item
with cv:
    make_an_item_available()
    cv.notify()
\end{verbatim}

The \texttt{while} loop checking for the application's condition is necessary because \texttt{wait()} can return after an arbitrary long time, and the condition which prompted the \texttt{notify()} call may no longer hold true. This is inherent to multi-threaded programming. The \texttt{wait\_for()} method can be used to automate the condition checking, and eases the computation of timeouts:

\begin{verbatim}
# Consume an item
with cv:
    cv.wait\_for(an_item_is_available)
    get_an_available_item()
\end{verbatim}

To choose between \texttt{notify()} and \texttt{notify\_all()}, consider whether one state change can be interesting for only one or several waiting threads. E.g. in a typical producer-consumer situation, adding
one item to the buffer only needs to wake up one consumer thread.

```python
class threading.Condition(lock=None)
```

This class implements condition variable objects. A condition variable allows one or more threads to wait until they are notified by another thread.

If the `lock` argument is given and not `None`, it must be a `Lock` or `RLock` object, and it is used as the underlying lock. Otherwise, a new `RLock` object is created and used as the underlying lock.

*Changed in version 3.3:* changed from a factory function to a class.

```python
acquire(*args)
```

Acquire the underlying lock. This method calls the corresponding method on the underlying lock; the return value is whatever that method returns.

```python
release()
```

Release the underlying lock. This method calls the corresponding method on the underlying lock; there is no return value.

```python
wait(timeout=None)
```

Wait until notified or until a timeout occurs. If the calling thread has not acquired the lock when this method is called, a `RuntimeError` is raised.

This method releases the underlying lock, and then blocks until it is awakened by a `notify()` or `notify_all()` call for the same condition variable in another thread, or until the optional timeout occurs. Once awakened or timed out, it re-acquires the lock and returns.
When the *timeout* argument is present and not *None*, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof).

When the underlying lock is an *RLock*, it is not released using its *release()* method, since this may not actually unlock the lock when it was acquired multiple times recursively. Instead, an internal interface of the *RLock* class is used, which really unlocks it even when it has been recursively acquired several times. Another internal interface is then used to restore the recursion level when the lock is reacquired.

The return value is *True* unless a given *timeout* expired, in which case it is *False*.

*Changed in version 3.2:* Previously, the method always returned *None*.

**wait_for**(*predicate, timeout=None*)

Wait until a condition evaluates to true. *predicate* should be a callable which result will be interpreted as a boolean value. A *timeout* may be provided giving the maximum time to wait.

This utility method may call *wait()* repeatedly until the predicate is satisfied, or until a timeout occurs. The return value is the last return value of the predicate and will evaluate to *False* if the method timed out.

Ignoring the timeout feature, calling this method is roughly equivalent to writing:

```python
while not predicate():
    cv.wait()
```
Therefore, the same rules apply as with \texttt{wait()}: The lock must be held when called and is re-acquired on return. The predicate is evaluated with the lock held.

\textit{New in version 3.2.}

\textbf{notify}(n=1)

By default, wake up one thread waiting on this condition, if any. If the calling thread has not acquired the lock when this method is called, a \texttt{RuntimeError} is raised.

This method wakes up at most \textit{n} of the threads waiting for the condition variable; it is a no-op if no threads are waiting.

The current implementation wakes up exactly \textit{n} threads, if at least \textit{n} threads are waiting. However, it's not safe to rely on this behavior. A future, optimized implementation may occasionally wake up more than \textit{n} threads.

Note: an awakened thread does not actually return from its \texttt{wait()} call until it can reacquire the lock. Since \texttt{notify()} does not release the lock, its caller should.

\textbf{notify\_all()}

Wake up all threads waiting on this condition. This method acts like \texttt{notify()}, but wakes up all waiting threads instead of one. If the calling thread has not acquired the lock when this method is called, a \texttt{RuntimeError} is raised.
17.1.6. Semaphore Objects

This is one of the oldest synchronization primitives in the history of computer science, invented by the early Dutch computer scientist Edsger W. Dijkstra (he used the names \texttt{P()} and \texttt{V()} instead of \texttt{acquire()} and \texttt{release()}).

A semaphore manages an internal counter which is decremented by each \texttt{acquire()} call and incremented by each \texttt{release()} call. The counter can never go below zero; when \texttt{acquire()} finds that it is zero, it blocks, waiting until some other thread calls \texttt{release()}.

Semaphores also support the context management protocol.

\texttt{class threading.
Semaphore(value=1)}

This class implements semaphore objects. A semaphore manages an atomic counter representing the number of \texttt{release()} calls minus the number of \texttt{acquire()} calls, plus an initial value. The \texttt{acquire()} method blocks if necessary until it can return without making the counter negative. If not given, \texttt{value} defaults to 1.

The optional argument gives the initial \texttt{value} for the internal counter; it defaults to 1. If the \texttt{value} given is less than 0, \texttt{ValueError} is raised.

\textit{Changed in version 3.3:} changed from a factory function to a class.

\texttt{acquire(blocking=True, timeout=None)}

Acquire a semaphore.

When invoked without arguments:
- If the internal counter is larger than zero on entry, decrement it by one and return true immediately.
- If the internal counter is zero on entry, block until awoken by a call to `release()`. Once awoken (and the counter is greater than 0), decrement the counter by 1 and return true. Exactly one thread will be awoken by each call to `release()`. The order in which threads are awoken should not be relied on.

When invoked with `blocking` set to false, do not block. If a call without an argument would block, return false immediately; otherwise, do the same thing as when called without arguments, and return true.

When invoked with a `timeout` other than `None`, it will block for at most `timeout` seconds. If `acquire` does not complete successfully in that interval, return false. Return true otherwise.

*Changed in version 3.2*: The `timeout` parameter is new.

`release()`

Release a semaphore, incrementing the internal counter by one. When it was zero on entry and another thread is waiting for it to become larger than zero again, wake up that thread.

class threading.BoundedSemaphore(value=1)

Class implementing bounded semaphore objects. A bounded semaphore checks to make sure its current value doesn’t exceed its initial value. If it does, `ValueError` is raised. In most situations semaphores are used to guard resources with limited capacity. If the semaphore is released too many times it's a sign of a bug. If not given, `value` defaults to 1.

*Changed in version 3.3*: changed from a factory function to a class.
17.1.6.1. **Semaphore Example**

Semaphores are often used to guard resources with limited capacity, for example, a database server. In any situation where the size of the resource is fixed, you should use a bounded semaphore. Before spawning any worker threads, your main thread would initialize the semaphore:

```python
maxconnections = 5
# ...
pool_sema = BoundedSemaphore(value=maxconnections)
```

Once spawned, worker threads call the semaphore's acquire and release methods when they need to connect to the server:

```python
with pool_sema:
    conn = connectdb()
    try:
        # ... use connection ...
    finally:
        conn.close()
```

The use of a bounded semaphore reduces the chance that a programming error which causes the semaphore to be released more than it's acquired will go undetected.
17.1.7. Event Objects

This is one of the simplest mechanisms for communication between threads: one thread signals an event and other threads wait for it.

An event object manages an internal flag that can be set to true with the `set()` method and reset to false with the `clear()` method. The `wait()` method blocks until the flag is true.

class threading.Event

Class implementing event objects. An event manages a flag that can be set to true with the `set()` method and reset to false with the `clear()` method. The `wait()` method blocks until the flag is true. The flag is initially false.

*Changed in version 3.3:* changed from a factory function to a class.

**is_set()**

Return true if and only if the internal flag is true.

**set()**

Set the internal flag to true. All threads waiting for it to become true are awakened. Threads that call `wait()` once the flag is true will not block at all.

**clear()**

Reset the internal flag to false. Subsequently, threads calling `wait()` will block until `set()` is called to set the internal flag to true again.

**wait(timeout=None)**

Block until the internal flag is true. If the internal flag is true on
entry, return immediately. Otherwise, block until another thread calls `set()` to set the flag to true, or until the optional timeout occurs.

When the timeout argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof).

This method returns true if and only if the internal flag has been set to true, either before the wait call or after the wait starts, so it will always return `True` except if a timeout is given and the operation times out.

*Changed in version 3.1:* Previously, the method always returned `None`. 
17.1.8. Timer Objects

This class represents an action that should be run only after a certain amount of time has passed — a timer. Timer is a subclass of Thread and as such also functions as an example of creating custom threads.

Timers are started, as with threads, by calling their start() method. The timer can be stopped (before its action has begun) by calling the cancel() method. The interval the timer will wait before executing its action may not be exactly the same as the interval specified by the user.

For example:

```python
def hello():
    print("hello, world")

t = Timer(30.0, hello)
t.start()  # after 30 seconds, "hello, world" will be printed
```

```python
class threading.Timer(interval, function, args=None, kwargs=None)

Create a timer that will run function with arguments args and keyword arguments kwargs, after interval seconds have passed. If args is None (the default) then an empty list will be used. If kwargs is None (the default) then an empty dict will be used.

Changed in version 3.3: changed from a factory function to a class.
```

cancel()

Stop the timer, and cancel the execution of the timer's action. This will only work if the timer is still in its waiting stage.
17.1.9. Barrier Objects

*New in version 3.2.*

This class provides a simple synchronization primitive for use by a fixed number of threads that need to wait for each other. Each of the threads tries to pass the barrier by calling the `wait()` method and will block until all of the threads have made their `wait()` calls. At this point, the threads are released simultaneously.

The barrier can be reused any number of times for the same number of threads.

As an example, here is a simple way to synchronize a client and server thread:

```python
b = Barrier(2, timeout=5)

def server():
    start_server()
    b.wait()
    while True:
        connection = accept_connection()
        process_server_connection(connection)

def client():
    b.wait()
    while True:
        connection = make_connection()
        process_client_connection(connection)
```

```
class threading.Barrier(parties, action=None, timeout=None)

Create a barrier object for parties number of threads. An action, when provided, is a callable to be called by one of the threads
```
when they are released. *timeout* is the default timeout value if none is specified for the *wait()* method.

**wait**(*timeout=None*)

Pass the barrier. When all the threads party to the barrier have called this function, they are all released simultaneously. If a *timeout* is provided, it is used in preference to any that was supplied to the class constructor.

The return value is an integer in the range 0 to *parties* – 1, different for each thread. This can be used to select a thread to do some special housekeeping, e.g.:

```python
i = barrier.wait()
if i == 0:
    # Only one thread needs to print this
    print("passed the barrier")
```

If an *action* was provided to the constructor, one of the threads will have called it prior to being released. Should this call raise an error, the barrier is put into the broken state.

If the call times out, the barrier is put into the broken state.

This method may raise a *BrokenBarrierError* exception if the barrier is broken or reset while a thread is waiting.

**reset()**

Return the barrier to the default, empty state. Any threads waiting on it will receive the *BrokenBarrierError* exception.

Note that using this function may can require some external synchronization if there are other threads whose state is unknown. If a barrier is broken it may be better to just leave it
and create a new one.

**abort()**

Put the barrier into a broken state. This causes any active or future calls to `wait()` to fail with the `BrokenBarrierError`. Use this for example if one of the needs to abort, to avoid deadlocking the application.

It may be preferable to simply create the barrier with a sensible `timeout` value to automatically guard against one of the threads going awry.

**parties**

The number of threads required to pass the barrier.

**n_waiting**

The number of threads currently waiting in the barrier.

**broken**

A boolean that is `True` if the barrier is in the broken state.

**exception** threading. `BrokenBarrierError`

This exception, a subclass of `RuntimeError`, is raised when the `Barrier` object is reset or broken.
17.1.10. Using locks, conditions, and semaphores in the `with` statement

All of the objects provided by this module that have `acquire()` and `release()` methods can be used as context managers for a `with` statement. The `acquire()` method will be called when the block is entered, and `release()` will be called when the block is exited. Hence, the following snippet:

```python
with some_lock:
    # do something...
```

is equivalent to:

```python
some_lock.acquire()
try:
    # do something...
finally:
    some_lock.release()
```

Currently, `Lock`, `RLock`, `Condition`, `Semaphore`, and `BoundedSemaphore` objects may be used as `with` statement context managers.
17.2. multiprocessing — Process-based parallelism

Source code: Lib/multiprocessing/
17.2.1. Introduction

`multiprocessing` is a package that supports spawning processes using an API similar to the `threading` module. The `multiprocessing` package offers both local and remote concurrency, effectively side-stepping the Global Interpreter Lock by using subprocesses instead of threads. Due to this, the `multiprocessing` module allows the programmer to fully leverage multiple processors on a given machine. It runs on both Unix and Windows.

The `multiprocessing` module also introduces APIs which do not have analogs in the `threading` module. A prime example of this is the `Pool` object which offers a convenient means of parallelizing the execution of a function across multiple input values, distributing the input data across processes (data parallelism). The following example demonstrates the common practice of defining such functions in a module so that child processes can successfully import that module. This basic example of data parallelism using `Pool`,

```python
from multiprocessing import Pool

def f(x):
    return x*x

if __name__ == '__main__':
    with Pool(5) as p:
        print(p.map(f, [1, 2, 3]))
```

will print to standard output

```
[1, 4, 9]
```
17.2.1.1. The **Process** class

In **multiprocessing**, processes are spawned by creating a **Process** object and then calling its **start()** method. **Process** follows the API of **threading.Thread**. A trivial example of a multiprocess program is

```python
from multiprocessing import Process

def f(name):
    print('hello', name)

if __name__ == '__main__':
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()
```

To show the individual process IDs involved, here is an expanded example:

```python
from multiprocessing import Process
import os

def info(title):
    print(title)
    print('module name:', __name__)
    print('parent process:', os.getppid())
    print('process id:', os.getpid())

def f(name):
    info('function f')
    print('hello', name)

if __name__ == '__main__':
    info('main line')
```
```python
p = Process(target=f, args=('bob',))
p.start()
p.join()
```

For an explanation of why the `if __name__ == '__main__'` part is necessary, see Programming guidelines.

### 17.2.1.2. Contexts and start methods

Depending on the platform, `multiprocessing` supports three ways to start a process. These *start methods* are

- **spawn**
  - The parent process starts a fresh python interpreter process. The child process will only inherit those resources necessary to run the process objects `run()` method. In particular, unnecessary file descriptors and handles from the parent process will not be inherited. Starting a process using this method is rather slow compared to using `fork` or `forkserver`.

  Available on Unix and Windows. The default on Windows.

- **fork**
  - The parent process uses `os.fork()` to fork the Python interpreter. The child process, when it begins, is effectively identical to the parent process. All resources of the parent are inherited by the child process. Note that safely forking a multithreaded process is problematic.

  Available on Unix only. The default on Unix.

- **forkserver**
  - When the program starts and selects the `forkserver` start
method, a server process is started. From then on, whenever a new process is needed, the parent process connects to the server and requests that it fork a new process. The fork server process is single threaded so it is safe for it to use `os.fork()`. No unnecessary resources are inherited.

Available on Unix platforms which support passing file descriptors over Unix pipes.

*Changed in version 3.4:* `spawn` added on all unix platforms, and `forkserver` added for some unix platforms. Child processes no longer inherit all of the parents inheritable handles on Windows.

On Unix using the `spawn` or `forkserver` start methods will also start a semaphore tracker process which tracks the unlinked named semaphores created by processes of the program. When all processes have exited the semaphore tracker unlinks any remaining semaphores. Usually there should be none, but if a process was killed by a signal there may be some “leaked” semaphores. (Unlinking the named semaphores is a serious matter since the system allows only a limited number, and they will not be automatically unlinked until the next reboot.)

To select a start method you use the `set_start_method()` in the `if __name__ == '__main__'` clause of the main module. For example:

```python
import multiprocessing as mp

def foo(q):
    q.put('hello')

if __name__ == '__main__':
    mp.set_start_method('spawn')
```
```python
q = mp.Queue()
p = mp.Process(target=foo, args=(q,))
p.start()
print(q.get())
p.join()
```

`set_start_method()` should not be used more than once in the program.

Alternatively, you can use `get_context()` to obtain a context object. Context objects have the same API as the multiprocessing module, and allow one to use multiple start methods in the same program.

```python
import multiprocessing as mp

def foo(q):
    q.put('hello')

if __name__ == '__main__':
    ctx = mp.get_context('spawn')
    q = ctx.Queue()
    p = ctx.Process(target=foo, args=(q,))
p.start()
print(q.get())
p.join()
```

Note that objects related to one context may not be compatible with processes for a different context. In particular, locks created using the `fork` context cannot be passed to processes started using the `spawn` or `forkserver` start methods.

A library which wants to use a particular start method should probably use `get_context()` to avoid interfering with the choice of the library user.
17.2.1.3. Exchanging objects between processes

`multiprocessing` supports two types of communication channel between processes:

**Queues**

The `Queue` class is a near clone of `queue.Queue`. For example:

```python
from multiprocessing import Process, Queue

def f(q):
    q.put([42, None, 'hello'])

if __name__ == '__main__':
    q = Queue()
    p = Process(target=f, args=(q,))
    p.start()
    print(q.get())  # prints '[42, None, 'hello']'
    p.join()
```

Queues are thread and process safe.

**Pipes**

The `Pipe()` function returns a pair of connection objects connected by a pipe which by default is duplex (two-way). For example:

```python
from multiprocessing import Process, Pipe

def f(conn):
    conn.send([42, None, 'hello'])
    conn.close()
```
if __name__ == '__main__':
    parent_conn, child_conn = Pipe()
    p = Process(target=f, args=(child_conn,))
    p.start()
    print(parent_conn.recv())  # prints "[42, None, 'hello']"
    p.join()

The two connection objects returned by `Pipe()` represent the two ends of the pipe. Each connection object has `send()` and `recv()` methods (among others). Note that data in a pipe may become corrupted if two processes (or threads) try to read from or write to the same end of the pipe at the same time. Of course there is no risk of corruption from processes using different ends of the pipe at the same time.

### 17.2.1.4. Synchronization between processes

`multiprocessing` contains equivalents of all the synchronization primitives from `threading`. For instance one can use a lock to ensure that only one process prints to standard output at a time:

```python
from multiprocessing import Process, Lock

def f(l, i):
    l.acquire()
    try:
        print('hello world', i)
    finally:
        l.release()

if __name__ == '__main__':
    lock = Lock()
```
for num in range(10):
    Process(target=f, args=(lock, num)).start()

Without using the lock output from the different processes is liable to get all mixed up.

17.2.1.5. Sharing state between processes

As mentioned above, when doing concurrent programming it is usually best to avoid using shared state as far as possible. This is particularly true when using multiple processes.

However, if you really do need to use some shared data then multiprocessing provides a couple of ways of doing so.

Shared memory

Data can be stored in a shared memory map using **Value** or **Array**. For example, the following code

```python
from multiprocessing import Process, Value, Array

def f(n, a):
    n.value = 3.1415927
    for i in range(len(a)):
        a[i] = -a[i]

if __name__ == '__main__':
    num = Value('d', 0.0)
    arr = Array('i', range(10))

    p = Process(target=f, args=(num, arr))
    p.start()
    p.join()
```
```
print(num.value)
print(arr[:])
```

will print

```
3.1415927
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
```

The 'd' and 'i' arguments used when creating `num` and `arr` are typecodes of the kind used by the `array` module: 'd' indicates a double precision float and 'i' indicates a signed integer. These shared objects will be process and thread-safe.

For more flexibility in using shared memory one can use the `multiprocessing.sharedctypes` module which supports the creation of arbitrary ctypes objects allocated from shared memory.

**Server process**

A manager object returned by `Manager()` controls a server process which holds Python objects and allows other processes to manipulate them using proxies.

A manager returned by `Manager()` will support types `list`, `dict`, `Namespace`, `Lock`, `RLock`, `Semaphore`, `BoundedSemaphore`, `Condition`, `Event`, `Barrier`, `Queue`, `Value` and `Array`. For example,

```
from multiprocessing import Process, Manager

def f(d, l):
    d[1] = '1'
```
Server process managers are more flexible than using shared memory objects because they can be made to support arbitrary object types. Also, a single manager can be shared by processes on different computers over a network. They are, however, slower than using shared memory.

### 17.2.1.6. Using a pool of workers

The `Pool` class represents a pool of worker processes. It has methods which allows tasks to be offloaded to the worker processes in a few different ways.

For example:
from multiprocessing import Pool, TimeoutError
import time
import os

def f(x):
    return x*x

if __name__ == '__main__':
    # start 4 worker processes
    with Pool(processes=4) as pool:

        # print "[0, 1, 4,..., 81]"
        print(pool.map(f, range(10)))

        # print same numbers in arbitrary order
        for i in pool.imap_unordered(f, range(10)):
            print(i)

        # evaluate "f(20)" asynchronously
        res = pool.apply_async(f, (20,))  # runs
        print(res.get(timeout=1))  # prints

        # evaluate "os.getpid()" asynchronously
        res = pool.apply_async(os.getpid, ())  # runs
        print(res.get(timeout=1))  # prints

        # launching multiple evaluations asynchronously
        multiple_results = [pool.apply_async(os.getpid, ()) for i in range(10)]
        print([res.get(timeout=1) for res in multiple_results])

        # make a single worker sleep for 10 secs
        res = pool.apply_async(time.sleep, (10,))
        try:
            print(res.get(timeout=1))
        except TimeoutError:
            print("We lacked patience and got a mult

print("For the moment, the pool remains available")

# exiting the 'with'-block has stopped the pool
print("Now the pool is closed and no longer available")

Note that the methods of a pool should only ever be used by the process which created it.

**Note:** Functionality within this package requires that the `__main__` module be importable by the children. This is covered in Programming guidelines however it is worth pointing out here. This means that some examples, such as the `multiprocessing.pool.Pool` examples will not work in the interactive interpreter. For example:

```python
def f(x):
    return x**x

>>> from multiprocessing import Pool
>>> p = Pool(5)
>>> p.map(f, [1,2,3])
```

```
Process PoolWorker-1:  
Process PoolWorker-2:  
Process PoolWorker-3:  
Traceback (most recent call last):
  AttributeError: 'module' object has no attribute 'f'
  AttributeError: 'module' object has no attribute 'f'
  AttributeError: 'module' object has no attribute 'f'
```
17.2.2. Reference

The `multiprocessing` package mostly replicates the API of the `threading` module.

17.2.2.1. Process and exceptions

```python
class multiprocessing.Process(group=None, target=None, name=None, args=(), kwarsgs={}, *, daemon=None)
```

Process objects represent activity that is run in a separate process. The `Process` class has equivalents of all the methods of `threading.Thread`.

The constructor should always be called with keyword arguments. `group` should always be `None`; it exists solely for compatibility with `threading.Thread`. `target` is the callable object to be invoked by the `run()` method. It defaults to `None`, meaning nothing is called. `name` is the process name (see `name` for more details). `args` is the argument tuple for the target invocation. `kwargs` is a dictionary of keyword arguments for the target invocation. If provided, the keyword-only `daemon` argument sets the process `daemon` flag to `True` or `False`. If `None` (the default), this flag will be inherited from the creating process.

By default, no arguments are passed to `target`.

If a subclass overrides the constructor, it must make sure it invokes the base class constructor (`Process.__init__()`)) before doing anything else to the process.

*Changed in version 3.3: Added the `daemon` argument.*
run()
Method representing the process's activity.

You may override this method in a subclass. The standard run() method invokes the callable object passed to the object’s constructor as the target argument, if any, with sequential and keyword arguments taken from the args and kwargs arguments, respectively.

start()
Start the process's activity.

This must be called at most once per process object. It arranges for the object's run() method to be invoked in a separate process.

join([timeout])
If the optional argument timeout is None (the default), the method blocks until the process whose join() method is called terminates. If timeout is a positive number, it blocks at most timeout seconds. Note that the method returns None if its process terminates or if the method times out. Check the process's exitcode to determine if it terminated.

A process can be joined many times.

A process cannot join itself because this would cause a deadlock. It is an error to attempt to join a process before it has been started.

name
The process's name. The name is a string used for identification purposes only. It has no semantics. Multiple processes may be
given the same name.

The initial name is set by the constructor. If no explicit name is provided to the constructor, a name of the form ‘Process-N₁:N₂:...:Nₖ’ is constructed, where each Nₖ is the N-th child of its parent.

**is_alive()**

Return whether the process is alive.

Roughly, a process object is alive from the moment the **start()** method returns until the child process terminates.

**daemon**

The process’s daemon flag, a Boolean value. This must be set before **start()** is called.

The initial value is inherited from the creating process.

When a process exits, it attempts to terminate all of its daemonic child processes.

Note that a daemonic process is not allowed to create child processes. Otherwise a daemonic process would leave its children orphaned if it gets terminated when its parent process exits. Additionally, these are not Unix daemons or services, they are normal processes that will be terminated (and not joined) if non-daemonic processes have exited.

In addition to the **threading.Thread** API, **Process** objects also support the following attributes and methods:

**pid**

Return the process ID. Before the process is spawned, this will
be None.

**exitcode**

The child’s exit code. This will be None if the process has not yet terminated. A negative value -N indicates that the child was terminated by signal N.

**authkey**

The process's authentication key (a byte string).

When *multiprocessing* is initialized the main process is assigned a random string using `os.urandom()`.

When a *Process* object is created, it will inherit the authentication key of its parent process, although this may be changed by setting *authkey* to another byte string.

See Authentication keys.

**sentinel**

A numeric handle of a system object which will become “ready” when the process ends.

You can use this value if you want to wait on several events at once using *multiprocessing.connection.wait()*. Otherwise calling *join()* is simpler.

On Windows, this is an OS handle usable with the WaitForSingleObject and WaitForMultipleObjects family of API calls. On Unix, this is a file descriptor usable with primitives from the *select* module.

*New in version 3.3.*
**terminate()**

Terminate the process. On Unix this is done using the SIGTERM signal; on Windows TerminateProcess() is used. Note that exit handlers and finally clauses, etc., will not be executed.

Note that descendant processes of the process will *not* be terminated – they will simply become orphaned.

**Warning:** If this method is used when the associated process is using a pipe or queue then the pipe or queue is liable to become corrupted and may become unusable by other process. Similarly, if the process has acquired a lock or semaphore etc. then terminating it is liable to cause other processes to deadlock.

**kill()**

Same as `terminate()` but using the SIGKILL signal on Unix.

*New in version 3.7.*

**close()**

Close the `Process` object, releasing all resources associated with it. `ValueError` is raised if the underlying process is still running. Once `close()` returns successfully, most other methods and attributes of the `Process` object will raise `ValueError`.

*New in version 3.7.*

Note that the `start()`, `join()`, `is_alive()`, `terminate()` and `exitcode` methods should only be called by the process that
created the process object.

Example usage of some of the methods of `Process`:

```python
>>> import multiprocessing, time, signal
>>> p = multiprocessing.Process(target=time.sleep)
>>> print(p, p.is_alive())
<Process(Process-1, initial)> False
>>> p.start()
>>> print(p, p.is_alive())
<Process(Process-1, started)> True
>>> p.terminate()
>>> time.sleep(0.1)
>>> print(p, p.is_alive())
<Process(Process-1, stopped[SIGTERM])> False
>>> p.exitcode == -signal.SIGTERM
True
```

`exception` `multiprocessing.ProcessError`  
The base class of all `multiprocessing` exceptions.

`exception` `multiprocessing.BufferTooShort`  
Exception raised by `Connection.recv_bytes_into()` when the supplied buffer object is too small for the message read.

If `e` is an instance of `BufferTooShort` then `e.args[0]` will give the message as a byte string.

`exception` `multiprocessing.AuthenticationError`  
Raised when there is an authentication error.

`exception` `multiprocessing.TimeoutError`  
Raised by methods with a timeout when the timeout expires.
17.2.2.2. Pipes and Queues

When using multiple processes, one generally uses message passing for communication between processes and avoids having to use any synchronization primitives like locks.

For passing messages one can use `Pipe()` (for a connection between two processes) or a queue (which allows multiple producers and consumers).

The `Queue`, `SimpleQueue` and `JoinableQueue` types are multi-producer, multi-consumer **FIFO** queues modelled on the `queue.Queue` class in the standard library. They differ in that `Queue` lacks the `task_done()` and `join()` methods introduced into Python 2.5's `queue.Queue` class.

If you use `JoinableQueue` then you **must** call `JoinableQueue.task_done()` for each task removed from the queue or else the semaphore used to count the number of unfinished tasks may eventually overflow, raising an exception.

Note that one can also create a shared queue by using a manager object – see Managers.

**Note:** `multiprocessing` uses the usual `queue.Empty` and `queue.Full` exceptions to signal a timeout. They are not available in the `multiprocessing` namespace so you need to import them from `queue`.

**Note:** When an object is put on a queue, the object is pickled and a background thread later flushes the pickled data to an underlying pipe. This has some consequences which are a little surprising, but
should not cause any practical difficulties – if they really bother you then you can instead use a queue created with a manager.

1. After putting an object on an empty queue there may be an infinitesimal delay before the queue’s `empty()` method returns `False` and `get_nowait()` can return without raising `queue.Empty`.
2. If multiple processes are enqueuing objects, it is possible for the objects to be received at the other end out-of-order. However, objects enqueued by the same process will always be in the expected order with respect to each other.

**Warning:** If a process is killed using `Process.terminate()` or `os.kill()` while it is trying to use a `Queue`, then the data in the queue is likely to become corrupted. This may cause any other process to get an exception when it tries to use the queue later on.

**Warning:** As mentioned above, if a child process has put items on a queue (and it has not used `JoinableQueue.cancel_join_thread`), then that process will not terminate until all buffered items have been flushed to the pipe.

This means that if you try joining that process you may get a deadlock unless you are sure that all items which have been put on the queue have been consumed. Similarly, if the child process is non-daemonic then the parent process may hang on exit when it tries to join all its non-daemonic children.

Note that a queue created using a manager does not have this issue. See Programming guidelines.

For an example of the usage of queues for interprocess
communication see Examples.

`multiprocessing.Pipe([duplex])`

Returns a pair \((conn1, conn2)\) of `Connection` objects representing the ends of a pipe.

If `duplex` is `True` (the default) then the pipe is bidirectional. If `duplex` is `False` then the pipe is unidirectional: `conn1` can only be used for receiving messages and `conn2` can only be used for sending messages.

`class multiprocessing.Queue([maxsize])`

Returns a process shared queue implemented using a pipe and a few locks/semaphores. When a process first puts an item on the queue a feeder thread is started which transfers objects from a buffer into the pipe.

The usual `queue.Empty` and `queue.Full` exceptions from the standard library’s `queue` module are raised to signal timeouts.

`Queue` implements all the methods of `queue.Queue` except for `task_done()` and `join()`.

`qsize()`

Return the approximate size of the queue. Because of multithreading/multiprocessing semantics, this number is not reliable.

Note that this may raise `NotImplementedError` on Unix platforms like Mac OS X where `sem_getvalue()` is not implemented.
empty()
   Return True if the queue is empty, False otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

full()
   Return True if the queue is full, False otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

put(obj[, block[, timeout]])
   Put obj into the queue. If the optional argument block is True (the default) and timeout is None (the default), block if necessary until a free slot is available. If timeout is a positive number, it blocks at most timeout seconds and raises the queue.Full exception if no free slot was available within that time. Otherwise (block is False), put an item on the queue if a free slot is immediately available, else raise the queue.Full exception (timeout is ignored in that case).

put_nowait(obj)
   Equivalent to put(obj, False).

get([block[, timeout]])
   Remove and return an item from the queue. If optional args block is True (the default) and timeout is None (the default), block if necessary until an item is available. If timeout is a positive number, it blocks at most timeout seconds and raises the queue.Empty exception if no item was available within that time. Otherwise (block is False), return an item if one is immediately available, else raise the queue.Empty exception (timeout is ignored in that case).
**get_nowait()**
Equivalent to get(False).

*multiprocessing.Queue* has a few additional methods not found in *queue.Queue*. These methods are usually unnecessary for most code:

**close()**
Indicate that no more data will be put on this queue by the current process. The background thread will quit once it has flushed all buffered data to the pipe. This is called automatically when the queue is garbage collected.

**join_thread()**
Join the background thread. This can only be used after *close()* has been called. It blocks until the background thread exits, ensuring that all data in the buffer has been flushed to the pipe.

By default if a process is not the creator of the queue then on exit it will attempt to join the queue's background thread. The process can call *cancel_join_thread()* to make *join_thread()* do nothing.

**cancel_join_thread()**
Prevent *join_thread()* from blocking. In particular, this prevents the background thread from being joined automatically when the process exits – see *join_thread()*.

A better name for this method might be *allow_exit_without_flush()*. It is likely to cause enqueued data to lost, and you almost certainly will not need to
use it. It is really only there if you need the current process to exit immediately without waiting to flush enqueued data to the underlying pipe, and you don’t care about lost data.

Note: This class’s functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the functionality in this class will be disabled, and attempts to instantiate a `Queue` will result in an `ImportError`. See bpo-3770 for additional information. The same holds true for any of the specialized queue types listed below.

class multiprocessing.SimpleQueue

It is a simplified `Queue` type, very close to a locked `Pipe`.

**empty()**

Return `True` if the queue is empty, `False` otherwise.

**get()**

Remove and return an item from the queue.

**put(item)**

Put `item` into the queue.

class multiprocessing.JoinableQueue([maxsize])

`JoinableQueue`, a `Queue` subclass, is a queue which additionally has `task_done()` and `join()` methods.

**task_done()**

Indicate that a formerly enqueued task is complete. Used by queue consumers. For each `get()` used to fetch a task, a subsequent call to `task_done()` tells the queue that the processing on the task is complete.
If a `join()` is currently blocking, it will resume when all items have been processed (meaning that a `task_done()` call was received for every item that had been `put()` into the queue).

Raises a `ValueError` if called more times than there were items placed in the queue.

**join()**
Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer calls `task_done()` to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, `join()` unblocks.

### 17.2.2.3. Miscellaneous

**multiprocessing.**`active_children()`
Return list of all live children of the current process.

Calling this has the side effect of “joining” any processes which have already finished.

**multiprocessing.**`cpu_count()`
Return the number of CPUs in the system.

This number is not equivalent to the number of CPUs the current process can use. The number of usable CPUs can be obtained with `len(os.sched_getaffinity(0))`
May raise `NotImplementedError`.

See also: `os.cpu_count()`

`multiprocessing.current_process()`

Return the `Process` object corresponding to the current process.

An analogue of `threading.current_thread()`.

`multiprocessing.freeze_support()`

Add support for when a program which uses `multiprocessing` has been frozen to produce a Windows executable. (Has been tested with `py2exe`, `PyInstaller` and `cx_Freeze`.)

One needs to call this function straight after the `if __name__ == '__main__'` line of the main module. For example:

```python
from multiprocessing import Process, freeze_support

def f():
    print('hello world!')

if __name__ == '__main__':
    freeze_support()
    Process(target=f).start()
```

If the `freeze_support()` line is omitted then trying to run the frozen executable will raise `RuntimeError`.

Calling `freeze_support()` has no effect when invoked on any operating system other than Windows. In addition, if the module is being run normally by the Python interpreter on Windows (the
program has not been frozen), then freeze_support() has no effect.

**multiprocessing.get_all_start_methods()**

Returns a list of the supported start methods, the first of which is the default. The possible start methods are 'fork', 'spawn' and 'forkserver'. On Windows only 'spawn' is available. On Unix 'fork' and 'spawn' are always supported, with 'fork' being the default.

*New in version 3.4.*

**multiprocessing.get_context**(method=None)

Return a context object which has the same attributes as the multiprocessing module.

If method is None then the default context is returned. Otherwise method should be 'fork', 'spawn', 'forkserver'. ValueError is raised if the specified start method is not available.

*New in version 3.4.*

**multiprocessing.get_start_method**(allow_none=False)

Return the name of start method used for starting processes.

If the start method has not been fixed and allow_none is false, then the start method is fixed to the default and the name is returned. If the start method has not been fixed and allow_none is true then None is returned.

The return value can be 'fork', 'spawn', 'forkserver' or None. 'fork' is the default on Unix, while 'spawn' is the default on Windows.
**New in version 3.4.**

**multiprocessing.set_executable()**

Sets the path of the Python interpreter to use when starting a child process. (By default `sys.executable` is used). Embedders will probably need to do some thing like

```python
set_executable(os.path.join(sys.exec_prefix, 'pythonw.exe'))
```

before they can create child processes.

*Changed in version 3.4:* Now supported on Unix when the `spawn` start method is used.

**multiprocessing.set_start_method(method)**

Set the method which should be used to start child processes. `method` can be `fork`, `spawn` or `forkserver`.

Note that this should be called at most once, and it should be protected inside the `if __name__ == '__main__'` clause of the main module.

**New in version 3.4.**

**Note:** `multiprocessing` contains no analogues of `threading.active_count()`, `threading.enumerate()`, `threading.settrace()`, `threading.setprofile()`, `threading.Timer`, or `threading.local`.

### 17.2.2.4. Connection Objects

Connection objects allow the sending and receiving of picklable
objects or strings. They can be thought of as message oriented connected sockets.

Connection objects are usually created using `Pipe()` — see also Listeners and Clients.

class multiprocessing.Connection

    send(obj)
        Send an object to the other end of the connection which should be read using `recv()`.

        The object must be picklable. Very large pickles (approximately 32 MiB+, though it depends on the OS) may raise a `ValueError` exception.

    recv()
        Return an object sent from the other end of the connection using `send()`. Blocks until there is something to receive. Raises `EOFError` if there is nothing left to receive and the other end was closed.

    fileno()
        Return the file descriptor or handle used by the connection.

    close()
        Close the connection.

        This is called automatically when the connection is garbage collected.

    poll([timeout])
        Return whether there is any data available to be read.
If *timeout* is not specified then it will return immediately. If *timeout* is a number then this specifies the maximum time in seconds to block. If *timeout* is `None` then an infinite timeout is used.

Note that multiple connection objects may be polled at once by using `multiprocessing.connection.wait()`.

**send_bytes**(buffer*, offset*, size)*

Send byte data from a bytes-like object as a complete message.

If *offset* is given then data is read from that position in *buffer*. If *size* is given then that many bytes will be read from buffer. Very large buffers (approximately 32 MiB+, though it depends on the OS) may raise a *ValueError* exception.

**recv_bytes**(maxlength)*

Return a complete message of byte data sent from the other end of the connection as a string. Blocks until there is something to receive. Raises *EOFError* if there is nothing left to receive and the other end has closed.

If *maxlength* is specified and the message is longer than *maxlength* then *OSError* is raised and the connection will no longer be readable.

*Changed in version 3.3:* This function used to raise *IOError*, which is now an alias of *OSError*.

**recv_bytes_into**(buffer*, offset)*

Read into *buffer* a complete message of byte data sent from the
other end of the connection and return the number of bytes in the message. Blocks until there is something to receive. Raises **EOFError** if there is nothing left to receive and the other end was closed.

*buffer* must be a writable **bytes-like object**. If *offset* is given then the message will be written into the buffer from that position. Offset must be a non-negative integer less than the length of *buffer* (in bytes).

If the buffer is too short then a **BufferTooShort** exception is raised and the complete message is available as *e.args[0]* where *e* is the exception instance.

*Changed in version 3.3*: Connection objects themselves can now be transferred between processes using **Connection.send()** and **Connection.recv()**.

*New in version 3.3*: Connection objects now support the context management protocol – see **Context Manager Types**. **__enter__()** returns the connection object, and **__exit__()** calls **close()**.

For example:

```python
>>> from multiprocessing import Pipe
>>> a, b = Pipe()
>>> a.send([1, 'hello', None])
>>> b.recv()
[1, 'hello', None]
>>> b.send_bytes(b'thank you')
>>> a.recv_bytes()
b'thank you'
>>> import array
```
>>> arr1 = array.array('i', range(5))
>>> arr2 = array.array('i', [0] * 10)
>>> a.send_bytes(arr1)
>>> count = b.recv_bytes_into(arr2)
>>> assert count == len(arr1) * arr1.itemsize
>>> arr2
array('i', [0, 1, 2, 3, 4, 0, 0, 0, 0, 0])

Warning: The Connection.recv() method automatically unpickles the data it receives, which can be a security risk unless you can trust the process which sent the message.

Therefore, unless the connection object was produced using Pipe() you should only use the recv() and send() methods after performing some sort of authentication. See Authentication keys.

Warning: If a process is killed while it is trying to read or write to a pipe then the data in the pipe is likely to become corrupted, because it may become impossible to be sure where the message boundaries lie.

17.2.2.5. Synchronization primitives

Generally synchronization primitives are not as necessary in a multiprocess program as they are in a multithreaded program. See the documentation for threading module.

Note that one can also create synchronization primitives by using a manager object – see Managers.

class multiprocessing.Barrierパーティ、アクション、タイムアウト]})
A barrier object: a clone of `threading.Barrier`.

*New in version 3.3.*

```python
class multiprocessing.BoundedSemaphore([value])
A bounded semaphore object: a close analog of `threading.BoundedSemaphore`.
```

A solitary difference from its close analog exists: its `acquire` method's first argument is named `block`, as is consistent with `Lock.acquire()`.

**Note:** On Mac OS X, this is indistinguishable from `Semaphore` because `sem_getvalue()` is not implemented on that platform.

```python
class multiprocessing.Condition([lock])
```

If `lock` is specified then it should be a `Lock` or `RLock` object from `multiprocessing`.

*Changed in version 3.3:* The `wait_for()` method was added.

```python
class multiprocessing.Event
A clone of `threading.Event`.
```

```python
class multiprocessing.Lock
A non-recursive lock object: a close analog of `threading.Lock`.
```

Once a process or thread has acquired a lock, subsequent attempts to acquire it from any process or thread will block until it is released; any process or thread may release it. The concepts and behaviors of `threading.Lock` as it applies to threads are
replicated here in `multiprocessing.Lock` as it applies to either processes or threads, except as noted.

Note that `Lock` is actually a factory function which returns an instance of `multiprocessing.synchronize.Lock` initialized with a default context.

`Lock` supports the `context manager` protocol and thus may be used in `with` statements.

`acquire(block=True, timeout=None)`

Acquire a lock, blocking or non-blocking.

With the `block` argument set to `True` (the default), the method call will block until the lock is in an unlocked state, then set it to locked and return `True`. Note that the name of this first argument differs from that in `threading.Lock.acquire()`.

With the `block` argument set to `False`, the method call does not block. If the lock is currently in a locked state, return `False`; otherwise set the lock to a locked state and return `True`.

When invoked with a positive, floating-point value for `timeout`, block for at most the number of seconds specified by `timeout` as long as the lock can not be acquired. Invocations with a negative value for `timeout` are equivalent to a `timeout` of zero. Invocations with a `timeout` value of `None` (the default) set the timeout period to infinite. Note that the treatment of negative or `None` values for `timeout` differs from the implemented behavior in `threading.Lock.acquire()`. The `timeout` argument has no practical implications if the `block` argument is set to `False` and is thus ignored. Returns `True` if the lock has been acquired
or False if the timeout period has elapsed.

**release()**
Release a lock. This can be called from any process or thread, not only the process or thread which originally acquired the lock.

Behavior is the same as in `threading.Lock.release()` except that when invoked on an unlocked lock, a `ValueError` is raised.

**class multiprocessing.RLock**
A recursive lock object: a close analog of `threading.RLock`. A recursive lock must be released by the process or thread that acquired it. Once a process or thread has acquired a recursive lock, the same process or thread may acquire it again without blocking; that process or thread must release it once for each time it has been acquired.

Note that `RLock` is actually a factory function which returns an instance of `multiprocessing.synchronize.RLock` initialized with a default context.

`RLock` supports the context manager protocol and thus may be used in `with` statements.

**acquire**(block=True, timeout=None)
Acquire a lock, blocking or non-blocking.

When invoked with the `block` argument set to True, block until the lock is in an unlocked state (not owned by any process or thread) unless the lock is already owned by the current process or thread. The current process or thread then takes ownership
of the lock (if it does not already have ownership) and the recursion level inside the lock increments by one, resulting in a return value of True. Note that there are several differences in this first argument's behavior compared to the implementation of `threading.RLock.acquire()`, starting with the name of the argument itself.

When invoked with the block argument set to False, do not block. If the lock has already been acquired (and thus is owned) by another process or thread, the current process or thread does not take ownership and the recursion level within the lock is not changed, resulting in a return value of False. If the lock is in an unlocked state, the current process or thread takes ownership and the recursion level is incremented, resulting in a return value of True.

Use and behaviors of the timeout argument are the same as in `Lock.acquire()`. Note that some of these behaviors of timeout differ from the implemented behaviors in `threading.RLock.acquire()`.

release()

Release a lock, decrementing the recursion level. If after the decrement the recursion level is zero, reset the lock to unlocked (not owned by any process or thread) and if any other processes or threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling process or thread.

Only call this method when the calling process or thread owns the lock. An AssertionError is raised if this method is called
by a process or thread other than the owner or if the lock is in an unlocked (unowned) state. Note that the type of exception raised in this situation differs from the implemented behavior in `threading.RLock.release()`.

```python
class multiprocessing.Semaphore([value])
```
A semaphore object: a close analog of `threading.Semaphore`.

A solitary difference from its close analog exists: its `acquire` method's first argument is named `block`, as is consistent with `Lock.acquire()`.

**Note:** On Mac OS X, `sem_timedwait` is unsupported, so calling `acquire()` with a timeout will emulate that function's behavior using a sleeping loop.

**Note:** If the SIGINT signal generated by Ctrl-C arrives while the main thread is blocked by a call to `BoundedSemaphore.acquire()`, `Lock.acquire()`, `RLock.acquire()`, `Semaphore.acquire()`, `Condition.acquire()` or `Condition.wait()` then the call will be immediately interrupted and `KeyboardInterrupt` will be raised.

This differs from the behaviour of `threading` where SIGINT will be ignored while the equivalent blocking calls are in progress.

**Note:** Some of this package's functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the `multiprocessing.synchronize` module will be disabled, and attempts to import it will result in an `ImportError`. 
17.2.2.6. Shared **ctypes** Objects

It is possible to create shared objects using shared memory which can be inherited by child processes.

```python
multiprocessing.Value(typecode_or_type, *args, lock=True)
```

Return a **ctypes** object allocated from shared memory. By default the return value is actually a synchronized wrapper for the object. The object itself can be accessed via the `value` attribute of a `Value`.

`typecode_or_type` determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used by the `array` module. `*args` is passed on to the constructor for the type.

If `lock` is `True` (the default) then a new recursive lock object is created to synchronize access to the value. If `lock` is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If `lock` is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Operations like `+=` which involve a read and write are not atomic. So if, for instance, you want to atomically increment a shared value it is insufficient to just do

```python
counter.value += 1
```

Assuming the associated lock is recursive (which it is by default)
you can instead do

```python
with counter.get_lock():
    counter.value += 1
```

Note that `lock` is a keyword-only argument.

`multiprocessing.Array(typecode_or_type, size_or_initializer, *, lock=True)`

Return a ctypes array allocated from shared memory. By default the return value is actually a synchronized wrapper for the array.

`typecode_or_type` determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the `array` module. If `size_or_initializer` is an integer, then it determines the length of the array, and the array will be initially zeroed. Otherwise, `size_or_initializer` is a sequence which is used to initialize the array and whose length determines the length of the array.

If `lock` is `True` (the default) then a new lock object is created to synchronize access to the value. If `lock` is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If `lock` is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that `lock` is a keyword only argument.

Note that an array of `ctypes.c_char` has `value` and `raw` attributes which allow one to use it to store and retrieve strings.

17.2.2.6.1. The `multiprocessing.sharedctypes` module
The `multiprocessing.sharedctypes` module provides functions for allocating `ctypes` objects from shared memory which can be inherited by child processes.

**Note:** Although it is possible to store a pointer in shared memory remember that this will refer to a location in the address space of a specific process. However, the pointer is quite likely to be invalid in the context of a second process and trying to dereference the pointer from the second process may cause a crash.

`multiprocessing.sharedctypes.RawArray(typecode_or_type, size_or_initializer)`

Return a ctypes array allocated from shared memory.

*typecode_or_type* determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the `array` module. If *size_or_initializer* is an integer then it determines the length of the array, and the array will be initially zeroed. Otherwise *size_or_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

Note that setting and getting an element is potentially non-atomic – use `Array()` instead to make sure that access is automatically synchronized using a lock.

`multiprocessing.sharedctypes.RawValue(typecode_or_type, *args)`

Return a ctypes object allocated from shared memory.

*typecode_or_type* determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used
by the `array` module. `*args` is passed on to the constructor for the type.

Note that setting and getting the value is potentially non-atomic – use `Value()` instead to make sure that access is automatically synchronized using a lock.

Note that an array of `ctypes.c_char` has `value` and `raw` attributes which allow one to use it to store and retrieve strings – see documentation for `ctypes`.

```
multiprocessing.sharedctypes.Array(typecode_or_type, size_or_initializer, *, lock=True)
```

The same as `RawArray()` except that depending on the value of `lock` a process-safe synchronization wrapper may be returned instead of a raw ctypes array.

If `lock` is `True` (the default) then a new lock object is created to synchronize access to the value. If `lock` is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If `lock` is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that `lock` is a keyword-only argument.

```
multiprocessing.sharedctypes.Value(typecode_or_type, *args, lock=True)
```

The same as `RawValue()` except that depending on the value of `lock` a process-safe synchronization wrapper may be returned instead of a raw ctypes object.

If `lock` is `True` (the default) then a new lock object is created to synchronize access to the value. If `lock` is a `Lock` or `RLock` object
then that will be used to synchronize access to the value. If lock is False then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that lock is a keyword-only argument.

**multiprocessing.sharedctypes.copy(obj)**

Return a ctypes object allocated from shared memory which is a copy of the ctypes object obj.

**multiprocessing.sharedctypes.synchronized(obj[, lock])**

Return a process-safe wrapper object for a ctypes object which uses lock to synchronize access. If lock is None (the default) then a multiprocessing.RLock object is created automatically.

A synchronized wrapper will have two methods in addition to those of the object it wraps: get_obj() returns the wrapped object and get_lock() returns the lock object used for synchronization.

Note that accessing the ctypes object through the wrapper can be a lot slower than accessing the raw ctypes object.

*Changed in version 3.5:* Synchronized objects support the context manager protocol.

The table below compares the syntax for creating shared ctypes objects from shared memory with the normal ctypes syntax. (In the table MyStruct is some subclass of ctypes.Structure.)

<table>
<thead>
<tr>
<th>ctypes</th>
<th>sharedctypes using type</th>
<th>sharedctypes using typecode</th>
</tr>
</thead>
<tbody>
<tr>
<td>c_double(2.4)</td>
<td>RawValue(c_double, 2.4)</td>
<td>RawValue('d', 2.4)</td>
</tr>
</tbody>
</table>
Below is an example where a number of ctypes objects are modified by a child process:

```python
from multiprocessing import Process, Lock
from multiprocessing.sharedctypes import Value, Array
from ctypes import Structure, c_double

class Point(Structure):
    _fields_ = [('x', c_double), ('y', c_double)]

def modify(n, x, s, A):
    n.value **= 2
    x.value **= 2
    s.value = s.value.upper()
    for a in A:
        a.x **= 2
        a.y **= 2

if __name__ == '__main__':
    lock = Lock()

    n = Value('i', 7)
    x = Value(c_double, 1.0/3.0, lock=False)
    s = Array('c', b'hello world', lock=lock)
    A = Array(Point, [(1.875,-6.25), (-5.75,2.0)], (2

    p = Process(target=modify, args=(n, x, s, A))
    p.start()
    p.join()```
The results printed are

49
0.1111111111111111
HELLO WORLD
[(3.515625, 39.0625), (33.0625, 4.0), (5.640625, 90.0)]

17.2.2.7. Managers

Managers provide a way to create data which can be shared between different processes, including sharing over a network between processes running on different machines. A manager object controls a server process which manages shared objects. Other processes can access the shared objects by using proxies.

```
import multiprocessing

class Manager:
    def __init__(self):
        self.manager = self._create_manager()

    def _create_manager(self):
        return SyncManager()

    def get_manager(self):
        return self.manager

Manager().get_manager()  # Returns a started SyncManager object which can be used for sharing objects between processes.
```

Manager processes will be shutdown as soon as they are garbage collected or their parent process exits. The manager classes are defined in the `multiprocessing.managers` module:

```
class BaseManager:
    def __init__(self, address, authkey=None):
        self.manager = self._create_manager(address, authkey)

    def _create_manager(self, address, authkey=None):
        return SyncManager(address, authkey)

BaseManager(address, authkey)
```
Create a BaseManager object.

Once created one should call \texttt{start()} or \texttt{get_server().serve_forever()} to ensure that the manager object refers to a started manager process.

\texttt{address} is the address on which the manager process listens for new connections. If \texttt{address} is \texttt{None} then an arbitrary one is chosen.

\texttt{authkey} is the authentication key which will be used to check the validity of incoming connections to the server process. If \texttt{authkey} is \texttt{None} then \texttt{current_process().authkey} is used. Otherwise \texttt{authkey} is used and it must be a byte string.

\texttt{start([\texttt{initializer[, initargs]}])}

Start a subprocess to start the manager. If \texttt{initializer} is not \texttt{None} then the subprocess will call \texttt{initializer(*initargs)} when it starts.

\texttt{get_server()}

Returns a Server object which represents the actual server under the control of the Manager. The Server object supports the \texttt{serve_forever()} method:

```python
>>> from multiprocessing.managers import BaseManager
>>> manager = BaseManager(address=('', 50000),
>>> server = manager.get_server()
>>> server.serve_forever()
```

Server additionally has an \texttt{address} attribute.
**connect()**

Connect a local manager object to a remote manager process:

```python
>>> from multiprocessing.managers import BaseManager
>>> m = BaseManager(address=('127.0.0.1', 5000))
>>> m.connect()
```

**shutdown()**

Stop the process used by the manager. This is only available if `start()` has been used to start the server process.

This can be called multiple times.

**register(typeid[, callable[, proxytype[, exposed[, method_to_typeid[, create_method]]]])**

A classmethod which can be used for registering a type or callable with the manager class.

- `typeid` is a “type identifier” which is used to identify a particular type of shared object. This must be a string.

- `callable` is a callable used for creating objects for this type identifier. If a manager instance will be connected to the server using the `connect()` method, or if the `create_method` argument is `False` then this can be left as `None`.

- `proxytype` is a subclass of `BaseProxy` which is used to create proxies for shared objects with this `typeid`. If `None` then a proxy class is created automatically.

- `exposed` is used to specify a sequence of method names which proxies for this `typeid` should be allowed to access using
BaseProxy._callmethod(). (If exposed is None then proxytype._exposed_ is used instead if it exists.) In the case where no exposed list is specified, all “public methods” of the shared object will be accessible. (Here a “public method” means any attribute which has a __call__() method and whose name does not begin with '_'.)

*method_to_typeid* is a mapping used to specify the return type of those exposed methods which should return a proxy. It maps method names to typeid strings. (If *method_to_typeid* is None then proxytype._method_to_typeid_ is used instead if it exists.) If a method's name is not a key of this mapping or if the mapping is None then the object returned by the method will be copied by value.

*create_method* determines whether a method should be created with name typeid which can be used to tell the server process to create a new shared object and return a proxy for it. By default it is True.

**BaseManager** instances also have one read-only property:

**address**

The address used by the manager.

*Changed in version 3.3:* Manager objects support the context management protocol – see Context Manager Types. __enter__() starts the server process (if it has not already started) and then returns the manager object. __exit__() calls shutdown().

In previous versions __enter__() did not start the manager's
server process if it was not already started.

class multiprocessing.managers.SyncManager
A subclass of BaseManager which can be used for the synchronization of processes. Objects of this type are returned by multiprocessing.Manager().

Its methods create and return Proxy Objects for a number of commonly used data types to be synchronized across processes. This notably includes shared lists and dictionaries.

Barrier(\texttt{parties[, action[, timeout]]})
Create a shared \texttt{threading.Barrier} object and return a proxy for it.

\textit{New in version 3.3.}

BoundedSemaphore(\texttt{[value]})
Create a shared \texttt{threading.BoundedSemaphore} object and return a proxy for it.

Condition(\texttt{[lock]})
Create a shared \texttt{threading.Condition} object and return a proxy for it.

\textit{If} \texttt{lock} \textit{is supplied then it should be a proxy for a} \texttt{threading.Lock} \textit{or} \texttt{threading.RLock} \textit{object.}

\textit{Changed in version 3.3: The} \texttt{wait\_for()} \textit{method was added.}

Event()
Create a shared \texttt{threading.Event} object and return a proxy
for it.

**Lock()**
Create a shared `threading.Lock` object and return a proxy for it.

**Namespace()**
Create a shared `Namespace` object and return a proxy for it.

**Queue([maxsize])**
Create a shared `queue.Queue` object and return a proxy for it.

**RLock()**
Create a shared `threading.RLock` object and return a proxy for it.

**Semaphore([value])**
Create a shared `threading.Semaphore` object and return a proxy for it.

**Array(typecode, sequence)**
Create an array and return a proxy for it.

**Value(typecode, value)**
Create an object with a writable `value` attribute and return a proxy for it.

**dict()**
**dict(mapping)**
**dict(sequence)**
Create a shared `dict` object and return a proxy for it.
list()
list(sequence)

Create a shared list object and return a proxy for it.

Changed in version 3.6: Shared objects are capable of being nested. For example, a shared container object such as a shared list can contain other shared objects which will all be managed and synchronized by the SyncManager.

class multiprocessing.managers.Namespace
A type that can register with SyncManager.

A namespace object has no public methods, but does have writable attributes. Its representation shows the values of its attributes.

However, when using a proxy for a namespace object, an attribute beginning with '_ will be an attribute of the proxy and not an attribute of the referent:

```python
>>> manager = multiprocessing.Manager()
>>> Global = manager.Namespace()
>>> Global.x = 10
>>> Global.y = 'hello'
>>> Global._z = 12.3  # this is an attribute of
>>> print(Global)
Namespace(x=10, y='hello')
```

17.2.2.7.1. Customized managers

To create one's own manager, one creates a subclass of BaseManager and uses the register() classmethod to register new types or callables with the manager class. For example:
```python
from multiprocessing.managers import BaseManager

class MathsClass:
    def add(self, x, y):
        return x + y
    def mul(self, x, y):
        return x * y

class MyManager(BaseManager):
    pass

MyManager.register('Maths', MathsClass)

if __name__ == '__main__':
    with MyManager() as manager:
        maths = manager.Maths()
        print(maths.add(4, 3))  # prints 7
        print(maths.mul(7, 8))  # prints 56

17.2.2.7.2. Using a remote manager

It is possible to run a manager server on one machine and have clients use it from other machines (assuming that the firewalls involved allow it).

Running the following commands creates a server for a single shared queue which remote clients can access:

```
One client can access the server as follows:

```python
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000),)
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.put('hello')
```

Another client can also use it:

```python
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000),)
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.get()
'hello'
```

Local processes can also access that queue, using the code from above on the client to access it remotely:

```python
>>> from multiprocessing import Process, Queue
>>> from multiprocessing.managers import BaseManager
>>> class Worker(Process):
...     def __init__(self, q):
...         self.q = q
...     super(Worker, self).__init__()
...     def run(self):
...         self.q.put('local hello')
```
17.2.2.8. Proxy Objects

A proxy is an object which refers to a shared object which lives (presumably) in a different process. The shared object is said to be the referent of the proxy. Multiple proxy objects may have the same referent.

A proxy object has methods which invoke corresponding methods of its referent (although not every method of the referent will necessarily be available through the proxy). In this way, a proxy can be used just like its referent can:

```python
>>> from multiprocessing import Manager
>>> manager = Manager()
>>> l = manager.list([i*i for i in range(10)])
>>> print(l)
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
>>> print(repr(l))
<ListProxy object, typeid 'list' at 0x...>
>>> l[4]
16
>>> l[2:5]
[4, 9, 16]
```
Notice that applying `str()` to a proxy will return the representation of the referent, whereas applying `repr()` will return the representation of the proxy.

An important feature of proxy objects is that they are pickleable so they can be passed between processes. As such, a referent can contain **Proxy Objects**. This permits nesting of these managed lists, dicts, and other **Proxy Objects**:

```python
>>> a = manager.list()
>>> b = manager.list()
>>> a.append(b)                        # referent of a now contains
>>> print(a, b)
[<ListProxy object, typeid 'list' at ...>] []
>>> b.append('hello')
>>> print(a[0], b)
['hello'] ['hello']
```

Similarly, dict and list proxies may be nested inside one another:

```python
>>> l_outer = manager.list([ manager.dict() for i in...
>>> d_first_inner = l_outer[0]
>>> d_first_inner['a'] = 1
>>> d_first_inner['b'] = 2
>>> l_outer[1]['c'] = 3
>>> l_outer[1]['z'] = 26
>>> print(l_outer[0])
{'a': 1, 'b': 2}
>>> print(l_outer[1])
{'c': 3, 'z': 26}
```

If standard (non-proxy) `list` or `dict` objects are contained in a referent, modifications to those mutable values will not be propagated
through the manager because the proxy has no way of knowing when the values contained within are modified. However, storing a value in a container proxy (which triggers a `__setitem__` on the proxy object) does propagate through the manager and so to effectively modify such an item, one could re-assign the modified value to the container proxy:

```python
# create a list proxy and append a mutable object (a dictionary)
lproxy = manager.list()
lproxy.append({})
# now mutate the dictionary
d = lproxy[0]
d['a'] = 1
d['b'] = 2
# at this point, the changes to d are not yet synced
# updating the dictionary, the proxy is notified of change
lproxy[0] = d
```

This approach is perhaps less convenient than employing nested Proxy Objects for most use cases but also demonstrates a level of control over the synchronization.

**Note:** The proxy types in multiprocessing do nothing to support comparisons by value. So, for instance, we have:

```python
>>> manager.list([1, 2, 3]) == [1, 2, 3]
False
```

One should just use a copy of the referent instead when making comparisons.

class multiprocessing.managers.BaseProxy

Proxy objects are instances of subclasses of BaseProxy.
_callmethod(methodname[, args[, kwds]])

Call and return the result of a method of the proxy's referent.

If `proxy` is a proxy whose referent is `obj` then the expression

```
proxy._callmethod(methodname, args, kwds)
```

will evaluate the expression

```
getattr(obj, methodname)(*args, **kwds)
```

in the manager's process.

The returned value will be a copy of the result of the call or a proxy to a new shared object – see documentation for the `method_to_typeid` argument of `BaseManager.register()`.

If an exception is raised by the call, then is re-raised by `_callmethod()`. If some other exception is raised in the manager's process then this is converted into a RemoteError exception and is raised by `_callmethod()`.

Note in particular that an exception will be raised if `methodname` has not been exposed.

An example of the usage of `_callmethod()`:

```
>>> l = manager.list(range(10))
>>> l._callmethod('__len__')
10
>>> l._callmethod('__getitem__', (slice(2, 7),))
[2, 3, 4, 5, 6]
>>> l._callmethod('__getitem__', (20,))
Traceback (most recent call last):
```
... 

```
IndexError: list index out of range
```

__getvalue__()  
Return a copy of the referent.  
If the referent is unpicklable then this will raise an exception.

__repr__()  
Return a representation of the proxy object.

__str__()  
Return the representation of the referent.

17.2.2.8.1. Cleanup

A proxy object uses a weakref callback so that when it gets garbage collected it deregisters itself from the manager which owns its referent.

A shared object gets deleted from the manager process when there are no longer any proxies referring to it.

17.2.2.9. Process Pools

One can create a pool of processes which will carry out tasks submitted to it with the Pool class.

```
class multiprocessing.pool.Pool([processes[, initializer[, initargs[, maxtasksperchild[, context]]]]])
```

A process pool object which controls a pool of worker processes to which jobs can be submitted. It supports asynchronous results with timeouts and callbacks and has a parallel map implementation.
processes is the number of worker processes to use. If processes is None then the number returned by os.cpu_count() is used.

If initializer is not None then each worker process will call initializer(*initargs) when it starts.

maxtasksperchild is the number of tasks a worker process can complete before it will exit and be replaced with a fresh worker process, to enable unused resources to be freed. The default maxtasksperchild is None, which means worker processes will live as long as the pool.

context can be used to specify the context used for starting the worker processes. Usually a pool is created using the function multiprocessing.Pool() or the Pool() method of a context object. In both cases context is set appropriately.

Note that the methods of the pool object should only be called by the process which created the pool.

New in version 3.2: maxtasksperchild

New in version 3.4: context

Note: Worker processes within a Pool typically live for the complete duration of the Pool's work queue. A frequent pattern found in other systems (such as Apache, mod_wsgi, etc) to free resources held by workers is to allow a worker within a pool to complete only a set amount of work before being exiting, being cleaned up and a new process spawned to replace the old one. The maxtasksperchild argument to the Pool exposes this ability to the end user.
**apply(func[, args[, kwds]])**

Call `func` with arguments `args` and keyword arguments `kwds`. It blocks until the result is ready. Given this blocks, `apply_async()` is better suited for performing work in parallel. Additionally, `func` is only executed in one of the workers of the pool.

**apply_async(func[, args[, kwds[, callback[, error_callback]]]])**

A variant of the `apply()` method which returns a result object.

If `callback` is specified then it should be a callable which accepts a single argument. When the result becomes ready `callback` is applied to it, that is unless the call failed, in which case the `error_callback` is applied instead.

If `error_callback` is specified then it should be a callable which accepts a single argument. If the target function fails, then the `error_callback` is called with the exception instance.

Callbacks should complete immediately since otherwise the thread which handles the results will get blocked.

**map(func, iterable[, chunksize])**

A parallel equivalent of the `map()` built-in function (it supports only one `iterable` argument though). It blocks until the result is ready.

This method chops the iterable into a number of chunks which it submits to the process pool as separate tasks. The (approximate) size of these chunks can be specified by setting `chunksize` to a positive integer.
map_async(func, iterable[, chunksize[, callback[, error_callback]]]])

A variant of the map() method which returns a result object.

If callback is specified then it should be a callable which accepts a single argument. When the result becomes ready callback is applied to it, that is unless the call failed, in which case the error_callback is applied instead.

If error_callback is specified then it should be a callable which accepts a single argument. If the target function fails, then the error_callback is called with the exception instance.

Callbacks should complete immediately since otherwise the thread which handles the results will get blocked.

imap(func, iterable[, chunksize])

A lazier version of map().

The chunksize argument is the same as the one used by the map() method. For very long iterables using a large value for chunksize can make the job complete much faster than using the default value of 1.

Also if chunksize is 1 then the next() method of the iterator returned by the imap() method has an optional timeout parameter: next(timeout) will raise multiprocessing.TimeoutError if the result cannot be returned within timeout seconds.

imap_unordered(func, iterable[, chunksize])

The same as imap() except that the ordering of the results
from the returned iterator should be considered arbitrary. (Only when there is only one worker process is the order guaranteed to be “correct”.)

**starmap**(*func*, *iterable[, chunksize]*)

Like `map()` except that the elements of the *iterable* are expected to be iterables that are unpacked as arguments.

Hence an *iterable* of `[(1, 2), (3, 4)]` results in `[func(1, 2), func(3, 4)]`.

*New in version 3.3.*

**starmap_async**(*func*, *iterable[, chunksize[, callback[, error_callback]]]*)

A combination of `starmap()` and `map_async()` that iterates over *iterable* of iterables and calls *func* with the iterables unpacked. Returns a result object.

*New in version 3.3.*

**close**()

Prevents any more tasks from being submitted to the pool. Once all the tasks have been completed the worker processes will exit.

**terminate**()

 Stops the worker processes immediately without completing outstanding work. When the pool object is garbage collected `terminate()` will be called immediately.

**join**()
Wait for the worker processes to exit. One must call `close()` or `terminate()` before using `join()`.

*New in version 3.3:* Pool objects now support the context management protocol – see Context Manager Types. `__enter__()` returns the pool object, and `__exit__()` calls `terminate()`.

```python
class multiprocessing.pool.AsyncResult
```

The class of the result returned by `Pool.apply_async()` and `Pool.map_async()`.

```python
get([timeout])
```

Return the result when it arrives. If `timeout` is not `None` and the result does not arrive within `timeout` seconds then `multiprocessing.TimeoutError` is raised. If the remote call raised an exception then that exception will be reraised by `get()`.

```python
wait([timeout])
```

Wait until the result is available or until `timeout` seconds pass.

```python
ready()
```

Return whether the call has completed.

```python
successful()
```

Return whether the call completed without raising an exception. Will raise `AssertionError` if the result is not ready.

The following example demonstrates the use of a pool:

```python
from multiprocessing import Pool
```
import time

def f(x):
    return x**2

if __name__ == '__main__':
    with Pool(processes=4) as pool:
        result = pool.apply_async(f, (10,))  # evaluate "f(10)" asynchronously in a single process
        print(result.get(timeout=1))  # prints "100" unless your computer is *very* slow
        print(pool.map(f, range(10)))  # prints "[0, 1, 4, ..., 81]"
        it = pool.imap(f, range(10))
        print(next(it))  # prints
        print(next(it))  # prints
        print(it.next(timeout=1))  # prints

        result = pool.apply_async(time.sleep, (10,))  # raises multiprocessing.TimeoutError
        print(result.get(timeout=1))

17.2.2.10. Listeners and Clients

Usually message passing between processes is done using queues or by using Connection objects returned by Pipe().

However, the multiprocessing.connection module allows some extra flexibility. It basically gives a high level message oriented API for dealing with sockets or Windows named pipes. It also has support for digest authentication using the hmac module, and for polling multiple connections at the same time.

multiprocessing.connection.deliver_challenge(connection, authkey)

Send a randomly generated message to the other end of the
connection and wait for a reply.

If the reply matches the digest of the message using authkey as the key then a welcome message is sent to the other end of the connection. Otherwise AuthenticationError is raised.

```
multiprocessing.connection.answer_challenge(connection, authkey)
```

Receive a message, calculate the digest of the message using authkey as the key, and then send the digest back.

If a welcome message is not received, then AuthenticationError is raised.

```
multiprocessing.connection.Client(address[, family[, authkey]])
```

Attempt to set up a connection to the listener which is using address address, returning a Connection.

The type of the connection is determined by family argument, but this can generally be omitted since it can usually be inferred from the format of address. (See Address Formats)

If authkey is given and not None, it should be a byte string and will be used as the secret key for an HMAC-based authentication challenge. No authentication is done if authkey is None. AuthenticationError is raised if authentication fails. See Authentication keys.

```
class multiprocessing.connection.Listener([address[, family[, backlog[, authkey]]]])
```

A wrapper for a bound socket or Windows named pipe which is
listening’ for connections.

`address` is the address to be used by the bound socket or named pipe of the listener object.

**Note:** If an address of ‘0.0.0.0’ is used, the address will not be a connectable end point on Windows. If you require a connectable end-point, you should use ‘127.0.0.1’.

`family` is the type of socket (or named pipe) to use. This can be one of the strings `AF_INET` (for a TCP socket), `AF_UNIX` (for a Unix domain socket) or `AF_PIPE` (for a Windows named pipe). Of these only the first is guaranteed to be available. If `family` is `None` then the family is inferred from the format of `address`. If `address` is also `None` then a default is chosen. This default is the family which is assumed to be the fastest available. See Address Formats. Note that if `family` is `AF_UNIX` and `address` is `None` then the socket will be created in a private temporary directory created using `tempfile.mkstemp()`.

If the listener object uses a socket then `backlog` (1 by default) is passed to the `listen()` method of the socket once it has been bound.

If `authkey` is given and not `None`, it should be a byte string and will be used as the secret key for an HMAC-based authentication challenge. No authentication is done if `authkey` is `None`. `AuthenticationError` is raised if authentication fails. See Authentication keys.

`accept()`

Accept a connection on the bound socket or named pipe of the
listener object and return a Connection object. If authentication is attempted and fails, then AuthenticationError is raised.

`close()`

Close the bound socket or named pipe of the listener object. This is called automatically when the listener is garbage collected. However it is advisable to call it explicitly.

Listener objects have the following read-only properties:

`address`

The address which is being used by the Listener object.

`last_accepted`

The address from which the last accepted connection came. If this is unavailable then it is `None`.

New in version 3.3: Listener objects now support the context management protocol – see Context Manager Types. `__enter__()` returns the listener object, and `__exit__()` calls `close()`.

`multiprocessing.connection.wait(object_list, timeout=None)`

Wait till an object in `object_list` is ready. Returns the list of those objects in `object_list` which are ready. If `timeout` is a float then the call blocks for at most that many seconds. If `timeout` is None then it will block for an unlimited period. A negative timeout is equivalent to a zero timeout.

For both Unix and Windows, an object can appear in `object_list` if it is
- a readable `Connection` object;
- a connected and readable `socket.socket` object; or
- the `sentinel` attribute of a `Process` object.

A connection or socket object is ready when there is data available to be read from it, or the other end has been closed.

**Unix**: `wait(object_list, timeout)` almost equivalent to `select.select(object_list, [], [], timeout)`. The difference is that, if `select.select()` is interrupted by a signal, it can raise `OSError` with an error number of `EINTR`, whereas `wait()` will not.

**Windows**: An item in `object_list` must either be an integer handle which is waitable (according to the definition used by the documentation of the Win32 function `WaitForMultipleObjects()`) or it can be an object with a `fileno()` method which returns a socket handle or pipe handle. (Note that pipe handles and socket handles are not waitable handles.)

*New in version 3.3.*

**Examples**

The following server code creates a listener which uses `secret password` as an authentication key. It then waits for a connection and sends some data to the client:

```python
from multiprocessing.connection import Listener
from array import array

address = ('localhost', 6000)  # family is deduced
```
with Listener(address, authkey=b'secret password') as listener:
    with listener.accept() as conn:
        print('connection accepted from', listener.last_accepted)
        conn.send([2.25, None, 'junk', float])
        conn.send_bytes(b'hello')
        conn.send_bytes(array('i', [42, 1729]))

The following code connects to the server and receives some data from the server:

from multiprocessing.connection import Client
from array import array

address = ('localhost', 6000)

with Client(address, authkey=b'secret password') as conn:
    print(conn.recv())  # => [2.25,
    print(conn.recv_bytes())  # => 'hello'
    arr = array('i', [0, 0, 0, 0, 0])
    print(conn.recv_bytes_into(arr))  # => 8
    print(arr)  # => array('i',

The following code uses wait() to wait for messages from multiple processes at once:

import time, random
from multiprocessing import Process, Pipe, current_process
from multiprocessing.connection import wait

def foo(w):

for i in range(10):
    w.send(((i, current_process().name)))
w.close()

if __name__ == '__main__':
    readers = []

    for i in range(4):
        r, w = Pipe(duplex=False)
        readers.append(r)
        p = Process(target=foo, args=(w,))
p.start()
        # We close the writable end of the pipe now
        # p is the only process which owns a handle
        # ensures that when p closes its handle for
        # wait() will promptly report the readable end.
w.close()

    while readers:
        for r in wait(readers):
            try:
                msg = r.recv()
            except EOFError:
                readers.remove(r)
            else:
                print(msg)

17.2.2.10.1. Address Formats

- An 'AF_INET' address is a tuple of the form (hostname, port) where hostname is a string and port is an integer.
- An 'AF_UNIX' address is a string representing a filename on the filesystem.
- An 'AF_PIPE' address is a string of the form r'\.\pipe\PipeName'. To use Client() to connect to a
named pipe on a remote computer called ServerName one should use an address of the form r'\ServerName\pipe\PipeName' instead.

Note that any string beginning with two backslashes is assumed by default to be an 'AF_PIPE' address rather than an 'AF_UNIX' address.

17.2.2.11. Authentication keys

When one uses Connection.recv, the data received is automatically unpickled. Unfortunately unpickling data from an untrusted source is a security risk. Therefore Listener and Client() use the hmac module to provide digest authentication.

An authentication key is a byte string which can be thought of as a password: once a connection is established both ends will demand proof that the other knows the authentication key. (Demonstrating that both ends are using the same key does not involve sending the key over the connection.)

If authentication is requested but no authentication key is specified then the return value of current_process().authkey is used (see Process). This value will be automatically inherited by any Process object that the current process creates. This means that (by default) all processes of a multi-process program will share a single authentication key which can be used when setting up connections between themselves.

Suitable authentication keys can also be generated by using os.urandom().
17.2.2.12. Logging

Some support for logging is available. Note, however, that the `logging` package does not use process shared locks so it is possible (depending on the handler type) for messages from different processes to get mixed up.

`multiprocessing.get_logger()`

Returns the logger used by `multiprocessing`. If necessary, a new one will be created.

When first created the logger has level `logging.NOTSET` and no default handler. Messages sent to this logger will not by default propagate to the root logger.

Note that on Windows child processes will only inherit the level of the parent process's logger – any other customization of the logger will not be inherited.

`multiprocessing.log_to_stderr()`

This function performs a call to `get_logger()` but in addition to returning the logger created by `get_logger`, it adds a handler which sends output to `sys.stderr` using format `[%(levelname)s/%(processName)s] %(message)s`.

Below is an example session with logging turned on:

```python
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
>>> logger.setLevel(logging.INFO)
>>> logger.warning('doomed')
[WARNING/MainProcess] doomed
>>> m = multiprocessing.Manager()
```
For a full table of logging levels, see the `logging` module.

17.2.2.13. The `multiprocessing.dummy` module

`multiprocessing.dummy` replicates the API of `multiprocessing` but is no more than a wrapper around the `threading` module.
17.2.3. Programming guidelines

There are certain guidelines and idioms which should be adhered to when using `multiprocessing`.

17.2.3.1. All start methods

The following applies to all start methods.

Avoid shared state

As far as possible one should try to avoid shifting large amounts of data between processes.

It is probably best to stick to using queues or pipes for communication between processes rather than using the lower level synchronization primitives.

Picklability

Ensure that the arguments to the methods of proxies are picklable.

Thread safety of proxies

Do not use a proxy object from more than one thread unless you protect it with a lock.

(There is never a problem with different processes using the same proxy.)

Joining zombie processes

On Unix when a process finishes but has not been joined it
becomes a zombie. There should never be very many because each time a new process starts (or `active_children()` is called) all completed processes which have not yet been joined will be joined. Also calling a finished process’s `Process.is_alive` will join the process. Even so it is probably good practice to explicitly join all the processes that you start.

Better to inherit than pickle/unpickle

When using the `spawn` or `forkserver` start methods many types from `multiprocessing` need to be picklable so that child processes can use them. However, one should generally avoid sending shared objects to other processes using pipes or queues. Instead you should arrange the program so that a process which needs access to a shared resource created elsewhere can inherit it from an ancestor process.

Avoid terminating processes

Using the `Process.terminate` method to stop a process is liable to cause any shared resources (such as locks, semaphores, pipes and queues) currently being used by the process to become broken or unavailable to other processes.

Therefore it is probably best to only consider using `Process.terminate` on processes which never use any shared resources.

Joining processes that use queues

Bear in mind that a process that has put items in a queue will wait before terminating until all the buffered items are fed by the “feeder” thread to the underlying pipe. (The child process can call the `Queue.cancel_join_thread` method of the queue to
avoid this behaviour.)

This means that whenever you use a queue you need to make sure that all items which have been put on the queue will eventually be removed before the process is joined. Otherwise you cannot be sure that processes which have put items on the queue will terminate. Remember also that non-daemonic processes will be joined automatically.

An example which will deadlock is the following:

```python
from multiprocessing import Process, Queue

def f(q):
    q.put('X' * 1000000)

if __name__ == '__main__':
    queue = Queue()
    p = Process(target=f, args=(queue,))
    p.start()
    p.join()  # this deadlocks
    obj = queue.get()
```

A fix here would be to swap the last two lines (or simply remove the `p.join()` line).

Explicitly pass resources to child processes

On Unix using the `fork` start method, a child process can make use of a shared resource created in a parent process using a global resource. However, it is better to pass the object as an argument to the constructor for the child process.

Apart from making the code (potentially) compatible with Windows
and the other start methods this also ensures that as long as the child process is still alive the object will not be garbage collected in the parent process. This might be important if some resource is freed when the object is garbage collected in the parent process.

So for instance

```python
from multiprocessing import Process, Lock

def f():
    ... do something using "lock" ... 

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f).start()
```

should be rewritten as

```python
from multiprocessing import Process, Lock

def f(l):
    ... do something using "l" ... 

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f, args=(lock,)).start()
```

Beware of replacing `sys.stdin` with a “file like object”

`multiprocessing` originally unconditionally called:

```python
os.close(sys.stdin.fileno())
```
in the multiprocessing.Process._bootstrap() method — this resulted in issues with processes-in-processes. This has been changed to:

```python
sys.stdin.close()
sys.stdin = open(os.open(os.devnull, os.O_RDONLY), sys.stdin)
```

Which solves the fundamental issue of processes colliding with each other resulting in a bad file descriptor error, but introduces a potential danger to applications which replace `sys.stdin()` with a “file-like object” with output buffering. This danger is that if multiple processes call `close()` on this file-like object, it could result in the same data being flushed to the object multiple times, resulting in corruption.

If you write a file-like object and implement your own caching, you can make it fork-safe by storing the pid whenever you append to the cache, and discarding the cache when the pid changes. For example:

```python
@property
def cache(self):
    pid = os.getpid()
    if pid != self._pid:
        self._pid = pid
        self._cache = []
    return self._cache
```

For more information, see bpo-5155, bpo-5313 and bpo-5331

17.2.3.2. The `spawn` and `forkserver` start methods

There are a few extra restriction which don’t apply to the `fork` start
method.

More picklability

Ensure that all arguments to `Process.__init__()` are picklable. Also, if you subclass `Process` then make sure that instances will be picklable when the `Process.start` method is called.

Global variables

Bear in mind that if code run in a child process tries to access a global variable, then the value it sees (if any) may not be the same as the value in the parent process at the time that `Process.start` was called.

However, global variables which are just module level constants cause no problems.

Safe importing of main module

Make sure that the main module can be safely imported by a new Python interpreter without causing unintended side effects (such a starting a new process).

For example, using the `spawn` or `forkserver` start method running the following module would fail with a `RuntimeError`:

```python
from multiprocessing import Process

def foo():
    print('hello')

p = Process(target=foo)
p.start()
```
Instead one should protect the “entry point” of the program by using `if __name__ == '__main__':` as follows:

```python
from multiprocessing import Process, freeze_support

def foo():
    print('hello')

if __name__ == '__main__':
    freeze_support()
    set_start_method('spawn')
    p = Process(target=foo)
    p.start()
```

(The `freeze_support()` line can be omitted if the program will be run normally instead of frozen.)

This allows the newly spawned Python interpreter to safely import the module and then run the module’s `foo()` function.

Similar restrictions apply if a pool or manager is created in the main module.
Demonstration of how to create and use customized managers and proxies:

```python
from multiprocessing import freeze_support
from multiprocessing.managers import BaseManager, BaseProxy
import operator

##

class Foo:
    def f(self):
        print('you called Foo.f()')
    def g(self):
        print('you called Foo.g()')
    def _h(self):
        print('you called Foo._h()')

# A simple generator function
def baz():
    for i in range(10):
        yield i*i

# Proxy type for generator objects
class GeneratorProxy(BaseProxy):
    _exposed_ = ['__next__']
    def __iter__(self):
        return self
    def __next__(self):
        return self._callmethod('__next__')

# Function to return the operator module
def get_operator_module():
    return operator
```
```python
##

class MyManager(BaseManager):
    pass

# register the Foo class; make `f()` and `g()` accessible via proxy
MyManager.register('Foo1', Foo)

# register the Foo class; make `g()` and `_h()` accessible via proxy
MyManager.register('Foo2', Foo, exposed=('g', '_h'))

# register the generator function baz; use `GeneratorProxy` to make proxies
MyManager.register('baz', baz, proxytype=GeneratorProxy)

# register get_operator_module(); make public functions accessible via proxy
MyManager.register('operator', get_operator_module)

##

def test():
    manager = MyManager()
    manager.start()

    print('-' * 20)

    f1 = manager.Foo1()
    f1.f()
    f1.g()
    assert not hasattr(f1, '_h')
    assert sorted(f1._exposed_) == sorted(['f', 'g'])

    print('-' * 20)

    f2 = manager.Foo2()
    f2.g()
    f2._h()```
assert not hasattr(f2, 'f')
assert sorted(f2._exposed_) == sorted(['g', '_h'])

print('-' * 20)

it = manager.baz()
for i in it:
    print('<%d>' % i, end=' ')
print()

print('-' * 20)

op = manager.operator()
print('op.add(23, 45) =', op.add(23, 45))
print('op.pow(2, 94) =', op.pow(2, 94))
print('op._exposed_ =', op._exposed_)

##

if __name__ == '__main__':
    freeze_support()
test()

Using Pool:

import multiprocessing
import time
import random
import sys

#
# Functions used by test code
#

def calculate(func, args):
    result = func(*args)
return '%%s says that %%s%%s = %%s' % (multiprocessing.current_process().name, func.__name__, args, result)

def calculatestar(args):
    return calculate(*args)

def mul(a, b):
    time.sleep(0.5 * random.random())
    return a * b

def plus(a, b):
    time.sleep(0.5 * random.random())
    return a + b

def f(x):
    return 1.0 / (x - 5.0)

def pow3(x):
    return x ** 3

def noop(x):
    pass

# # Test code # #

def test():
    PROCESSES = 4
    print('Creating pool with %d processes\n' % PROCESSES)

    with multiprocessing.Pool(PROCESSES) as pool:
        # # Tests # #
TASKS = [(mul, (i, 7)) for i in range(10)] +
[(plus, (i, 8)) for i in range(10)]

results = [pool.apply_async(calculate, t) for i in range(10)]
imap_it = pool.imap(calculatestar, TASKS)
imap_unordered_it = pool.imap_unordered(calculatestar)

print('Ordered results using pool.apply_async():'
for r in results:
    print('	', r.get())
print()

print('Ordered results using pool.imap():'
for x in imap_it:
    print('	', x)
print()

print('Unordered results using pool.imap_unordered():'
for x in imap_unordered_it:
    print('	', x)
print()

print('Ordered results using pool.map() ---'
for x in pool.map(calculatestar, TASKS):
    print('	', x)
print()

#
# Test error handling
#

print('Testing error handling: ')

try:
    print(pool.apply(f, (5,)))
except ZeroDivisionError:
try:
    print(pool.map(f, list(range(10))))
except ZeroDivisionError:
    print('	Got ZeroDivisionError as expected from pool.map()')
else:
    raise AssertionError('expected ZeroDivisionError')

try:
    print(list(pool.imap(f, list(range(10)))))
except ZeroDivisionError:
    print('	Got ZeroDivisionError as expected from list(pool.imap())')
else:
    raise AssertionError('expected ZeroDivisionError')

it = pool.imap(f, list(range(10)))
for i in range(10):
    try:
        x = next(it)
    except ZeroDivisionError:
        if i == 5:
            pass
        except StopIteration:
            break
    else:
        if i == 5:
            raise AssertionError('expected ZeroDivisionError')

assert i == 9
print('	Got ZeroDivisionError as expected for i == 5')
print()
An example showing how to use queues to feed tasks to a collection of worker processes and collect the results:

```python
import time
```
import random

from multiprocessing import Process, Queue, current_process

#  Function run by worker processes  
# 
def worker(input, output):
    #for func, args in iter(input.get, 'STOP'): 
    result = calculate(func, args) 
    output.put(result)

#  Function used to calculate result  
# 
def calculate(func, args):
    result = func(*args) 
    return '%s says that %s%s = %s' % \ 
        (current_process().name, func.__name__, args

#  Functions referenced by tasks  
#
def mul(a, b):
    time.sleep(0.5*random.random())
    return a * b

def plus(a, b):
    time.sleep(0.5*random.random())
    return a + b

#  #
def test():
    NUMBER_OF_PROCESSES = 4
    TASKS1 = [(mul, (i, 7)) for i in range(20)]
    TASKS2 = [(plus, (i, 8)) for i in range(10)]

    # Create queues
    task_queue = Queue()
    done_queue = Queue()

    # Submit tasks
    for task in TASKS1:
        task_queue.put(task)

    # Start worker processes
    for i in range(NUMBER_OF_PROCESSES):
        Process(target=worker, args=(task_queue, done_queue)).start()

    # Get and print results
    print('Unordered results:
    for i in range(len(TASKS1)):
        print('	', done_queue.get())

    # Add more tasks using `put`
    for task in TASKS2:
        task_queue.put(task)

    # Get and print some more results
    for i in range(len(TASKS2)):
        print('	', done_queue.get())

    # Tell child processes to stop
    for i in range(NUMBER_OF_PROCESSES):
        task_queue.put('STOP')

if __name__ == '__main__':
17.3. The concurrent package

Currently, there is only one module in this package:

- `concurrent.futures` – Launching parallel tasks
17.4. `concurrent.futures` — Launching parallel tasks

*New in version 3.2.*

**Source code:**  `Lib/concurrent/futures/thread.py` and `Lib/concurrent/futures/process.py` 

The `concurrent.futures` module provides a high-level interface for asynchronously executing callables.

The asynchronous execution can be performed with threads, using `ThreadPoolExecutor`, or separate processes, using `ProcessPoolExecutor`. Both implement the same interface, which is defined by the abstract `Executor` class.
17.4.1. Executor Objects

class concurrent.futures.Executor

An abstract class that provides methods to execute calls asynchronously. It should not be used directly, but through its concrete subclasses.

submit(fn, *args, **kwargs)

Schedules the callable, fn, to be executed as fn(*args **kwargs) and returns a Future object representing the execution of the callable.

```
with ThreadPoolExecutor(max_workers=1) as executor:
    future = executor.submit(pow, 323, 1235)
    print(future.result())
```

map(func, *iterables, timeout=None, chunksize=1)

Similar to map(func, *iterables) except:

- the iterables are collected immediately rather than lazily;
- func is executed asynchronously and several calls to func may be made concurrently.

The returned iterator raises a concurrent.futures.TimeoutError if __next__() is called and the result isn't available after timeout seconds from the original call to Executor.map(). timeout can be an int or a float. If timeout is not specified or None, there is no limit to the wait time.

If a func call raises an exception, then that exception will be
raised when its value is retrieved from the iterator.

When using `ProcessPoolExecutor`, this method chops `iterables` into a number of chunks which it submits to the pool as separate tasks. The (approximate) size of these chunks can be specified by setting `chunksize` to a positive integer. For very long iterables, using a large value for `chunksize` can significantly improve performance compared to the default size of 1. With `ThreadPoolExecutor`, `chunksize` has no effect.

*Changed in version 3.5: Added the `chunksize` argument.*

**shutdown**(*`wait=True`*)

Signal the executor that it should free any resources that it is using when the currently pending futures are done executing. Calls to `Executor.submit()` and `Executor.map()` made after shutdown will raise `RuntimeError`.

If `wait` is `True` then this method will not return until all the pending futures are done executing and the resources associated with the executor have been freed. If `wait` is `False` then this method will return immediately and the resources associated with the executor will be freed when all pending futures are done executing. Regardless of the value of `wait`, the entire Python program will not exit until all pending futures are done executing.

You can avoid having to call this method explicitly if you use the `with` statement, which will shutdown the `Executor` (waiting as if `Executor.shutdown()` were
called with `wait` set to `True`):

```python
import shutil
with ThreadPoolExecutor(max_workers=4) as e:
    e.submit(shutil.copy, 'src1.txt', 'dest1.txt')
    e.submit(shutil.copy, 'src2.txt', 'dest2.txt')
    e.submit(shutil.copy, 'src3.txt', 'dest3.txt')
    e.submit(shutil.copy, 'src4.txt', 'dest4.txt')
```
17.4.2. ThreadPoolExecutor

ThreadPoolExecutor is an Executor subclass that uses a pool of threads to execute calls asynchronously.

Deadlocks can occur when the callable associated with a Future waits on the results of another Future. For example:

```python
import time
def wait_on_b():
    time.sleep(5)
    print(b.result())  # b will never complete because it is waiting on a.
    return 5
def wait_on_a():
    time.sleep(5)
    print(a.result())  # a will never complete because it is waiting on b.
    return 6

executor = ThreadPoolExecutor(max_workers=2)
a = executor.submit(wait_on_b)
b = executor.submit(wait_on_a)
```

And:

```python
def wait_on_future():
    f = executor.submit(pow, 5, 2)
    # This will never complete because there is only one worker thread and it is executing this function.
    print(f.result())

executor = ThreadPoolExecutor(max_workers=1)
executor.submit(wait_on_future)
```
class concurrent.futures.ThreadPoolExecutor(max_workers=None, thread_name_prefix='', initializer=None, initargs=())

An Executor subclass that uses a pool of at most max_workers threads to execute calls asynchronously.

initializer is an optional callable that is called at the start of each worker thread; initargs is a tuple of arguments passed to the initializer. Should initializer raise an exception, all currently pending jobs will raise a BrokenThreadPool, as well any attempt to submit more jobs to the pool.

Changed in version 3.5: If max_workers is None or not given, it will default to the number of processors on the machine, multiplied by 5, assuming that ThreadPoolExecutor is often used to overlap I/O instead of CPU work and the number of workers should be higher than the number of workers for ProcessPoolExecutor.

New in version 3.6: The thread_name_prefix argument was added to allow users to control the threading.Thread names for worker threads created by the pool for easier debugging.

Changed in version 3.7: Added the initializer and initargs arguments.

17.4.2.1. ThreadPoolExecutor Example

```python
import concurrent.futures
import urllib.request

URLS = ['http://www.foxnews.com/',
        'http://www.cnn.com/']
```
# Retrieve a single page and report the URL and contents

```python
def load_url(url, timeout):
    with urllib.request.urlopen(url, timeout=timeout):
        return conn.read()
```

# We can use a with statement to ensure threads are cleaned up

```python
with concurrent.futures.ThreadPoolExecutor(max_workers=)
    # Start the load operations and mark each future
    future_to_url = {executor.submit(load_url, url, for future in concurrent.futures.as_completed(future_to_url):
        url = future_to_url[future]
        try:
            data = future.result()
        except Exception as exc:
            print('%r generated an exception: %s' %
        else:
            print('%r page is %d bytes' % (url, len(data)))
```
```
17.4.3. ProcessPoolExecutor

The `ProcessPoolExecutor` class is an `Executor` subclass that uses a pool of processes to execute calls asynchronously. `ProcessPoolExecutor` uses the `multiprocessing` module, which allows it to side-step the `Global Interpreter Lock` but also means that only picklable objects can be executed and returned.

The `__main__` module must be importable by worker subprocesses. This means that `ProcessPoolExecutor` will not work in the interactive interpreter.

Calling `Executor` or `Future` methods from a callable submitted to a `ProcessPoolExecutor` will result in deadlock.

```python
class concurrent.futures.ProcessPoolExecutor(max_workers=None, mp_context=None, initializer=None, initargs=())
```

An `Executor` subclass that executes calls asynchronously using a pool of at most `max_workers` processes. If `max_workers` is `None` or not given, it will default to the number of processors on the machine. If `max_workers` is lower or equal to 0, then a `ValueError` will be raised. `mp_context` can be a multiprocessing context or `None`. It will be used to launch the workers. If `mp_context` is `None` or not given, the default multiprocessing context is used.

`initializer` is an optional callable that is called at the start of each worker process; `initargs` is a tuple of arguments passed to the initializer. Should `initializer` raise an exception, all currently pending jobs will raise a `BrokenThreadPool`, as well any attempt to
submit more jobs to the pool.

*Changed in version 3.3:* When one of the worker processes terminates abruptly, a BrokenProcessPool error is now raised. Previously, behaviour was undefined but operations on the executor or its futures would often freeze or deadlock.

*Changed in version 3.7:* The `mp_context` argument was added to allow users to control the start_method for worker processes created by the pool.

Added the *initializer* and *initargs* arguments.

### 17.4.3.1. ProcessPoolExecutor Example

```python
import concurrent.futures
import math

PRIMES = [112272535095293,
          112582705942171,
          112272535095293,
          115280095190773,
          115797848077099,
          1099726899285419]

def is_prime(n):
    if n % 2 == 0:
        return False
    sqrt_n = int(math.floor(math.sqrt(n)))
    for i in range(3, sqrt_n + 1, 2):
        if n % i == 0:
            return False
    return True
```
def main():
    with concurrent.futures.ProcessPoolExecutor() as executor:
        for number, prime in zip(PRIMES, executor.map(print, PRIMES)):
            print('%d is prime: %s' % (number, prime))

if __name__ == '__main__':
    main()
17.4.4. Future Objects

The **Future** class encapsulates the asynchronous execution of a callable. **Future** instances are created by **Executor.submit()**.

```python
class concurrent.futures.Future
    Encapsulates the asynchronous execution of a callable. Future instances are created by Executor.submit() and should not be created directly except for testing.

    cancel()
    Attempt to cancel the call. If the call is currently being executed and cannot be cancelled then the method will return False, otherwise the call will be cancelled and the method will return True.

    cancelled()
    Return True if the call was successfully cancelled.

    running()
    Return True if the call is currently being executed and cannot be cancelled.

    done()
    Return True if the call was successfully cancelled or finished running.

    result(timeout=None)
    Return the value returned by the call. If the call hasn't yet completed then this method will wait up to timeout seconds. If the call hasn't completed in timeout seconds,
then a `concurrent.futures.TimeoutError` will be raised. `timeout` can be an int or float. If `timeout` is not specified or `None`, there is no limit to the wait time.

If the future is cancelled before completing then `CancelledError` will be raised.

If the call raised, this method will raise the same exception.

**exception**(*timeout=None*)

Return the exception raised by the call. If the call hasn’t yet completed then this method will wait up to `timeout` seconds. If the call hasn’t completed in `timeout` seconds, then a `concurrent.futures.TimeoutError` will be raised. `timeout` can be an int or float. If `timeout` is not specified or `None`, there is no limit to the wait time.

If the future is cancelled before completing then `CancelledError` will be raised.

If the call completed without raising, `None` is returned.

**add_done_callback**(*fn*)

Attaches the callable `fn` to the future. `fn` will be called, with the future as its only argument, when the future is cancelled or finishes running.

Added callables are called in the order that they were added and are always called in a thread belonging to the process that added them. If the callable raises an `Exception` subclass, it will be logged and ignored. If the callable raises a `BaseException` subclass, the behavior is undefined.
If the future has already completed or been cancelled, \textit{fn} will be called immediately.

The following \textit{Future} methods are meant for use in unit tests and \textit{Executor} implementations.

\textbf{set\_running\_or\_notify\_cancel()}
This method should only be called by \textit{Executor} implementations before executing the work associated with the \textit{Future} and by unit tests.

If the method returns \textit{False} then the \textit{Future} was cancelled, i.e. \textit{Future.cancel()} was called and returned \textit{True}. Any threads waiting on the \textit{Future} completing (i.e. through \textit{as\_completed()} or \textit{wait()}) will be woken up.

If the method returns \textit{True} then the \textit{Future} was not cancelled and has been put in the running state, i.e. calls to \textit{Future.running()} will return \textit{True}.

This method can only be called once and cannot be called after \textit{Future.set\_result()} or \textit{Future.set\_exception()} have been called.

\textbf{set\_result}(\textit{result})
Sets the result of the work associated with the \textit{Future} to \textit{result}.

This method should only be used by \textit{Executor} implementations and unit tests.

\textbf{set\_exception}(\textit{exception})
Sets the result of the work associated with the `Future` to the `Exception` exception.

This method should only be used by `Executor` implementations and unit tests.
17.4.5. Module Functions

concurrent.futures.wait(fs, timeout=None, return_when=ALL_COMPLETED)

Wait for the Future instances (possibly created by different Executor instances) given by fs to complete. Returns a named 2-tuple of sets. The first set, named done, contains the futures that completed (finished or were cancelled) before the wait completed. The second set, named not_done, contains uncompleted futures.

timeout can be used to control the maximum number of seconds to wait before returning. timeout can be an int or float. If timeout is not specified or None, there is no limit to the wait time.

return_when indicates when this function should return. It must be one of the following constants:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIRST_COMPLETED</td>
<td>The function will return when any future finishes or is cancelled.</td>
</tr>
<tr>
<td>FIRST_EXCEPTION</td>
<td>The function will return when any future finishes by raising an exception.</td>
</tr>
<tr>
<td></td>
<td>If no future raises an exception then it is equivalent to ALL_COMPLETED.</td>
</tr>
<tr>
<td>ALL_COMPLETED</td>
<td>The function will return when all futures finish or are cancelled.</td>
</tr>
</tbody>
</table>

concurrent.futures.as_completed(fs, timeout=None)

Returns an iterator over the Future instances (possibly created by different Executor instances) given by fs that yields futures as
they complete (finished or were cancelled). Any futures given by $fs$
that are duplicated will be returned once. Any futures that
completed before `as_completed()` is called will be yielded first.
The returned iterator raises a `concurrent.futures.TimeoutError` if
`__next__()` is called and the result isn’t available after `timeout`
seconds from the original call to `as_completed()`. `timeout` can be
an int or float. If `timeout` is not specified or `None`, there is no
limit to the wait time.

See also:

**PEP 3148 – futures - execute computations asynchronously**

The proposal which described this feature for inclusion in the
Python standard library.
17.4.6. Exception classes

*exception* concurrent.futures.**CancelledError**

Raised when a future is cancelled.

*exception* concurrent.futures.**TimeoutError**

Raised when a future operation exceeds the given timeout.

*exception* concurrent.futures.**BrokenExecutor**

Derived from *RuntimeError*, this exception class is raised when an executor is broken for some reason, and cannot be used to submit or execute new tasks.

*New in version 3.7.*

*exception* concurrent.futures.thread.**BrokenThreadPool**

Derived from *BrokenExecutor*, this exception class is raised when one of the workers of a ThreadPoolExecutor has failed initializing.

*New in version 3.7.*

*exception* concurrent.futures.process.**BrokenProcessPool**

Derived from *BrokenExecutor* (formerly *RuntimeError*), this exception class is raised when one of the workers of a ProcessPoolExecutor has terminated in a non-clean fashion (for example, if it was killed from the outside).

*New in version 3.3.*
17.5. `subprocess` — Subprocess management

**Source code:** Lib/subprocess.py

The `subprocess` module allows you to spawn new processes, connect to their input/output/error pipes, and obtain their return codes. This module intends to replace several older modules and functions:

```python
os.system
os.spawn*
```

Information about how the `subprocess` module can be used to replace these modules and functions can be found in the following sections.

**See also:** PEP 324 – PEP proposing the subprocess module
17.5.1. Using the `subprocess` Module

The recommended approach to invoking subprocesses is to use the `run()` function for all use cases it can handle. For more advanced use cases, the underlying `Popen` interface can be used directly.

The `run()` function was added in Python 3.5; if you need to retain compatibility with older versions, see the Older high-level API section.

```python
subprocess.run(args, *, stdin=None, input=None, stdout=None, stderr=None, shell=False, cwd=None, timeout=None, check=False, encoding=None, errors=None)
```

Run the command described by `args`. Wait for command to complete, then return a `CompletedProcess` instance.

The arguments shown above are merely the most common ones, described below in Frequently Used Arguments (hence the use of keyword-only notation in the abbreviated signature). The full function signature is largely the same as that of the `Popen` constructor - most of the arguments to this function are passed through to that interface. (`timeout`, `input`, `check`, and `capture_output` are not.)

If `capture_output` is true, stdout and stderr will be captured. When used, the internal `Popen` object is automatically created with `stdout=PIPE` and `stderr=PIPE`. The `stdout` and `stderr` arguments may not be used as well.

The `timeout` argument is passed to `Popen.communicate()`. If the timeout expires, the child process will be killed and waited for. The `TimeoutExpired` exception will be re-raised after the child process has terminated.
The `input` argument is passed to `Popen.communicate()` and thus to the subprocess's stdin. If used it must be a byte sequence, or a string if `encoding` or `errors` is specified or `text` is true. When used, the internal `Popen` object is automatically created with `stdin=PIPE`, and the `stdin` argument may not be used as well.

If `check` is true, and the process exits with a non-zero exit code, a `CalledProcessError` exception will be raised. Attributes of that exception hold the arguments, the exit code, and stdout and stderr if they were captured.

If `encoding` or `errors` are specified, or `text` is true, file objects for stdin, stdout and stderr are opened in text mode using the specified `encoding` and `errors` or the `io.TextIOWrapper` default. The `universal_newlines` argument is equivalent to `text` and is provided for backwards compatibility. By default, file objects are opened in binary mode.

Examples:

```python
>>> subprocess.run(['ls', '-l'])  # doesn't capture output
CompletedProcess(args=['ls', '-l'], returncode=0)

>>> subprocess.run('exit 1', shell=True, check=True)
Traceback (most recent call last):
...
subprocess.CalledProcessError: Command 'exit 1' ran with return code 1

>>> subprocess.run(['ls', '-l', '/dev/null'], capture_output=True)
CompletedProcess(args=['ls', '-l', '/dev/null'], returncode=0, stdout=b'crw-rw-rw- 1 root root 1, 3 Jan 23 16:23 /dev/null', stderr=b'')
```

*New in version 3.5.*
Changed in version 3.6: Added `encoding` and `errors` parameters

Changed in version 3.7: Added the `text` parameter, as a more understandable alias of `universal_newlines`. Added the `capture_output` parameter.

class subprocess.**CompletedProcess**

The return value from `run()`, representing a process that has finished.

**args**

The arguments used to launch the process. This may be a list or a string.

**returncode**

Exit status of the child process. Typically, an exit status of 0 indicates that it ran successfully.

A negative value `-N` indicates that the child was terminated by signal `N` (POSIX only).

**stdout**

Captured stdout from the child process. A bytes sequence, or a string if `run()` was called with an encoding, errors, or `text=True`. None if stdout was not captured.

If you ran the process with `stderr=subprocess.STDOUT`, stdout and stderr will be combined in this attribute, and `stderr` will be None.

**stderr**

Captured stderr from the child process. A bytes sequence, or a string if `run()` was called with an encoding, errors, or
check_returncode()

If returncode is non-zero, raise a CalledProcessError.

New in version 3.5.

subprocess.DEVNULL

Special value that can be used as the stdin, stdout or stderr argument to Popen and indicates that the special file os.devnull will be used.

New in version 3.3.

subprocess.PIPE

Special value that can be used as the stdin, stdout or stderr argument to Popen and indicates that a pipe to the standard stream should be opened. Most useful with Popen.communicate().

subprocessSTDOUT

Special value that can be used as the stderr argument to Popen and indicates that standard error should go into the same handle as standard output.

exception subprocess.SubprocessError

Base class for all other exceptions from this module.

New in version 3.3.

exception subprocess.TimeoutExpired

Subclass of SubprocessError, raised when a timeout expires while waiting for a child process.
**cmd**

Command that was used to spawn the child process.

**timeout**

Timeout in seconds.

**output**

Output of the child process if it was captured by `run()` or `check_output()`. Otherwise, `None`.

**stdout**

Alias for output, for symmetry with `stderr`.

**stderr**

Stderr output of the child process if it was captured by `run()`. Otherwise, `None`.

*New in version 3.3.*

*Changed in version 3.5:* `stdout` and `stderr` attributes added

**exception** `subprocess.CalledProcessError`

Subclass of `SubprocessError`, raised when a process run by `check_call()` or `check_output()` returns a non-zero exit status.

**returncode**

Exit status of the child process. If the process exited due to a signal, this will be the negative signal number.

**cmd**

Command that was used to spawn the child process.
output
Output of the child process if it was captured by run() or check_output(). Otherwise, None.

stdout
Alias for output, for symmetry with stderr.

stderr
Stderr output of the child process if it was captured by run(). Otherwise, None.

*Changed in version 3.5: stdout and stderr attributes added*

17.5.1.1. Frequently Used Arguments

To support a wide variety of use cases, the Popen constructor (and the convenience functions) accept a large number of optional arguments. For most typical use cases, many of these arguments can be safely left at their default values. The arguments that are most commonly needed are:

*args is required for all calls and should be a string, or a sequence of program arguments. Providing a sequence of arguments is generally preferred, as it allows the module to take care of any required escaping and quoting of arguments (e.g. to permit spaces in file names). If passing a single string, either shell must be True (see below) or else the string must simply name the program to be executed without specifying any arguments.

stdin, stdout and stderr specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are PIPE, DEVNULL, an existing file
descriptor (a positive integer), an existing file object, and None. PIPE indicates that a new pipe to the child should be created. DEVNULL indicates that the special file os.devnull will be used. With the default settings of None, no redirection will occur; the child's file handles will be inherited from the parent. Additionally, stderr can be STDOUT, which indicates that the stderr data from the child process should be captured into the same file handle as for stdout.

If encoding or errors are specified, or universal_newlines is true, the file objects stdin, stdout and stderr will be opened in text mode using the encoding and errors specified in the call or the defaults for io.TextIOWrapper.

For stdin, line ending characters \n in the input will be converted to the default line separator os.linesep. For stdout and stderr, all line endings in the output will be converted to \n. For more information see the documentation of the io.TextIOWrapper class when the newline argument to its constructor is None.

If text mode is not used, stdin, stdout and stderr will be opened as binary streams. No encoding or line ending conversion is performed.

New in version 3.6: Added encoding and errors parameters.

Note: The newlines attribute of the file objects Popen.stdin, Popen.stdout and Popen.stderr are not updated by the Popen.communicate() method.

If shell is True, the specified command will be executed through
the shell. This can be useful if you are using Python primarily for the enhanced control flow it offers over most system shells and still want convenient access to other shell features such as shell pipes, filename wildcards, environment variable expansion, and expansion of ~ to a user's home directory. However, note that Python itself offers implementations of many shell-like features (in particular, `glob`, `fnmatch`, `os.walk()`, `os.path.expandvars()`, `os.path.expanduser()`, and `shutil`).

*Changed in version 3.3:* When `universal_newlines` is `True`, the class uses the encoding `locale.getpreferredencoding(False)` instead of `locale.getpreferredencoding()`. See the `io.TextIOWrapper` class for more information on this change.

**Note:** Read the Security Considerations section before using `shell=True`.

These options, along with all of the other options, are described in more detail in the `Popen` constructor documentation.

### 17.5.1.2. Popen Constructor

The underlying process creation and management in this module is handled by the `Popen` class. It offers a lot of flexibility so that developers are able to handle the less common cases not covered by the convenience functions.

```python
class subprocess.**Popen**(args, bufsize=-1, executable=None, stdin=None, stdout=None, stderr=None, preexec_fn=None, close_fds=True, shell=False, cwd=None, env=None,
```
Execute a child program in a new process. On POSIX, the class uses `os.execvp()`-like behavior to execute the child program. On Windows, the class uses the Windows `CreateProcess()` function. The arguments to `Popen` are as follows.

`args` should be a sequence of program arguments or else a single string or path-like object. By default, the program to execute is the first item in `args` if `args` is a sequence. If `args` is a string, the interpretation is platform-dependent and described below. See the `shell` and `executable` arguments for additional differences from the default behavior. Unless otherwise stated, it is recommended to pass `args` as a sequence.

On POSIX, if `args` is a string, the string is interpreted as the name or path of the program to execute. However, this can only be done if not passing arguments to the program.

```python
>>> import shlex, subprocess
>>> command_line = input()
/bin/vikings -input eggs.txt -output "spam spam."
>>> args = shlex.split(command_line)
>>> print(args)
[/bin/vikings', '-input', 'eggs.txt', '-output'
>>> p = subprocess.Popen(args) # Success!
```

Note: `shlex.split()` can be useful when determining the correct tokenization for `args`, especially in complex cases:

Note in particular that options (such as `-input`) and arguments (such as `eggs.txt`) that are separated by whitespace in the shell
go in separate list elements, while arguments that need quoting or backslash escaping when used in the shell (such as filenames containing spaces or the echo command shown above) are single list elements.

On Windows, if args is a sequence, it will be converted to a string in a manner described in Converting an argument sequence to a string on Windows. This is because the underlying CreateProcess() operates on strings.

The shell argument (which defaults to False) specifies whether to use the shell as the program to execute. If shell is True, it is recommended to pass args as a string rather than as a sequence.

On POSIX with shell=True, the shell defaults to /bin/sh. If args is a string, the string specifies the command to execute through the shell. This means that the string must be formatted exactly as it would be when typed at the shell prompt. This includes, for example, quoting or backslash escaping filenames with spaces in them. If args is a sequence, the first item specifies the command string, and any additional items will be treated as additional arguments to the shell itself. That is to say, Popen does the equivalent of:

```python
Popen(['/bin/sh', '-c', args[0], args[1], ...])
```

On Windows with shell=True, the COMSPEC environment variable specifies the default shell. The only time you need to specify shell=True on Windows is when the command you wish to execute is built into the shell (e.g. dir or copy). You do not need shell=True to run a batch file or console-based executable.
bufsize will be supplied as the corresponding argument to the open() function when creating the stdin/stdout/stderr pipe file objects:

- 0 means unbuffered (read and write are one system call and can return short)
- 1 means line buffered (only usable if universal_newlines=True i.e., in a text mode)
- any other positive value means use a buffer of approximately that size
- negative bufsize (the default) means the system default of io.DEFAULT_BUFFER_SIZE will be used.

*Changed in version 3.3.1:* bufsize now defaults to -1 to enable buffering by default to match the behavior that most code expects. In versions prior to Python 3.2.4 and 3.3.1 it incorrectly defaulted to 0 which was unbuffered and allowed short reads. This was unintentional and did not match the behavior of Python 2 as most code expected.

The executable argument specifies a replacement program to execute. It is very seldom needed. When shell=False, executable replaces the program to execute specified by args. However, the original args is still passed to the program. Most programs treat the program specified by args as the command name, which can then be different from the program actually executed. On POSIX, the args name becomes the display name for the executable in utilities such as ps. If shell=True, on POSIX the executable argument specifies a replacement shell for the default /bin/sh.
stdin, stdout and stderr specify the executed program’s standard input, standard output and standard error file handles, respectively. Valid values are PIPE, DEVNULL, an existing file descriptor (a positive integer), an existing file object, and None. PIPE indicates that a new pipe to the child should be created. DEVNULL indicates that the special file os.devnull will be used. With the default settings of None, no redirection will occur; the child’s file handles will be inherited from the parent. Additionally, stderr can be STDOUT, which indicates that the stderr data from the applications should be captured into the same file handle as for stdout.

If preexec_fn is set to a callable object, this object will be called in the child process just before the child is executed. (POSIX only)

**Warning:** The preexec_fn parameter is not safe to use in the presence of threads in your application. The child process could deadlock before exec is called. If you must use it, keep it trivial! Minimize the number of libraries you call into.

**Note:** If you need to modify the environment for the child use the env parameter rather than doing it in a preexec_fn. The start_new_session parameter can take the place of a previously common use of preexec_fn to call os.setsid() in the child.

If close_fds is true, all file descriptors except 0, 1 and 2 will be closed before the child process is executed. On Windows, if close_fds is true then no handles will be inherited by the child process unless explicitly passed in the handle_list element of STARTUPINFO.lpAttributeList, or by standard handle redirection.

*Changed in version 3.2:* The default for close_fds was changed
from False to what is described above.

*Changed in version 3.7:* On Windows the default for close_fds was changed from False to True when redirecting the standard handles. It’s now possible to set close_fds to True when redirecting the standard handles.

pass_fds is an optional sequence of file descriptors to keep open between the parent and child. Providing any pass_fds forces close_fds to be True. (POSIX only)

*New in version 3.2:* The pass_fds parameter was added.

If cwd is not None, the function changes the working directory to cwd before executing the child. cwd can be a str and path-like object. In particular, the function looks for executable (or for the first item in args) relative to cwd if the executable path is a relative path.

*Changed in version 3.6:* cwd parameter accepts a path-like object.

If restore_signals is true (the default) all signals that Python has set to SIG_IGN are restored to SIG_DFL in the child process before the exec. Currently this includes the SIGPIPE, SIGXFZ and SIGXFSZ signals. (POSIX only)

*Changed in version 3.2:* restore_signals was added.

If start_new_session is true the setsid() system call will be made in the child process prior to the execution of the subprocess. (POSIX only)

*Changed in version 3.2:* start_new_session was added.

If env is not None, it must be a mapping that defines the
environment variables for the new process; these are used instead of the default behavior of inheriting the current process' environment.

**Note:** If specified, `env` must provide any variables required for the program to execute. On Windows, in order to run a side-by-side assembly the specified `env` must include a valid `SystemRoot`.

If `encoding` or `errors` are specified, the file objects `stdin`, `stdout` and `stderr` are opened in text mode with the specified encoding and `errors`, as described above in Frequently Used Arguments. If `universal_newlines` is `True`, they are opened in text mode with default encoding. Otherwise, they are opened as binary streams.

*New in version 3.6: encoding and errors were added.*

If given, `startupinfo` will be a `STARTUPINFO` object, which is passed to the underlying `CreateProcess` function. `creationflags`, if given, can be one or more of the following flags:

- `CREATE_NEW_CONSOLE`
- `CREATE_NEW_PROCESS_GROUP`
- `ABOVE_NORMAL_PRIORITY_CLASS`
- `BELOW_NORMAL_PRIORITY_CLASS`
- `HIGH_PRIORITY_CLASS`
- `IDLE_PRIORITY_CLASS`
- `NORMAL_PRIORITY_CLASS`
- `REALTIME_PRIORITY_CLASS`
- `CREATE_NO_WINDOW`
- `DETACHED_PROCESS`
- `CREATE_DEFAULT_ERROR_MODE`
- `CREATE_BREAKAWAY_FROM_JOB`
Popen objects are supported as context managers via the `with` statement: on exit, standard file descriptors are closed, and the process is waited for.

```python
with Popen(['ifconfig'], stdout=PIPE) as proc:
    log.write(proc.stdout.read())
```

*Changed in version 3.2:* Added context manager support.

*Changed in version 3.6:* Popen destructor now emits a `ResourceWarning` warning if the child process is still running.

*Changed in version 3.7:* `args`, or the first element of `args` if `args` is a sequence, can now be a path-like object.

### 17.5.1.3. Exceptions

Exceptions raised in the child process, before the new program has started to execute, will be re-raised in the parent. Additionally, the exception object will have one extra attribute called `child_traceback`, which is a string containing traceback information from the child’s point of view.

The most common exception raised is `OSError`. This occurs, for example, when trying to execute a non-existent file. Applications should prepare for `OSError` exceptions.

A `ValueError` will be raised if `Popen` is called with invalid arguments.

`check_call()` and `check_output()` will raise `CalledProcessError` if the called process returns a non-zero return code.
All of the functions and methods that accept a `timeout` parameter, such as `call()` and `Popen.communicate()` will raise `TimeoutExpired` if the timeout expires before the process exits.

Exceptions defined in this module all inherit from `SubprocessError`.

*New in version 3.3:* The `SubprocessError` base class was added.
17.5.2. Security Considerations

Unlike some other popen functions, this implementation will never implicitly call a system shell. This means that all characters, including shell metacharacters, can safely be passed to child processes. If the shell is invoked explicitly, via `shell=True`, it is the application’s responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid shell injection vulnerabilities.

When using `shell=True`, the `shlex.quote()` function can be used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.
17.5.3. Popen Objects

Instances of the Popen class have the following methods:

Popen.\texttt{poll()}  
Check if child process has terminated. Set and return \texttt{returncode} attribute. Otherwise, returns \texttt{None}.

Popen.\texttt{wait(\textit{timeout=None})}  
Wait for child process to terminate. Set and return \texttt{returncode} attribute.

If the process does not terminate after \textit{timeout} seconds, raise a \texttt{TimeoutExpired} exception. It is safe to catch this exception and retry the wait.

\textbf{Note:} This will deadlock when using std\texttt{out}=PIPE or std\texttt{err}=PIPE and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use Popen.\texttt{communicate()} when using pipes to avoid that.

\textbf{Note:} The function is implemented using a busy loop (non-blocking call and short sleeps). Use the \texttt{asyncio} module for an asynchronous wait: see \texttt{asyncio.create_subprocess_exec}.

\textit{Changed in version 3.3:} \textit{timeout} was added.

Popen.\texttt{communicate(\textit{input=None}, \textit{timeout=None})}  
Interact with process: Send data to stdin. Read data from stdout
and stderr, until end-of-file is reached. Wait for process to terminate. The optional input argument should be data to be sent to the child process, or None, if no data should be sent to the child. If streams were opened in text mode, input must be a string. Otherwise, it must be bytes.

communicate() returns a tuple (stdout_data, stderr_data). The data will be strings if streams were opened in text mode; otherwise, bytes.

Note that if you want to send data to the process’s stdin, you need to create the Popen object with stdin=PIPE. Similarly, to get anything other than None in the result tuple, you need to give stdout=PIPE and/or stderr=PIPE too.

If the process does not terminate after timeout seconds, a TimeoutExpired exception will be raised. Catching this exception and retrying communication will not lose any output.

The child process is not killed if the timeout expires, so in order to cleanup properly a well-behaved application should kill the child process and finish communication:

```python
proc = subprocess.Popen(...)  
try:  
    outs, errs = proc.communicate(timeout=15)  
except TimeoutExpired:  
    proc.kill()  
    outs, errs = proc.communicate()
```

Note: The data read is buffered in memory, so do not use this method if the data size is large or unlimited.
Changed in version 3.3: timeout was added.

Popen. **send_signal**(signal)

Sends the signal `signal` to the child.

**Note:** On Windows, SIGTERM is an alias for `terminate()`. CTRL_C_EVENT and CTRL_BREAK_EVENT can be sent to processes started with a `creationflags` parameter which includes `CREATE_NEW_PROCESS_GROUP`.

Popen. **terminate()**

Stop the child. On Posix OSs the method sends SIGTERM to the child. On Windows the Win32 API function `TerminateProcess()` is called to stop the child.

Popen. **kill()**

Kills the child. On Posix OSs the function sends SIGKILL to the child. On Windows `kill()` is an alias for `terminate()`.

The following attributes are also available:

Popen. **args**

The `args` argument as it was passed to `Popen` – a sequence of program arguments or else a single string.

*New in version 3.3.*

Popen. **stdin**

If the `stdin` argument was `PIPE`, this attribute is a writeable stream object as returned by `open()`. If the `encoding` or `errors` arguments were specified or the `universal_newlines` argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the `stdin`
argument was not **PIPE**, this attribute is *None*.

**Popen. `stdout`**

If the `stdout` argument was **PIPE**, this attribute is a readable stream object as returned by `open()`. Reading from the stream provides output from the child process. If the `encoding` or `errors` arguments were specified or the `universal_newlines` argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the `stdout` argument was not **PIPE**, this attribute is *None*.

**Popen. `stderr`**

If the `stderr` argument was **PIPE**, this attribute is a readable stream object as returned by `open()`. Reading from the stream provides error output from the child process. If the `encoding` or `errors` arguments were specified or the `universal_newlines` argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the `stderr` argument was not **PIPE**, this attribute is *None*.

**Warning:** Use `communicate()` rather than `.stdin.write`, `.stdout.read` or `.stderr.read` to avoid deadlocks due to any of the other OS pipe buffers filling up and blocking the child process.

**Popen. `pid`**

The process ID of the child process.

Note that if you set the `shell` argument to `True`, this is the process ID of the spawned shell.

**Popen. `returncode`**

The child return code, set by `poll()` and `wait()` (and indirectly by `communicate()`). A *None* value indicates that the process hasn't terminated yet.
A negative value -N indicates that the child was terminated by signal N (POSIX only).
17.5.4. Windows Popen Helpers

The **STARTUPINFO** class and following constants are only available on Windows.

```python
class subprocess.STARTUPINFO(*, dwFlags=0, hStdInput=None, hStdOutput=None, hStdError=None, wShowWindow=0, lpAttributeList=None)
```

Partial support of the Windows **STARTUPINFO** structure is used for **Popen** creation. The following attributes can be set by passing them as keyword-only arguments.

*Changed in version 3.7:* Keyword-only argument support was added.

**dwFlags**

A bit field that determines whether certain **STARTUPINFO** attributes are used when the process creates a window.

```python
si = subprocess.STARTUPINFO()
si.dwFlags = subprocess.STARTF_USESTDHANDLES |
```

**hStdInput**

If **dwFlags** specifies **STARTF_USESTDHANDLES**, this attribute is the standard input handle for the process. If **STARTF_USESTDHANDLES** is not specified, the default for standard input is the keyboard buffer.

**hStdOutput**

If **dwFlags** specifies **STARTF_USESTDHANDLES**, this attribute is the standard output handle for the process. Otherwise, this
attribute is ignored and the default for standard output is the console window's buffer.

**hStdError**

If `dwFlags` specifies `STARTF_USESTDHANDLES`, this attribute is the standard error handle for the process. Otherwise, this attribute is ignored and the default for standard error is the console window's buffer.

**wShowWindow**

If `dwFlags` specifies `STARTF_USESHOWWINDOW`, this attribute can be any of the values that can be specified in the `nCmdShow` parameter for the `ShowWindow` function, except for `SW_SHOWDEFAULT`. Otherwise, this attribute is ignored.

`SW_HIDE` is provided for this attribute. It is used when `Popen` is called with `shell=True`.

**lpAttributeList**

A dictionary of additional attributes for process creation as given in `STARTUPINFOEX`, see `UpdateProcThreadAttribute`.

Supported attributes:

**handle_list**

Sequence of handles that will be inherited. `close_fds` must be true if non-empty.

The handles must be temporarily made inheritable by `os.set_handle_inheritable()` when passed to the `Popen` constructor, else `OSError` will be raised with Windows error `ERROR_INVALID_PARAMETER` (87).
Warning: In a multithreaded process, use caution to avoid leaking handles that are marked inheritable when combining this feature with concurrent calls to other process creation functions that inherit all handles such as `os.system()`. This also applies to standard handle redirection, which temporarily creates inheritable handles.

New in version 3.7.

17.5.4.1. Windows Constants

The `subprocess` module exposes the following constants.

**subprocess.** `STD_INPUT_HANDLE`

The standard input device. Initially, this is the console input buffer, `CONIN$`.

**subprocess.** `STD_OUTPUT_HANDLE`

The standard output device. Initially, this is the active console screen buffer, `CONOUT$`.

**subprocess.** `STD_ERROR_HANDLE`

The standard error device. Initially, this is the active console screen buffer, `CONOUT$`.

**subprocess.** `SW_HIDE`

Hides the window. Another window will be activated.

**subprocess.** `STARTF_USESTDHANDLES`

Specifies that the `STARTUPINFO.hStdInput`, `STARTUPINFO.hStdOutput`, and `STARTUPINFO.hStdError` attributes contain additional information.
subprocess. **STARTF_USESHOWWINDOW**

Specifies that the `STARTUPINFO.wShowWindow` attribute contains additional information.

subprocess. **CREATE_NEW_CONSOLE**

The new process has a new console, instead of inheriting its parent's console (the default).

subprocess. **CREATE_NEW_PROCESS_GROUP**

A `Popen` `creationflags` parameter to specify that a new process group will be created. This flag is necessary for using `os.kill()` on the subprocess.

This flag is ignored if **CREATE_NEW_CONSOLE** is specified.

subprocess. **ABOVE_NORMAL_PRIORITY_CLASS**

A `Popen` `creationflags` parameter to specify that a new process will have an above average priority.

*New in version 3.7.*

subprocess. **BELOW_NORMAL_PRIORITY_CLASS**

A `Popen` `creationflags` parameter to specify that a new process will have a below average priority.

*New in version 3.7.*

subprocess. **HIGH_PRIORITY_CLASS**

A `Popen` `creationflags` parameter to specify that a new process will have a high priority.

*New in version 3.7.*

subprocess. **IDLE_PRIORITY_CLASS**
A `Popen` `creationflags` parameter to specify that a new process will have an idle (lowest) priority.

*New in version 3.7.*

subprocess. `NORMAL_PRIORITY_CLASS`

A `Popen` `creationflags` parameter to specify that a new process will have an normal priority. (default)

*New in version 3.7.*

subprocess. `REALTIME_PRIORITY_CLASS`

A `Popen` `creationflags` parameter to specify that a new process will have realtime priority. You should almost never use `REALTIME_PRIORITY_CLASS`, because this interrupts system threads that manage mouse input, keyboard input, and background disk flushing. This class can be appropriate for applications that “talk” directly to hardware or that perform brief tasks that should have limited interruptions.

*New in version 3.7.*

subprocess. `CREATE_NO_WINDOW`

A `Popen` `creationflags` parameter to specify that a new process will not create a window

*New in version 3.7.*

subprocess. `DETACHED_PROCESS`

A `Popen` `creationflags` parameter to specify that a new process will not inherit its parent’s console. This value cannot be used with `CREATE_NEW_CONSOLE`.

*New in version 3.7.*
subprocess. **CREATE_DEFAULT_ERROR_MODE**

A `Popen` `creationflags` parameter to specify that a new process does not inherit the error mode of the calling process. Instead, the new process gets the default error mode. This feature is particularly useful for multithreaded shell applications that run with hard errors disabled.

*New in version 3.7.*

subprocess. **CREATE_BREAKAWAY_FROM_JOB**

A `Popen` `creationflags` parameter to specify that a new process is not associated with the job.

*New in version 3.7.*
17.5.5. Older high-level API

Prior to Python 3.5, these three functions comprised the high level API to subprocess. You can now use `run()` in many cases, but lots of existing code calls these functions.

```python
subprocess.call(args, *, stdin=None, stdout=None, stderr=None, shell=False, cwd=None, timeout=None)
```

Run the command described by `args`. Wait for command to complete, then return the `returncode` attribute.

This is equivalent to:

```python
run(...).returncode
```

(except that the `input` and `check` parameters are not supported)

The arguments shown above are merely the most common ones. The full function signature is largely the same as that of the `Popen` constructor - this function passes all supplied arguments other than `timeout` directly through to that interface.

**Note:** Do not use `stdout=PIPE` or `stderr=PIPE` with this function. The child process will block if it generates enough output to a pipe to fill up the OS pipe buffer as the pipes are not being read from.

*Changed in version 3.3: `timeout` was added.*

```python
subprocess.check_call(args, *, stdin=None, stdout=None, stderr=None, shell=False, cwd=None, timeout=None)
```

Run command with arguments. Wait for command to complete. If
the return code was zero then return, otherwise raise
\texttt{CalledProcessError}. The \texttt{CalledProcessError} object will
have the return code in the \texttt{returncode} attribute.

This is equivalent to:

\begin{verbatim}
run(..., check=True)
\end{verbatim}

(except that the \textit{input} parameter is not supported)

The arguments shown above are merely the most common ones.
The full function signature is largely the same as that of the \texttt{Popen}
constructor - this function passes all supplied arguments other than
\textit{timeout} directly through to that interface.

\textbf{Note:} Do not use \texttt{stdout=PIPE} or \texttt{stderr=PIPE} with this
function. The child process will block if it generates enough
output to a pipe to fill up the OS pipe buffer as the pipes are not
being read from.

\textit{Changed in version 3.3: timeout} was added.

\begin{verbatim}
subprocess.check_output(args, *, stdin=None, stderr=None,
shell=False, cwd=None, encoding=None, errors=None,
universal_newlines=False, timeout=None)
\end{verbatim}

Run command with arguments and return its output.

If the return code was non-zero it raises a
\texttt{CalledProcessError}. The \texttt{CalledProcessError} object will
have the return code in the \texttt{returncode} attribute and any output
in the \texttt{output} attribute.

This is equivalent to:
run(..., check=True, stdout=PIPE).stdout

The arguments shown above are merely the most common ones. The full function signature is largely the same as that of run() - most arguments are passed directly through to that interface. However, explicitly passing input=None to inherit the parent's standard input file handle is not supported.

By default, this function will return the data as encoded bytes. The actual encoding of the output data may depend on the command being invoked, so the decoding to text will often need to be handled at the application level.

This behaviour may be overridden by setting universal_newlines to True as described above in Frequently Used Arguments.

To also capture standard error in the result, use stderr=subprocess.STDOUT:

```python
>>> subprocess.check_output(
...     "ls non_existent_file; exit 0",
...     stderr=subprocess.STDOUT,
...     shell=True)
'ls: non_existent_file: No such file or directory'
```

New in version 3.1.

Changed in version 3.3: timeout was added.

Changed in version 3.4: Support for the input keyword argument was added.
17.5.6. Replacing Older Functions with the subprocess Module

In this section, “a becomes b” means that b can be used as a replacement for a.

**Note:** All “a” functions in this section fail (more or less) silently if the executed program cannot be found; the “b” replacements raise OSError instead.

In addition, the replacements using `check_output()` will fail with a CalledProcessError if the requested operation produces a non-zero return code. The output is still available as the output attribute of the raised exception.

In the following examples, we assume that the relevant functions have already been imported from the subprocess module.

### 17.5.6.1. Replacing /bin/sh shell backquote

```python
output=`mycmd myarg`
```

becomes:

```python
output = check_output(["mycmd", "myarg"])
```

### 17.5.6.2. Replacing shell pipeline

```python
output=`dmesg | grep hda`
```
becomes:

```python
def main():
    p1 = Popen(['dmesg'], stdout=PIPE)
    p2 = Popen(['grep', 'hda'], stdin=p1.stdout, stdout=p1.stdout)
    p1.stdout.close()  # Allow p1 to receive a SIGPIPE if p2 exits
    output = p2.communicate()[0]
```

The `p1.stdout.close()` call after starting the `p2` is important in order for `p1` to receive a SIGPIPE if `p2` exits before `p1`.

Alternatively, for trusted input, the shell's own pipeline support may still be used directly:

```bash
output='dmesg | grep hda'
```

becomes:

```bash
output=check_output('dmesg | grep hda', shell=True)
```

### 17.5.6.3. Replacing `os.system()`

```python
sts = os.system('mycmd "myarg"
# becomes
sts = call('mycmd "myarg", shell=True)
```

Notes:

- Calling the program through the shell is usually not required.

A more realistic example would look like this:

```python
try:
    retcode = call('mycmd "myarg", shell=True)
if retcode < 0:
```
print("Child was terminated by signal", -retcode)
else:
    print("Child returned", retcode, file=sys.stderr)
except OSError as e:
    print("Execution failed:", e, file=sys.stderr)

17.5.6.4. Replacing the os.spawn family

P_NOWAIT example:

```python
pid = os.spawnlp(os.P_NOWAIT, "/bin/mycmd", "mycmd",
==>
pid = Popen(["/bin/mycmd", "myarg"]).pid
```

P_WAIT example:

```python
retcode = os.spawnlpe(os.P_NOWAIT, "/bin/mycmd", "mycmd",
==>
retcode = call(["/bin/mycmd", "myarg"])
```

Vector example:

```python
os.spawnvp(os.P_NOWAIT, path, args)
==>
Popen([path] + args[1:])
```

Environment example:

```python
os.spawnlpe(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg",
==>
Popen(["/bin/mycmd", "myarg"], env={"PATH": "/usr/bin"})
```
17.5.6.5. Replacing `os.popen()`, `os.popen2()`, `os.popen3()`

```

(child_stdin, child_stdout) = os.popen2(cmd, mode, bufsize)

p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)

(child_stdin, child_stdout) = (p.stdin, p.stdout)
```

```

(child_stdin, child_stdout, child_stderr) = os.popen3(cmd, mode, bufsize)

p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=PIPE, close_fds=True)

(child_stdin, child_stdout, child_stderr) = (p.stdin, p.stdout, p.stderr)
```

```

(child_stdin, child_stdout_and_stderr) = os.popen4(cmd)

p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=STDOUT, close_fds=True)

(child_stdin, child_stdout_and_stderr) = (p.stdin, p.stdout)
```

Return code handling translates as follows:

```
pipe = os.popen(cmd, 'w')
...
rc = pipe.close()
if rc is not None and rc >> 8:
    print("There were some errors")
```
process = Popen(cmd, stdin=PIPE)
...
process.stdin.close()
if process.wait() != 0:
    print("There were some errors")

17.5.6.6. Replacing functions from the popen2 module

**Note:** If the cmd argument to popen2 functions is a string, the command is executed through /bin/sh. If it is a list, the command is directly executed.

```python
(child_stdout, child_stdin) = popen2.popen2("somestring")
p = Popen("somestring", shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```

```
(child_stdout, child_stdin) = popen2.popen2("mycmd")
p = Popen(["mycmd", "myarg"], bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```

*popen2.Popen3* and *popen2.Popen4* basically work as *subprocess.Popen*, except that:

- *Popen* raises an exception if the execution fails.
- the *capturestderr* argument is replaced with the *stderr* argument.
- *stdin=PIPE* and *stdout=PIPE* must be specified.
- popen2 closes all file descriptors by default, but you have to specify `close_fds=True` with `Popen` to guarantee this behavior on all platforms or past Python versions.
17.5.7. Legacy Shell Invocation Functions

This module also provides the following legacy functions from the 2.x commands module. These operations implicitly invoke the system shell and none of the guarantees described above regarding security and exception handling consistency are valid for these functions.

subprocess.getstatusoutput(cmd)

Return (exitcode, output) of executing cmd in a shell.

Execute the string cmd in a shell with Popen.check_output() and return a 2-tuple (exitcode, output). The locale encoding is used; see the notes on Frequently Used Arguments for more details.

A trailing newline is stripped from the output. The exit code for the command can be interpreted as the return code of subprocess. Example:

```python
>>> subprocess.getstatusoutput('ls /bin/ls')
(0, '/bin/ls')
>>> subprocess.getstatusoutput('cat /bin/junk')
(1, 'cat: /bin/junk: No such file or directory')
>>> subprocess.getstatusoutput('/bin/junk')
(127, 'sh: /bin/junk: not found')
>>> subprocess.getstatusoutput('/bin/kill $$')
(-15, '')
```

Availability: POSIX & Windows

Changed in version 3.3.4: Windows support was added.

The function now returns (exitcode, output) instead of (status,
output) as it did in Python 3.3.3 and earlier. See WEXITSTATUS().

subprocess.getoutput(cmd)
Return output (stdout and stderr) of executing cmd in a shell.

Like getstatusoutput(), except the exit status is ignored and
the return value is a string containing the command’s output.
Example:

```python
>>> subprocess.getoutput('ls /bin/ls')
'/bin/ls'
```

Availability: POSIX & Windows

Changed in version 3.3.4: Windows support added
17.5.8. Notes

17.5.8.1. Converting an argument sequence to a string on Windows

On Windows, an args sequence is converted to a string that can be parsed using the following rules (which correspond to the rules used by the MS C runtime):

1. Arguments are delimited by white space, which is either a space or a tab.
2. A string surrounded by double quotation marks is interpreted as a single argument, regardless of white space contained within. A quoted string can be embedded in an argument.
3. A double quotation mark preceded by a backslash is interpreted as a literal double quotation mark.
4. Backslashes are interpreted literally, unless they immediately precede a double quotation mark.
5. If backslashes immediately precede a double quotation mark, every pair of backslashes is interpreted as a literal backslash. If the number of backslashes is odd, the last backslash escapes the next double quotation mark as described in rule 3.

See also:

shlex

Module which provides function to parse and escape command lines.
The `sched` module defines a class which implements a general purpose event scheduler:

```python
class sched.scheduler(timefunc=time.monotonic, delayfunc=time.sleep)
```

The `scheduler` class defines a generic interface to scheduling events. It needs two functions to actually deal with the “outside world” — `timefunc` should be callable without arguments, and return a number (the “time”, in any units whatsoever). If `time.monotonic` is not available, the `timefunc` default is `time.time` instead. The `delayfunc` function should be callable with one argument, compatible with the output of `timefunc`, and should delay that many time units. `delayfunc` will also be called with the argument 0 after each event is run to allow other threads an opportunity to run in multi-threaded applications.

*Changed in version 3.3:* `timefunc` and `delayfunc` parameters are optional.

*Changed in version 3.3:* `scheduler` class can be safely used in multi-threaded environments.

Example:

```python
>>> import sched, time
>>> s = sched.scheduler(time.time, time.sleep)
>>> def print_time(a='default'):
```
...    print("From print_time", time.time(), a)
...

>>> def print_some_times():
...    print(time.time())
...    s.enter(10, 1, print_time)
...    s.enter(5, 2, print_time, argument=('positional'))
...    s.enter(5, 1, print_time, kwargs={'a': 'keyword'})
...    s.run()
...    print(time.time())
...

>>> print_some_times()
930343690.257
From print_time 930343695.274 positional
From print_time 930343695.275 keyword
From print_time 930343700.273 default
930343700.276
17.6.1. Scheduler Objects

`scheduler` instances have the following methods and attributes:

`scheduler.enterabs(time, priority, action, argument=(), kwargs={})`

Schedule a new event. The `time` argument should be a numeric type compatible with the return value of the `timefunc` function passed to the constructor. Events scheduled for the same `time` will be executed in the order of their `priority`. A lower number represents a higher priority.

Executing the event means executing `action(*argument, **kwargs)`. `argument` is a sequence holding the positional arguments for `action`. `kwargs` is a dictionary holding the keyword arguments for `action`.

Return value is an event which may be used for later cancellation of the event (see `cancel()`).

StateChanged in version 3.3: `argument` parameter is optional.

New in version 3.3: `kwargs` parameter was added.

`scheduler.enter(delay, priority, action, argument=(), kwargs={})`

Schedule an event for `delay` more time units. Other than the relative time, the other arguments, the effect and the return value are the same as those for `enterabs()`.

StateChanged in version 3.3: `argument` parameter is optional.

New in version 3.3: `kwargs` parameter was added.
scheduler. **cancel**(event)

Remove the event from the queue. If *event* is not an event currently in the queue, this method will raise a **ValueError**.

scheduler. **empty**( )

Return true if the event queue is empty.

scheduler. **run**( blocking=True )

Run all scheduled events. This method will wait (using the `delayfunc()` function passed to the constructor) for the next event, then execute it and so on until there are no more scheduled events.

If *blocking* is false executes the scheduled events due to expire soonest (if any) and then return the deadline of the next scheduled call in the scheduler (if any).

Either *action* or *delayfunc* can raise an exception. In either case, the scheduler will maintain a consistent state and propagate the exception. If an exception is raised by *action*, the event will not be attempted in future calls to **run**( ).

If a sequence of events takes longer to run than the time available before the next event, the scheduler will simply fall behind. No events will be dropped; the calling code is responsible for canceling events which are no longer pertinent.

*New in version 3.3:* *blocking* parameter was added.

scheduler. **queue**( )

Read-only attribute returning a list of upcoming events in the order they will be run. Each event is shown as a **named tuple** with the following fields: time, priority, action, argument, kwargs.
The `queue` module implements multi-producer, multi-consumer queues. It is especially useful in threaded programming when information must be exchanged safely between multiple threads. The `Queue` class in this module implements all the required locking semantics. It depends on the availability of thread support in Python; see the `threading` module.

The module implements three types of queue, which differ only in the order in which the entries are retrieved. In a FIFO queue, the first tasks added are the first retrieved. In a LIFO queue, the most recently added entry is the first retrieved (operating like a stack). With a priority queue, the entries are kept sorted (using the `heapq` module) and the lowest valued entry is retrieved first.

Internally, those three types of queues use locks to temporarily block competing threads; however, they are not designed to handle reentrancy within a thread.

In addition, the module implements a “simple” FIFO queue type where specific implementations can provide additional guarantees in exchange for the smaller functionality.

The `queue` module defines the following classes and exceptions:

```python
class queue.Queue(maxsize=0)
```
Constructor for a **FIFO** queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

```python
class queue.LifoQueue(maxsize=0)
```

Constructor for a **LIFO** queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

```python
class queue.PriorityQueue(maxsize=0)
```

Constructor for a priority queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

The lowest valued entries are retrieved first (the lowest valued entry is the one returned by `sorted(list(entries))[0]`). A typical pattern for entries is a tuple in the form: `(priority_number, data)`.

If the *data* elements are not comparable, the data can be wrapped in a class that ignores the data item and only compares the priority number:

```python
from dataclasses import dataclass, field
from typing import Any

@dataclass(order=True)
```
**class** PrioritizedItem:
```python
    priority: int
    item: Any=field(compare=False)
```

**class** queue. SimpleQueue

Constructor for an unbounded FIFO queue. Simple queues lack advanced functionality such as task tracking.

*New in version 3.7.*

**exception** queue. Empty

Exception raised when non-blocking get() (or get_nowait()) is called on a Queue object which is empty.

**exception** queue. Full

Exception raised when non-blocking put() (or put_nowait()) is called on a Queue object which is full.
17.7.1. Queue Objects

Queue objects (Queue, LifoQueue, or PriorityQueue) provide the public methods described below.

Queue.qsize()
Return the approximate size of the queue. Note, qsize() > 0 doesn’t guarantee that a subsequent get() will not block, nor will qsize() < maxsize guarantee that put() will not block.

Queue.empty()
Return True if the queue is empty, False otherwise. If empty() returns True it doesn’t guarantee that a subsequent call to put() will not block. Similarly, if empty() returns False it doesn’t guarantee that a subsequent call to get() will not block.

Queue.full()
Return True if the queue is full, False otherwise. If full() returns True it doesn’t guarantee that a subsequent call to get() will not block. Similarly, if full() returns False it doesn’t guarantee that a subsequent call to put() will not block.

Queue.put(item, block=True, timeout=None)
Put item into the queue. If optional args block is true and timeout is None (the default), block if necessary until a free slot is available. If timeout is a positive number, it blocks at most timeout seconds and raises the Full exception if no free slot was available within that time. Otherwise (block is false), put an item on the queue if a free slot is immediately available, else raise the Full exception (timeout is ignored in that case).
Queue. **put_nowait**(item)
   Equivalent to put(item, False).

Queue. **get**(block=True, timeout=None)
   Remove and return an item from the queue. If optional args block is true and timeout is None (the default), block if necessary until an item is available. If timeout is a positive number, it blocks at most timeout seconds and raises the **Empty** exception if no item was available within that time. Otherwise (block is false), return an item if one is immediately available, else raise the **Empty** exception (timeout is ignored in that case).

Queue. **get_nowait**()
   Equivalent to get(False).

Two methods are offered to support tracking whether enqueued tasks have been fully processed by daemon consumer threads.

Queue. **task_done**()
   Indicate that a formerly enqueued task is complete. Used by queue consumer threads. For each get() used to fetch a task, a subsequent call to task_done() tells the queue that the processing on the task is complete.

   If a **join**() is currently blocking, it will resume when all items have been processed (meaning that a task_done() call was received for every item that had been put() into the queue).

   Raises a **ValueError** if called more times than there were items placed in the queue.

Queue. **join**()
Blocks until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls task_done() to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, join() unblocks.

Example of how to wait for enqueued tasks to be completed:

```python
def worker():
    while True:
        item = q.get()
        if item is None:
            break
        do_work(item)
        q.task_done()

q = queue.Queue()
threads = []
for i in range(num_worker_threads):
    t = threading.Thread(target=worker)
    t.start()
    threads.append(t)

for item in source():
    q.put(item)

    # block until all tasks are done
    q.join()

    # stop workers
    for i in range(num_worker_threads):
        q.put(None)
    for t in threads:
```
t.join()
17.7.2. SimpleQueue Objects

SimpleQueue objects provide the public methods described below.

SimpleQueue. `qsize()`

Return the approximate size of the queue. Note, qsize() > 0 doesn’t guarantee that a subsequent get() will not block.

SimpleQueue. `empty()`

Return True if the queue is empty, False otherwise. If empty() returns False it doesn’t guarantee that a subsequent call to get() will not block.

SimpleQueue. `put(item, block=True, timeout=None)`

Put item into the queue. The method never blocks and always succeeds (except for potential low-level errors such as failure to allocate memory). The optional args block and timeout are ignored and only provided for compatibility with Queue.put().

**CPython implementation detail:** This method has a C implementation which is reentrant. That is, a put() or get() call can be interrupted by another put() call in the same thread without deadlocking or corrupting internal state inside the queue. This makes it appropriate for use in destructors such as `__del__` methods or weakref callbacks.

SimpleQueue. `put_nowait(item)`

Equivalent to put(item), provided for compatibility with Queue.put_nowait().

SimpleQueue. `get(block=True, timeout=None)`
Remove and return an item from the queue. If optional args `block` is true and `timeout` is `None` (the default), block if necessary until an item is available. If `timeout` is a positive number, it blocks at most `timeout` seconds and raises the `Empty` exception if no item was available within that time. Otherwise (`block` is false), return an item if one is immediately available, else raise the `Empty` exception (`timeout` is ignored in that case).

**SimpleQueue**. `get_nowait()`

Equivalent to `get(False)`.

**See also:**

**Class** `multiprocessing.Queue`

A queue class for use in a multi-processing (rather than multi-threading) context.

**collections.deque** is an alternative implementation of unbounded queues with fast atomic `append()` and `popleft()` operations that do not require locking.
17.8. _thread — Low-level threading API

This module provides low-level primitives for working with multiple threads (also called light-weight processes or tasks) — multiple threads of control sharing their global data space. For synchronization, simple locks (also called mutexes or binary semaphores) are provided. The `threading` module provides an easier to use and higher-level threading API built on top of this module.

*Changed in version 3.7:* This module used to be optional, it is now always available.

This module defines the following constants and functions:

**exception** _thread.error

Raised on thread-specific errors.

*Changed in version 3.3:* This is now a synonym of the built-in `RuntimeError`.

**_thread.LockType**

This is the type of lock objects.

**_thread.start_new_thread(function, args[, kwargs])**

Start a new thread and return its identifier. The thread executes the function `function` with the argument list `args` (which must be a tuple). The optional `kwargs` argument specifies a dictionary of keyword arguments. When the function returns, the thread silently exits. When the function terminates with an unhandled exception, a
stack trace is printed and then the thread exits (but other threads continue to run).

_thread.interrupt_main()
Raise a KeyboardInterrupt exception in the main thread. A subthread can use this function to interrupt the main thread.

_thread.exit()
Raise the SystemExit exception. When not caught, this will cause the thread to exit silently.

_thread.allocate_lock()
Return a new lock object. Methods of locks are described below. The lock is initially unlocked.

_thread.get_ident()
Return the ‘thread identifier’ of the current thread. This is a nonzero integer. Its value has no direct meaning; it is intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

_thread.stack_size([size])
Return the thread stack size used when creating new threads. The optional size argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If size is not specified, 0 is used. If changing the thread stack size is unsupported, a RuntimeException is raised. If the specified stack size is invalid, a ValueError is raised and the stack size is unmodified. 32 KiB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself.
Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32 KiB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4 KiB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information). Availability: Windows, systems with POSIX threads.

_thread.TIMEOUT_MAX

The maximum value allowed for the timeout parameter of Lock.acquire(). Specifying a timeout greater than this value will raise an OverflowError.

New in version 3.2.

Lock objects have the following methods:

lock.acquire(waitflag=1, timeout=-1)

Without any optional argument, this method acquires the lock unconditionally, if necessary waiting until it is released by another thread (only one thread at a time can acquire a lock — that's their reason for existence).

If the integer waitflag argument is present, the action depends on its value: if it is zero, the lock is only acquired if it can be acquired immediately without waiting, while if it is nonzero, the lock is acquired unconditionally as above.

If the floating-point timeout argument is present and positive, it specifies the maximum wait time in seconds before returning. A negative timeout argument specifies an unbounded wait. You cannot specify a timeout if waitflag is zero.
The return value is **True** if the lock is acquired successfully, **False** if not.

*Changed in version 3.2*: The **timeout** parameter is new.

*Changed in version 3.2*: Lock acquires can now be interrupted by signals on POSIX.

```python
lock.release()
```

Releases the lock. The lock must have been acquired earlier, but not necessarily by the same thread.

```python
lock.locked()
```

Return the status of the lock: **True** if it has been acquired by some thread, **False** if not.

In addition to these methods, lock objects can also be used via the **with** statement, e.g.:

```python
import _thread

a_lock = _thread.allocate_lock()

with a_lock:
    print("a_lock is locked while this executes")
```

**Caveats:**

- Threads interact strangely with interrupts: the **KeyboardInterrupt** exception will be received by an arbitrary thread. (When the **signal** module is available, interrupts always go to the main thread.)
- Calling **sys.exit()** or raising the **SystemExit** exception is equivalent to calling **_thread.exit()**.
• It is not possible to interrupt the acquire() method on a lock — the `KeyboardInterrupt` exception will happen after the lock has been acquired.

• When the main thread exits, it is system defined whether the other threads survive. On most systems, they are killed without executing `try ... finally` clauses or executing object destructors.

• When the main thread exits, it does not do any of its usual cleanup (except that `try ... finally` clauses are honored), and the standard I/O files are not flushed.
17.9. _dummy_thread — Drop-in replacement for the _thread module

Source code: Lib/_dummy_thread.py

*Deprecated since version 3.7:* Python now always has threading enabled. Please use _thread (or, better, threading) instead.

This module provides a duplicate interface to the _thread module. It was meant to be imported when the _thread module was not provided on a platform.

Be careful to not use this module where deadlock might occur from a thread being created that blocks waiting for another thread to be created. This often occurs with blocking I/O.
17.10. **dummy_threading** — Drop-in replacement for the **threading** module

**Source code:** Lib/dummy_threading.py

*Deprecated since version 3.7:* Python now always has threading enabled. Please use **threading** instead.

This module provides a duplicate interface to the **threading** module. It was meant to be imported when the **_thread** module was not provided on a platform.

Be careful to not use this module where deadlock might occur from a thread being created that blocks waiting for another thread to be created. This often occurs with blocking I/O.
18. Interprocess Communication and Networking

The modules described in this chapter provide mechanisms for different processes to communicate.

Some modules only work for two processes that are on the same machine, e.g. `signal` and `mmap`. Other modules support networking protocols that two or more processes can use to communicate across machines.

The list of modules described in this chapter is:

- **18.1. socket — Low-level networking interface**
  - 18.1.1. Socket families
  - 18.1.2. Module contents
    - 18.1.2.1. Exceptions
    - 18.1.2.2. Constants
    - 18.1.2.3. Functions
      - 18.1.2.3.1. Creating sockets
      - 18.1.2.3.2. Other functions
  - 18.1.3. Socket Objects
  - 18.1.4. Notes on socket timeouts

18.9. mmap — Memory-mapped file support
18.1. **socket** — Low-level networking interface

**Source code:** [Lib/socket.py](https://example.com)

This module provides access to the BSD `socket` interface. It is available on all modern Unix systems, Windows, MacOS, and probably additional platforms.

**Note:** Some behavior may be platform dependent, since calls are made to the operating system socket APIs.

The Python interface is a straightforward transliteration of the Unix system call and library interface for sockets to Python’s object-oriented style: the `socket()` function returns a *socket object* whose methods implement the various socket system calls. Parameter types are somewhat higher-level than in the C interface: as with `read()` and `write()` operations on Python files, buffer allocation on receive operations is automatic, and buffer length is implicit on send operations.

**See also:**

**Module** `socketserver`

Classes that simplify writing network servers.

**Module** `ssl`

A TLS/SSL wrapper for socket objects.
18.1.1. Socket families

Depending on the system and the build options, various socket families are supported by this module.

The address format required by a particular socket object is automatically selected based on the address family specified when the socket object was created. Socket addresses are represented as follows:

- The address of an AF_UNIX socket bound to a file system node is represented as a string, using the file system encoding and the 'surrogateescape' error handler (see PEP 383). An address in Linux's abstract namespace is returned as a bytes-like object with an initial null byte; note that sockets in this namespace can communicate with normal file system sockets, so programs intended to run on Linux may need to deal with both types of address. A string or bytes-like object can be used for either type of address when passing it as an argument.

  *Changed in version 3.3:* Previously, AF_UNIX socket paths were assumed to use UTF-8 encoding.

  *Changed in version 3.5:* Writable bytes-like object is now accepted.

- A pair (host, port) is used for the AF_INET address family, where host is a string representing either a hostname in Internet domain notation like 'daring.cwi.nl' or an IPv4 address like '100.50.200.5', and port is an integer.

- For AF_INET6 address family, a four-tuple (host, port,
flowinfo, scopeid) is used, where flowinfo and scopeid represent the sin6_flowinfo and sin6_scope_id members in struct sockaddr_in6 in C. For socket module methods, flowinfo and scopeid can be omitted just for backward compatibility. Note, however, omission of scopeid can cause problems in manipulating scoped IPv6 addresses.

- AF_NETLINK sockets are represented as pairs (pid, groups).

- Linux-only support for TIPC is available using the AF_TIPC address family. TIPC is an open, non-IP based networked protocol designed for use in clustered computer environments. Addresses are represented by a tuple, and the fields depend on the address type. The general tuple form is (addr_type, v1, v2, v3 [, scope]), where:
  - addr_type is one of TIPC_ADDR_NAMESEQ, TIPC_ADDR_NAME, or TIPC_ADDR_ID.
  - scope is one of TIPC_ZONE_SCOPE, TIPC_CLUSTER_SCOPE, and TIPC_NODE_SCOPE.
  - If addr_type is TIPC_ADDR_NAME, then v1 is the server type, v2 is the port identifier, and v3 should be 0.
  - If addr_type is TIPC_ADDR_NAMESEQ, then v1 is the server type, v2 is the lower port number, and v3 is the upper port number.
  - If addr_type is TIPC_ADDR_ID, then v1 is the node, v2 is the reference, and v3 should be set to 0.
- A tuple \((\text{interface, } \_\_)\) is used for the \texttt{AF\_CAN} address family, where \textit{interface} is a string representing a network interface name like 'can0'. The network interface name '' can be used to receive packets from all network interfaces of this family.

  - \texttt{CAN\_ISOTP} protocol requires a tuple \((\text{interface, rx_addr, tx_addr})\) where both additional parameters are unsigned long integer that represent a CAN identifier (standard or extended).

- A string or a tuple \((\text{id, unit})\) is used for the \texttt{SYSPROTO\_CONTROL} protocol of the \texttt{PF\_SYSTEM} family. The string is the name of a kernel control using a dynamically-assigned ID. The tuple can be used if ID and unit number of the kernel control are known or if a registered ID is used.

  \textit{New in version 3.3.}

- \texttt{AF\_BLUETOOTH} supports the following protocols and address formats:

  - \texttt{BTPROTO\_L2CAP} accepts \((\text{bdaddr, psm})\) where \texttt{bdaddr} is the Bluetooth address as a string and \texttt{psm} is an integer.

  - \texttt{BTPROTO\_RFCOMM} accepts \((\text{bdaddr, channel})\) where \texttt{bdaddr} is the Bluetooth address as a string and \texttt{channel} is an integer.

  - \texttt{BTPROTO\_HCI} accepts \((\text{device_id,})\) where \texttt{device_id} is either an integer or a string with the Bluetooth address of the interface. (This depends on your OS; NetBSD and DragonFlyBSD expect a Bluetooth address while everything else expects an integer.)
Changed in version 3.2: NetBSD and DragonFlyBSD support added.

- BTPROTO SCO accepts bdaddr where bdaddr is a bytes object containing the Bluetooth address in a string format. (ex. b'12:23:34:45:56:67') This protocol is not supported under FreeBSD.

- **AF_ALG** is a Linux-only socket based interface to Kernel cryptography. An algorithm socket is configured with a tuple of two to four elements (type, name [, feat [, mask]]), where:

  - **type** is the algorithm type as string, e.g. aead, hash, skcipher or rng.
  - **name** is the algorithm name and operation mode as string, e.g. sha256, hmac(sha256), cbc(aes) or drbg_nopr_ctr_aes256.
  - **feat** and **mask** are unsigned 32bit integers.

Availability Linux 2.6.38, some algorithm types require more recent Kernels.

New in version 3.6.

- **AF_VSOCK** allows communication between virtual machines and their hosts. The sockets are represented as a (CID, port) tuple where the context ID or CID and port are integers.

  Availability: Linux >= 4.8 QEMU >= 2.8 ESX >= 4.0 ESX Workstation >= 6.5

New in version 3.7.

- Certain other address families (AF_PACKET, AF_CAN) support
specific representations.

For IPv4 addresses, two special forms are accepted instead of a host address: the empty string represents INADDR_ANY, and the string '<broadcast>' represents INADDR_BROADCAST. This behavior is not compatible with IPv6, therefore, you may want to avoid these if you intend to support IPv6 with your Python programs.

If you use a hostname in the host portion of IPv4/v6 socket address, the program may show a nondeterministic behavior, as Python uses the first address returned from the DNS resolution. The socket address will be resolved differently into an actual IPv4/v6 address, depending on the results from DNS resolution and/or the host configuration. For deterministic behavior use a numeric address in host portion.

All errors raise exceptions. The normal exceptions for invalid argument types and out-of-memory conditions can be raised; starting from Python 3.3, errors related to socket or address semantics raise OSError or one of its subclasses (they used to raise socket.error).

Non-blocking mode is supported through setblocking(). A generalization of this based on timeouts is supported through settimeout().
18.1.2. Module contents

The module `socket` exports the following elements.

18.1.2.1. Exceptions

`exception socket.error`

A deprecated alias of `OSError`.

*Changed in version 3.3:* Following [PEP 3151](https://www.python.org/dev/peps/pep-03151/), this class was made an alias of `OSError`.

`exception socket.herror`

A subclass of `OSError`, this exception is raised for address-related errors, i.e. for functions that use `h_errno` in the POSIX C API, including `gethostbyname_ex()` and `gethostbyaddr()`. The accompanying value is a pair `(h_errno, string)` representing an error returned by a library call. `h_errno` is a numeric value, while `string` represents the description of `h_errno`, as returned by the `hstrerror()` C function.

*Changed in version 3.3:* This class was made a subclass of `OSError`.

`exception socket.gaierror`

A subclass of `OSError`, this exception is raised for address-related errors by `getaddrinfo()` and `getnameinfo()`. The accompanying value is a pair `(error, string)` representing an error returned by a library call. `string` represents the description of `error`, as returned by the `gai_strerror()` C function. The numeric `error` value will match one of the EAI_* constants defined
in this module.

*Changed in version 3.3:* This class was made a subclass of OSError.

**exception** `socket.timeout`

A subclass of OSError, this exception is raised when a timeout occurs on a socket which has had timeouts enabled via a prior call to `settimeout()` (or implicitly through `setdefaulttimeout()`). The accompanying value is a string whose value is currently always “timed out”.

*Changed in version 3.3:* This class was made a subclass of OSError.

### 18.1.2.2. Constants

The AF_* and SOCK_* constants are now AddressFamily and SocketKind IntEnum collections.

*New in version 3.4.*

- `socket.AF_UNIX`
- `socket.AF_INET`
- `socket.AF_INET6`

These constants represent the address (and protocol) families, used for the first argument to `socket()`. If the AF_UNIX constant is not defined then this protocol is unsupported. More constants may be available depending on the system.

- `socket.SOCK_STREAM`
- `socket.SOCK_DGRAM`
- `socket.SOCK_RAW`
socket. **SOCK_RDM**  
socket. **SOCK_SEQPACKET**  
These constants represent the socket types, used for the second argument to `socket()`. More constants may be available depending on the system. (Only **SOCK_STREAM** and **SOCK_DGRAM** appear to be generally useful.)

socket. **SOCK_CLOEXEC**  
socket. **SOCK_NONBLOCK**  
These two constants, if defined, can be combined with the socket types and allow you to set some flags atomically (thus avoiding possible race conditions and the need for separate calls).

**See also:** Secure File Descriptor Handling for a more thorough explanation.

Availability: Linux >= 2.6.27.

*New in version 3.2.*

**SO_**
socket. **SOMAXCONN**
**MSG_**
**SOL_**
**SCM_**
**IPPROTO_**
**IPPORT_**
**INADDR_**
**IP_**
**IPV6_**
**EAI_**
**AI_**
**NI_**
TCP_*

Many constants of these forms, documented in the Unix documentation on sockets and/or the IP protocol, are also defined in the socket module. They are generally used in arguments to the setsockopt() and getsockopt() methods of socket objects. In most cases, only those symbols that are defined in the Unix header files are defined; for a few symbols, default values are provided.

* Changed in version 3.6: SO_DOMAIN, SO_PROTOCOL, SO_PEERSEC, SO_PASSSEC, TCP_USER_TIMEOUT, TCP_CONGESTION were added.

* Changed in version 3.7: TCP_NOTSENT_LOWAT was added.

socket.AF_CAN
socket.PF_CAN
SOL_CAN_*
CAN_*

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.6.25.

* New in version 3.3.

socket.CAN_BCM
CAN_BCM_*

CAN_BCM, in the CAN protocol family, is the broadcast manager (BCM) protocol. Broadcast manager constants, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.6.25.
New in version 3.4.

socket. **CAN_RAW_FD_FRAMES**

Enables CAN FD support in a CAN_RAW socket. This is disabled by default. This allows your application to send both CAN and CAN FD frames; however, you must accept both CAN and CAN FD frames when reading from the socket.

This constant is documented in the Linux documentation.

Availability: Linux >= 3.6.

New in version 3.5.

socket. **CAN_ISOTP**

CAN_ISOTP, in the CAN protocol family, is the ISO-TP (ISO 15765-2) protocol. ISO-TP constants, documented in the Linux documentation.

Availability: Linux >= 2.6.25

New in version 3.7.

socket. **AF_RDS**
socket. **PF_RDS**
socket. **SOL_RDS**
**RDS_***

Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

Availability: Linux >= 2.6.30.

New in version 3.3.

socket. **SIO_RCVALL**
socket.SIO_KEEPALIVE_VALS
socket.SIO_LOOPBACK_FAST_PATH
RCVALL_*
  Constants for Windows’ WSAIoctl(). The constants are used as arguments to the ioctl() method of socket objects.

  Changed in version 3.6: SIO_LOOPBACK_FAST_PATH was added.

TIPC_*
  TIPC related constants, matching the ones exported by the C socket API. See the TIPC documentation for more information.

socket.AF_ALG
socket.SOL_ALG
ALG_*
  Constants for Linux Kernel cryptography.

  Availability: Linux >= 2.6.38.

    New in version 3.6.

socket.AF_VSOCK
socket.IOCTL_VM_SOCKETS_GET_LOCAL_CID
VMADDR*
SO_VM*
  Constants for Linux host/guest communication.

  Availability: Linux >= 4.8.

    New in version 3.7.

socket.AF_LINK
  Availability: BSD, OSX.
New in version 3.4.

socket.\texttt{has\_ipv6}

This constant contains a boolean value which indicates if IPv6 is supported on this platform.

socket.\texttt{BDADDR\_ANY}
socket.\texttt{BDADDR\_LOCAL}

These are string constants containing Bluetooth addresses with special meanings. For example, \texttt{BDADDR\_ANY} can be used to indicate any address when specifying the binding socket with BTPROTO\_RFCOMM.

socket.\texttt{HCI\_FILTER}
socket.\texttt{HCI\_TIME\_STAMP}
socket.\texttt{HCI\_DATA\_DIR}

For use with BTPROTO\_HCI. \texttt{HCI\_FILTER} is not available for NetBSD or DragonFlyBSD. \texttt{HCI\_TIME\_STAMP} and \texttt{HCI\_DATA\_DIR} are not available for FreeBSD, NetBSD, or DragonFlyBSD.

18.1.2.3. Functions

18.1.2.3.1. Creating sockets

The following functions all create socket objects.

socket.\texttt{socket}(family=AF\_INET, type=SOCK\_STREAM, proto=0, fileno=None)

Create a new socket using the given address family, socket type and protocol number. The address family should be AF\_INET (the default), AF\_INET6, AF\_UNIX, AF\_CAN or AF\_RDS. The socket
type should be **SOCK_STREAM** (the default), **SOCK_DGRAM**, **SOCK_RAW** or perhaps one of the other **SOCK_** constants. The protocol number is usually zero and may be omitted or in the case where the address family is **AF_CAN** the protocol should be one of **CAN_RAW**, **CAN_BCM** or **CAN_ISO**

If *fileno* is specified, the values for *family*, *type*, and *proto* are auto-detected from the specified file descriptor. Auto-detection can be overruled by calling the function with explicit *family*, *type*, or *proto* arguments. This only affects how Python represents e.g. the return value of `socket.getpeername()` but not the actual OS resource. Unlike `socket.fromfd()`, *fileno* will return the same socket and not a duplicate. This may help close a detached socket using `socket.close()`.

The newly created socket is **non-inheritable**.

*Changed in version 3.3:* The **AF_CAN** family was added. The **AF_RDS** family was added.

*Changed in version 3.4:* The **CAN_BCM** protocol was added.

*Changed in version 3.4:* The returned socket is now non-inheritable.

*Changed in version 3.7:* The **CAN_ISO** protocol was added.

*Changed in version 3.7:* When **SOCK_NONBLOCK** or **SOCK_CLOEXEC** bit flags are applied to *type* they are cleared, and `socket.type` will not reflect them. They are still passed to the underlying system `socket()` call. Therefore::

```python
sock = socket.socket(
```
socket.AF_INET, socket.SOCK_STREAM | 
socket.SOCK_NONBLOCK)

will still create a non-blocking socket on OSes that support 
SOCK_NONBLOCK, but sock.type will be set to 
socket.SOCK_STREAM.

socket.socketpair([family[, type[, proto]]])

Build a pair of connected socket objects using the given address family, socket type, and protocol number. Address family, socket type, and protocol number are as for the socket() function above. The default family is AF_UNIX if defined on the platform; otherwise, the default is AF_INET.

The newly created sockets are non-inheritable.

Changed in version 3.2: The returned socket objects now support the whole socket API, rather than a subset.

Changed in version 3.4: The returned sockets are now non-inheritable.

Changed in version 3.5: Windows support added.

socket.create_connection(address[, timeout[, 
source_address]])

Connect to a TCP service listening on the Internet address (a 2-tuple (host, port)), and return the socket object. This is a higher-level function than socket.connect(): if host is a non-numeric hostname, it will try to resolve it for both AF_INET and AF_INET6, and then try to connect to all possible addresses in turn until a connection succeeds. This makes it easy to write clients
that are compatible to both IPv4 and IPv6.

Passing the optional `timeout` parameter will set the timeout on the socket instance before attempting to connect. If no `timeout` is supplied, the global default timeout setting returned by `getdefaulttimeout()` is used.

If supplied, `source_address` must be a 2-tuple `(host, port)` for the socket to bind to as its source address before connecting. If host or port are "" or 0 respectively the OS default behavior will be used.

*Changed in version 3.2: source_address was added.*

```
socket.fromfd(fd, family, type, proto=0)
```

Duplicate the file descriptor `fd` (an integer as returned by a file object’s `fileno()` method) and build a socket object from the result. Address family, socket type and protocol number are as for the `socket()` function above. The file descriptor should refer to a socket, but this is not checked — subsequent operations on the object may fail if the file descriptor is invalid. This function is rarely needed, but can be used to get or set socket options on a socket passed to a program as standard input or output (such as a server started by the Unix inet daemon). The socket is assumed to be in blocking mode.

The newly created socket is non-inheritable.

*Changed in version 3.4: The returned socket is now non-inheritable.*

```
socket.fromshare(data)
```

Instantiate a socket from data obtained from the
socket.share() method. The socket is assumed to be in blocking mode.

Availability: Windows.

New in version 3.3.

socket.SocketType

This is a Python type object that represents the socket object type. It is the same as `type(socket(...))`.

18.1.2.3.2. Other functions

The socket module also offers various network-related services:

socket.close(fd)

Close a socket file descriptor. This is like os.close(), but for sockets. On some platforms (most noticeable Windows) os.close() does not work for socket file descriptors.

New in version 3.7.

socket.getaddrinfo(host, port, family=0, type=0, proto=0, flags=0)

Translate the host/port argument into a sequence of 5-tuples that contain all the necessary arguments for creating a socket connected to that service. host is a domain name, a string representation of an IPv4/v6 address or None. port is a string service name such as 'http', a numeric port number or None. By passing None as the value of host and port, you can pass NULL to the underlying C API.

The family, type and proto arguments can be optionally specified in
order to narrow the list of addresses returned. Passing zero as a value for each of these arguments selects the full range of results. The flags argument can be one or several of the AI_* constants, and will influence how results are computed and returned. For example, AI_NUMERICHOST will disable domain name resolution and will raise an error if host is a domain name.

The function returns a list of 5-tuples with the following structure:

(family, type, proto, canonname, sockaddr)

In these tuples, family, type, proto are all integers and are meant to be passed to the socket() function. canonname will be a string representing the canonical name of the host if AI_CANONNAME is part of the flags argument; else canonname will be empty. sockaddr is a tuple describing a socket address, whose format depends on the returned family (a (address, port) 2-tuple for AF_INET, a (address, port, flow info, scope id) 4-tuple for AF_INET6), and is meant to be passed to the socket.connect() method.

The following example fetches address information for a hypothetical TCP connection to example.org on port 80 (results may differ on your system if IPv6 isn’t enabled):

```python
>>> socket.getaddrinfo("example.org", 80, proto=s)
[<AddressFamily.AF_INET6: 10>, <SocketType.SOCKSTREAM: 1>, 6, '', ('2606:2800:220:1:248:1893:25c8:1946', 80), (<AddressFamily.AF_INET: 2>, <SocketType.SOCK_STREAM: 1>, 6, '', ('93.184.216.34', 80))]
```

*Changed in version 3.2*: parameters can now be passed using
keyword arguments.

socket\texttt{.getfqdn([name])}
Return a fully qualified domain name for \texttt{name}. If \texttt{name} is omitted or empty, it is interpreted as the local host. To find the fully qualified name, the hostname returned by \texttt{gethostbyaddr()} is checked, followed by aliases for the host, if available. The first name which includes a period is selected. In case no fully qualified domain name is available, the hostname as returned by \texttt{gethostname()} is returned.

socket\texttt{.gethostbyname(hostname)}
Translate a host name to IPv4 address format. The IPv4 address is returned as a string, such as \\
\texttt{'100.50.200.5'}. If the host name is an IPv4 address itself it is returned unchanged. See \texttt{gethostbyname\_ex()} for a more complete interface. \texttt{gethostbyname()} does not support IPv6 name resolution, and \texttt{getaddrinfo()} should be used instead for IPv4/v6 dual stack support.

socket\texttt{.gethostbyname\_ex(hostname)}
Translate a host name to IPv4 address format, extended interface. Return a triple (hostname, aliaslist, ipaddrlist) where \texttt{hostname} is the primary host name responding to the given \texttt{ip\_address}, \texttt{aliaslist} is a (possibly empty) list of alternative host names for the same address, and \texttt{ipaddrlist} is a list of IPv4 addresses for the same interface on the same host (often but not always a single address). \texttt{gethostbyname\_ex()} does not support IPv6 name resolution, and \texttt{getaddrinfo()} should be used instead for IPv4/v6 dual stack support.

socket\texttt{.gethostname()}
Return a string containing the hostname of the machine where the Python interpreter is currently executing.

Note: `gethostname()` doesn't always return the fully qualified domain name; use `getfqdn()` for that.

`socket.gethostbyaddr(ip_address)`

Return a triple `(hostname, aliaslist, ipaddrlist)` where `hostname` is the primary host name responding to the given `ip_address`, `aliaslist` is a (possibly empty) list of alternative host names for the same address, and `ipaddrlist` is a list of IPv4/IPv6 addresses for the same interface on the same host (most likely containing only a single address). To find the fully qualified domain name, use the function `getfqdn()`. `gethostbyaddr()` supports both IPv4 and IPv6.

`socket.getnameinfo(sockaddr, flags)`

Translate a socket address `sockaddr` into a 2-tuple `(host, port)`. Depending on the settings of `flags`, the result can contain a fully-qualified domain name or numeric address representation in `host`. Similarly, `port` can contain a string port name or a numeric port number.

`socket.getprotobynamel(protocolname)`

Translate an Internet protocol name (for example, `'icmp'`) to a constant suitable for passing as the (optional) third argument to the `socket()` function. This is usually only needed for sockets opened in “raw” mode (`SOCK_RAW`); for the normal socket modes, the correct protocol is chosen automatically if the protocol is omitted or zero.

`socket.getservbyname(servicename[, protocolname])`
Translate an Internet service name and protocol name to a port number for that service. The optional protocol name, if given, should be 'tcp' or 'udp', otherwise any protocol will match.

socket.\texttt{getservbyport}(\texttt{port}, \texttt{protocolname})

Translate an Internet port number and protocol name to a service name for that service. The optional protocol name, if given, should be 'tcp' or 'udp', otherwise any protocol will match.

socket.\texttt{nthol}(x)

Convert 32-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

socket.\texttt{nthos}(x)

Convert 16-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

\textit{Deprecated since version 3.7:} In case $x$ does not fit in 16-bit unsigned integer, but does fit in a positive C int, it is silently truncated to 16-bit unsigned integer. This silent truncation feature is deprecated, and will raise an exception in future versions of Python.

socket.\texttt{htonl}(x)

Convert 32-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.
socket.**htons**(x)

Convert 16-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

*Deprecated since version 3.7:* In case `x` does not fit in 16-bit unsigned integer, but does fit in a positive C int, it is silently truncated to 16-bit unsigned integer. This silent truncation feature is deprecated, and will raise an exception in future versions of Python.

socket.**inet_aton**(ip_string)

Convert an IPv4 address from dotted-quad string format (for example, ‘123.45.67.89’) to 32-bit packed binary format, as a bytes object four characters in length. This is useful when conversing with a program that uses the standard C library and needs objects of type `struct in_addr`, which is the C type for the 32-bit packed binary this function returns.

`inet_aton()` also accepts strings with less than three dots; see the Unix manual page `inet(3)` for details.

If the IPv4 address string passed to this function is invalid, `OSError` will be raised. Note that exactly what is valid depends on the underlying C implementation of `inet_aton()`.

`inet_aton()` does not support IPv6, and `inet_pton()` should be used instead for IPv4/v6 dual stack support.

socket.**inet_ntoa**(packed_ip)

Convert a 32-bit packed IPv4 address (a bytes-like object four bytes in length) to its standard dotted-quad string representation
(for example, ‘123.45.67.89’). This is useful when conversing with a program that uses the standard C library and needs objects of type struct in_addr, which is the C type for the 32-bit packed binary data this function takes as an argument.

If the byte sequence passed to this function is not exactly 4 bytes in length, OSError will be raised./inet_ntoa() does not support IPv6, and inet_ntop() should be used instead for IPv4/v6 dual stack support.

*Changed in version 3.5:* Writable bytes-like object is now accepted.

socket.

inet_pnton(address_family, ip_string)

Convert an IP address from its family-specific string format to a packed, binary format. inet_pnton() is useful when a library or network protocol calls for an object of type struct in_addr (similar to inet_aton()) or struct in6_addr.

Supported values for address_family are currently AF_INET and AF_INET6. If the IP address string ip_string is invalid, OSError will be raised. Note that exactly what is valid depends on both the value of address_family and the underlying implementation of inet_pnton().

Availability: Unix (maybe not all platforms), Windows.

*Changed in version 3.4:* Windows support added

socket.

inet_ntop(address_family, packed_ip)

Convert a packed IP address (a bytes-like object of some number of bytes) to its standard, family-specific string representation (for example, '7.10.0.5' or '5aef:2b::8'). inet_ntop() is useful when a library or network protocol returns an object of type
struct in_addr (similar to inet_ntoa()) or struct in6_addr.

Supported values for address_family are currently AF_INET and AF_INET6. If the bytes object packed_ip is not the correct length for the specified address family, ValueError will be raised. OSError is raised for errors from the call to inet_ntop().

Availability: Unix (maybe not all platforms), Windows.

*Changed in version 3.4:* Windows support added

*Changed in version 3.5:* Writable bytes-like object is now accepted.

socket.CMSG_LEN(length)

Return the total length, without trailing padding, of an ancillary data item with associated data of the given length. This value can often be used as the buffer size for recvmsg() to receive a single item of ancillary data, but RFC 3542 requires portable applications to use CMSG_SPACE() and thus include space for padding, even when the item will be the last in the buffer. Raises OverflowError if length is outside the permissible range of values.

Availability: most Unix platforms, possibly others.

*New in version 3.3.*

socket.CMSG_SPACE(length)

Return the buffer size needed for recvmsg() to receive an ancillary data item with associated data of the given length, along with any trailing padding. The buffer space needed to receive multiple items is the sum of the CMSG_SPACE() values for their
associated data lengths. Raises OverflowError if length is outside the permissible range of values.

Note that some systems might support ancillary data without providing this function. Also note that setting the buffer size using the results of this function may not precisely limit the amount of ancillary data that can be received, since additional data may be able to fit into the padding area.

Availability: most Unix platforms, possibly others.

New in version 3.3.

socket.getdefaulttimeout()

Return the default timeout in seconds (float) for new socket objects. A value of None indicates that new socket objects have no timeout. When the socket module is first imported, the default is None.

socket.setdefaulttimeout(timeout)

Set the default timeout in seconds (float) for new socket objects. When the socket module is first imported, the default is None. See settimeout() for possible values and their respective meanings.

socket.sethostname(name)

Set the machine’s hostname to name. This will raise an OSError if you don’t have enough rights.

Availability: Unix.

New in version 3.3.

socket.if_nameindex()
Return a list of network interface information (index int, name string) tuples. \texttt{OSError} if the system call fails.

Availability: Unix.

\textit{New in version 3.3.}

\texttt{socket.if_nametoindex(if\_name)}

Return a network interface index number corresponding to an interface name. \texttt{OSError} if no interface with the given name exists.

Availability: Unix.

\textit{New in version 3.3.}

\texttt{socket.if_indextoindex(if\_index)}

Return a network interface name corresponding to an interface index number. \texttt{OSError} if no interface with the given index exists.

Availability: Unix.

\textit{New in version 3.3.}
18.1.3. Socket Objects

Socket objects have the following methods. Except for `makefile()`, these correspond to Unix system calls applicable to sockets.

*Changed in version 3.2:* Support for the `context manager` protocol was added. Exiting the context manager is equivalent to calling `close()`.

**socket.accept()**

Accept a connection. The socket must be bound to an address and listening for connections. The return value is a pair `(conn, address)` where `conn` is a new socket object usable to send and receive data on the connection, and `address` is the address bound to the socket on the other end of the connection.

The newly created socket is non-inheritable.

*Changed in version 3.4:* The socket is now non-inheritable.

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an `InterruptedError` exception (see PEP 475 for the rationale).

**socket.bind(address)**

Bind the socket to `address`. The socket must not already be bound. (The format of `address` depends on the address family — see above.)

**socket.close()**

Mark the socket closed. The underlying system resource (e.g. a file descriptor) is also closed when all file objects from `makefile()`
are closed. Once that happens, all future operations on the socket object will fail. The remote end will receive no more data (after queued data is flushed).

Sockets are automatically closed when they are garbage-collected, but it is recommended to close() them explicitly, or to use a with statement around them.

*Changed in version 3.6:* OSError is now raised if an error occurs when the underlying close() call is made.

**Note:** close() releases the resource associated with a connection but does not necessarily close the connection immediately. If you want to close the connection in a timely fashion, call shutdown() before close().

socket.connect(address)

Connect to a remote socket at address. (The format of address depends on the address family — see above.)

If the connection is interrupted by a signal, the method waits until the connection completes, or raise a socket.timeout on timeout, if the signal handler doesn’t raise an exception and the socket is blocking or has a timeout. For non-blocking sockets, the method raises an InterruptedError exception if the connection is interrupted by a signal (or the exception raised by the signal handler).

*Changed in version 3.5:* The method now waits until the connection completes instead of raising an InterruptedError exception if the connection is interrupted by a signal, the signal handler doesn’t raise an exception and the socket is blocking or has a timeout (see
the **PEP 475** for the rationale).

socket.``connect_ex``(*address*)

Like `connect(*address*)`, but return an error indicator instead of raising an exception for errors returned by the C-level `connect()` call (other problems, such as “host not found,” can still raise exceptions). The error indicator is 0 if the operation succeeded, otherwise the value of the `errno` variable. This is useful to support, for example, asynchronous connects.

socket.``detach``()

Put the socket object into closed state without actually closing the underlying file descriptor. The file descriptor is returned, and can be reused for other purposes.

*New in version 3.2.*

socket.``dup``()

Duplicate the socket.

The newly created socket is **non-inheritable**.

*Changed in version 3.4*: The socket is now non-inheritable.

socket.``fileno``()

Return the socket’s file descriptor (a small integer), or -1 on failure. This is useful with `select.select()`.

Under Windows the small integer returned by this method cannot be used where a file descriptor can be used (such as `os.fdopen()`). Unix does not have this limitation.

socket.``get_inheritable``()
Get the **inheritable flag** of the socket's file descriptor or socket's handle: `True` if the socket can be inherited in child processes, `False` if it cannot.

*New in version 3.4.*

`socket.getpeername()`

Return the remote address to which the socket is connected. This is useful to find out the port number of a remote IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.) On some systems this function is not supported.

`socket.getsockname()`

Return the socket's own address. This is useful to find out the port number of an IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.)

`socket.getsockopt(level, optname[, buflen])`

Return the value of the given socket option (see the Unix man page `getsockopt(2)`). The needed symbolic constants (`SO_*` etc.) are defined in this module. If `buflen` is absent, an integer option is assumed and its integer value is returned by the function. If `buflen` is present, it specifies the maximum length of the buffer used to receive the option in, and this buffer is returned as a bytes object. It is up to the caller to decode the contents of the buffer (see the optional built-in module `struct` for a way to decode C structures encoded as byte strings).

`socket.getblocking()`

Return `True` if socket is in blocking mode, `False` if in non-blocking.
This is equivalent to checking `socket.gettimeout() == 0`.

*New in version 3.7.*

**socket**. `gettimeout()`

Return the timeout in seconds (float) associated with socket operations, or `None` if no timeout is set. This reflects the last call to `setblocking()` or `settimeout()`.

**socket**. `ioctl(control, option)`

*Platform:* Windows

The `ioctl()` method is a limited interface to the WSAIoctl system interface. Please refer to the Win32 documentation for more information.

On other platforms, the generic `fcntl.fcntl()` and `fcntl.ioctl()` functions may be used; they accept a socket object as their first argument.

Currently only the following control codes are supported: `SIO_RCVALL`, `SIO_KEEPALIVE_VALS`, and `SIO_LOOPBACK_FAST_PATH`.

*Changed in version 3.6:* `SIO_LOOPBACK_FAST_PATH` was added.

**socket**. `listen([backlog])`

Enable a server to accept connections. If `backlog` is specified, it must be at least 0 (if it is lower, it is set to 0); it specifies the number of unaccepted connections that the system will allow before refusing new connections. If not specified, a default reasonable value is chosen.
Changed in version 3.5: The `backlog` parameter is now optional.

```python
socket.makefile(mode='r', buffering=None, *, encoding=None, errors=None, newline=None)
```

Return a file object associated with the socket. The exact returned type depends on the arguments given to `makefile()`. These arguments are interpreted the same way as by the built-in `open()` function, except the only supported `mode` values are `'r'` (default), `'w'` and `'b'`.

The socket must be in blocking mode; it can have a timeout, but the file object's internal buffer may end up in an inconsistent state if a timeout occurs.

Closing the file object returned by `makefile()` won't close the original socket unless all other file objects have been closed and `socket.close()` has been called on the socket object.

**Note:** On Windows, the file-like object created by `makefile()` cannot be used where a file object with a file descriptor is expected, such as the stream arguments of `subprocess.Popen()`.

```python
socket.recv(bufsize[, flags])
```

Receive data from the socket. The return value is a bytes object representing the data received. The maximum amount of data to be received at once is specified by `bufsize`. See the Unix manual page `recv(2)` for the meaning of the optional argument `flags`; it defaults to zero.

**Note:** For best match with hardware and network realities, the value of `bufsize` should be a relatively small power of 2, for
example, 4096.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an InterruptedError exception (see PEP 475 for the rationale).

socket.recvfrom(bufsize[, flags])
Receive data from the socket. The return value is a pair (bytes, address) where bytes is a bytes object representing the data received and address is the address of the socket sending the data. See the Unix manual page recv(2) for the meaning of the optional argument flags; it defaults to zero. (The format of address depends on the address family — see above.)

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an InterruptedError exception (see PEP 475 for the rationale).

socket.recvmsg(bufsize[, ancbufsize[, flags]])
Receive normal data (up to bufsize bytes) and ancillary data from the socket. The ancbufsize argument sets the size in bytes of the internal buffer used to receive the ancillary data; it defaults to 0, meaning that no ancillary data will be received. Appropriate buffer sizes for ancillary data can be calculated using CMSG_SPACE() or CMSG_LEN(), and items which do not fit into the buffer might be truncated or discarded. The flags argument defaults to 0 and has the same meaning as for recv().

The return value is a 4-tuple: (data, ancdata, msg_flags, address). The data item is a bytes object holding the non-
ancillary data received. The \textit{ancdata} item is a list of zero or more tuples \((\text{cmsg\_level}, \text{cmsg\_type}, \text{cmsg\_data})\) representing the ancillary data (control messages) received: \text{cmsg\_level} and \text{cmsg\_type} are integers specifying the protocol level and protocol-specific type respectively, and \text{cmsg\_data} is a \texttt{bytes} object holding the associated data. The \textit{msg\_flags} item is the bitwise OR of various flags indicating conditions on the received message; see your system documentation for details. If the receiving socket is unconnected, \textit{address} is the address of the sending socket, if available; otherwise, its value is unspecified.

On some systems, \texttt{sendmsg()} and \texttt{recvmsg()} can be used to pass file descriptors between processes over an \texttt{AF\_UNIX} socket. When this facility is used (it is often restricted to \texttt{SOCK\_STREAM} sockets), \texttt{recvmsg()} will return, in its ancillary data, items of the form \((\text{socket.SOL\_SOCKET, socket.SCM\_RIGHTS, fds})\), where \textit{fds} is a \texttt{bytes} object representing the new file descriptors as a binary array of the native C \texttt{int} type. If \texttt{recvmsg()} raises an exception after the system call returns, it will first attempt to close any file descriptors received via this mechanism.

Some systems do not indicate the truncated length of ancillary data items which have been only partially received. If an item appears to extend beyond the end of the buffer, \texttt{recvmsg()} will issue a \texttt{RuntimeWarning}, and will return the part of it which is inside the buffer provided it has not been truncated before the start of its associated data.

On systems which support the \texttt{SCM\_RIGHTS} mechanism, the following function will receive up to \textit{maxfds} file descriptors, returning the message data and a list containing the descriptors (while ignoring unexpected conditions such as unrelated control
messages being received). See also `sendmsg()`.

```python
import socket, array

def recv_fds(sock, msglen, maxfds):
    fds = array.array('i')  # Array of ints
    msg, ancdata, flags, addr = sock.recvmsg(msglen)
    for cmsg_level, cmsg_type, cmsg_data in ancdata:
        if (cmsg_level == socket.SOL_SOCKET and cmsg_type:  # Append data, ignoring any truncated
            fds.fromstring(cmsg_data[:len(cmsg_data)])
    return msg, list(fds)
```

Availability: most Unix platforms, possibly others.

*New in version 3.3.*

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an `InterruptedError` exception (see PEP 475 for the rationale).

```python
socket.recvmsg_into(buffers[, ancbufsize[, flags]])
```

Receive normal data and ancillary data from the socket, behaving as `recvmsg()` would, but scatter the non-ancillary data into a series of buffers instead of returning a new bytes object. The `buffers` argument must be an iterable of objects that export writable buffers (e.g. `bytearray` objects); these will be filled with successive chunks of the non-ancillary data until it has all been written or there are no more buffers. The operating system may set a limit (sysconf() value `SC_IOV_MAX`) on the number of buffers that can be used. The `ancbufsize` and `flags` arguments have the same meaning as for `recvmsg()`.
The return value is a 4-tuple: \((nbytes, \text{ancdata}, \text{msg\_flags}, \text{address})\), where \(nbytes\) is the total number of bytes of non-ancillary data written into the buffers, and \(\text{ancdata}, \text{msg\_flags}\) and \(\text{address}\) are the same as for \texttt{recvmsg()}.

Example:

```python
>>> import socket
>>> s1, s2 = socket.socketpair()
>>> b1 = bytearray(b'----')
>>> b2 = bytearray(b'0123456789')
>>> b3 = bytearray(b'--------------')
>>> s1.send(b'Mary had a little lamb')
22
>>> s2.recvmsg_into([b1, memoryview(b2)[2:9]], b3)
(22, [], 0, None)
```

Availability: most Unix platforms, possibly others.

New in version 3.3.

socket.\texttt{recvfrom\_into}(\texttt{buffer}[\texttt{], nbytes}[\texttt{], flags}])

Receive data from the socket, writing it into \texttt{buffer} instead of creating a new bytestring. The return value is a pair \((nbytes, \text{address})\) where \(nbytes\) is the number of bytes received and \texttt{address} is the address of the socket sending the data. See the Unix manual page \texttt{recv(2)} for the meaning of the optional argument \texttt{flags}; it defaults to zero. (The format of \texttt{address} depends on the address family — see above.)

```
```

socket.\texttt{recv\_into}(\texttt{buffer}[\texttt{], nbytes}[\texttt{], flags}])
Receive up to \texttt{nbytes} bytes from the socket, storing the data into a buffer rather than creating a new bytestring. If \texttt{nbytes} is not specified (or 0), receive up to the size available in the given buffer. Returns the number of bytes received. See the Unix manual page \texttt{recv(2)} for the meaning of the optional argument \texttt{flags}; it defaults to zero.

\begin{verbatim}
socket.send(bytes[, flags])
\end{verbatim}

Send data to the socket. The socket must be connected to a remote socket. The optional \texttt{flags} argument has the same meaning as for \texttt{recv()} above. Returns the number of bytes sent. Applications are responsible for checking that all data has been sent; if only some of the data was transmitted, the application needs to attempt delivery of the remaining data. For further information on this topic, consult the Socket Programming HOWTO.

\textit{Changed in version 3.5:} If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an \texttt{InterruptedError} exception (see \texttt{PEP 475} for the rationale).

\begin{verbatim}
socket.sendall(bytes[, flags])
\end{verbatim}

Send data to the socket. The socket must be connected to a remote socket. The optional \texttt{flags} argument has the same meaning as for \texttt{recv()} above. Unlike \texttt{send()}, this method continues to send data from \texttt{bytes} until either all data has been sent or an error occurs. \texttt{None} is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully sent.

\textit{Changed in version 3.5:} The socket timeout is no more reset each
time data is sent successfully. The socket timeout is now the maximum total duration to send all data.

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](https://www.python.org/dev/peps/pep-0475/) for the rationale).

```python
socket.sendto(bytes, address)
```

```python
socket.sendto(bytes, flags, address)
```

Send data to the socket. The socket should not be connected to a remote socket, since the destination socket is specified by `address`. The optional `flags` argument has the same meaning as for `recv()` above. Return the number of bytes sent. (The format of `address` depends on the address family — see above.)

*Changed in version 3.5:* If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an `InterruptedError` exception (see [PEP 475](https://www.python.org/dev/peps/pep-0475/) for the rationale).

```python
socket.sendmsg(buffers[, ancdata[, flags[, address]]]])
```

Send normal and ancillary data to the socket, gathering the non-ancillary data from a series of buffers and concatenating it into a single message. The `buffers` argument specifies the non-ancillary data as an iterable of bytes-like objects (e.g. `bytes` objects); the operating system may set a limit (`sysconf()` value `SC_IOV_MAX`) on the number of buffers that can be used. The `ancdata` argument specifies the ancillary data (control messages) as an iterable of zero or more tuples `(cmsg_level, cmsg_type, cmsg_data)`, where `cmsg_level` and `cmsg_type` are integers specifying the protocol level and protocol-specific type respectively, and
cmsg_data is a bytes-like object holding the associated data. Note that some systems (in particular, systems without \texttt{CMSG\_SPACE()}) might support sending only one control message per call. The \texttt{flags} argument defaults to 0 and has the same meaning as for \texttt{send()}. If \texttt{address} is supplied and not \texttt{None}, it sets a destination address for the message. The return value is the number of bytes of non-ancillary data sent.

The following function sends the list of file descriptors \texttt{fds} over an \texttt{AF\_UNIX} socket, on systems which support the \texttt{SCM\_RIGHTS} mechanism. See also \texttt{recvmsg()}.  

\begin{verbatim}
import socket, array

def send_fds(sock, msg, fds):
    return sock.sendmsg([msg], [(socket.SOL_SOCKET, 0, 0, b'', 0)])
\end{verbatim}

Availability: most Unix platforms, possibly others.  

\textit{New in version 3.3.}

\textit{Changed in version 3.5:} If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an \texttt{InterruptedError} exception (see \texttt{PEP 475} for the rationale).

\texttt{socket.sendmsg\_afalg([msg,]*, op[, iv[, assoclen[, flags]]])}

Specialized version of \texttt{sendmsg()} for \texttt{AF\_ALG} socket. Set mode, IV, AEAD associated data length and flags for \texttt{AF\_ALG} socket.  

Availability: Linux >= 2.6.38  

\textit{New in version 3.6.}
socket.sendfile(file, offset=0, count=None)

Send a file until EOF is reached by using high-performance os.sendfile and return the total number of bytes which were sent. file must be a regular file object opened in binary mode. If os.sendfile is not available (e.g. Windows) or file is not a regular file send() will be used instead. offset tells from where to start reading the file. If specified, count is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is updated on return or also in case of error in which case file.tell() can be used to figure out the number of bytes which were sent. The socket must be of SOCK_STREAM type. Non-blocking sockets are not supported.

New in version 3.5.

socket.set_inheritable(inheritable)

Set the inheritable flag of the socket's file descriptor or socket's handle.

New in version 3.4.

socket.setblocking(flag)

Set blocking or non-blocking mode of the socket: if flag is false, the socket is set to non-blocking, else to blocking mode.

This method is a shorthand for certain settimeout() calls:

- sock.setblocking(True) is equivalent to
  sock.settimeout(None)
- sock.setblocking(False) is equivalent to
  sock.settimeout(0.0)

Changed in version 3.7: The method no longer applies
SOCK_NONBLOCK flag on socket.type.

socket.settimeout(value)
Set a timeout on blocking socket operations. The value argument can be a nonnegative floating point number expressing seconds, or None. If a non-zero value is given, subsequent socket operations will raise a timeout exception if the timeout period value has elapsed before the operation has completed. If zero is given, the socket is put in non-blocking mode. If None is given, the socket is put in blocking mode.

For further information, please consult the notes on socket timeouts.

Changed in version 3.7: The method no longer toggles SOCK_NONBLOCK flag on socket.type.

socket.setsockopt(level, optname, value: int)
socket.setsockopt(level, optname, value: buffer)
socket.setsockopt(level, optname, None, optlen: int)
Set the value of the given socket option (see the Unix manual page setsockopt(2)). The needed symbolic constants are defined in the socket module (SO_* etc.). The value can be an integer, None or a bytes-like object representing a buffer. In the later case it is up to the caller to ensure that the bytestring contains the proper bits (see the optional built-in module struct for a way to encode C structures as bytestrings). When value is set to None, optlen argument is required. It’s equivalent to call setsockopt C function with optval=NULL and optlen=optlen.

Changed in version 3.5: Writable bytes-like object is now accepted.
Changed in version 3.6: setsockopt(level, optname, None, optlen: int) form added.

socket.shutdown(how)
Shut down one or both halves of the connection. If how is SHUT_RD, further receives are disallowed. If how is SHUT_WR, further sends are disallowed. If how is SHUT_RDWR, further sends and receives are disallowed.

socket.share(process_id)
Duplicate a socket and prepare it for sharing with a target process. The target process must be provided with process_id. The resulting bytes object can then be passed to the target process using some form of interprocess communication and the socket can be recreated there using fromshare(). Once this method has been called, it is safe to close the socket since the operating system has already duplicated it for the target process.

Availability: Windows.

New in version 3.3.

Note that there are no methods read() or write(); use recv() and send() without flags argument instead.

Socket objects also have these (read-only) attributes that correspond to the values given to the socket constructor.

socket.family
The socket family.

socket.type
The socket type.
socket.proto

The socket protocol.
18.1.4. Notes on socket timeouts

A socket object can be in one of three modes: blocking, non-blocking, or timeout. Sockets are by default always created in blocking mode, but this can be changed by calling `setdefaulttimeout()`.

- In blocking mode, operations block until complete or the system returns an error (such as connection timed out).
- In non-blocking mode, operations fail (with an error that is unfortunately system-dependent) if they cannot be completed immediately: functions from the `select` can be used to know when and whether a socket is available for reading or writing.
- In timeout mode, operations fail if they cannot be completed within the timeout specified for the socket (they raise a `timeout` exception) or if the system returns an error.

**Note:** At the operating system level, sockets in timeout mode are internally set in non-blocking mode. Also, the blocking and timeout modes are shared between file descriptors and socket objects that refer to the same network endpoint. This implementation detail can have visible consequences if e.g. you decide to use the `fileno()` of a socket.

18.1.4.1. Timeouts and the connect method

The `connect()` operation is also subject to the timeout setting, and in general it is recommended to call `settimeout()` before calling `connect()` or pass a timeout parameter to `create_connection()`. However, the system network stack may also return a connection timeout error of its own regardless of any Python socket timeout setting.
18.1.4.2. Timeouts and the accept method

If `getdefaulttimeout()` is not `None`, sockets returned by the `accept()` method inherit that timeout. Otherwise, the behaviour depends on settings of the listening socket:

- if the listening socket is in *blocking mode* or in *timeout mode*, the socket returned by `accept()` is in *blocking mode*;
- if the listening socket is in *non-blocking mode*, whether the socket returned by `accept()` is in blocking or non-blocking mode is operating system-dependent. If you want to ensure cross-platform behaviour, it is recommended you manually override this setting.
18.1.5. Example

Here are four minimal example programs using the TCP/IP protocol: a server that echoes all data that it receives back (servicing only one client), and a client using it. Note that a server must perform the sequence `socket()`, `bind()`, `listen()`, `accept()` (possibly repeating the `accept()` to service more than one client), while a client only needs the sequence `socket()`, `connect()`. Also note that the server does not `sendall()`/`recv()` on the socket it is listening on but on the new socket returned by `accept()`.

The first two examples support IPv4 only.

```python
# Echo server program
import socket

HOST = ''  # Symbolic name meaning all available interfaces
PORT = 50007  # Arbitrary non-privileged port

with socket.socket(socket.AF_INET, socket.SOCK_STREAM) as s:
    s.bind((HOST, PORT))
    s.listen(1)
    conn, addr = s.accept()
    with conn:
        print('Connected by', addr)
        while True:
            data = conn.recv(1024)
            if not data: break
            conn.sendall(data)
```

```python
# Echo client program
import socket

HOST = 'daring.cwi.nl'  # The remote host
```
PORT = 50007    # The same port as used by

with socket.socket(socket.AF_INET, socket.SOCK_STREAM) as s:
    s.connect((HOST, PORT))
    s.sendall(b'Hello, world')
data = s.recv(1024)
print('Received', repr(data))

The next two examples are identical to the above two, but support both IPv4 and IPv6. The server side will listen to the first address family available (it should listen to both instead). On most of IPv6-ready systems, IPv6 will take precedence and the server may not accept IPv4 traffic. The client side will try to connect to the all addresses returned as a result of the name resolution, and sends traffic to the first one connected successfully.

# Echo server program
import socket
import sys

HOST = None    # Symbolic name meaning all available interfaces
PORT = 50007    # Arbitrary non-privileged port
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_INET,
                               socket.SOCK_STREAM, 0,
                               af, socktype, proto, canonname, sa = res
                               try:
                                   s = socket.socket(af, socktype, proto)
                               except OSError as msg:
                                   s = None
                                   continue
                               try:
                                   s.bind(sa)
                                   s.listen(1)
                               except OSError as msg:
                                   s.close()
```python
s = None
continue
break
if s is None:
    print('could not open socket')
    sys.exit(1)
conn, addr = s.accept()
with conn:
    print('Connected by', addr)
    while True:
        data = conn.recv(1024)
        if not data: break
        conn.send(data)
```

# Echo client program
```python
import socket
import sys

HOST = 'daring.cwi.nl'  # The remote host
PORT = 50007            # The same port as used by
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_INET, socket.SOCK_STREAM, 0, socket.AI_ADDRCONFIG):
    try:
        s = socket.socket(res[0], res[1], res[2])
    except OSError as msg:
        s = None
        continue
    try:
        s.connect(res[4])
    except OSError as msg:
        s.close()
        s = None
        continue
    break
if s is None:
```
print('could not open socket')
sys.exit(1)

with s:
    s.sendall(b'Hello, world')
data = s.recv(1024)
print('Received', repr(data))

The next example shows how to write a very simple network sniffer with raw sockets on Windows. The example requires administrator privileges to modify the interface:

```python
import socket

# the public network interface
HOST = socket.gethostbyname(socket.gethostname())

# create a raw socket and bind it to the public interface
s = socket.socket(socket.AF_INET, socket.SOCK_RAW, socket.IPPROTO_IP)
s.bind((HOST, 0))

# Include IP headers
s.setsockopt(socket.IPPROTO_IP, socket.IP_HDRINCL, 1)

# receive all packages
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_ON)

# receive a package
print(s.recvfrom(65565))

# disabled promiscuous mode
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_OFF)
```

The next example shows how to use the socket interface to communicate to a CAN network using the raw socket protocol. To use
CAN with the broadcast manager protocol instead, open a socket with:

```python
socket.socket(socket.AF_CAN, socket.SOCK_DGRAM, socket.CAN_RAW)
```

After binding (CAN_RAW) or connecting (CAN_BCM) the socket, you can use the `socket.send()` and the `socket.recv()` operations (and their counterparts) on the socket object as usual.

This last example might require special privileges:

```python
import socket
import struct

# CAN frame packing/unpacking (see 'struct can_frame' in <linux/can.h>)

can_frame_fmt = '=IB3x8s'
can_frame_size = struct.calcsize(can_frame_fmt)

def build_can_frame(can_id, data):
    can_dlc = len(data)
    data = data.ljust(8, b'\x00')
    return struct.pack(can_frame_fmt, can_id, can_dlc)

def dissect_can_frame(frame):
    can_id, can_dlc, data = struct.unpack(can_frame_fmt, frame)
    return (can_id, can_dlc, data[:can_dlc])

# create a raw socket and bind it to the 'vcan0' interface
s = socket.socket(socket.AF_CAN, socket.SOCK_RAW, socket.CAN_RAW)
s.bind(('vcan0',))

while True:
    cf, addr = s.recvfrom(can_frame_size)
```
print('Received: can_id=%x, can_dlc=%x, data=%s')

try:
s.send(cf)
except OSError:
    print('Error sending CAN frame')

try:
s.send(build_can_frame(0x01, b'\x01\x02\x03'))
except OSError:
    print('Error sending CAN frame')

Running an example several times with too small delay between executions, could lead to this error:

OSError: [Errno 98] Address already in use

This is because the previous execution has left the socket in a TIME_WAIT state, and can't be immediately reused.

There is a socket flag to set, in order to prevent this, socket.SO_REUSEADDR:

s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.setsockopt(socket.SOL_SOCKET, socket.SO_REUSEADDR, s.bind((HOST, PORT))

the SO_REUSEADDR flag tells the kernel to reuse a local socket in TIME_WAIT state, without waiting for its natural timeout to expire.

See also: For an introduction to socket programming (in C), see the following papers:
• *An Introductory 4.3BSD Interprocess Communication Tutorial*, by Stuart Sechrest

• *An Advanced 4.3BSD Interprocess Communication Tutorial*, by Samuel J. Leffler et al,

both in the UNIX Programmer’s Manual, Supplementary Documents 1 (sections PS1:7 and PS1:8). The platform-specific reference material for the various socket-related system calls are also a valuable source of information on the details of socket semantics. For Unix, refer to the manual pages; for Windows, see the WinSock (or Winsock 2) specification. For IPv6-ready APIs, readers may want to refer to [RFC 3493](http://www.ietf.org/rfc/rfc3493.txt) titled Basic Socket Interface Extensions for IPv6.
18.2. **ssl** — TLS/SSL wrapper for socket objects

**Source code:** [Lib/ssl.py](#)

This module provides access to Transport Layer Security (often known as “Secure Sockets Layer”) encryption and peer authentication facilities for network sockets, both client-side and server-side. This module uses the OpenSSL library. It is available on all modern Unix systems, Windows, Mac OS X, and probably additional platforms, as long as OpenSSL is installed on that platform.

**Note:** Some behavior may be platform dependent, since calls are made to the operating system socket APIs. The installed version of OpenSSL may also cause variations in behavior. For example, TLSv1.1 and TLSv1.2 come with openssl version 1.0.1.

**Warning:** Don’t use this module without reading the Security considerations. Doing so may lead to a false sense of security, as the default settings of the ssl module are not necessarily appropriate for your application.

This section documents the objects and functions in the `ssl` module; for more general information about TLS, SSL, and certificates, the reader is referred to the documents in the “See Also” section at the bottom.

This module provides a class, `ssl.SSLSocket`, which is derived from the `socket.socket` type, and provides a socket-like wrapper that
also encrypts and decrypts the data going over the socket with SSL. It supports additional methods such as getpeercert(), which retrieves the certificate of the other side of the connection, and cipher(), which retrieves the cipher being used for the secure connection.

For more sophisticated applications, the ssl.SSLContext class helps manage settings and certificates, which can then be inherited by SSL sockets created through the SSLContext.wrap_socket() method.

*Changed in version 3.6:* OpenSSL 0.9.8, 1.0.0 and 1.0.1 are deprecated and no longer supported. In the future the ssl module will require at least OpenSSL 1.0.2 or 1.1.0.
18.2.1. Functions, Constants, and Exceptions

```python
exception ssl.SSLError

Raised to signal an error from the underlying SSL implementation (currently provided by the OpenSSL library). This signifies some problem in the higher-level encryption and authentication layer that's superimposed on the underlying network connection. This error is a subtype of OSError. The error code and message of SSLError instances are provided by the OpenSSL library.

Changed in version 3.3: SSLError used to be a subtype of socket.error.
```

```python
library

A string mnemonic designating the OpenSSL submodule in which the error occurred, such as SSL, PEM or X509. The range of possible values depends on the OpenSSL version.

New in version 3.3.
```

```python
reason

A string mnemonic designating the reason this error occurred, for example CERTIFICATE_VERIFY_FAILED. The range of possible values depends on the OpenSSL version.

New in version 3.3.
```

```python
exception ssl.SSLZeroReturnError

A subclass of SSLError raised when trying to read or write and the SSL connection has been closed cleanly. Note that this doesn't
mean that the underlying transport (read TCP) has been closed.

*New in version 3.3.*

**exception ssl.** **SSLWantReadError**
A subclass of `SSLError` raised by a non-blocking SSL socket when trying to read or write data, but more data needs to be received on the underlying TCP transport before the request can be fulfilled.

*New in version 3.3.*

**exception ssl.** **SSLWantWriteError**
A subclass of `SSLError` raised by a non-blocking SSL socket when trying to read or write data, but more data needs to be sent on the underlying TCP transport before the request can be fulfilled.

*New in version 3.3.*

**exception ssl.** **SSLSyscallError**
A subclass of `SSLError` raised when a system error was encountered while trying to fulfill an operation on a SSL socket. Unfortunately, there is no easy way to inspect the original errno number.

*New in version 3.3.*

**exception ssl.** **SSLEOFError**
A subclass of `SSLError` raised when the SSL connection has been terminated abruptly. Generally, you shouldn’t try to reuse the underlying transport when this error is encountered.

*New in version 3.3.*
exception ssl.SSLCertVerificationError
A subclass of SSLError raised when certificate validation has failed.

New in version 3.7.

verify_code
A numeric error number that denotes the verification error.

verify_message
A human readable string of the verification error.

exception ssl.CertificateError
An alias for SSLCertVerificationError.

Changed in version 3.7: The exception is now an alias for SSLCertVerificationError.

18.2.1.1. Socket creation

The following function allows for standalone socket creation. Starting from Python 3.2, it can be more flexible to use SSLContext.wrap_socket() instead.

ssl.wrap_socket(sock, keyfile=None, certfile=None, server_side=False, cert_reqs=CERT_NONE, ssl_version={see docs}, ca_certs=None, do_handshake_on_connect=True, suppress_ragged_eofs=True, ciphers=None)

Takes an instance of socket.socket, and returns an instance of ssl.SSLSocket, a subtype of socket.socket, which wraps the underlying socket in an SSL context. sock must be a SOCK_STREAM socket; other socket types are unsupported.
For client-side sockets, the context construction is lazy; if the underlying socket isn't connected yet, the context construction will be performed after connect() is called on the socket. For server-side sockets, if the socket has no remote peer, it is assumed to be a listening socket, and the server-side SSL wrapping is automatically performed on client connections accepted via the accept() method. wrap_socket() may raise SSLError.

The keyfile and certfile parameters specify optional files which contain a certificate to be used to identify the local side of the connection. See the discussion of Certificates for more information on how the certificate is stored in the certfile.

The parameter server_side is a boolean which identifies whether server-side or client-side behavior is desired from this socket.

The parameter cert_reqs specifies whether a certificate is required from the other side of the connection, and whether it will be validated if provided. It must be one of the three values CERT_NONE (certificates ignored), CERT_OPTIONAL (not required, but validated if provided), or CERT_REQUIRED (required and validated). If the value of this parameter is not CERT_NONE, then the ca_certs parameter must point to a file of CA certificates.

The ca_certs file contains a set of concatenated “certification authority” certificates, which are used to validate certificates passed from the other end of the connection. See the discussion of Certificates for more information about how to arrange the certificates in this file.

The parameter ssl_version specifies which version of the SSL
protocol to use. Typically, the server chooses a particular protocol version, and the client must adapt to the server’s choice. Most of the versions are not interoperable with the other versions. If not specified, the default is PROTOCOL_TLS; it provides the most compatibility with other versions.

Here’s a table showing which versions in a client (down the side) can connect to which versions in a server (along the top):

<table>
<thead>
<tr>
<th>client / server</th>
<th>SSLv2</th>
<th>SSLv3</th>
<th>TLS [3]</th>
<th>TLSv1</th>
<th>TLSv1.1</th>
<th>TLSv1</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSLv2</td>
<td>yes</td>
<td>no</td>
<td>no [1]</td>
<td>no</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td>SSLv3</td>
<td>no</td>
<td>yes</td>
<td>no [2]</td>
<td>no</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td>TLSv1</td>
<td>no</td>
<td>no</td>
<td>yes</td>
<td>yes</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td>TLSv1.1</td>
<td>no</td>
<td>no</td>
<td>yes</td>
<td>no</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td>TLSv1.2</td>
<td>no</td>
<td>no</td>
<td>yes</td>
<td>no</td>
<td>no</td>
<td>yes</td>
</tr>
</tbody>
</table>

Footnotes

[1] (1, 2) SSLContext disables SSLv2 with OP_NO_SSLv2 by default.

[2] (1, 2) SSLContext disables SSLv3 with OP_NO_SSLv3 by default.

(1, 2) TLS 1.3 protocol will be available with PROTOCOL_TLS in OpenSSL >= 1.1.1. There is no dedicated PROTOCOL constant for just TLS 1.3.
Note: Which connections succeed will vary depending on the version of OpenSSL. For example, before OpenSSL 1.0.0, an SSLv23 client would always attempt SSLv2 connections.

The *ciphers* parameter sets the available ciphers for this SSL object. It should be a string in the OpenSSL cipher list format.

The parameter *do_handshake_on_connect* specifies whether to do the SSL handshake automatically after doing a `socket.connect()`, or whether the application program will call it explicitly, by invoking the `SSLSocket.do_handshake()` method. Calling `SSLSocket.do_handshake()` explicitly gives the program control over the blocking behavior of the socket I/O involved in the handshake.

The parameter *suppress_ragged_eofs* specifies how the `SSLSocket.recv()` method should signal unexpected EOF from the other end of the connection. If specified as *True* (the default), it returns a normal EOF (an empty bytes object) in response to unexpected EOF errors raised from the underlying socket; if *False*, it will raise the exceptions back to the caller.

*Changed in version 3.2*: New optional argument *ciphers*.

### 18.2.1.2. Context creation

A convenience function helps create `SSLContext` objects for common purposes.

```python
ssl.create_default_context(purpose=Purpose.SERVER_AUTH, cafile=None, capath=None, cadata=None)
```
Return a new `SSLContext` object with default settings for the given `purpose`. The settings are chosen by the `ssl` module, and usually represent a higher security level than when calling the `SSLContext` constructor directly.

`cafile`, `capath`, `cadata` represent optional CA certificates to trust for certificate verification, as in `SSLContext.load_verify_locations()`. If all three are `None`, this function can choose to trust the system's default CA certificates instead.

The settings are: `PROTOCOL_TLS`, `OP_NO_SSLv2`, and `OP_NO_SSLv3` with high encryption cipher suites without RC4 and without unauthenticated cipher suites. Passing `SERVER_AUTH` as `purpose` sets `verify_mode` to `CERT_REQUIRED` and either loads CA certificates (when at least one of `cafile`, `capath` or `cadata` is given) or uses `SSLContext.load_default_certs()` to load default CA certificates.

**Note:** The protocol, options, cipher and other settings may change to more restrictive values anytime without prior deprecation. The values represent a fair balance between compatibility and security.

If your application needs specific settings, you should create a `SSLContext` and apply the settings yourself.

**Note:** If you find that when certain older clients or servers attempt to connect with a `SSLContext` created by this function that they get an error stating “Protocol or cipher suite mismatch”, it may be that they only support SSL3.0 which this function excludes using the `OP_NO_SSLv3`. SSL3.0 is widely considered
to be completely broken. If you still wish to continue to use this function but still allow SSL 3.0 connections you can re-enable them using:

```python
ctx = ssl.create_default_context(Purpose.CLIENTCERT
ctx.options &= ~ssl.OP_NO_SSLv3
```

New in version 3.4.

Changed in version 3.4.4: RC4 was dropped from the default cipher string.

Changed in version 3.6: ChaCha20/Poly1305 was added to the default cipher string.

3DES was dropped from the default cipher string.

Changed in version 3.7: TLS 1.3 cipher suites TLS_AES_128_GCM_SHA256, TLS_AES_256_GCM_SHA384, and TLS_CHACHA20_POLY1305_SHA256 were added to the default cipher string.

18.2.1.3. Random generation

```python
ssl.RAND_bytes(num)
```

Return num cryptographically strong pseudo-random bytes. Raises an SSLError if the PRNG has not been seeded with enough data or if the operation is not supported by the current RAND method. RAND_status() can be used to check the status of the PRNG and RAND_add() can be used to seed the PRNG.

For almost all applications os.urandom() is preferable.
Read the Wikipedia article, **Cryptographically secure pseudorandom number generator (CSPRNG)**, to get the requirements of a cryptographically generator.

*New in version 3.3.*

**ssl.**\[\text{RAND}_\text{pseudo}_\text{bytes}(num)\]**

Return (bytes, is\_cryptographic): bytes are \textit{num} pseudo-random bytes, \textit{is\_cryptographic} is \texttt{True} if the bytes generated are cryptographically strong. Raises an **SSLError** if the operation is not supported by the current RAND method.

Generated pseudo-random byte sequences will be unique if they are of sufficient length, but are not necessarily unpredictable. They can be used for non-cryptographic purposes and for certain purposes in cryptographic protocols, but usually not for key generation etc.

For almost all applications \texttt{os.urandom()} is preferable.

*New in version 3.3.*

*Deprecated since version 3.6:* OpenSSL has deprecated \texttt{ssl.RAND\_pseudo\_bytes()}, use \texttt{ssl.RAND\_bytes()} instead.

**ssl.**\[\text{RAND}_\text{status}()\]**

Return \texttt{True} if the SSL pseudo-random number generator has been seeded with ‘enough’ randomness, and \texttt{False} otherwise. You can use \texttt{ssl.RAND\_egd()} and \texttt{ssl.RAND\_add()} to increase the randomness of the pseudo-random number generator.

**ssl.**\[\text{RAND}_\text{egd}(path)\]**
If you are running an entropy-gathering daemon (EGD) somewhere, and path is the pathname of a socket connection open to it, this will read 256 bytes of randomness from the socket, and add it to the SSL pseudo-random number generator to increase the security of generated secret keys. This is typically only necessary on systems without better sources of randomness.

Availability: not available with LibreSSL and OpenSSL > 1.1.0

```python
ssl.RAND_add(bytes, entropy)
```
Mix the given bytes into the SSL pseudo-random number generator. The parameter entropy (a float) is a lower bound on the entropy contained in string (so you can always use 0.0). See RFC 1750 for more information on sources of entropy.

*Changed in version 3.5:* Writable bytes-like object is now accepted.

### 18.2.1.4. Certificate handling

```python
ssl.match_hostname(cert, hostname)
```
Verify that cert (in decoded format as returned by SSLSocket.getpeercert()) matches the given hostname. The rules applied are those for checking the identity of HTTPS servers as outlined in RFC 2818, RFC 5280 and RFC 6125. In addition to HTTPS, this function should be suitable for checking the identity of servers in various SSL-based protocols such as FTPS, IMAPS, POPS and others.

CertificateError is raised on failure. On success, the function
returns nothing:

```python
>>> cert = {'subject': ((('commonName', 'example.com'),
                      ssl.match_hostname(cert, 'example.com'))
```  

```python
>>> ssl.match_hostname(cert, 'example.org')
ssl.CertificateError: hostname 'example.org' doesn't match 'example.com'
```

Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/py3k/Lib/ssl.py", line 130, in match_hostname
ssl.CertificateError: hostname 'example.org' does
```

*New in version 3.2.*

*Changed in version 3.3.3:* The function now follows [RFC 6125](https://tools.ietf.org/html/rfc6125), section 6.4.3 and does neither match multiple wildcards (e.g. `*.example.com` or `a*.example.org`) nor a wildcard inside an internationalized domain names (IDN) fragment. IDN A-labels such as `www*.xn--pthon-kva.org` are still supported, but `x*.python.org` no longer matches `xn--tda.python.org`.

*Changed in version 3.5:* Matching of IP addresses, when present in the subjectAltName field of the certificate, is now supported.

*Changed in version 3.7:* The function is no longer used to TLS connections. Hostname matching is now performed by OpenSSL.

Allow wildcard when it is the leftmost and the only character in that segment. Partial wildcards like `www*.example.com` are no longer supported.

*Deprecated since version 3.7.*

```python
ssl.cert_time_to_seconds(cert_time)
```

Return the time in seconds since the Epoch, given the `cert_time`
string representing the “notBefore” or “notAfter” date from a certificate in "%b %d %H:%M:%S %Y %Z" strftime format (C locale).

Here's an example:

```python
>>> import ssl
>>> timestamp = ssl.cert_time_to_seconds("Jan 5 09:34:43 2018 GMT")
1515144883
>>> from datetime import datetime
>>> print(datetime.utcfromtimestamp(timestamp))
2018-01-05 09:34:43
```

“notBefore” or “notAfter” dates must use GMT (RFC 5280).

*Changed in version 3.5:* Interpret the input time as a time in UTC as specified by ‘GMT’ timezone in the input string. Local timezone was used previously. Return an integer (no fractions of a second in the input format)

```python
ssl.get_server_certificate(addr, ssl_version=PROTOCOL_TLS, ca_certs=None)
```

Given the address `addr` of an SSL-protected server, as a `(hostname, port-number)` pair, fetches the server’s certificate, and returns it as a PEM-encoded string. If `ssl_version` is specified, uses that version of the SSL protocol to attempt to connect to the server. If `ca_certs` is specified, it should be a file containing a list of root certificates, the same format as used for the same parameter in `wrap_socket()`. The call will attempt to validate the server certificate against that set of root certificates, and will fail if the validation attempt fails.
Changed in version 3.3: This function is now IPv6-compatible.

Changed in version 3.5: The default ssl_version is changed from PROTOCOL_SSLv3 to PROTOCOL_TLS for maximum compatibility with modern servers.

ssl.DER_cert_to_PEM_cert(DER_cert_bytes)
Given a certificate as a DER-encoded blob of bytes, returns a PEM-encoded string version of the same certificate.

ssl.PEM_cert_to_DER_cert(PEM_cert_string)
Given a certificate as an ASCII PEM string, returns a DER-encoded sequence of bytes for that same certificate.

ssl.get_default_verify_paths()
Returns a named tuple with paths to OpenSSL's default cafile and capath. The paths are the same as used by SSLContext.set_default_verify_paths(). The return value is a named tuple DefaultVerifyPaths:

- cafile - resolved path to cafile or None if the file doesn't exist,
- capath - resolved path to capath or None if the directory doesn't exist,
- openssl_cafile_env - OpenSSL's environment key that points to a cafile,
- openssl_cafile - hard coded path to a cafile,
- openssl_capath_env - OpenSSL's environment key that points to a capath,
- openssl_capath - hard coded path to a capath directory

Availability: LibreSSL ignores the environment vars openssl_cafile_env and openssl_capath_env
New in version 3.4.

**ssl.enum_certificates(store_name)**

Retrieve certificates from Windows’ system cert store. `store_name` may be one of `CA`, `ROOT` or `MY`. Windows may provide additional cert stores, too.

The function returns a list of (cert_bytes, encoding_type, trust) tuples. The encoding_type specifies the encoding of cert_bytes. It is either `x509_asn` for X.509 ASN.1 data or `pkcs_7_asn` for PKCS#7 ASN.1 data. Trust specifies the purpose of the certificate as a set of OIDs or exactly `True` if the certificate is trustworthy for all purposes.

Example:

```python
>>> ssl.enum_certificates("CA")
[(b'data...', 'x509_asn', {'1.3.6.1.5.5.7.3.1', '1.3.6.1.5.5.7.3.2'}),
 (b'data...', 'x509_asn', True)]
```

Availability: Windows.

New in version 3.4.

**ssl.enum_crls(store_name)**

Retrieve CRLs from Windows’ system cert store. `store_name` may be one of `CA`, `ROOT` or `MY`. Windows may provide additional cert stores, too.

The function returns a list of (cert_bytes, encoding_type, trust) tuples. The encoding_type specifies the encoding of cert_bytes. It is either `x509_asn` for X.509 ASN.1 data or `pkcs_7_asn` for PKCS#7 ASN.1 data.
Availability: Windows.

New in version 3.4.

18.2.1.5. Constants

All constants are now enum.IntEnum or enum.IntFlag collections.

New in version 3.6.

ssl. CERT_NONE
Possible value for SSLContext.verify_mode, or the cert_reqs parameter to wrap_socket(). In this mode (the default), no certificates will be required from the other side of the socket connection. If a certificate is received from the other end, no attempt to validate it is made.

See the discussion of Security considerations below.

ssl. CERT_OPTIONAL
Possible value for SSLContext.verify_mode, or the cert_reqs parameter to wrap_socket(). In this mode no certificates will be required from the other side of the socket connection; but if they are provided, validation will be attempted and an SSLError will be raised on failure.

Use of this setting requires a valid set of CA certificates to be passed, either to SSLContext.load_verify_locations() or as a value of the ca_certs parameter to wrap_socket().

ssl. CERT_REQUIRED
Possible value for SSLContext.verify_mode, or the
cert_reqs parameter to wrap_socket(). In this mode, certificates are required from the other side of the socket connection; an SSLError will be raised if no certificate is provided, or if its validation fails.

Use of this setting requires a valid set of CA certificates to be passed, either to SSLContext.load_verify_locations() or as a value of the ca_certs parameter to wrap_socket().

class ssl.VerifyMode
enum.IntEnum collection of CERT_* constants.

    New in version 3.6.

ssl.VERIFY_DEFAULT
    Possible value for SSLContext.verify_flags. In this mode, certificate revocation lists (CRLs) are not checked. By default OpenSSL does neither require nor verify CRLs.

    New in version 3.4.

ssl.VERIFY_CRL_CHECK_LEAF
    Possible value for SSLContext.verify_flags. In this mode, only the peer cert is check but none of the intermediate CA certificates. The mode requires a valid CRL that is signed by the peer cert's issuer (its direct ancestor CA). If no proper has been loaded SSLContext.load_verify_locations, validation will fail.

    New in version 3.4.

ssl.VERIFY_CRL_CHECK_CHAIN
    Possible value for SSLContext.verify_flags. In this mode,
CRLs of all certificates in the peer cert chain are checked.

*New in version 3.4.*

**ssl.** `VERIFY_X509 STRICT`  
Possible value for `SSLContext.verify_flags` to disable workarounds for broken X.509 certificates.

*New in version 3.4.*

**ssl.** `VERIFY_X509 TRUSTED_FIRST`  
Possible value for `SSLContext.verify_flags`. It instructs OpenSSL to prefer trusted certificates when building the trust chain to validate a certificate. This flag is enabled by default.

*New in version 3.4.4.*

**class ssl.** `VerifyFlags`  
`enum.IntFlag` collection of `VERIFY_*` constants.

*New in version 3.6.*

**ssl.** `PROTOCOL_TLS`  
Selects the highest protocol version that both the client and server support. Despite the name, this option can select both “SSL” and “TLS” protocols.

*New in version 3.6.*

**ssl.** `PROTOCOL_TLS_CLIENT`  
Auto-negotiate the highest protocol version like `PROTOCOL_TLS`, but only support client-side `SSLSocket` connections. The protocol enables `CERT_REQUIRED` and `check_hostname` by default.
New in version 3.6.

ssl. **PROTOCOL_TLS_SERVER**
Auto-negotiate the highest protocol version like `PROTOCOL_TLS`, but only support server-side `SSLSocket` connections.

New in version 3.6.

ssl. **PROTOCOL_SSLv23**
Alias for data: `PROTOCOL_TLS`.

*Deprecated since version 3.6:* Use `PROTOCOL_TLS` instead.

ssl. **PROTOCOL_SSLv2**
Selects SSL version 2 as the channel encryption protocol.

This protocol is not available if OpenSSL is compiled with the `OPENSSL_NO_SSL2` flag.

**Warning:** SSL version 2 is insecure. Its use is highly discouraged.

*Deprecated since version 3.6:* OpenSSL has removed support for SSLv2.

ssl. **PROTOCOL_SSLv3**
Selects SSL version 3 as the channel encryption protocol.

This protocol is not be available if OpenSSL is compiled with the `OPENSSL_NO_SSLv3` flag.

**Warning:** SSL version 3 is insecure. Its use is highly discouraged.
Deprecated since version 3.6: OpenSSL has deprecated all version specific protocols. Use the default protocol PROTOCOL_TLS with flags like OP_NO_SSLv3 instead.

ssl.PROTOCOL_TLSv1
Selects TLS version 1.0 as the channel encryption protocol.

Deprecated since version 3.6: OpenSSL has deprecated all version specific protocols. Use the default protocol PROTOCOL_TLS with flags like OP_NO_SSLv3 instead.

ssl.PROTOCOL_TLSv1_1
Selects TLS version 1.1 as the channel encryption protocol. Available only with openssl version 1.0.1+.

New in version 3.4.

Deprecated since version 3.6: OpenSSL has deprecated all version specific protocols. Use the default protocol PROTOCOL_TLS with flags like OP_NO_SSLv3 instead.

ssl.PROTOCOL_TLSv1_2
Selects TLS version 1.2 as the channel encryption protocol. This is the most modern version, and probably the best choice for maximum protection, if both sides can speak it. Available only with openssl version 1.0.1+.

New in version 3.4.

Deprecated since version 3.6: OpenSSL has deprecated all version specific protocols. Use the default protocol PROTOCOL_TLS with flags like OP_NO_SSLv3 instead.
ssl. **OP_ALL**

Enables workarounds for various bugs present in other SSL implementations. This option is set by default. It does not necessarily set the same flags as OpenSSL's `SSL_OP_ALL` constant.

*New in version 3.2.*

ssl. **OP_NO_SSLv2**

Prevents an SSLv2 connection. This option is only applicable in conjunction with `PROTOCOL_TLS`. It prevents the peers from choosing SSLv2 as the protocol version.

*New in version 3.2.*

*Deprecated since version 3.6: SSLv2 is deprecated*

ssl. **OP_NO_SSLv3**

Prevents an SSLv3 connection. This option is only applicable in conjunction with `PROTOCOL_TLS`. It prevents the peers from choosing SSLv3 as the protocol version.

*New in version 3.2.*

*Deprecated since version 3.6: SSLv3 is deprecated*

ssl. **OP_NO_TLSv1**

Prevents a TLSv1 connection. This option is only applicable in conjunction with `PROTOCOL_TLS`. It prevents the peers from choosing TLSv1 as the protocol version.

*New in version 3.2.*

ssl. **OP_NO_TLSv1_1**
Prevents a TLSv1.1 connection. This option is only applicable in conjunction with `PROTOCOL_TLS`. It prevents the peers from choosing TLSv1.1 as the protocol version. Available only with openssl version 1.0.1+.

*New in version 3.4.*

**ssl. OP_NO_TLSv1_2**

Prevents a TLSv1.2 connection. This option is only applicable in conjunction with `PROTOCOL_TLS`. It prevents the peers from choosing TLSv1.2 as the protocol version. Available only with openssl version 1.0.1+.

*New in version 3.4.*

**ssl. OP_NO_TLSv1_3**

Prevents a TLSv1.3 connection. This option is only applicable in conjunction with `PROTOCOL_TLS`. It prevents the peers from choosing TLSv1.3 as the protocol version. TLS 1.3 is available with OpenSSL 1.1.1 or later. When Python has been compiled against an older version of OpenSSL, the flag defaults to 0.

*New in version 3.7.*

**ssl. OP_CIPHER_SERVER_PREFERENCE**

Use the server’s cipher ordering preference, rather than the client’s. This option has no effect on client sockets and SSLv2 server sockets.

*New in version 3.3.*

**ssl. OP_SINGLE_DH_USE**

Prevents re-use of the same DH key for distinct SSL sessions. This
improves forward secrecy but requires more computational resources. This option only applies to server sockets.

*New in version 3.3.*

**ssl. OP_SINGLE_ECDH_USE**
Prevents re-use of the same ECDH key for distinct SSL sessions. This improves forward secrecy but requires more computational resources. This option only applies to server sockets.

*New in version 3.3.*

**ssl. OP_NO_COMPRESSION**
Disable compression on the SSL channel. This is useful if the application protocol supports its own compression scheme.

This option is only available with OpenSSL 1.0.0 and later.

*New in version 3.3.*

**class ssl. Options**

*enum.IntFlag* collection of OP_* constants.

**ssl. OP_NO_TICKET**
Prevent client side from requesting a session ticket.

*New in version 3.6.*

**ssl. HAS_ALPN**
Whether the OpenSSL library has built-in support for the Application-Layer Protocol Negotiation TLS extension as described in [RFC 7301].

*New in version 3.5.*
ssl. **HAS.Never_Check_Common_Name**

Whether the OpenSSL library has built-in support not checking subject common name and `
SSLContext.hostname_checks_common_name` is writeable.

*New in version 3.7.*

ssl. **HAS.ECDH**

Whether the OpenSSL library has built-in support for Elliptic Curve-based Diffie-Hellman key exchange. This should be true unless the feature was explicitly disabled by the distributor.

*New in version 3.3.*

ssl. **HAS.SNI**

Whether the OpenSSL library has built-in support for the `Server Name Indication` extension (as defined in RFC 6066).

*New in version 3.2.*

ssl. **HAS.NPN**

Whether the OpenSSL library has built-in support for `Next Protocol Negotiation` as described in the `Application Layer Protocol Negotiation`. When true, you can use the `SSLContext.set_npn_protocols()` method to advertise which protocols you want to support.

*New in version 3.3.*

ssl. **HAS.TLSv1_3**

Whether the OpenSSL library has built-in support for the TLS 1.3 protocol.

*New in version 3.7.*
ssl.CHANNEL_BINDING_TYPES
List of supported TLS channel binding types. Strings in this list can be used as arguments to SSLSocket.get_channel_binding().

New in version 3.3.

ssl.OPENSSL_VERSION
The version string of the OpenSSL library loaded by the interpreter:

```python
>>> ssl.OPENSSL_VERSION
'OpenSSL 1.0.2k 26 Jan 2017'
```

New in version 3.2.

ssl.OPENSSL_VERSION_INFO
A tuple of five integers representing version information about the OpenSSL library:

```python
>>> ssl.OPENSSL_VERSION_INFO
(1, 0, 2, 11, 15)
```

New in version 3.2.

ssl.OPENSSL_VERSION_NUMBER
The raw version number of the OpenSSL library, as a single integer:

```python
>>> ssl.OPENSSL_VERSION_NUMBER
268443839
>>> hex(ssl.OPENSSL_VERSION_NUMBER)
'0x100020bf'
```

New in version 3.2.
Alert Descriptions from RFC 5246 and others. The IANA TLS Alert Registry contains this list and references to the RFCs where their meaning is defined.

Used as the return value of the callback function in `SSLContext.set_servername_callback()`.

*New in version 3.4.*

```python
class ssl.AlertDescription
    enum.IntEnum collection of ALERT_DESCRIPTION_* constants.

*New in version 3.6.*
```

Purpose. **SERVER_AUTH**

Option for `create_default_context()` and `SSLContext.load_default_certs()`. This value indicates that the context may be used to authenticate Web servers (therefore, it will be used to create client-side sockets).

*New in version 3.4.*

Purpose. **CLIENT_AUTH**

Option for `create_default_context()` and `SSLContext.load_default_certs()`. This value indicates that the context may be used to authenticate Web clients (therefore, it will be used to create server-side sockets).

*New in version 3.4.*

```python
class ssl.SSLErrorNumber
```
enum.IntEnum collection of SSL_ERROR_* constants.

New in version 3.6.
18.2.2. SSL Sockets

`class ssl.SSLSocket(socket.socket)`

SSL sockets provide the following methods of Socket Objects:

- `accept()`
- `bind()`
- `close()`
- `connect()`
- `detach()`
- `fileno()`
- `getpeername()`, `getsockname()`
- `getsockopt()`, `setsockopt()`
- `gettimeout()`, `settimeout()`, `setblocking()`
- `listen()`
- `makefile()`
- `recv()`, `recv_into()` (but passing a non-zero flags argument is not allowed)
- `send()`, `sendall()` (with the same limitation)
- `sendfile()` (but `os.sendfile` will be used for plain-text sockets only, else `send()` will be used)
- `shutdown()`

However, since the SSL (and TLS) protocol has its own framing atop of TCP, the SSL sockets abstraction can, in certain respects, diverge from the specification of normal, OS-level sockets. See especially the notes on non-blocking sockets.

Usually, `SSLSocket` are not created directly, but using the `SSLContext.wrap_socket()` method.

*Changed in version 3.5:* The `sendfile()` method was added.
Changed in version 3.5: The `shutdown()` does not reset the socket timeout each time bytes are received or sent. The socket timeout is now to maximum total duration of the shutdown.

Deprecated since version 3.6: It is deprecated to create a `SSLSocket` instance directly, use `SSLContext.wrap_socket()` to wrap a socket.

SSL sockets also have the following additional methods and attributes:

`SSLSocket.read(len=1024, buffer=None)`

Read up to `len` bytes of data from the SSL socket and return the result as a `bytes` instance. If `buffer` is specified, then read into the buffer instead, and return the number of bytes read.

Raise `SSLWantReadError` or `SSLWantWriteError` if the socket is non-blocking and the read would block.

As at any time a re-negotiation is possible, a call to `read()` can also cause write operations.

Changed in version 3.5: The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration to read up to `len` bytes.

Deprecated since version 3.6: Use `recv()` instead of `read()`.

`SSLSocket.write(buf)`

Write `buf` to the SSL socket and return the number of bytes written. The `buf` argument must be an object supporting the buffer interface.

Raise `SSLWantReadError` or `SSLWantWriteError` if the
socket is **non-blocking** and the write would block.

As at any time a re-negotiation is possible, a call to `write()` can also cause read operations.

*Changed in version 3.5:* The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration to write `buf`.

*Deprecated since version 3.6:* Use `send()` instead of `write()`.

**Note:** The `read()` and `write()` methods are the low-level methods that read and write unencrypted, application-level data and decrypt/encrypt it to encrypted, wire-level data. These methods require an active SSL connection, i.e. the handshake was completed and `SSLSocket.unwrap()` was not called.

Normally you should use the socket API methods like `recv()` and `send()` instead of these methods.

`SSLSocket.do_handshake()`

Perform the SSL setup handshake.

*Changed in version 3.4:* The handshake method also performs `match_hostname()` when the `check_hostname` attribute of the socket's `context` is true.

*Changed in version 3.5:* The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration of the handshake.

*Changed in version 3.7:* Hostname or IP address is matched by OpenSSL during handshake. The function `match_hostname()` is
no longer used. In case OpenSSL refuses a hostname or IP address, the handshake is aborted early and a TLS alert message is send to the peer.

SSLSocket.getpeercert(binary_form=False)

If there is no certificate for the peer on the other end of the connection, return None. If the SSL handshake hasn’t been done yet, raise ValueError.

If the binary_form parameter is False, and a certificate was received from the peer, this method returns a dict instance. If the certificate was not validated, the dict is empty. If the certificate was validated, it returns a dict with several keys, amongst them subject (the principal for which the certificate was issued) and issuer (the principal issuing the certificate). If a certificate contains an instance of the Subject Alternative Name extension (see RFC 3280), there will also be a subjectAltName key in the dictionary.

The subject and issuer fields are tuples containing the sequence of relative distinguished names (RDNs) given in the certificate’s data structure for the respective fields, and each RDN is a sequence of name-value pairs. Here is a real-world example:

```python
{'issuer': (((('countryName', 'IL'),),
((('organizationName', 'StartCom Ltd.'),
(('organizationalUnitName', 'Secure Digital Certificate Signing
(('commonName', 'StartCom Class 2 Primary Intermediate

'notAfter': 'Nov 22 08:15:19 2013 GMT',
'notBefore': 'Nov 21 03:09:52 2011 GMT',
'serialNumber': '95F0',
```
Note: To validate a certificate for a particular service, you can use the `match_hostname()` function.

If the `binary_form` parameter is `True`, and a certificate was provided, this method returns the DER-encoded form of the entire certificate as a sequence of bytes, or `None` if the peer did not provide a certificate. Whether the peer provides a certificate depends on the SSL socket's role:

- for a client SSL socket, the server will always provide a certificate, regardless of whether validation was required;
- for a server SSL socket, the client will only provide a certificate when requested by the server; therefore `getpeercert()` will return `None` if you used `CERT_NONE` (rather than `CERT_OPTIONAL` or `CERT_REQUIRED`).

*Changed in version 3.2:* The returned dictionary includes additional items such as `issuer` and `notBefore`.

*Changed in version 3.4:* `ValueError` is raised when the handshake isn't done. The returned dictionary includes additional X509v3 extension items such as `crlDistributionPoints`, `caIssuers` and OCSP URIs.
SSLSSocket.cipher()

Returns a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used. If no connection has been established, returns None.

SSLSSocket.shared_ciphers()

Return the list of ciphers shared by the client during the handshake. Each entry of the returned list is a three-value tuple containing the name of the cipher, the version of the SSL protocol that defines its use, and the number of secret bits the cipher uses. shared_ciphers() returns None if no connection has been established or the socket is a client socket.

New in version 3.5.

SSLSSocket.compression()

Return the compression algorithm being used as a string, or None if the connection isn’t compressed.

If the higher-level protocol supports its own compression mechanism, you can use OP_NO_COMPRESSION to disable SSL-level compression.

New in version 3.3.

SSLSSocket.get_channel_binding(cb_type="tls-unique")

Get channel binding data for current connection, as a bytes object. Returns None if not connected or the handshake has not been completed.

The cb_type parameter allow selection of the desired channel binding type. Valid channel binding types are listed in the
**CHANNEL_BINDING_TYPES** list. Currently only the ‘tls-unique’ channel binding, defined by RFC 5929, is supported. `ValueError` will be raised if an unsupported channel binding type is requested.

*New in version 3.3.*

**SSLSocket**. `selected_alpn_protocol()`  
Return the protocol that was selected during the TLS handshake. If `SSLContext.set_alpn_protocols()` was not called, if the other party does not support ALPN, if this socket does not support any of the client’s proposed protocols, or if the handshake has not happened yet, `None` is returned.

*New in version 3.5.*

**SSLSocket**. `selected_npn_protocol()`  
Return the higher-level protocol that was selected during the TLS/SSL handshake. If `SSLContext.set_npn_protocols()` was not called, or if the other party does not support NPN, or if the handshake has not yet happened, this will return `None`.

*New in version 3.3.*

**SSLSocket**. `unwrap()`  
Performs the SSL shutdown handshake, which removes the TLS layer from the underlying socket, and returns the underlying socket object. This can be used to go from encrypted operation over a connection to unencrypted. The returned socket should always be used for further communication with the other side of the connection, rather than the original socket.

**SSLSocket**. `version()`  
Return the actual SSL protocol version negotiated by the
connection as a string, or None is no secure connection is established. As of this writing, possible return values include "SSLv2", "SSLv3", "TLSv1", "TLSv1.1" and "TLSv1.2". Recent OpenSSL versions may define more return values.

New in version 3.5.

SSLSocket.pending()

Returns the number of already decrypted bytes available for read, pending on the connection.

SSLSocket.context

The SSLContext object this SSL socket is tied to. If the SSL socket was created using the top-level wrap_socket() function (rather than SSLContext.wrap_socket()), this is a custom context object created for this SSL socket.

New in version 3.2.

SSLSocket.server_side

A boolean which is True for server-side sockets and False for client-side sockets.

New in version 3.2.

SSLSocket.server_hostname

Hostname of the server: str type, or None for server-side socket or if the hostname was not specified in the constructor.

New in version 3.2.

SSLSocket.session

The SSLSession for this SSL connection. The session is available
for client and server side sockets after the TLS handshake has been performed. For client sockets the session can be set before `do_handshake()` has been called to reuse a session.

*New in version 3.6.*

`SSLSocket.session_reused`

*New in version 3.6.*
18.2.3. SSL Contexts

New in version 3.2.

An SSL context holds various data longer-lived than single SSL connections, such as SSL configuration options, certificate(s) and private key(s). It also manages a cache of SSL sessions for server-side sockets, in order to speed up repeated connections from the same clients.

class ssl.SSLContext(protocol=PROTOCOL_TLS)

Create a new SSL context. You may pass protocol which must be one of the PROTOCOL_* constants defined in this module. PROTOCOL_TLS is currently recommended for maximum interoperability and default value.

See also: create_default_context() lets the ssl module choose security settings for a given purpose.

Changed in version 3.6: The context is created with secure default values. The options OP_NO_COMPRESSION, OP_CIPHER_SERVER_PREFERENCE, OP_SINGLE_DH_USE, OP_SINGLE_ECDH_USE, OP_NO_SSLv2 (except for PROTOCOL_SSLv2), and OP_NO_SSLv3 (except for PROTOCOL_SSLv3) are set by default. The initial cipher suite list contains only HIGH ciphers, no NULL ciphers and no MD5 ciphers (except for PROTOCOL_SSLv2).

SSLContext objects have the following methods and attributes:

SSLContext.cert_store_stats()
Get statistics about quantities of loaded X.509 certificates, count of X.509 certificates flagged as CA certificates and certificate revocation lists as dictionary.

Example for a context with one CA cert and one other cert:

```python
>>> context.cert_store_stats()
{'crl': 0, 'x509_ca': 1, 'x509': 2}
```

*New in version 3.4.*

**SSLContext.load_cert_chain**(*certfile*, *keyfile=None*, *password=None*)

Load a private key and the corresponding certificate. The *certfile* string must be the path to a single file in PEM format containing the certificate as well as any number of CA certificates needed to establish the certificate's authenticity. The *keyfile* string, if present, must point to a file containing the private key in. Otherwise the private key will be taken from *certfile* as well. See the discussion of **Certificates** for more information on how the certificate is stored in the *certfile*.

The *password* argument may be a function to call to get the password for decrypting the private key. It will only be called if the private key is encrypted and a password is necessary. It will be called with no arguments, and it should return a string, bytes, or bytearray. If the return value is a string it will be encoded as UTF-8 before using it to decrypt the key. Alternatively a string, bytes, or bytearray value may be supplied directly as the *password* argument. It will be ignored if the private key is not encrypted and no password is needed.

If the *password* argument is not specified and a password is
required, OpenSSL's built-in password prompting mechanism will be used to interactively prompt the user for a password.

An `SSLError` is raised if the private key doesn’t match with the certificate.

*Changed in version 3.3:* New optional argument `password`.

```python
SSLContext.load_default_certs(purpose=Purpose.SERVER_AUTH)
```

Load a set of default “certification authority” (CA) certificates from default locations. On Windows it loads CA certs from the **CA** and **ROOT** system stores. On other systems it calls `SSLContext.set_default_verify_paths()`. In the future the method may load CA certificates from other locations, too.

The `purpose` flag specifies what kind of CA certificates are loaded. The default settings `Purpose.SERVER_AUTH` loads certificates, that are flagged and trusted for TLS web server authentication (client side sockets). `Purpose.CLIENT_AUTH` loads CA certificates for client certificate verification on the server side.

*New in version 3.4.*

```python
SSLContext.load_verify_locations(cafile=None, capath=None, cadata=None)
```

Load a set of “certification authority” (CA) certificates used to validate other peers’ certificates when `verify_mode` is other than `CERT_NONE`. At least one of `cafile` or `capath` must be specified.

This method can also load certification revocation lists (CRLs) in PEM or DER format. In order to make use of CRLs, `SSLContext.verify_flags` must be configured properly.
The `cafile` string, if present, is the path to a file of concatenated CA certificates in PEM format. See the discussion of `Certificates` for more information about how to arrange the certificates in this file.

The `capath` string, if present, is the path to a directory containing several CA certificates in PEM format, following an OpenSSL specific layout.

The `cadata` object, if present, is either an ASCII string of one or more PEM-encoded certificates or a bytes-like object of DER-encoded certificates. Like with `capath` extra lines around PEM-encoded certificates are ignored but at least one certificate must be present.

*Changed in version 3.4:* New optional argument `cadata`

`SSLContext.get_ca_certs(binary_form=False)`

Get a list of loaded “certification authority” (CA) certificates. If the `binary_form` parameter is `False` each list entry is a dict like the output of `SSLSocket.getpeercert()`. Otherwise the method returns a list of DER-encoded certificates. The returned list does not contain certificates from `capath` unless a certificate was requested and loaded by a SSL connection.

**Note:** Certificates in a capath directory aren’t loaded unless they have been used at least once.

*New in version 3.4.*

`SSLContext.get_ciphers()`

Get a list of enabled ciphers. The list is in order of cipher priority. See `SSLContext.set_ciphers()`.
Example:

```python
>>> ctx = ssl.SSLContext(ssl.PROTOCOL_SSLv23)
>>> ctx.set_ciphers('ECDHE+AESGCM:!ECDSA')
>>> ctx.get_ciphers()  # OpenSSL 1.0.x
[['alg_bits': 256,
  'description': 'ECDHE-RSA-AES256-GCM-SHA384 TLS
  Enc=AESGCM(256) Mac=AEAD',
  'id': 50380848,
  'name': 'ECDHE-RSA-AES256-GCM-SHA384',
  'protocol': 'TLSv1/SSLv3',
  'strength_bits': 256},
{'alg_bits': 128,
  'description': 'ECDHE-RSA-AES128-GCM-SHA256 TLS
  Enc=AESGCM(128) Mac=AEAD',
  'id': 50380847,
  'name': 'ECDHE-RSA-AES128-GCM-SHA256',
  'protocol': 'TLSv1/SSLv3',
  'strength_bits': 128}]
```

On OpenSSL 1.1 and newer the cipher dict contains additional fields:

```python
>>> ctx.get_ciphers()  # OpenSSL 1.1+
[['aead': True,
  'alg_bits': 256,
  'auth': 'auth-rsa',
  'description': 'ECDHE-RSA-AES256-GCM-SHA384 TLS
  Enc=AESGCM(256) Mac=AEAD',
  'digest': None,
  'id': 50380848,
  'kea': 'kx-ecdhe',
  'name': 'ECDHE-RSA-AES256-GCM-SHA384',
  'protocol': 'TLSv1.2',
  'strength_bits': 256,
  'symmetric': 'aes-256-gcm'],
```
Availability: OpenSSL 1.0.2+

New in version 3.6.

**SSLContext.set_default_verify_paths()**

Load a set of default “certification authority” (CA) certificates from a filesystem path defined when building the OpenSSL library. Unfortunately, there’s no easy way to know whether this method succeeds: no error is returned if no certificates are to be found. When the OpenSSL library is provided as part of the operating system, though, it is likely to be configured properly.

**SSLContext.set_ciphers(ciphers)**

Set the available ciphers for sockets created with this context. It should be a string in the OpenSSL cipher list format. If no cipher can be selected (because compile-time options or other configuration forbids use of all the specified ciphers), an SSLError will be raised.

**Note:** when connected, the SSLSocket.cipher() method of
SSLContext.set_alpn_protocols(protocols)

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of ASCII strings, like 
['http/1.1', 'spdy/2'], ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to RFC 7301. After a successful handshake, the SSLSocket.selected_alpn_protocol() method will return the agreed-upon protocol.

This method will raise NotImplementedError if HAS_ALPN is False.

OpenSSL 1.1.0 to 1.1.0e will abort the handshake and raise SSLError when both sides support ALPN but cannot agree on a protocol. 1.1.0f+ behaves like 1.0.2, SSLSocket.selected_alpn_protocol() returns None.

New in version 3.5.

SSLContext.set_npn_protocols(protocols)

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of strings, like 
['http/1.1', 'spdy/2'], ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to the Application Layer Protocol Negotiation. After a successful handshake, the SSLSocket.selected_npn_protocol() method will return the agreed-upon protocol.

This method will raise NotImplementedError if HAS_NPN is
SSLContext.set_servername_callback(server_name_callback)

Register a callback function that will be called after the TLS Client Hello handshake message has been received by the SSL/TLS server when the TLS client specifies a server name indication. The server name indication mechanism is specified in RFC 6066 section 3 - Server Name Indication.

Only one callback can be set per SSLContext. If server_name_callback is None then the callback is disabled. Calling this function a subsequent time will disable the previously registered callback.

The callback function, server_name_callback, will be called with three arguments; the first being the ssl.SSLSocket, the second is a string that represents the server name that the client is intending to communicate (or None if the TLS Client Hello does not contain a server name) and the third argument is the original SSLContext. The server name argument is the IDNA decoded server name.

A typical use of this callback is to change the ssl.SSLSocket's SSLSocket.context attribute to a new object of type SSLContext representing a certificate chain that matches the server name.

Due to the early negotiation phase of the TLS connection, only limited methods and attributes are usable like SSLSocket.selected_alpn_protocol() and SSLSocket.context. SSLSocket.getpeercert(),
SSL socket methods require that the TLS connection has progressed beyond the TLS Client Hello and therefore will not contain return meaningful values nor can they be called safely.

The `server_name_callback` function must return `None` to allow the TLS negotiation to continue. If a TLS failure is required, a constant `ALERT_DESCRIPTION_*` can be returned. Other return values will result in a TLS fatal error with `ALERT_DESCRIPTION_INTERNAL_ERROR`.

If there is an IDNA decoding error on the server name, the TLS connection will terminate with an `ALERT_DESCRIPTION_INTERNAL_ERROR` fatal TLS alert message to the client.

If an exception is raised from the `server_name_callback` function the TLS connection will terminate with a fatal TLS alert message `ALERT_DESCRIPTION_HANDSHAKE_FAILURE`.

This method will raise `NotImplementedError` if the OpenSSL library had `OPENSSL_NO_TLSEXT` defined when it was built.

`New in version 3.4.`

`SSLContext.load_dh_params(dhfile)`

Load the key generation parameters for Diffie-Helman (DH) key exchange. Using DH key exchange improves forward secrecy at the expense of computational resources (both on the server and on the client). The `dhfile` parameter should be the path to a file containing DH parameters in PEM format.
This setting doesn’t apply to client sockets. You can also use the `OP_SINGLE_DH_USE` option to further improve security.

*New in version 3.3.*

**SSLContext.set_ecdh_curve** *(curve_name)*

Set the curve name for Elliptic Curve-based Diffie-Hellman (ECDH) key exchange. ECDH is significantly faster than regular DH while arguably as secure. The `curve_name` parameter should be a string describing a well-known elliptic curve, for example `prime256v1` for a widely supported curve.

This setting doesn’t apply to client sockets. You can also use the `OP_SINGLE_ECDH_USE` option to further improve security.

This method is not available if `HAS_ECDH` is `False`.

*New in version 3.3.*

<tr>
<td>Vincent Bernat.</td>
</tr>
</tbody>
</table>

**SSLContext.wrap_socket** *(sock, server_side=False, do_handshake_on_connect=True, suppress_ragged_eofs=True, server_hostname=None, session=None)*

Wrap an existing Python socket `sock` and return an instance of `SSLContext.sslsocket_class` (default `SSLSocket`). `sock` must be a `SOCK_STREAM` socket; other socket types are unsupported.

The returned SSL socket is tied to the context, its settings and certificates. The parameters `server_side`, `do_handshake_on_connect`, `suppress_ragged_eofs`, `server_hostname`, and `session` are passed to `SSLSocket`. The `server_side` parameter determines whether the SSL socket is used as a client or a server. If `server_side` is `True`, the SSL socket will be used as a server. If `server_side` is `False`, the SSL socket will be used as a client. The `do_handshake_on_connect` parameter determines whether the SSL handshake should be performed immediately after the socket is created. If `do_handshake_on_connect` is `True`, the SSL handshake will be performed. If `do_handshake_on_connect` is `False`, the SSL handshake will be performed when the socket is used. The `suppress_ragged_eofs` parameter determines whether error messages should be suppressed when the socket is closed. If `suppress_ragged_eofs` is `True`, error messages will be suppressed. If `suppress_ragged_eofs` is `False`, error messages will be displayed. The `server_hostname` parameter is used to specify the hostname of the server. If `server_hostname` is not specified, the hostname will be inferred from the socket. The `session` parameter is used to specify a previously established SSL session. If `session` is specified, the SSL context will be used to resume the session.
do_handshake_on_connect and suppress_ragged_eofs have the same meaning as in the top-level wrap_socket() function.

On client connections, the optional parameter server_hostname specifies the hostname of the service which we are connecting to. This allows a single server to host multiple SSL-based services with distinct certificates, quite similarly to HTTP virtual hosts. Specifying server_hostname will raise a ValueError if server_side is true.

session, see session.

Changed in version 3.5: Always allow a server_hostname to be passed, even if OpenSSL does not have SNI.

Changed in version 3.6: session argument was added.

Changed in version 3.7: The method returns on instance of SSLContext.sslsocket_class instead of hard-coded SSLSocket.

SSLContext.sslsocket_class
The return type of SSLContext.wrap_sockets(), defaults to SSLSocket. The attribute can be overridden on instance of class in order to return a custom subclass of SSLSocket.

New in version 3.7.

SSLContext.wrap_bio(incoming, outgoing, server_side=False, server_hostname=None, session=None)
Wrap the BIO objects incoming and outgoing and return an instance of attr:SSLContext.sslobject_class (default SSLObject). The SSL routines will read input data from the incoming BIO and
write data to the outgoing BIO.

The server_side, server_hostname and session parameters have the same meaning as in SSLContext.wrap_socket().

*Changed in version 3.6:* session argument was added.

*Changed in version 3.7:* The method returns an instance of SSLContext.sslobject_class instead of hard-coded SSLObject.

**SSLContext.sslobject_class**

The return type of SSLContext.wrap_bio(), defaults to SSLObject. The attribute can be overridden on instance of class in order to return a custom subclass of SSLObject.

*New in version 3.7.*

**SSLContext.session_stats()**

Get statistics about the SSL sessions created or managed by this context. A dictionary is returned which maps the names of each piece of information to their numeric values. For example, here is the total number of hits and misses in the session cache since the context was created:

```python
>>> stats = context.session_stats()
>>> stats['hits'], stats['misses']
(0, 0)
```

**SSLContext.check_hostname**

Whether to match the peer cert's hostname with match_hostname() in SSLSocket.do_handshake(). The context's verify_mode must be set to CERT_OPTIONAL or
CERT_REQUIRED, and you must pass server_hostname to wrap_socket() in order to match the hostname. Enabling hostname checking automatically sets verify_mode from CERT_NONE to CERT_REQUIRED. It cannot be set back to CERT_NONE as long as hostname checking is enabled.

Example:

```python
import socket, ssl

context = ssl.SSLContext(ssl.PROTOCOL_TLSv1)
context.verify_mode = ssl.CERT_REQUIRED
context.check_hostname = True
context.load_default_certs()

s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
ssl_sock = context.wrap_socket(s, server_hostname=s.connect(('www.verisign.com', 443)))
```

New in version 3.4.

Changed in version 3.7: verify_mode is now automatically changed to CERT_REQUIRED when hostname checking is enabled and verify_mode is CERT_NONE. Previously the same operation would have failed with a ValueError.

Note: This features requires OpenSSL 0.9.8f or newer.

SSLContext.options

An integer representing the set of SSL options enabled on this context. The default value is OP_ALL, but you can specify other options such as OP_NO_SSLv2 by ORing them together.
**Note:** With versions of OpenSSL older than 0.9.8m, it is only possible to set options, not to clear them. Attempting to clear an option (by resetting the corresponding bits) will raise a ValueError.

*Changed in version 3.6:* `SSLContext.options` returns `Options` flags:

```python
>>> ssl.create_default_context().options
<Options.OP_ALL|OP_NO_SSLv3|OP_NO_SSLv2|OP_NO_COMPRESSION:
```

`SSLContext.protocol`

The protocol version chosen when constructing the context. This attribute is read-only.

`SSLContext.hostname_checks_common_name`

Whether `check_hostname` falls back to verify the cert’s subject common name in the absence of a subject alternative name extension (default: true).

*New in version 3.7.*

**Note:** Only writeable with OpenSSL 1.1.0 or higher.

`SSLContext.verify_flags`

The flags for certificate verification operations. You can set flags like `VERIFY_CRL_CHECK_LEAF` by ORing them together. By default OpenSSL does neither require nor verify certificate revocation lists (CRLs). Available only with openssl version 0.9.8+.

*New in version 3.4.*
Changed in version 3.6: `SSLContext.verify_flags` returns `VerifyFlags` flags:

```python
>>> ssl.create_default_context().verify_flags
<VerifyFlagsVERIFY_X509_TRUSTED_FIRST: 32768>
```

`SSLContext.verify_mode`

Whether to try to verify other peers’ certificates and how to behave if verification fails. This attribute must be one of `CERT_NONE`, `CERT_OPTIONAL` or `CERT_REQUIRED`.

Changed in version 3.6: `SSLContext.verify_mode` returns `VerifyMode` enum:

```python
>>> ssl.create_default_context().verify_mode
<VerifyMode.CERT_REQUIRED: 2>
```
18.2.4. Certificates

Certificates in general are part of a public-key / private-key system. In this system, each principal, (which may be a machine, or a person, or an organization) is assigned a unique two-part encryption key. One part of the key is public, and is called the public key; the other part is kept secret, and is called the private key. The two parts are related, in that if you encrypt a message with one of the parts, you can decrypt it with the other part, and only with the other part.

A certificate contains information about two principals. It contains the name of a subject, and the subject’s public key. It also contains a statement by a second principal, the issuer, that the subject is who he claims to be, and that this is indeed the subject’s public key. The issuer’s statement is signed with the issuer’s private key, which only the issuer knows. However, anyone can verify the issuer’s statement by finding the issuer’s public key, decrypting the statement with it, and comparing it to the other information in the certificate. The certificate also contains information about the time period over which it is valid. This is expressed as two fields, called “notBefore” and “notAfter”.

In the Python use of certificates, a client or server can use a certificate to prove who they are. The other side of a network connection can also be required to produce a certificate, and that certificate can be validated to the satisfaction of the client or server that requires such validation. The connection attempt can be set to raise an exception if the validation fails. Validation is done automatically, by the underlying OpenSSL framework; the application need not concern itself with its mechanics. But the application does usually need to provide sets of certificates to allow this process to take place.

Python uses files to contain certificates. They should be formatted as
“PEM” (see RFC 1422), which is a base-64 encoded form wrapped with a header line and a footer line:

```
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

18.2.4.1. Certificate chains

The Python files which contain certificates can contain a sequence of certificates, sometimes called a certificate chain. This chain should start with the specific certificate for the principal who “is” the client or server, and then the certificate for the issuer of that certificate, and then the certificate for the issuer of that certificate, and so on up the chain till you get to a certificate which is self-signed, that is, a certificate which has the same subject and issuer, sometimes called a root certificate. The certificates should just be concatenated together in the certificate file. For example, suppose we had a three certificate chain, from our server certificate to the certificate of the certification authority that signed our server certificate, to the root certificate of the agency which issued the certification authority’s certificate:

```
-----BEGIN CERTIFICATE-----
... (certificate for your server)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the certificate for the CA)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the root certificate for the CA's issuer)...
-----END CERTIFICATE-----
```

18.2.4.2. CA certificates
If you are going to require validation of the other side of the connection's certificate, you need to provide a “CA certs” file, filled with the certificate chains for each issuer you are willing to trust. Again, this file just contains these chains concatenated together. For validation, Python will use the first chain it finds in the file which matches. The platform's certificates file can be used by calling `SSLContext.load_default_certs()`, this is done automatically with `create_default_context()`.

18.2.4.3. Combined key and certificate

Often the private key is stored in the same file as the certificate; in this case, only the `certfile` parameter to `SSLContext.load_cert_chain()` and `wrap_socket()` needs to be passed. If the private key is stored with the certificate, it should come before the first certificate in the certificate chain:

```
-----BEGIN RSA PRIVATE KEY-----
... (private key in base64 encoding) ...
-----END RSA PRIVATE KEY-----
-----BEGIN RSA PRIVATE KEY-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

18.2.4.4. Self-signed certificates

If you are going to create a server that provides SSL-encrypted connection services, you will need to acquire a certificate for that service. There are many ways of acquiring appropriate certificates, such as buying one from a certification authority. Another common practice is to generate a self-signed certificate. The simplest way to do
this is with the OpenSSL package, using something like the following:

```bash
% openssl req -new -x509 -days 365 -nodes -out cert.pem
Generating a 1024 bit RSA private key
........+++++
.......................+++++
writing new private key to 'cert.pem'
-----
You are about to be asked to enter information that into your certificate request.
What you are about to enter is what is called a Dist
There are quite a few fields but you can leave some
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MyState
Locality Name (eg, city) []:Some City
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Organization
Organizational Unit Name (eg, section) []:My Group
Common Name (eg, YOUR name) []:myserver.mygroup.myorganization.com
Email Address []:ops@myserver.mygroup.myorganization.com
```

The disadvantage of a self-signed certificate is that it is its own root certificate, and no one else will have it in their cache of known (and trusted) root certificates.
18.2.5. Examples

18.2.5.1. Testing for SSL support

To test for the presence of SSL support in a Python installation, user code should use the following idiom:

```python
try:
    import ssl
except ImportError:
    pass
else:
    ... # do something that requires SSL support
```

18.2.5.2. Client-side operation

This example creates a SSL context with the recommended security settings for client sockets, including automatic certificate verification:

```python
>>> context = ssl.create_default_context()
```

If you prefer to tune security settings yourself, you might create a context from scratch (but beware that you might not get the settings right):

```python
>>> context = ssl.SSLContext(ssl.PROTOCOL_TLS)
>>> context.verify_mode = ssl.CERT_REQUIRED
>>> context.check_hostname = True
>>> context.load_verify_locations("/etc/ssl/certs/ca-bundle.crt")
```

(this snippet assumes your operating system places a bundle of all CA certificates in `/etc/ssl/certs/ca-bundle.crt`; if not, you'll get
an error and have to adjust the location)

When you use the context to connect to a server, CERT_REQUIRED validates the server certificate: it ensures that the server certificate was signed with one of the CA certificates, and checks the signature for correctness:

```python
>>> conn = context.wrap_socket(socket.socket(socket.
... server_hostname="www.
>>> conn.connect(('www.python.org', 443))
```

You may then fetch the certificate:

```python
>>> cert = conn.getpeercert()
```

Visual inspection shows that the certificate does identify the desired service (that is, the HTTPS host www.python.org):

```python
>>> pprint.pprint(cert)
{'OCSP': ('http://ocsp.digicert.com',),
 'caIssuers': ('http://cacerts.digicert.com/DigiCert
 'crlDistributionPoints': ('http://crl3.digicert.com
     'http://crl4.digicert.com
 'issuer': ((('countryName', 'US'),),
    ('organizationName', 'DigiCert Inc'),),
    ('organizationalUnitName', 'www.digicert
    ('commonName', 'DigiCert SHA2 Extended
 'notAfter': 'Sep 9 12:00:00 2016 GMT',
 'notBefore': 'Sep 5 00:00:00 2014 GMT',
 'serialNumber': '01BB6F00122B177F36CAB49CEA8B6B26',
 'subject': ((('businessCategory', 'Private Organization
    ('1.3.6.1.4.1.311.60.2.1.3', 'US'),),
    ('1.3.6.1.4.1.311.60.2.1.2', 'Delaware
    ('serialNumber', '3359300'),),
    ('streetAddress', '16 Allen Rd'),),
```
Now the SSL channel is established and the certificate verified, you can proceed to talk with the server:

```python
>>> conn.sendall(b"HEAD / HTTP/1.0\r\nHost: linuxfr.org\r\n\r\n")
>>> pprint.pprint(conn.recv(1024).split(b"\r\n"))
[b'HTTP/1.1 200 OK',
 b'Date: Sat, 18 Oct 2014 18:27:20 GMT',
 b'Server: nginx',
 b'Content-Type: text/html; charset=utf-8',
 b'X-Frame-Options: SAMEORIGIN',
 b'Content-Length: 45679',
 b'Accept-Ranges: bytes',
 b'Via: 1.1 varnish',
```
See the discussion of Security considerations below.

18.2.5.3. Server-side operation

For server operation, typically you'll need to have a server certificate, and private key, each in a file. You'll first create a context holding the key and the certificate, so that clients can check your authenticity. Then you'll open a socket, bind it to a port, call listen() on it, and start waiting for clients to connect:

```python
import socket, ssl

context = ssl.create_default_context(ssl.Purpose.CLIENT_AUTH)
context.load_cert_chain(certificate_file="mycertfile", keyfile="mykeyfile")

bindsocket = socket.socket()
bindsocket.bind(('myaddr.mydomain.com', 10023))
bindsocket.listen(5)
```

When a client connects, you'll call accept() on the socket to get the new socket from the other end, and use the context's `SSLContext.wrap_socket()` method to create a server-side SSL socket for the connection:
```python
while True:
    newsocket, fromaddr = bindsocket.accept()
    connstream = context.wrap_socket(newsocket, server_side=True)
    try:
        deal_with_client(connstream)
    finally:
        connstream.shutdown(socket.SHUT_RDWR)
        connstream.close()
```
18.2.6. Notes on non-blocking sockets

SSL sockets behave slightly different than regular sockets in non-blocking mode. When working with non-blocking sockets, there are thus several things you need to be aware of:

- Most `SSLSocket` methods will raise either `SSLWantWriteError` or `SSLWantReadError` instead of `BlockingIOError` if an I/O operation would block. `SSLWantReadError` will be raised if a read operation on the underlying socket is necessary, and `SSLWantWriteError` for a write operation on the underlying socket. Note that attempts to `write` to an SSL socket may require `reading` from the underlying socket first, and attempts to `read` from the SSL socket may require a prior `write` to the underlying socket.

  *Changed in version 3.5:* In earlier Python versions, the `SSLSocket.send()` method returned zero instead of raising `SSLWantWriteError` or `SSLWantReadError`.

- Calling `select()` tells you that the OS-level socket can be read from (or written to), but it does not imply that there is sufficient data at the upper SSL layer. For example, only part of an SSL frame might have arrived. Therefore, you must be ready to handle `SSLSocket.recv()` and `SSLSocket.send()` failures, and retry after another call to `select()`.

- Conversely, since the SSL layer has its own framing, a SSL socket may still have data available for reading without `select()` being aware of it. Therefore, you should first call `SSLSocket.recv()` to drain any potentially available data, and
then only block on a `select()` call if still necessary.

(of course, similar provisions apply when using other primitives such as `poll()`, or those in the `selectors` module)

- The SSL handshake itself will be non-blocking: the `SSLSocket.do_handshake()` method has to be retried until it returns successfully. Here is a synopsis using `select()` to wait for the socket's readiness:

```python
while True:
    try:
        sock.do_handshake()
    break
except ssl.SSLWantReadError:
    select.select([sock], [], [])
except ssl.SSLWantWriteError:
    select.select([], [sock], [])
```

See also: The `asyncio` module supports non-blocking SSL sockets and provides a higher level API. It polls for events using the `selectors` module and handles `SSLWantWriteError`, `SSLWantReadError` and `BlockingIOError` exceptions. It runs the SSL handshake asynchronously as well.
18.2.7. Memory BIO Support

*New in version 3.5.*

Ever since the SSL module was introduced in Python 2.6, the `SSLSocket` class has provided two related but distinct areas of functionality:

- SSL protocol handling
- Network IO

The network IO API is identical to that provided by `socket.socket`, from which `SSLSocket` also inherits. This allows an SSL socket to be used as a drop-in replacement for a regular socket, making it very easy to add SSL support to an existing application.

Combining SSL protocol handling and network IO usually works well, but there are some cases where it doesn’t. An example is async IO frameworks that want to use a different IO multiplexing model than the “select/poll on a file descriptor” (readiness based) model that is assumed by `socket.socket` and by the internal OpenSSL socket IO routines. This is mostly relevant for platforms like Windows where this model is not efficient. For this purpose, a reduced scope variant of `SSLSocket` called `SSLObject` is provided.

```python
class ssl.SSLObject
```

A reduced-scope variant of `SSLSocket` representing an SSL protocol instance that does not contain any network IO methods. This class is typically used by framework authors that want to implement asynchronous IO for SSL through memory buffers.

This class implements an interface on top of a low-level SSL object
as implemented by OpenSSL. This object captures the state of an SSL connection but does not provide any network IO itself. IO needs to be performed through separate “BIO” objects which are OpenSSL's IO abstraction layer.

An SSLObject instance can be created using the wrap_bio() method. This method will create the SSLObject instance and bind it to a pair of BIOs. The incoming BIO is used to pass data from Python to the SSL protocol instance, while the outgoing BIO is used to pass data the other way around.

The following methods are available:

- context
- server_side
- server_hostname
- session
- session_reused
- read()
- write()
- getpeercert()
- selected_npn_protocol()
- cipher()
- shared_ciphers()
- compression()
- pending()
- do_handshake()
- unwrap()
- get_channel_binding()

When compared to SSLSocket, this object lacks the following features:
- Any form of network IO; `recv()` and `send()` read and write only to the underlying `MemoryBIO` buffers.
- There is no `do_handshake_on_connect` machinery. You must always manually call `do_handshake()` to start the handshake.
- There is no handling of `suppress_ragged_eofs`. All end-of-file conditions that are in violation of the protocol are reported via the `SSLEOFError` exception.
- The method `unwrap()` call does not return anything, unlike for an SSL socket where it returns the underlying socket.
- The `server_name_callback` callback passed to `SSLContext.set_servername_callback()` will get an `SSLObject` instance instead of a `SSLSocket` instance as its first parameter.

Some notes related to the use of `SSLObject`:

- All IO on an `SSLObject` is non-blocking. This means that for example `read()` will raise an `SSLWantReadError` if it needs more data than the incoming BIO has available.
- There is no module-level `wrap_bio()` call like there is for `wrap_socket()`. An `SSLObject` is always created via an `SSLContext`.

An SSLObject communicates with the outside world using memory buffers. The class `MemoryBIO` provides a memory buffer that can be used for this purpose. It wraps an OpenSSL memory BIO (Basic IO) object:

```python
class ssl.MemoryBIO
    A memory buffer that can be used to pass data between Python and an SSL protocol instance.
```

pending
Return the number of bytes currently in the memory buffer.

**eof**
A boolean indicating whether the memory BIO is current at the end-of-file position.

**read**(n=-1)
Read up to n bytes from the memory buffer. If n is not specified or negative, all bytes are returned.

**write**(buf)
Write the bytes from buf to the memory BIO. The buf argument must be an object supporting the buffer protocol.

The return value is the number of bytes written, which is always equal to the length of buf.

**write_eof()**
Write an EOF marker to the memory BIO. After this method has been called, it is illegal to call write(). The attribute eof will become true after all data currently in the buffer has been read.
18.2.8. SSL session

*New in version 3.6.*

```python
class ssl.SSLSession

    Session object used by `session`.
```

- id
- time
- timeout
- ticket_lifetime_hint
- has_ticket
18.2.9. Security considerations

18.2.9.1. Best defaults

For **client use**, if you don’t have any special requirements for your security policy, it is highly recommended that you use the `create_default_context()` function to create your SSL context. It will load the system’s trusted CA certificates, enable certificate validation and hostname checking, and try to choose reasonably secure protocol and cipher settings.

For example, here is how you would use the `smtplib.SMTP` class to create a trusted, secure connection to a SMTP server:

```python
>>> import ssl, smtplib
>>> smtp = smtplib.SMTP("mail.python.org", port=587)
>>> context = ssl.create_default_context()
>>> smtp.starttls(context=context)
(220, b'2.0.0 Ready to start TLS')
```

If a client certificate is needed for the connection, it can be added with `SSLContext.load_cert_chain()`.

By contrast, if you create the SSL context by calling the `SSLContext` constructor yourself, it will not have certificate validation nor hostname checking enabled by default. If you do so, please read the paragraphs below to achieve a good security level.

18.2.9.2. Manual settings

18.2.9.2.1. Verifying certificates
When calling the `SSLContext` constructor directly, `CERT_NONE` is the default. Since it does not authenticate the other peer, it can be insecure, especially in client mode where most of the time you would like to ensure the authenticity of the server you're talking to. Therefore, when in client mode, it is highly recommended to use `CERT_REQUIRED`. However, it is in itself not sufficient; you also have to check that the server certificate, which can be obtained by calling `SSLSocket.getpeercert()`, matches the desired service. For many protocols and applications, the service can be identified by the hostname; in this case, the `match_hostname()` function can be used. This common check is automatically performed when `SSLContext.check_hostname` is enabled.

*Changed in version 3.7:* Hostname matchings is now performed by OpenSSL. Python no longer uses `match_hostname()`.

In server mode, if you want to authenticate your clients using the SSL layer (rather than using a higher-level authentication mechanism), you'll also have to specify `CERT_REQUIRED` and similarly check the client certificate.

**Note:** In client mode, `CERT_OPTIONAL` and `CERT_REQUIRED` are equivalent unless anonymous ciphers are enabled (they are disabled by default).

### 18.2.9.2.2. Protocol versions

SSL versions 2 and 3 are considered insecure and are therefore dangerous to use. If you want maximum compatibility between clients and servers, it is recommended to use `PROTOCOL_TLS_CLIENT` or `PROTOCOL_TLS_SERVER` as the protocol version. SSLv2 and SSLv3
are disabled by default.

```python
>>> client_context = ssl.SSLContext(ssl.PROTOCOL_TLS_CLIENT)
>>> client_context.options |= ssl.OP_NO_TLSv1
>>> client_context.options |= ssl.OP_NO_TLSv1_1
```

The SSL context created above will only allow TLSv1.2 and later (if supported by your system) connections to a server. `PROTOCOL_TLS_CLIENT` implies certificate validation and hostname checks by default. You have to load certificates into the context.

**18.2.9.2.3. Cipher selection**

If you have advanced security requirements, fine-tuning of the ciphers enabled when negotiating a SSL session is possible through the `SSLContext.set_ciphers()` method. Starting from Python 3.2.3, the ssl module disables certain weak ciphers by default, but you may want to further restrict the cipher choice. Be sure to read OpenSSL's documentation about the cipher list format. If you want to check which ciphers are enabled by a given cipher list, use `SSLContext.get_ciphers()` or the `openssl ciphers` command on your system.

**18.2.9.3. Multi-processing**

If using this module as part of a multi-processed application (using, for example the `multiprocessing` or `concurrent.futures` modules), be aware that OpenSSL's internal random number generator does not properly handle forked processes. Applications must change the PRNG state of the parent process if they use any SSL feature with `os.fork()`. Any successful call of `RAND_add()`,
RAND_bytes() or RAND_pseudo_bytes() is sufficient.

18.3. select — Waiting for I/O completion

This module provides access to the `select()` and `poll()` functions available in most operating systems, `devpoll()` available on Solaris and derivatives, `epoll()` available on Linux 2.5+ and `kqueue()` available on most BSD. Note that on Windows, it only works for sockets; on other operating systems, it also works for other file types (in particular, on Unix, it works on pipes). It cannot be used on regular files to determine whether a file has grown since it was last read.

**Note:** The `selectors` module allows high-level and efficient I/O multiplexing, built upon the `select` module primitives. Users are encouraged to use the `selectors` module instead, unless they want precise control over the OS-level primitives used.

The module defines the following:

`exception select.error`

A deprecated alias of `OSError`.

*Changed in version 3.3:* Following [PEP 3151](https://www.python.org/dev/peps/pep-03151/), this class was made an alias of `OSError`.

`select.devpoll()`

(Only supported on Solaris and derivatives.) Returns a `/dev/poll` polling object; see section `/dev/poll Polling Objects` below for the methods supported by devpoll objects.
devpoll() objects are linked to the number of file descriptors allowed at the time of instantiation. If your program reduces this value, devpoll() will fail. If your program increases this value, devpoll() may return an incomplete list of active file descriptors.

The new file descriptor is non-inheritable.

*New in version 3.3.*

*Changed in version 3.4:* The new file descriptor is now non-inheritable.

```python
select.epoll(sizehint=-1, flags=0)
```

(Only supported on Linux 2.5.44 and newer.) Return an edge polling object, which can be used as Edge or Level Triggered interface for I/O events. `sizehint` and `flags` are deprecated and completely ignored.

See the [Edge and Level Trigger Polling (epoll) Objects section](#) below for the methods supported by epolling objects.

epoll objects support the context management protocol: when used in a `with` statement, the new file descriptor is automatically closed at the end of the block.

The new file descriptor is non-inheritable.

*Changed in version 3.3:* Added the `flags` parameter.

*Changed in version 3.4:* Support for the `with` statement was added. The new file descriptor is now non-inheritable.

*Deprecated since version 3.4:* The `flags` parameter. `select.EPOLL_CLOEXEC` is used by default now. Use
os.set_inheritable() to make the file descriptor inheritable.

select.poll()

(Not supported by all operating systems.) Returns a polling object, which supports registering and unregistering file descriptors, and then polling them for I/O events; see section Polling Objects below for the methods supported by polling objects.

select.kqueue()

(Only supported on BSD.) Returns a kernel queue object; see section Kqueue Objects below for the methods supported by kqueue objects.

The new file descriptor is non-inheritable.

Changed in version 3.4: The new file descriptor is now non-inheritable.

select.kevent(ident, filter=KQ_FILTER_READ, flags=KQ_EV_ADD, fflags=0, data=0, udata=0)

(Only supported on BSD.) Returns a kernel event object; see section Kevent Objects below for the methods supported by kevent objects.

select.select(rlist, wlist, xlist[], timeout[])

This is a straightforward interface to the Unix select() system call. The first three arguments are sequences of ‘waitable objects’: either integers representing file descriptors or objects with a parameterless method named fileno() returning such an integer:

- rlist: wait until ready for reading
- wlist: wait until ready for writing
- `xlist`: wait for an “exceptional condition” (see the manual page for what your system considers such a condition)

Empty sequences are allowed, but acceptance of three empty sequences is platform-dependent. (It is known to work on Unix but not on Windows.) The optional `timeout` argument specifies a time-out as a floating point number in seconds. When the `timeout` argument is omitted the function blocks until at least one file descriptor is ready. A time-out value of zero specifies a poll and never blocks.

The return value is a triple of lists of objects that are ready: subsets of the first three arguments. When the time-out is reached without a file descriptor becoming ready, three empty lists are returned.

Among the acceptable object types in the sequences are Python file objects (e.g. `sys.stdin`, or objects returned by `open()` or `os.popen()`), socket objects returned by `socket.socket()`. You may also define a wrapper class yourself, as long as it has an appropriate `fileno()` method (that really returns a file descriptor, not just a random integer).

**Note:** File objects on Windows are not acceptable, but sockets are. On Windows, the underlying `select()` function is provided by the WinSock library, and does not handle file descriptors that don’t originate from WinSock.

*Changed in version 3.5:* The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see PEP 475 for the rationale), instead of raising `InterruptedError`.

`select.PIPE_BUF`
The minimum number of bytes which can be written without blocking to a pipe when the pipe has been reported as ready for writing by \texttt{select()}, \texttt{poll()} or another interface in this module. This doesn’t apply to other kind of file-like objects such as sockets.

This value is guaranteed by POSIX to be at least 512. Availability: Unix.

\textit{New in version 3.2.}
18.3.1. /dev/poll Polling Objects

Solaris and derivatives have /dev/poll. While select() is $O(\text{highest file descriptor})$ and poll() is $O(\text{number of file descriptors})$, /dev/poll is $O(\text{active file descriptors})$.

/dev/poll behaviour is very close to the standard poll() object.

devpoll.close()

Close the file descriptor of the polling object.

*New in version 3.4.*

devpoll.closed

True if the polling object is closed.

*New in version 3.4.*

devpoll.fileno()

Return the file descriptor number of the polling object.

*New in version 3.4.*

devpoll.register(fd[, eventmask])

Register a file descriptor with the polling object. Future calls to the poll() method will then check whether the file descriptor has any pending I/O events. $fd$ can be either an integer, or an object with a fileno() method that returns an integer. File objects implement fileno(), so they can also be used as the argument.

eventmask is an optional bitmask describing the type of events you want to check for. The constants are the same that with poll()
object. The default value is a combination of the constants POLLIN, POLLPRI, and POLLOUT.

**Warning:** Registering a file descriptor that’s already registered is not an error, but the result is undefined. The appropriate action is to unregister or modify it first. This is an important difference compared with poll().

```python
devpoll.modify(fd[, eventmask])
```
This method does an `unregister()` followed by a `register()`. It is (a bit) more efficient that doing the same explicitly.

```python
devpoll.unregister(fd)
```
Remove a file descriptor being tracked by a polling object. Just like the `register()` method, `fd` can be an integer or an object with a `fileno()` method that returns an integer.

Attempting to remove a file descriptor that was never registered is safely ignored.

```python
devpoll.poll([timeout])
```
Polls the set of registered file descriptors, and returns a possibly-empty list containing `(fd, event)` 2-tuples for the descriptors that have events or errors to report. `fd` is the file descriptor, and `event` is a bitmask with bits set for the reported events for that descriptor — POLLIN for waiting input, POLLOUT to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If `timeout` is given, it specifies the length of time in milliseconds which the system will wait for events before returning. If `timeout` is omitted, -1, or `None`, the call will block until there is an
event for this poll object.

*Changed in version 3.5:* The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see [PEP 475](https://www.python.org/dev/peps/pep-0475)) for the rationale), instead of raising `InterruptedError`. 
### 18.3.2. Edge and Level Trigger Polling (epoll) Objects

[https://linux.die.net/man/4/epoll](https://linux.die.net/man/4/epoll)

**eventmask**

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPOLLIN</td>
<td>Available for read</td>
</tr>
<tr>
<td>EPOLLOUT</td>
<td>Available for write</td>
</tr>
<tr>
<td>EPOLLPRI</td>
<td>Urgent data for read</td>
</tr>
<tr>
<td>EPOLLERR</td>
<td>Error condition happened on the assoc. fd</td>
</tr>
<tr>
<td>EPOLLHUP</td>
<td>Hang up happened on the assoc. fd</td>
</tr>
<tr>
<td>EPOLLET</td>
<td>Set Edge Trigger behavior, the default is Level Trigger behavior</td>
</tr>
<tr>
<td>EPOLLONESHOT</td>
<td>Set one-shot behavior. After one event is pulled out, the fd is internally disabled</td>
</tr>
<tr>
<td>EPOLLEXCLUSIVE</td>
<td>Wake only one epoll object when the associated fd has an event. The default (if this flag is not set) is to wake all epoll objects polling on a fd.</td>
</tr>
<tr>
<td>EPOLLRDHUP</td>
<td>Stream socket peer closed connection or shut down writing half of connection.</td>
</tr>
<tr>
<td>EPOLLRDNORM</td>
<td>Equivalent to EPOLLIN</td>
</tr>
<tr>
<td>EPOLLRDBAND</td>
<td>Priority data band can be read.</td>
</tr>
<tr>
<td>EPOLLWRNORM</td>
<td>Equivalent to EPOLLOUT</td>
</tr>
<tr>
<td>EPOLLWRBAND</td>
<td>Priority data may be written.</td>
</tr>
<tr>
<td>EPOLLMSG</td>
<td>Ignored.</td>
</tr>
</tbody>
</table>

**`epoll.close()`**  
Close the control file descriptor of the epoll object.

**`epoll.closed`**  
True if the epoll object is closed.

**`epoll.fileno()`**  
Return the file descriptor number of the control fd.

**`epoll.fromfd(fd)`**  
Create an epoll object from a given file descriptor.

**`epoll.register(fd[, eventmask])`**  
Register a fd descriptor with the epoll object.

**`epoll.modify(fd, eventmask)`**  
Modify a registered file descriptor.

**`epoll.unregister(fd)`**  
Remove a registered file descriptor from the epoll object.

**`epoll.poll(timeout=-1, maxevents=-1)`**  
Wait for events. timeout in seconds (float)

*Changed in version 3.5:* The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see PEP 475 for the rationale), instead of raising `InterruptedError`. 
The `poll()` system call, supported on most Unix systems, provides better scalability for network servers that service many, many clients at the same time. `poll()` scales better because the system call only requires listing the file descriptors of interest, while `select()` builds a bitmap, turns on bits for the fds of interest, and then afterward the whole bitmap has to be linearly scanned again. `select()` is $O(\text{highest file descriptor})$, while `poll()` is $O(\text{number of file descriptors})$.

`poll. register(fd[, eventmask])`

Register a file descriptor with the polling object. Future calls to the `poll()` method will then check whether the file descriptor has any pending I/O events. `fd` can be either an integer, or an object with a `fileno()` method that returns an integer. File objects implement `fileno()`, so they can also be used as the argument.

`eventmask` is an optional bitmask describing the type of events you want to check for, and can be a combination of the constants `POLLIN`, `POLLPRI`, and `POLLOUT`, described in the table below. If not specified, the default value used will check for all 3 types of events.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>POLLIN</td>
<td>There is data to read</td>
</tr>
<tr>
<td>POLLPRI</td>
<td>There is urgent data to read</td>
</tr>
<tr>
<td>POLLOUT</td>
<td>Ready for output: writing will not block</td>
</tr>
<tr>
<td>POLLERR</td>
<td>Error condition of some sort</td>
</tr>
<tr>
<td>POLLHUP</td>
<td>Hung up</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------------------------</td>
</tr>
<tr>
<td>POLLRDHUP</td>
<td>Stream socket peer closed connection, or shut down writing half of connection</td>
</tr>
<tr>
<td>POLLNVAL</td>
<td>Invalid request: descriptor not open</td>
</tr>
</tbody>
</table>

Registering a file descriptor that’s already registered is not an error, and has the same effect as registering the descriptor exactly once.

**poll. modify**(fd, eventmask)

Modifies an already registered fd. This has the same effect as `register(fd, eventmask)`. Attempting to modify a file descriptor that was never registered causes an `OSError` exception with errno ENOENT to be raised.

**poll. unregister**(fd)

Remove a file descriptor being tracked by a polling object. Just like the `register()` method, `fd` can be an integer or an object with a `fileno()` method that returns an integer.

Attempting to remove a file descriptor that was never registered causes a `KeyError` exception to be raised.

**poll. poll**(timeout)

Polls the set of registered file descriptors, and returns a possibly-empty list containing `(fd, event)` 2-tuples for the descriptors that have events or errors to report. `fd` is the file descriptor, and `event` is a bitmask with bits set for the reported events for that descriptor — POLLIN for waiting input, POLLOUT to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If `timeout` is given, it specifies the length of time in milliseconds which the system will wait for events before returning.
If `timeout` is omitted, negative, or `None`, the call will block until there is an event for this poll object.

*Changed in version 3.5:* The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see PEP 475 for the rationale), instead of raising `InterruptedError`.
18.3.4. Kqueue Objects

kqueue.

\texttt{close()}

Close the control file descriptor of the kqueue object.

kqueue.

\texttt{closed}

\texttt{True} if the kqueue object is closed.

kqueue.

\texttt{fileno()}

Return the file descriptor number of the control fd.

kqueue.

\texttt{fromfd(fd)}

Create a kqueue object from a given file descriptor.

kqueue.

\texttt{control(changelist, max\_events[, timeout=None])} \rightarrow \texttt{eventlist}

Low level interface to kevent

- changelist must be an iterable of kevent object or \texttt{None}
- max\_events must be 0 or a positive integer
- timeout in seconds (floats possible)

\textit{Changed in version 3.5:} The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see \texttt{PEP 475} for the rationale), instead of raising \texttt{InterruptedError}. 
18.3.5. Kevent Objects

https://www.freebsd.org/cgi/man.cgi?query=kqueue&sektion=2

kevent. **ident**

Value used to identify the event. The interpretation depends on the filter but it's usually the file descriptor. In the constructor ident can either be an int or an object with a *fileno()* method. kevent stores the integer internally.

kevent. **filter**

Name of the kernel filter.

<table>

`kevent.data`
Filter specific data.

kevent.udata
User defined value.
18.4. `selectors` — High-level I/O multiplexing

*New in version 3.4.*

**Source code:** `Lib/selectors.py`
18.4.1. Introduction

This module allows high-level and efficient I/O multiplexing, built upon the `select` module primitives. Users are encouraged to use this module instead, unless they want precise control over the OS-level primitives used.

It defines a `BaseSelector` abstract base class, along with several concrete implementations (`KqueueSelector`, `EpollSelector`...), that can be used to wait for I/O readiness notification on multiple file objects. In the following, “file object” refers to any object with a `fileno()` method, or a raw file descriptor. See `file object`.

`DefaultSelector` is an alias to the most efficient implementation available on the current platform: this should be the default choice for most users.

**Note:** The type of file objects supported depends on the platform: on Windows, sockets are supported, but not pipes, whereas on Unix, both are supported (some other types may be supported as well, such as fifos or special file devices).

**See also:**

`select`

Low-level I/O multiplexing module.
18.4.2. Classes

Classes hierarchy:

```
BaseSelector
 +-- SelectSelector
 +--PollSelector
 +--EpollSelector
 +--DevpollSelector
 +-- KqueueSelector
```

In the following, `events` is a bitwise mask indicating which I/O events should be waited for on a given file object. It can be a combination of the modules constants below:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_READ</td>
<td>Available for read</td>
</tr>
<tr>
<td>EVENT_WRITE</td>
<td>Available for write</td>
</tr>
</tbody>
</table>

**class selectors**. `SelectorKey`

A `SelectorKey` is a `namedtuple` used to associate a file object to its underlying file descriptor, selected event mask and attached data. It is returned by several `BaseSelector` methods.

- **fileobj**
  File object registered.

- **fd**
  Underlying file descriptor.

- **events**
  Events that must be waited for on this file object.
Optional opaque data associated to this file object: for example, this could be used to store a per-client session ID.

class selectors.BaseSelector
A BaseSelector is used to wait for I/O event readiness on multiple file objects. It supports file stream registration, unregistration, and a method to wait for I/O events on those streams, with an optional timeout. It’s an abstract base class, so cannot be instantiated. Use DefaultSelector instead, or one of SelectSelector, KqueueSelector etc. if you want to specifically use an implementation, and your platform supports it. BaseSelector and its concrete implementations support the context manager protocol.

abstractmethod register(fileobj, events, data=None)
Register a file object for selection, monitoring it for I/O events.

fileobj is the file object to monitor. It may either be an integer file descriptor or an object with a fileno() method. events is a bitwise mask of events to monitor. data is an opaque object.

This returns a new SelectorKey instance, or raises a ValueError in case of invalid event mask or file descriptor, or KeyError if the file object is already registered.

abstractmethod unregister(fileobj)
Unregister a file object from selection, removing it from monitoring. A file object shall be unregistered prior to being closed.

fileobj must be a file object previously registered.
This returns the associated `SelectorKey` instance, or raises a `KeyError` if `fileobj` is not registered. It will raise `ValueError` if `fileobj` is invalid (e.g. it has no `fileno()` method or its `fileno()` method has an invalid return value).

**modify**(`fileobj`, `events`, `data=None`)
Change a registered file object's monitored events or attached data.

This is equivalent to `BaseSelector.unregister(fileobj)()` followed by `BaseSelector.register(fileobj, events, data)()`, except that it can be implemented more efficiently.

This returns a new `SelectorKey` instance, or raises a `ValueError` in case of invalid event mask or file descriptor, or `KeyError` if the file object is not registered.

**abstractmethod select**(`timeout=None`)
Wait until some registered file objects become ready, or the timeout expires.

If `timeout > 0`, this specifies the maximum wait time, in seconds. If `timeout <= 0`, the call won't block, and will report the currently ready file objects. If `timeout` is `None`, the call will block until a monitored file object becomes ready.

This returns a list of `(key, events)` tuples, one for each ready file object.

`key` is the `SelectorKey` instance corresponding to a ready file object. `events` is a bitmask of events ready on this file object.
**Note:** This method can return before any file object becomes ready or the timeout has elapsed if the current process receives a signal: in this case, an empty list will be returned.

*Changed in version 3.5:* The selector is now retried with a recomputed timeout when interrupted by a signal if the signal handler did not raise an exception (see PEP 475 for the rationale), instead of returning an empty list of events before the timeout.

**close()**

Close the selector.

This must be called to make sure that any underlying resource is freed. The selector shall not be used once it has been closed.

**get_key(fileobj)**

Return the key associated with a registered file object.

This returns the `SelectorKey` instance associated to this file object, or raises `KeyError` if the file object is not registered.

**abstractmethod get_map()**

Return a mapping of file objects to selector keys.

This returns a `Mapping` instance mapping registered file objects to their associated `SelectorKey` instance.

**class selectors.DefaultSelector**

The default selector class, using the most efficient implementation available on the current platform. This should be the default choice for most users.
class selectors. **SelectSelector**
select.select()-based selector.

class selectors. **PollSelector**
select.poll()-based selector.

class selectors. **EpollSelector**
select.epoll()-based selector.

**fileno()**
This returns the file descriptor used by the underlying select.epoll() object.

class selectors. **DevpollSelector**
select.devpoll()-based selector.

**fileno()**
This returns the file descriptor used by the underlying select.devpoll() object.

*New in version 3.5.*

class selectors. **KqueueSelector**
select.kqueue()-based selector.

**fileno()**
This returns the file descriptor used by the underlying select.kqueue() object.
18.4.3. Examples

Here is a simple echo server implementation:

```python
import selectors
import socket

sel = selectors.DefaultSelector()

def accept(sock, mask):
    conn, addr = sock.accept()  # Should be ready
    print('accepted', conn, 'from', addr)
    conn.setblocking(False)
    sel.register(conn, selectors.EVENT_READ, read)

def read(conn, mask):
    data = conn.recv(1000)  # Should be ready
    if data:
        print('echoing', repr(data), 'to', conn)
        conn.send(data)  # Hope it won't block
    else:
        print('closing', conn)
        sel.unregister(conn)
        conn.close()

sock = socket.socket()
sock.bind(('localhost', 1234))
sock.listen(100)
sock.setblocking(False)
sel.register(sock, selectors.EVENT_READ, accept)

while True:
    events = sel.select()
    for key, mask in events:
        callback = key.data
```
callback(key, fileobj, mask)
18.5. **asyncio** — Asynchronous I/O, event loop, coroutines and tasks

*New in version 3.4.*

**Source code:** Lib/asyncio/

This module provides infrastructure for writing single-threaded concurrent code using coroutines, multiplexing I/O access over sockets and other resources, running network clients and servers, and other related primitives. Here is a more detailed list of the package contents:

- a pluggable [event loop](#) with various system-specific implementations;
- [transport](#) and [protocol](#) abstractions (similar to those in Twisted);
- concrete support for TCP, UDP, SSL, subprocess pipes, delayed calls, and others (some may be system-dependent);
- a [Future](#) class that mimics the one in the [concurrent.futures](#) module, but adapted for use with the event loop;
- coroutines and tasks based on [yield from](#) (PEP 380), to help write concurrent code in a sequential fashion;
- cancellation support for Futures and coroutines;
- synchronization primitives for use between coroutines in a single thread, mimicking those in the [threading](#) module;
- an interface for passing work off to a threadpool, for times when you absolutely, positively have to use a library that makes blocking I/O calls.
Asynchronous programming is more complex than classical “sequential” programming: see the Develop with asyncio page which lists common traps and explains how to avoid them. Enable the debug mode during development to detect common issues.

asyncio — Asynchronous I/O, event loop, coroutines and tasks
18.5.1. Base Event Loop

Source code: Lib/asyncio/events.py

The event loop is the central execution device provided by asyncio. It provides multiple facilities, including:

- Registering, executing and cancelling delayed calls (timeouts).
- Creating client and server transports for various kinds of communication.
- Launching subprocesses and the associated transports for communication with an external program.
- Delegating costly function calls to a pool of threads.

class asyncio.BaseEventLoop

This class is an implementation detail. It is a subclass of AbstractEventLoop and may be a base class of concrete event loop implementations found in asyncio. It should not be used directly; use AbstractEventLoop instead. BaseEventLoop should not be subclassed by third-party code; the internal interface is not stable.

class asyncio.AbstractEventLoop

Abstract base class of event loops.

This class is not thread safe.
18.5.1.1. Run an event loop

AbstractEventLoop.run_forever()

Run until stop() is called. If stop() is called before run_forever() is called, this polls the I/O selector once with a timeout of zero, runs all callbacks scheduled in response to I/O events (and those that were already scheduled), and then exits. If stop() is called while run_forever() is running, this will run the current batch of callbacks and then exit. Note that callbacks scheduled by callbacks will not run in that case; they will run the next time run_forever() is called.

Changed in version 3.5.1.

AbstractEventLoop.run_until_complete(future)

Run until the Future is done.

If the argument is a coroutine object, it is wrapped by ensure_future().

Return the Future's result, or raise its exception.

AbstractEventLoop.is_running()

Returns running status of event loop.

AbstractEventLoop.stop()

Stop running the event loop.

This causes run_forever() to exit at the next suitable opportunity (see there for more details).

Changed in version 3.5.1.
AbstractEventLoop. **is_closed()**

Returns True if the event loop was closed.

*New in version 3.4.2.*

AbstractEventLoop. **close()**

Close the event loop. The loop must not be running. Pending callbacks will be lost.

This clears the queues and shuts down the executor, but does not wait for the executor to finish.

This is idempotent and irreversible. No other methods should be called after this one.

coroutine AbstractEventLoop. **shutdown_asyncgens()**

Schedule all currently open asynchronous generator objects to close with an `aclose()` call. After calling this method, the event loop will issue a warning whenever a new asynchronous generator is iterated. Should be used to finalize all scheduled asynchronous generators reliably. Example:

```python
try:
    loop.run_forever()
finally:
    loop.run_until_complete(loop.shutdown_asyncgens)
    loop.close()
```

*New in version 3.6.*
18.5.1.2. Calls

Most `asyncio` functions don’t accept keywords. If you want to pass keywords to your callback, use `functools.partial()`. For example, `loop.call_soon(functools.partial(print, "Hello", flush=True))` will call `print("Hello", flush=True)`.

**Note:** `functools.partial()` is better than lambda functions, because `asyncio` can inspect `functools.partial()` object to display parameters in debug mode, whereas lambda functions have a poor representation.

AbstractEventLoop. `call_soon(callback, *args)`

Arrange for a callback to be called as soon as possible. The callback is called after `call_soon()` returns, when control returns to the event loop.

This operates as a FIFO queue, callbacks are called in the order in which they are registered. Each callback will be called exactly once.

Any positional arguments after the callback will be passed to the callback when it is called.

An instance of `asyncio.Handle` is returned, which can be used to cancel the callback.

Use `functools.partial` to pass keywords to the callback.

AbstractEventLoop. `call_soon_threadsafe(callback,`
*args)

Like `call_soon()`, but thread safe.

See the concurrency and multithreading section of the documentation.
18.5.1.3. Delayed calls

The event loop has its own internal clock for computing timeouts. Which clock is used depends on the (platform-specific) event loop implementation; ideally it is a monotonic clock. This will generally be a different clock than `time.time()`.

**Note:** Timeouts (relative delay or absolute when) should not exceed one day.

AbstractEventLoop. `call_later(delay, callback, *args)`

Arrange for the `callback` to be called after the given delay seconds (either an int or float).

An instance of `asyncio.Handle` is returned, which can be used to cancel the callback.

`callback` will be called exactly once per call to `call_later()`. If two callbacks are scheduled for exactly the same time, it is undefined which will be called first.

The optional positional `args` will be passed to the callback when it is called. If you want the callback to be called with some named arguments, use a closure or `functools.partial()`.

Use `functools.partial` to pass keywords to the callback.

AbstractEventLoop. `call_at(when, callback, *args)`

Arrange for the `callback` to be called at the given absolute timestamp `when` (an int or float), using the same time reference as `AbstractEventLoop.time()`.
This method’s behavior is the same as \texttt{call\_later()}. An instance of \texttt{asyncio.Handle} is returned, which can be used to cancel the callback.

Use \texttt{functools.partial} to pass keywords to the callback.

\texttt{AbstractEventLoop.time()} 

Return the current time, as a \texttt{float} value, according to the event loop’s internal clock.

\textbf{See also:} The \texttt{asyncio.sleep()} function.
18.5.1.4. Futures

AbstractEventLoop.\texttt{create\_future}()

Create an \texttt{asyncio.Future} object attached to the loop.

This is a preferred way to create futures in asyncio, as event loop implementations can provide alternative implementations of the Future class (with better performance or instrumentation).

\textit{New in version 3.5.2.}
18.5.1.5. Tasks

AbstractEventLoop.\texttt{create\_task}(\texttt{coro})

Schedule the execution of a coroutine object: wrap it in a future. Return a Task object.

Third-party event loops can use their own subclass of Task for interoperability. In this case, the result type is a subclass of Task.

\textit{New in version 3.4.2.}\n
AbstractEventLoop.\texttt{set\_task\_factory}(\texttt{factory})

Set a task factory that will be used by AbstractEventLoop.\texttt{create\_task}().

If factory is None the default task factory will be set.

If factory is a callable, it should have a signature matching (\texttt{loop, coro}), where \texttt{loop} will be a reference to the active event loop, \texttt{coro} will be a coroutine object. The callable must return an \texttt{asyncio.Future} compatible object.

\textit{New in version 3.4.4.}\n
AbstractEventLoop.\texttt{get\_task\_factory}()

Return a task factory, or None if the default one is in use.

\textit{New in version 3.4.4.}\n
18.5.1.6. Creating connections

coroutine
AbstractEventLoop.create_connection(protocol_factory, host=None, port=None, *, ssl=None, family=0, proto=0, flags=0, sock=None, local_addr=None, server_hostname=None, ssl_handshake_timeout=None)

Create a streaming transport connection to a given Internet host and port: socket family AF_INET or AF_INET6 depending on host (or family if specified), socket type SOCK_STREAM. protocol_factory must be a callable returning a protocol instance.

This method will try to establish the connection in the background. When successful, it returns a (transport, protocol) pair.

The chronological synopsis of the underlying operation is as follows:

1. The connection is established, and a transport is created to represent it.
2. protocol_factory is called without arguments and must return a protocol instance.
3. The protocol instance is tied to the transport, and its connection_made() method is called.
4. The coroutine returns successfully with the (transport, protocol) pair.

The created transport is an implementation-dependent bidirectional stream.

Note: protocol_factory can be any kind of callable, not necessarily a class. For example, if you want to use a pre-created protocol instance, you can pass lambda:
my_protocol.

Options that change how the connection is created:

- **ssl**: if given and not false, a SSL/TLS transport is created (by default a plain TCP transport is created). If `ssl` is a `ssl.SSLContext` object, this context is used to create the transport; if `ssl` is `True`, a context with some unspecified default settings is used.

  See also: SSL/TLS security considerations

- **server_hostname**, is only for use together with `ssl`, and sets or overrides the hostname that the target server’s certificate will be matched against. By default the value of the `host` argument is used. If `host` is empty, there is no default and you must pass a value for `server_hostname`. If `server_hostname` is an empty string, hostname matching is disabled (which is a serious security risk, allowing for man-in-the-middle-attacks).

- **family**, **proto**, **flags** are the optional address family, protocol and flags to be passed through to getaddrinfo() for `host` resolution. If given, these should all be integers from the corresponding `socket` module constants.

- **sock**, if given, should be an existing, already connected `socket.socket` object to be used by the transport. If `sock` is given, none of `host`, `port`, `family`, `proto`, `flags` and `local_addr` should be specified.

- **local_addr**, if given, is a `(local_host, local_port)` tuple used to bind the socket to locally. The `local_host` and `local_port` are looked up using getaddrinfo(), similarly to `host`
and port.

• **ssl_handshake_timeout** is (for an SSL connection) the time in seconds to wait for the SSL handshake to complete before aborting the connection. 10.0 seconds if None (default).

*New in version 3.7:* The **ssl_handshake_timeout** parameter.

*Changed in version 3.5:* On Windows with **ProactorEventLoop**, SSL/TLS is now supported.

**See also:** The **open_connection()** function can be used to get a pair of (**StreamReader**, **StreamWriter**) instead of a protocol.

coroutine

AbstractEventLoop. **create_datagram_endpoint**(*protocol*,
local_addr=None, remote_addr=None, *, family=0, proto=0, flags=0,
reuse_address=None, reuse_port=None, allow_broadcast=None,
sock=None)

Create datagram connection: socket family **AF_INET**, **AF_INET6** or **AF_UNIX** depending on host (or family if specified), socket type **SOCK_DGRAM**. **protocol_factory** must be a callable returning a **protocol** instance.

This method will try to establish the connection in the background. When successful, the it returns a **(transport, protocol)** pair.

Options changing how the connection is created:

• **local_addr**, if given, is a (**local_host**, **local_port**) tuple used to bind the socket to locally. The **local_host** and **local_port** are looked up using **getaddrinfo()**.
- `remote_addr`, if given, is a `(remote_host, remote_port)` tuple used to connect the socket to a remote address. The `remote_host` and `remote_port` are looked up using `getaddrinfo()`.
- `family`, `proto`, `flags` are the optional address family, protocol and flags to be passed through to `getaddrinfo()` for host resolution. If given, these should all be integers from the corresponding socket module constants.
- `reuse_address` tells the kernel to reuse a local socket in TIME_WAIT state, without waiting for its natural timeout to expire. If not specified will automatically be set to `True` on UNIX.
- `reuse_port` tells the kernel to allow this endpoint to be bound to the same port as other existing endpoints are bound to, so long as they all set this flag when being created. This option is not supported on Windows and some UNIX's. If the `SO_REUSEPORT` constant is not defined then this capability is unsupported.
- `allow_broadcast` tells the kernel to allow this endpoint to send messages to the broadcast address.
- `sock` can optionally be specified in order to use a preexisting, already connected, `socket.socket` object to be used by the transport. If specified, `local_addr` and `remote_addr` should be omitted (must be `None`).

On Windows with `ProactorEventLoop`, this method is not supported.

See `UDP echo client protocol` and `UDP echo server protocol` examples.

```python
coroutine
AbstractEventLoop.create_unix_connection(protocol_f...path=None, *, ssl=None, sock=None, server_hostname=None,
Create UNIX connection: socket family `AF_UNIX`, socket type `SOCK_STREAM`. The `AF_UNIX` socket family is used to communicate between processes on the same machine efficiently.

This method will try to establish the connection in the background. When successful, the it returns a `(transport, protocol)` pair.

`path` is the name of a UNIX domain socket, and is required unless a `sock` parameter is specified. Abstract UNIX sockets, `str`, `bytes`, and `Path` paths are supported.

See the `AbstractEventLoop.create_connection()` method for parameters.

Availability: UNIX.

New in version 3.7: The `ssl_handshake_timeout` parameter.

Changed in version 3.7: The `path` parameter can now be a `Path` object.
18.5.1.7. Creating listening connections

coroutine
AbstractEventLoop.create_server(protocol_factory, host=None, port=None, *, family=socket.AF_UNSPEC, flags=socket.AI_PASSIVE, sock=None, backlog=100, ssl=None, reuse_address=None, reuse_port=None, ssl_handshake_timeout=None, start_serving=True)

Create a TCP server (socket type **SOCK_STREAM**) bound to host and port.

Return a Server object, its sockets attribute contains created sockets. Use the Server.close() method to stop the server: close listening sockets.

Parameters:

- The host parameter can be a string, in that case the TCP server is bound to host and port. The host parameter can also be a sequence of strings and in that case the TCP server is bound to all hosts of the sequence. If host is an empty string or None, all interfaces are assumed and a list of multiple sockets will be returned (most likely one for IPv4 and another one for IPv6).
- family can be set to either socket.AF_INET or AF_INET6 to force the socket to use IPv4 or IPv6. If not set it will be determined from host (defaults to socket.AF_UNSPEC).
- flags is a bitmask for getaddrinfo().
- sock can optionally be specified in order to use a preexisting socket object. If specified, host and port should be omitted (must be None).
- backlog is the maximum number of queued connections passed to listen() (defaults to 100).
- `ssl` can be set to an `SSLContext` to enable SSL over the accepted connections.
- `reuse_address` tells the kernel to reuse a local socket in `TIME_WAIT` state, without waiting for its natural timeout to expire. If not specified will automatically be set to `True` on UNIX.
- `reuse_port` tells the kernel to allow this endpoint to be bound to the same port as other existing endpoints are bound to, so long as they all set this flag when being created. This option is not supported on Windows.
- `ssl_handshake_timeout` is (for an SSL server) the time in seconds to wait for the SSL handshake to complete before aborting the connection. 10.0 seconds if `None` (default).
- `start_serving` set to `True` (the default) causes the created server to start accepting connections immediately. When set to `False`, the user should await on `Server.start_serving()` or `Server.serve_forever()` to make the server to start accepting connections.

*New in version 3.7:* `ssl_handshake_timeout` and `start_serving` parameters.

*Changed in version 3.5:* On Windows with `ProactorEventLoop`, SSL/TLS is now supported.

**See also:** The function `start_server()` creates a `(StreamReader, StreamWriter)` pair and calls back a function with this pair.

*Changed in version 3.5.1:* The `host` parameter can now be a sequence of strings.

`coroutine`
AbstractEventLoop.\texttt{create_unix_server}(\texttt{protocol\_factory},
\texttt{path=None}, *, \texttt{sock=None}, \texttt{backlog=100}, \texttt{ssl=None},
\texttt{ssl\_handshake\_timeout=None}, \texttt{start\_serving=True})

Similar to \texttt{AbstractEventLoop.create_server()}, but
specific to the socket family \texttt{AF\_UNIX}.

\texttt{path} is the name of a UNIX domain socket, and is required unless
a \texttt{sock} parameter is specified. Abstract UNIX sockets, \texttt{str},
\texttt{bytes}, and \texttt{Path} paths are supported.

Availability: UNIX.

\textit{New in version 3.7}: The \texttt{ssl\_handshake\_timeout} parameter.

\textit{Changed in version 3.7}: The \texttt{path} parameter can now be a \texttt{Path}
object.

coroutine

BaseEventLoop.\texttt{connect\_accepted\_socket}(\texttt{protocol\_factory},
\texttt{sock}, *, \texttt{ssl=None}, \texttt{ssl\_handshake\_timeout=None})

Handle an accepted connection.

This is used by servers that accept connections outside of asyncio
but that use asyncio to handle them.

Parameters:

- \texttt{sock} is a preexisting socket object returned from an \texttt{accept}
call.
- \texttt{ssl} can be set to an \texttt{SSLContext} to enable SSL over the
accepted connections.
- \texttt{ssl\_handshake\_timeout} is (for an SSL connection) the time in
seconds to wait for the SSL handshake to complete before aborting the connection. \texttt{10.0} seconds if \texttt{None} (default).
When completed it returns a (transport, protocol) pair.

*New in version 3.7:* The `ssl_handshake_timeout` parameter.

*New in version 3.5.3.*
18.5.1.8. File Transferring

coroutine AbstractEventLoop. sendfile(transport, file, offset=0, count=None, *, fallback=True)

Send a file to transport, return the total number of bytes which were sent.

The method uses high-performance os.sendfile() if available.

declare must be a regular file object opened in binary mode.

offset tells from where to start reading the file. If specified, count is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is updated on return or also in case of error in which case file.tell() can be used to figure out the number of bytes which were sent.

fallback set to True makes asyncio to manually read and send the file when the platform does not support the sendfile syscall (e.g. Windows or SSL socket on Unix).

Raise SendfileNotAvailableError if the system does not support sendfile syscall and fallback is False.

New in version 3.7.
18.5.1.9. TLS Upgrade

coroutine AbstractEventLoop. `start_tls`(
transport, protocol, sslcontext, *, server_side=False, server_hostname=None,
ssl_handshake_timeout=None)

Upgrades an existing connection to TLS.

Returns a new transport instance, that the protocol must start using immediately after the `await`. The transport instance passed to the `start_tls` method should never be used again.

Parameters:

- `transport` and `protocol` instances that methods like `create_server()` and `create_connection()` return.
- `sslcontext`: a configured instance of `SSLContext`.
- `server_side` pass `True` when a server-side connection is being upgraded (like the one created by `create_server()`).
- `server_hostname`: sets or overrides the host name that the target server’s certificate will be matched against.
- `ssl_handshake_timeout` is (for an SSL connection) the time in seconds to wait for the SSL handshake to complete before aborting the connection. 10.0 seconds if `None` (default).

*New in version 3.7.*
18.5.1.10. Watch file descriptors

On Windows with `SelectorEventLoop`, only socket handles are supported (ex: pipe file descriptors are not supported).

On Windows with `ProactorEventLoop`, these methods are not supported.

AbstractEventLoop.**add_reader**(fd, callback, *args)

Start watching the file descriptor for read availability and then call the `callback` with specified arguments.

*Use functools.partial to pass keywords to the callback.*

AbstractEventLoop.**remove_reader**(fd)

Stop watching the file descriptor for read availability.

AbstractEventLoop.**add_writer**(fd, callback, *args)

Start watching the file descriptor for write availability and then call the `callback` with specified arguments.

*Use functools.partial to pass keywords to the callback.*

AbstractEventLoop.**remove_writer**(fd)

Stop watching the file descriptor for write availability.

The **watch a file descriptor for read events** example uses the low-level `AbstractEventLoop.add_reader()` method to register the file descriptor of a socket.
18.5.1.11. Low-level socket operations

**coroutine** AbstractEventLoop. **sock_recv**(sock, nbytes)
Receive data from the socket. Modeled after blocking
`socket.socket.recv()` method.

The return value is a bytes object representing the data received. The maximum amount of data to be received at once is specified by `nbytes`.

With **SelectorEventLoop** event loop, the socket `sock` must be non-blocking.

*Changed in version 3.7:* Even though the method was always documented as a coroutine method, before Python 3.7 it returned a
**Future**. Since Python 3.7, this is an `async def` method.

**coroutine** AbstractEventLoop. **sock_recv_into**(sock, buf)
Receive data from the socket. Modeled after blocking
`socket.socket.recv_into()` method.

The received data is written into `buf` (a writable buffer). The return
value is the number of bytes written.

With **SelectorEventLoop** event loop, the socket `sock` must be non-blocking.

*New in version 3.7.*

**coroutine** AbstractEventLoop. **sock_sendall**(sock, data)
Send data to the socket. Modeled after blocking
`socket.socket.sendall()` method.
The socket must be connected to a remote socket. This method continues to send data from `data` until either all data has been sent or an error occurs. `None` is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully processed by the receiving end of the connection.

With `SelectorEventLoop` event loop, the socket `sock` must be non-blocking.

*Changed in version 3.7:* Even though the method was always documented as a coroutine method, before Python 3.7 it returned an `Future`. Since Python 3.7, this is an `async def` method.

```python
coroutine AbstractEventLoop.sock_connect(sock, address)
```

Connect to a remote socket at `address`. Modeled after blocking `socket.socket.connect()` method.

With `SelectorEventLoop` event loop, the socket `sock` must be non-blocking.

*Changed in version 3.5.2:* `address` no longer needs to be resolved. `sock_connect` will try to check if the `address` is already resolved by calling `socket.inet_pton()`. If not, `AbstractEventLoop.getaddrinfo()` will be used to resolve the `address`.

**See also:** `AbstractEventLoop.create_connection()` and `asyncio.open_connection()`.

```python
coroutine AbstractEventLoop.sock_accept(sock)
```

Accept a connection. Modeled after blocking
socket.socket.accept().

The socket must be bound to an address and listening for connections. The return value is a pair (conn, address) where conn is a new socket object usable to send and receive data on the connection, and address is the address bound to the socket on the other end of the connection.

The socket sock must be non-blocking.

Changed in version 3.7: Even though the method was always documented as a coroutine method, before Python 3.7 it returned a Future. Since Python 3.7, this is an async def method.

See also: AbstractEventLoop.create_server() and start_server().

coroutine AbstractEventLoop.

sock_sendfile(sock, file, offset=0, count=None, *, fallback=True)

Send a file using high-performance os.sendfile if possible and return the total number of bytes which were sent.

Asynchronous version of socket.socket.sendfile().

sock must be non-blocking socket of socket.SOCK_STREAM type.

file must be a regular file object opened in binary mode.

offset tells from where to start reading the file. If specified, count is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is updated on return or also in case of error in which case file.tell() can be used to figure
out the number of bytes which were sent.

*fallback* set to *True* makes asyncio to manually read and send the
file when the platform does not support the sendfile syscall (e.g.
Windows or SSL socket on Unix).

Raise *SendfileNotAvailableError* if the system does not
support *sendfile* syscall and *fallback* is False.

*New in version 3.7.*
18.5.1.12. Resolve host name

coroutine AbstractEventLoop.getaddrinfo(host, port, *,
family=0, type=0, proto=0, flags=0)

This method is a coroutine, similar to socket.getaddrinfo() function but non-blocking.

coroutine AbstractEventLoop.getnameinfo(sockaddr,
flags=0)

This method is a coroutine, similar to socket.getnameinfo() function but non-blocking.

Changed in version 3.7: Both getaddrinfo and getnameinfo methods were always documented to return a coroutine, but prior to Python 3.7 they were, in fact, returning asyncio.Future objects. Starting with Python 3.7 both methods are coroutines.
18.5.1.13. Connect pipes

On Windows with SelectorEventLoop, these methods are not supported. Use ProactorEventLoop to support pipes on Windows.

coroutine
AbstractEventLoop.connect_read_pipe(protocol_factory, pipe)
Register read pipe in eventloop.

protocol_factory should instantiate object with Protocol interface. pipe is a file-like object. Return pair (transport, protocol), where transport supports the ReadTransport interface.

With SelectorEventLoop event loop, the pipe is set to non-blocking mode.

coroutine
AbstractEventLoop.connect_write_pipe(protocol_factory, pipe)
Register write pipe in eventloop.

protocol_factory should instantiate object with BaseProtocol interface. pipe is file-like object. Return pair (transport, protocol), where transport supports WriteTransport interface.

With SelectorEventLoop event loop, the pipe is set to non-blocking mode.

See also: The AbstractEventLoop.subprocess_exec() and AbstractEventLoop.subprocess_shell() methods.
18.5.1.14. UNIX signals

Availability: UNIX only.

AbstractEventLoop.add_signal_handler(signum, callback, *args)
Add a handler for a signal.

Raise ValueError if the signal number is invalid or uncatchable.
Raise RuntimeError if there is a problem setting up the handler.

Use functools.partial to pass keywords to the callback.

AbstractEventLoop.remove_signal_handler(sig)
Remove a handler for a signal.

Return True if a signal handler was removed, False if not.

See also: The signal module.
18.5.1.15. Executor

Call a function in an Executor (pool of threads or pool of processes). By default, an event loop uses a thread pool executor (ThreadPoolExecutor).

AbstractEventLoop.run_in_executor(executor, func, *args)

Arrange for a func to be called in the specified executor.

The executor argument should be an Executor instance. The default executor is used if executor is None.

Use functools.partial to pass keywords to the *func*.

This method returns a asyncio.Future object.

Changed in version 3.5.3:
BaseEventLoop.run_in_executor() no longer configures the max_workers of the thread pool executor it creates, instead leaving it up to the thread pool executor (ThreadPoolExecutor) to set the default.

AbstractEventLoop.set_default_executor(executor)
Set the default executor used by run_in_executor().
18.5.1.16. Error Handling API

Allows customizing how exceptions are handled in the event loop.

AbstractEventLoop.set_exception_handler(handler)

Set handler as the new event loop exception handler.

If handler is None, the default exception handler will be set.

If handler is a callable object, it should have a matching signature to (loop, context), where loop will be a reference to the active event loop, context will be a dict object (see call_exception_handler() documentation for details about context).

AbstractEventLoop.get_exception_handler()

Return the exception handler, or None if the default one is in use.

New in version 3.5.2.

AbstractEventLoop.default_exception_handler(context)

Default exception handler.

This is called when an exception occurs and no exception handler is set, and can be called by a custom exception handler that wants to defer to the default behavior.

context parameter has the same meaning as in call_exception_handler().

AbstractEventLoop.call_exception_handler(context)

Call the current event loop exception handler.
context is a dict object containing the following keys (new keys may be introduced later):

- ‘message’: Error message;
- ‘exception’ (optional): Exception object;
- ‘future’ (optional): asyncio.Future instance;
- ‘handle’ (optional): asyncio.Handle instance;
- ‘protocol’ (optional): Protocol instance;
- ‘transport’ (optional): Transport instance;
- ‘socket’ (optional): socket.socket instance.

**Note:** Note: this method should not be overloaded in subclassed event loops. For any custom exception handling, use set_exception_handler() method.
18.5.1.17. Debug mode

AbstractEventLoop. **get_debug()**
Get the debug mode (**bool**) of the event loop.

The default value is **True** if the environment variable `PYTHONASYNCIODEBUG` is set to a non-empty string, **False** otherwise.

*New in version 3.4.2.*

AbstractEventLoop. **set_debug**(enabled: **bool**)
Set the debug mode of the event loop.

*New in version 3.4.2.*

**See also:** The debug mode of asyncio.
18.5.1.18. Server

class asyncio.Server

Server listening on sockets.

Object created by AbstractEventLoop.create_server(), AbstractEventLoop.create_unix_server(), start_server(), and start_unix_server() functions. Don’t instantiate the class directly.

Server objects are asynchronous context managers. When used in an async with statement, it’s guaranteed that the Server object is closed and not accepting new connections when the async with statement is completed:

```python
srv = await loop.create_server(...)  
async with srv:
    # some code

# At this point, srv is closed and no longer accepting new connections
```

Changed in version 3.7: Server object is an asynchronous context manager since Python 3.7.

close()

Stop serving: close listening sockets and set the sockets attribute to None.

The sockets that represent existing incoming client connections are left open.
The server is closed asynchronously, use the `wait_closed()` coroutine to wait until the server is closed.

**get_loop()**

Gives the event loop associated with the server object.

*New in version 3.7.*

**coroutine start_serving()**

Start accepting connections.

This method is idempotent, so it can be called when the server is already being serving.

The new `start_serving` keyword-only parameter to `AbstractEventLoop.create_server()` and `asyncio.start_server()` allows to create a Server object that is not accepting connections right away. In which case this method, or `Server.serve_forever()` can be used to make the Server object to start accepting connections.

*New in version 3.7.*

**coroutine serve_forever()**

Start accepting connections until the coroutine is cancelled. Cancellation of `serve_forever` task causes the server to be closed.

This method can be called if the server is already accepting connections. Only one `serve_forever` task can exist per one `Server` object.

Example:
async def client_connected(reader, writer):
    # Communicate with the client with
    # reader/writer streams. For example:
    await reader.readline()

async def main(host, port):
    srv = await asyncio.start_server(
        client_connected, host, port)
    await loop.schedule_forever()

asyncio.run(main('127.0.0.1', 0))

New in version 3.7.

is_serving()
    Return True if the server is accepting new connections.

    New in version 3.7.

Coroutine wait_closed()
    Wait until the close() method completes.

sockets
    List of socket.socket objects the server is listening to, or
    None if the server is closed.

    Changed in version 3.7: Prior to Python 3.7 Server.sockets
    used to return the internal list of server’s sockets directly. In 3.7
    a copy of that list is returned.
18.5.1.19. Handle

class asyncio.Handle

A callback wrapper object returned by
AbstractEventLoop.call_soon(),
AbstractEventLoop.call_soon_threadsafe(),
AbstractEventLoop.call_later(), and
AbstractEventLoop.call_at().

cancel()

Cancel the call. If the callback is already canceled or executed,
this method has no effect.

cancelled()

Return True if the call was cancelled.

New in version 3.7.
18.5.1.20. SendfileNotAvailableError

*exception* asyncio.SendfileNotAvailableError

Sendfile syscall is not available, subclass of RuntimeError.

Raised if the OS does not support sendfile syscall for given socket or file type.
18.5.1.21. Event loop examples

18.5.1.21.1. Hello World with call_soon()

Example using the `AbstractEventLoop.call_soon()` method to schedule a callback. The callback displays "Hello World" and then stops the event loop:

```python
import asyncio

def hello_world(loop):
    print('Hello World')
    loop.stop()

loop = asyncio.get_event_loop()

# Schedule a call to hello_world()
loop.call_soon(hello_world, loop)

# Blocking call interrupted by loop.stop()
loop.run_forever()
loop.close()
```

**See also:** The Hello World coroutine example uses a coroutine.

18.5.1.21.2. Display the current date with call_later()

Example of callback displaying the current date every second. The callback uses the `AbstractEventLoop.call_later()` method to reschedule itself during 5 seconds, and then stops the event loop:

```python
import asyncio
```
import datetime

def display_date(end_time, loop):
    print(datetime.datetime.now())
    if (loop.time() + 1.0) < end_time:
        loop.call_later(1, display_date, end_time, loop)
    else:
        loop.stop()

loop = asyncio.get_event_loop()

# Schedule the first call to display_date()
end_time = loop.time() + 5.0
loop.call_soon(display_date, end_time, loop)

# Blocking call interrupted by loop.stop()
loop.run_forever()
loop.close()

See also: The coroutine displaying the current date example uses a coroutine.

18.5.1.21.3. Watch a file descriptor for read events

Wait until a file descriptor received some data using the AbstractEventLoop.add_reader() method and then close the event loop:

```python
import asyncio
from socket import socketpair

# Create a pair of connected file descriptors
rsock, wsock = socketpair()
loop = asyncio.get_event_loop()
```
```python
def reader():
    data = rsock.recv(100)
    print("Received:", data.decode())
    # We are done: unregister the file descriptor
    loop.remove_reader(rsock)
    # Stop the event loop
    loop.stop()

    # Register the file descriptor for read event
    loop.add_reader(rsock, reader)

    # Simulate the reception of data from the network
    loop.call_soon(wsock.send, 'abc'.encode())

    # Run the event loop
    loop.run_forever()

    # We are done, close sockets and the event loop
    rsock.close()
    wsock.close()
    loop.close()
```

See also: The register an open socket to wait for data using a protocol example uses a low-level protocol created by the AbstractEventLoop.create_connection() method.

The register an open socket to wait for data using streams example uses high-level streams created by the open_connection() function in a coroutine.

18.5.1.21.4. Set signal handlers for SIGINT and SIGTERM
Register handlers for signals SIGINT and SIGTERM using the `AbstractEventLoop.add_signal_handler()` method:

```python
import asyncio
import functools
import os
import signal

def ask_exit(signame):
    print("got signal %s: exit" % signame)
    loop.stop()

loop = asyncio.get_event_loop()
for signame in ('SIGINT', 'SIGTERM'):
    loop.add_signal_handler(getattr(signal, signame), functools.partial(ask_exit))

print("Event loop running forever, press Ctrl+C to interrupt.
print("pid %s: send SIGINT or SIGTERM to exit." % os
try:
    loop.run_forever()
finally:
    loop.close()
```

This example only works on UNIX.
asyncio — Asynchronous I/O, event loop, coroutines and tasks
18.5.2. Event loops

Source code: Lib/asyncio/events.py
18.5.2.1. Event loop functions

The following functions are convenient shortcuts to accessing the methods of the global policy. Note that this provides access to the default policy, unless an alternative policy was set by calling `set_event_loop_policy()` earlier in the execution of the process.

```python
asyncio.get_event_loop()
```

Equivalent to calling `get_event_loop_policy().get_event_loop()`.

```python
asyncio.set_event_loop(loop)
```

Equivalent to calling `get_event_loop_policy().set_event_loop(loop)`.

```python
asyncio.new_event_loop()
```

Equivalent to calling `get_event_loop_policy().new_event_loop()`.

```python
asyncio.get_running_loop()
```
Return the running event loop in the current OS thread. If there is no running event loop a `RuntimeError` is raised.

*New in version 3.7.*
18.5.2.2. Available event loops

asyncio currently provides two implementations of event loops: `SelectorEventLoop` and `ProactorEventLoop`.

`class asyncio.SelectorEventLoop`
Event loop based on the `selectors` module. Subclass of `AbstractEventLoop`.

Use the most efficient selector available on the platform.

On Windows, only sockets are supported (ex: pipes are not supported): see the MSDN documentation of `select`.

`class asyncio.ProactorEventLoop`
Proactor event loop for Windows using “I/O Completion Ports” aka IOCP. Subclass of `AbstractEventLoop`.

Availability: Windows.

See also: MSDN documentation on I/O Completion Ports.

Example to use a `ProactorEventLoop` on Windows:

```python
import asyncio, sys
if sys.platform == 'win32':
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
```
18.5.2.3. Platform support

The asyncio module has been designed to be portable, but each platform still has subtle differences and may not support all asyncio features.

18.5.2.3.1. Windows

Common limits of Windows event loops:

- `create_unix_connection()` and `create_unix_server()` are not supported: the socket family `socket.AF_UNIX` is specific to UNIX
- `add_signal_handler()` and `remove_signal_handler()` are not supported
- `EventLoopPolicy.set_child_watcher()` is not supported. `ProactorEventLoop` supports subprocesses. It has only one implementation to watch child processes, there is no need to configure it.

`SelectorEventLoop` specific limits:

- `SelectSelector` is used which only supports sockets and is limited to 512 sockets.
- `add_reader()` and `add_writer()` only accept file descriptors of sockets
- Pipes are not supported (ex: `connect_read_pipe()`, `connect_write_pipe()`)
- Subprocesses are not supported (ex: `subprocess_exec()`, `subprocess_shell()`)

`ProactorEventLoop` specific limits:
- `create_datagram_endpoint()` (UDP) is not supported
- `add_reader()` and `add_writer()` are not supported

The resolution of the monotonic clock on Windows is usually around 15.6 msec. The best resolution is 0.5 msec. The resolution depends on the hardware (availability of HPET) and on the Windows configuration. See asyncio delayed calls.

*Changed in version 3.5:* **ProactorEventLoop** now supports SSL.

### 18.5.2.3.2. Mac OS X

Character devices like PTY are only well supported since Mavericks (Mac OS 10.9). They are not supported at all on Mac OS 10.5 and older.

On Mac OS 10.6, 10.7 and 10.8, the default event loop is **SelectorEventLoop** which uses `selectors.KqueueSelector`. **selectors.KqueueSelector** does not support character devices on these versions. The **SelectorEventLoop** can be used with **SelectSelector** or **PollSelector** to support character devices on these versions of Mac OS X. Example:

```python
import asyncio
import selectors

selector = selectors.SelectSelector()
loop = asyncio.SelectorEventLoop(selector)
asyncio.set_event_loop(loop)
```
18.5.2.4. Event loop policies and the default policy

Event loop management is abstracted with a *policy* pattern, to provide maximal flexibility for custom platforms and frameworks. Throughout the execution of a process, a single global policy object manages the event loops available to the process based on the calling context. A policy is an object implementing the `AbstractEventLoopPolicy` interface.

For most users of `asyncio`, policies never have to be dealt with explicitly, since the default global policy is sufficient (see below).

The module-level functions `get_event_loop()` and `set_event_loop()` provide convenient access to event loops managed by the default policy.
18.5.2.5. Event loop policy interface

An event loop policy must implement the following interface:

class asyncio.AbstractEventLoopPolicy
    Event loop policy.

    get_event_loop()
        Get the event loop for the current context.

        Returns an event loop object implementing the AbstractEventLoop interface.

        Raises an exception in case no event loop has been set for the current context and the current policy does not specify to create one. It must never return None.

    set_event_loop(loop)
        Set the event loop for the current context to loop.

    new_event_loop()
        Create and return a new event loop object according to this policy’s rules.

        If there’s need to set this loop as the event loop for the current context, set_event_loop() must be called explicitly.

The default policy defines context as the current thread, and manages an event loop per thread that interacts with asyncio. An exception to this rule happens when get_event_loop() is called from a running future/coroutine, in which case it will return the current loop running that future/coroutine.
If the current thread doesn’t already have an event loop associated with it, the default policy’s `get_event_loop()` method creates one when called from the main thread, but raises `RuntimeError` otherwise.
18.5.2.6. Access to the global loop policy

```python
asyncio.get_event_loop_policy()
```
Get the current event loop policy.

```python
asyncio.set_event_loop_policy(policy)
```
Set the current event loop policy. If `policy` is `None`, the default policy is restored.
18.5.2.7. Customizing the event loop policy

To implement a new event loop policy, it is recommended you subclass the concrete default event loop policy `DefaultEventLoopPolicy` and override the methods for which you want to change behavior, for example:

```python
class MyEventLoopPolicy(asyncio.DefaultEventLoopPolicy):
    def get_event_loop(self):
        """Get the event loop.
        This may be None or an instance of EventLoop.
        """
        loop = super().get_event_loop()
        # Do something with loop ...
        return loop

asyncio.set_event_loop_policy(MyEventLoopPolicy())
```
18.5.3. Tasks and coroutines

Source code: Lib/asyncio/tasks.py

Source code: Lib/asyncio/coroutines.py
18.5.3.1. Coroutines

Coroutines used with asyncio may be implemented using the async def statement, or by using generators. The async def type of coroutine was added in Python 3.5, and is recommended if there is no need to support older Python versions.

Generator-based coroutines should be decorated with @asyncio.coroutine, although this is not strictly enforced. The decorator enables compatibility with async def coroutines, and also serves as documentation. Generator-based coroutines use the yield from syntax introduced in PEP 380, instead of the original yield syntax.

The word “coroutine”, like the word “generator”, is used for two different (though related) concepts:

- The function that defines a coroutine (a function definition using async def or decorated with @asyncio.coroutine). If disambiguation is needed we will call this a coroutine function (iscoroutinefunction() returns True).
- The object obtained by calling a coroutine function. This object represents a computation or an I/O operation (usually a combination) that will complete eventually. If disambiguation is needed we will call it a coroutine object (iscoroutine() returns True).

Things a coroutine can do:

- `result = await future` or `result = yield from future` – suspends the coroutine until the future is done, then returns the future’s result, or raises an exception, which will be
propagated. (If the future is cancelled, it will raise a `CancelledError` exception.) Note that tasks are futures, and everything said about futures also applies to tasks.

- `result = await coroutine or result = yield from coroutine` – wait for another coroutine to produce a result (or raise an exception, which will be propagated). The coroutine expression must be a `call` to another coroutine.
- `return expression` – produce a result to the coroutine that is waiting for this one using `await` or `yield from`.
- `raise exception` – raise an exception in the coroutine that is waiting for this one using `await` or `yield from`.

Calling a coroutine does not start its code running – the coroutine object returned by the call doesn’t do anything until you schedule its execution. There are two basic ways to start it running: call `await coroutine` or `yield from coroutine` from another coroutine (assuming the other coroutine is already running!), or schedule its execution using the `ensure_future()` function or the `AbstractEventLoop.create_task()` method.

Coroutines (and tasks) can only run when the event loop is running.

`@asyncio.coroutine`

Decorator to mark generator-based coroutines. This enables the generator use `yield from` to call `async def` coroutines, and also enables the generator to be called by `async def` coroutines, for instance using an `await` expression.

There is no need to decorate `async def` coroutines themselves.

If the generator is not yielded from before it is destroyed, an error message is logged. See Detect coroutines never scheduled.
Note: In this documentation, some methods are documented as coroutines, even if they are plain Python functions returning a Future. This is intentional to have a freedom of tweaking the implementation of these functions in the future. If such a function is needed to be used in a callback-style code, wrap its result with ensure_future().

asyncio.run(coro, *, debug=False)

This function runs the passed coroutine, taking care of managing the asyncio event loop and finalizing asynchronous generators.

This function cannot be called when another asyncio event loop is running in the same thread.

If debug is True, the event loop will be run in debug mode.

This function always creates a new event loop and closes it at the end. It should be used as a main entry point for asyncio programs, and should ideally only be called once.

New in version 3.7.

18.5.3.1.1. Example: Hello World coroutine

Example of coroutine displaying "Hello World":

```python
import asyncio

async def hello_world():
    print("Hello World!")

asyncio.run(hello_world())
```
18.5.3.1.2. Example: Coroutine displaying the current date

Example of coroutine displaying the current date every second during 5 seconds using the `sleep()` function:

```python
import asyncio
import datetime

async def display_date():
    loop = asyncio.get_running_loop()
    end_time = loop.time() + 5.0
    while True:
        print(datetime.datetime.now())
        if (loop.time() + 1.0) >= end_time:
            break
        await asyncio.sleep(1)

asyncio.run(display_date())
```

See also: The `Hello World with call_soon()` example uses the `AbstractEventLoop.call_soon()` method to schedule a callback.

18.5.3.1.3. Example: Chain coroutines

Example chaining coroutines:

```python
import asyncio
```
async def compute(x, y):
    print("Compute %s + %s ..." % (x, y))
    await asyncio.sleep(1.0)
    return x + y

async def print_sum(x, y):
    result = await compute(x, y)
    print("%s + %s = %s" % (x, y, result))

loop = asyncio.get_event_loop()
loop.run_until_complete(print_sum(1, 2))
loop.close()

compute() is chained to print_sum(): print_sum() coroutine waits until compute() is completed before returning its result.

Sequence diagram of the example:

The Task is created by the AbstractEventLoop.run_until_complete() method when it gets a coroutine object instead of a task.
The diagram shows the control flow, it does not describe exactly how things work internally. For example, the sleep coroutine creates an internal future which uses `AbstractEventLoop.call_later()` to wake up the task in 1 second.
18.5.3.2. InvalidStateError

*exception asyncio.* InvalidStateError

The operation is not allowed in this state.
18.5.3.3. TimeoutError

_exception asyncio.TimeoutError_

The operation exceeded the given deadline.

**Note:** This exception is different from the builtin _TimeoutError_ exception!
18.5.3.4. Future

class asyncio.Future(*, loop=None)

This class is almost compatible with concurrent.futures.Future.

Differences:

- result() and exception() do not take a timeout argument and raise an exception when the future isn’t done yet.
- Callbacks registered with add_done_callback() are always called via the event loop’s call_soon().
- This class is not compatible with the wait() and as_completed() functions in the concurrent.futures package.

This class is not thread safe.

cancel()

Cancel the future and schedule callbacks.

If the future is already done or cancelled, return False. Otherwise, change the future’s state to cancelled, schedule the callbacks and return True.

cancelled()

Return True if the future was cancelled.

done()

Return True if the future is done.

Done means either that a result / exception are available, or
that the future was cancelled.

result()  
Return the result this future represents.

If the future has been cancelled, raises CancelledError. If the future's result isn't yet available, raises InvalidStateError. If the future is done and has an exception set, this exception is raised.

exception()  
Return the exception that was set on this future.

The exception (or None if no exception was set) is returned only if the future is done. If the future has been cancelled, raises CancelledError. If the future isn't done yet, raises InvalidStateError.

add_done_callback(fn)  
Add a callback to be run when the future becomes done.

The callback is called with a single argument - the future object. If the future is already done when this is called, the callback is scheduled with call_soon().

Use functools.partial to pass parameters to the callback. For example,

```
fut.add_done_callback(functools.partial(print, "Future:", flush=True)) will call print("Future:", fut, flush=True).
```

remove_done_callback(fn)  
Remove all instances of a callback from the “call when done”
list.

Returns the number of callbacks removed.

**set_result**(result)
Mark the future done and set its result.

If the future is already done when this method is called, raises **InvalidStateError**.

**set_exception**(exception)
Mark the future done and set an exception.

If the future is already done when this method is called, raises **InvalidStateError**.

**get_loop**()
Return the event loop the future object is bound to.

New in version 3.7.

18.5.3.4.1. Example: Future with run_until_complete()

Example combining a **Future** and a **coroutine function**:

```python
import asyncio

async def slow_operation(future):
    await asyncio.sleep(1)
    future.set_result('Future is done!')

loop = asyncio.get_event_loop()
future = asyncio.Future()
```
asyncio.ensure_future(slow_operation(future))
loop.run_until_complete(future)
print(future.result())
loop.close()

The coroutine function is responsible for the computation (which takes 1 second) and it stores the result into the future. The run_until_complete() method waits for the completion of the future.

**Note:** The run_until_complete() method uses internally the add_done_callback() method to be notified when the future is done.

### 18.5.3.4.2. Example: Future with run_forever()

The previous example can be written differently using the Future.add_done_callback() method to describe explicitly the control flow:

```python
import asyncio

async def slow_operation(future):
    await asyncio.sleep(1)
    future.set_result('Future is done!')

def got_result(future):
    print(future.result())
    loop.stop()

loop = asyncio.get_event_loop()
future = asyncio.Future()
asyncio.ensure_future(slow_operation(future))
future.add_done_callback(got_result)
```
try:
    loop.run_forever()
finally:
    loop.close()

In this example, the future is used to link `slow_operation()` to `got_result()`: when `slow_operation()` is done, `got_result()` is called with the result.
18.5.3.5. Task

asyncio.create_task(coro)

Wrap a coroutine `coro` into a task and schedule its execution. Return the task object.

The task is executed in `get_running_loop()` context, `RuntimeError` is raised if there is no running loop in current thread.

*New in version 3.7.*

class asyncio.Task(coro, *, loop=None)

A unit for concurrent running of coroutines, subclass of `Future`.

A task is responsible for executing a coroutine object in an event loop. If the wrapped coroutine yields from a future, the task suspends the execution of the wrapped coroutine and waits for the completion of the future. When the future is done, the execution of the wrapped coroutine restarts with the result or the exception of the future.

Event loops use cooperative scheduling: an event loop only runs one task at a time. Other tasks may run in parallel if other event loops are running in different threads. While a task waits for the completion of a future, the event loop executes a new task.

The cancellation of a task is different from the cancellation of a future. Calling `cancel()` will throw a `CancelledError` to the wrapped coroutine. `cancelled()` only returns `True` if the wrapped coroutine did not catch the `CancelledError` exception, or raised a `CancelledError` exception.
If a pending task is destroyed, the execution of its wrapped coroutine did not complete. It is probably a bug and a warning is logged: see Pending task destroyed.

Don't directly create Task instances: use the `create_task()` function or the `AbstractEventLoop.create_task()` method.

This class is not thread safe.

```python
classmethod all_tasks(loop=None)
    Return a set of all tasks for an event loop.

    By default all tasks for the current event loop are returned.
```

```python
classmethod current_task(loop=None)
    Return the currently running task in an event loop or None.

    By default the current task for the current event loop is returned.
    
    None is returned when called not in the context of a Task.
```

```python
cancel()
    Request that this task cancel itself.
    
    This arranges for a CancelledError to be thrown into the wrapped coroutine on the next cycle through the event loop. The coroutine then has a chance to clean up or even deny the request using try/except/finally.
    
    Unlike Future.cancel(), this does not guarantee that the task will be cancelled: the exception might be caught and acted upon, delaying cancellation of the task or preventing cancellation completely. The task may also return a value or raise a different exception.
```
Immediately after this method is called, `cancelled()` will not return `True` (unless the task was already cancelled). A task will be marked as cancelled when the wrapped coroutine terminates with a `CancelledError` exception (even if `cancel()` was not called).

**get_stack(*, limit=None)**

Return the list of stack frames for this task’s coroutine.

If the coroutine is not done, this returns the stack where it is suspended. If the coroutine has completed successfully or was cancelled, this returns an empty list. If the coroutine was terminated by an exception, this returns the list of traceback frames.

The frames are always ordered from oldest to newest.

The optional limit gives the maximum number of frames to return; by default all available frames are returned. Its meaning differs depending on whether a stack or a traceback is returned: the newest frames of a stack are returned, but the oldest frames of a traceback are returned. (This matches the behavior of the traceback module.)

For reasons beyond our control, only one stack frame is returned for a suspended coroutine.

**print_stack(*, limit=None, file=None)**

Print the stack or traceback for this task’s coroutine.

This produces output similar to that of the traceback module, for the frames retrieved by `get_stack()`. The limit argument is passed to `get_stack()`. The file argument is an I/O stream to
which the output is written; by default output is written to sys.stderr.

18.5.3.5.1. Example: Parallel execution of tasks

Example executing 3 tasks (A, B, C) in parallel:

```
import asyncio

async def factorial(name, number):
    f = 1
    for i in range(2, number+1):
        print("Task %s: Compute factorial(%s)..." % (name, number), end='')
        await asyncio.sleep(1)
        f *= i
        print("Task %s: factorial(%s) = %s" % (name, number, f), end='')

loop = asyncio.get_event_loop()
loop.run_until_complete(asyncio.gather(
    factorial("A", 2),
    factorial("B", 3),
    factorial("C", 4),
))
loop.close()
```

Output:

```
Task A: Compute factorial(2)...
Task B: Compute factorial(2)...
Task C: Compute factorial(2)...
Task A: factorial(2) = 2
Task B: Compute factorial(3)...
Task C: Compute factorial(3)...
Task B: factorial(3) = 6
Task C: Compute factorial(4)...
```
Task C: factorial(4) = 24

A task is automatically scheduled for execution when it is created. The event loop stops when all tasks are done.
18.5.3.6. Task functions

**Note:** In the functions below, the optional `loop` argument allows explicitly setting the event loop object used by the underlying task or coroutine. If it’s not provided, the default event loop is used.

**current_task(loop=None):**

Return the current running `Task` instance or `None`, if no task is running.

If `loop` is `None` `get_running_loop()` is used to get the current loop.

*New in version 3.7.*

**all_tasks(loop=None):**

Return a set of `Task` objects created for the loop.

If `loop` is `None` `get_event_loop()` is used for getting current loop.

*New in version 3.7.*

**`asyncio.as_completed(fs, *, loop=None, timeout=None)***

Return an iterator whose values, when waited for, are `Future` instances.

Raises `asyncio.TimeoutError` if the timeout occurs before all Futures are done.

Example:

```python
for f in as_completed(fs):
```
result = await f  # The 'await' may raise
# Use result

**Note:** The futures f are not necessarily members of fs.

```python
asyncio.ensure_future(coro_or_future, *, loop=None)
```

Schedule the execution of a **coroutine object**: wrap it in a future. Return a **Task** object.

If the argument is a **Future**, it is returned directly.

*New in version 3.4.4.*

*Changed in version 3.5.1:* The function accepts any **awaitable** object.

**Note:** **create_task()** (added in Python 3.7) is the preferable way for spawning new tasks.

**See also:** The **create_task()** function and `AbstractEventLoop.create_task()` method.

```python
asyncio.wrap_future(future, *, loop=None)
```

Wrap a **concurrent.futures.Future** object in a **Future** object.

```python
asyncio.gather(*coros_or_futures, loop=None, return_exceptions=False)
```

Return a future aggregating results from the given coroutine objects or futures.

All futures must share the same event loop. If all the tasks are
done successfully, the returned future's result is the list of results (in the order of the original sequence, not necessarily the order of results arrival). If return_exceptions is true, exceptions in the tasks are treated the same as successful results, and gathered in the result list; otherwise, the first raised exception will be immediately propagated to the returned future.

Cancellation: if the outer Future is cancelled, all children (that have not completed yet) are also cancelled. If any child is cancelled, this is treated as if it raised CancelledError – the outer Future is not cancelled in this case. (This is to prevent the cancellation of one child to cause other children to be cancelled.)

asyncio.iscoroutine(obj)

Return True if obj is a coroutine object, which may be based on a generator or an async def coroutine.

asyncio.iscoroutinefunction(func)

Return True if func is determined to be a coroutine function, which may be a decorated generator function or an async def function.

asyncio.run_coroutine_threadsafe(coro, loop)

Submit a coroutine object to a given event loop.

Return a concurrent.futures.Future to access the result.

This function is meant to be called from a different thread than the one where the event loop is running. Usage:

```python
# Create a coroutine
coro = asyncio.sleep(1, result=3)
# Submit the coroutine to a given loop
future = asyncio.run_coroutine_threadsafe(coro, loop)
```
# Wait for the result with an optional timeout argument

```python
assert future.result(timeout) == 3
```

If an exception is raised in the coroutine, the returned future will be notified. It can also be used to cancel the task in the event loop:

```python
try:
    result = future.result(timeout)
except asyncio.TimeoutError:
    print('The coroutine took too long, cancelling...')
    future.cancel()
except Exception as exc:
    print('The coroutine raised an exception: {!r}'.format(exc))
else:
    print('The coroutine returned: {!r}'.format(result))
```

See the concurrency and multithreading section of the documentation.

**Note:** Unlike other functions from the module, `run_coroutine_threadsafe()` requires the `loop` argument to be passed explicitly.

*New in version 3.5.1.*

`coroutine asyncio.sleep(delay, result=None, *, loop=None)`

Create a coroutine that completes after a given time (in seconds). If `result` is provided, it is produced to the caller when the coroutine completes.

The resolution of the sleep depends on the granularity of the event loop.
This function is a coroutine.

`asyncio.shield(arg, *, loop=None)`

Wait for a future, shielding it from cancellation.

The statement:

```python
res = await shield(something())
```

is exactly equivalent to the statement:

```python
res = await something()
```

except that if the coroutine containing it is cancelled, the task running in `something()` is not cancelled. From the point of view of `something()`, the cancellation did not happen. But its caller is still cancelled, so the yield-from expression still raises `CancelledError`. Note: If `something()` is cancelled by other means this will still cancel `shield()`.

If you want to completely ignore cancellation (not recommended) you can combine `shield()` with a try/except clause, as follows:

```python
try:
    res = await shield(something())
except CancelledError:
    res = None
```

`coroutine asyncio.wait(futures, *, loop=None, timeout=None,
return_when=ALL_COMPLETED)`

Wait for the Futures and coroutine objects given by the sequence `futures` to complete. Coroutines will be wrapped in Tasks. Returns two sets of `Future`: (done, pending).
The sequence `futures` must not be empty.

`timeout` can be used to control the maximum number of seconds to wait before returning. `timeout` can be an int or float. If `timeout` is not specified or `None`, there is no limit to the wait time.

`return_when` indicates when this function should return. It must be one of the following constants of the `concurrent.futures` module:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIRST_COMPLETED</td>
<td>The function will return when any future finishes or is cancelled.</td>
</tr>
<tr>
<td>FIRST_EXCEPTION</td>
<td>The function will return when any future finishes by raising an exception. If no future raises an exception then it is equivalent to ALL_COMPLETED.</td>
</tr>
<tr>
<td>ALL_COMPLETED</td>
<td>The function will return when all futures finish or are cancelled.</td>
</tr>
</tbody>
</table>

This function is a coroutine.

Usage:

```python
done, pending = await asyncio.wait(fs)
```

**Note:** This does not raise `asyncio.TimeoutError`! Futures that aren't done when the timeout occurs are returned in the second set.

**coroutine** `asyncio.wait_for(fut, timeout, *, loop=None)`

Wait for the single `Future` or coroutine object to complete with
timeout. If timeout is None, block until the future completes.

Coroutine will be wrapped in Task.

Returns result of the Future or coroutine. When a timeout occurs, it cancels the task and raises asyncio.TimeoutError. To avoid the task cancellation, wrap it in shield().

If the wait is cancelled, the future fut is also cancelled.

This function is a coroutine, usage:

```python
result = await asyncio.wait_for(fut, 60.0)
```

*Changed in version 3.4.3:* If the wait is cancelled, the future fut is now also cancelled.
18.5.4. Transports and protocols (callback based API)

Source code: Lib/asyncio/transports.py

Source code: Lib/asyncio/protocols.py
18.5.4.1. Transports

Transports are classes provided by asyncio in order to abstract various kinds of communication channels. You generally won’t instantiate a transport yourself; instead, you will call an AbstractEventLoop method which will create the transport and try to initiate the underlying communication channel, calling you back when it succeeds.

Once the communication channel is established, a transport is always paired with a protocol instance. The protocol can then call the transport’s methods for various purposes.

asyncio currently implements transports for TCP, UDP, SSL, and subprocess pipes. The methods available on a transport depend on the transport’s kind.

The transport classes are not thread safe.

*Changed in version 3.6:* The socket option TCP_NODELAY is now set by default.

18.5.4.1.1. BaseTransport

*class* asyncio.BaseTransport

Base class for transports.

*close()*

Close the transport. If the transport has a buffer for outgoing data, buffered data will be flushed asynchronously. No more data will be received. After all buffered data is flushed, the
protocol's connection_lost() method will be called with None as its argument.

**is_closing()**

Return True if the transport is closing or is closed.

*New in version 3.5.1.*

**get_extra_info(name, default=None)**

Return optional transport information. name is a string representing the piece of transport-specific information to get, default is the value to return if the information doesn't exist.

This method allows transport implementations to easily expose channel-specific information.

- socket:
  - 'peername': the remote address to which the socket is connected, result of `socket.socket.getpeername()` (None on error)
  - 'socket': socket.socket instance
  - 'sockname': the socket's own address, result of `socket.socket.getsockname()`

- SSL socket:
  - 'compression': the compression algorithm being used as a string, or None if the connection isn't compressed; result of `ssl.SSLSocket.compression()`
  - 'cipher': a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used; result of `ssl.SSLSocket.cipher()`
  - 'peercert': peer certificate; result of
ssl.SSLSocket.getpeercert()
- 'sslcontext': ssl.SSLContext instance
- 'ssl_object': ssl.SSLObject or ssl.SSLSocket instance

- pipe:
  - 'pipe': pipe object

- subprocess:
  - 'subprocess': subprocess.Popen instance

set_protocol(protocol)
Set a new protocol. Switching protocol should only be done when both protocols are documented to support the switch.

*New in version 3.5.3.*

get_protocol()
Return the current protocol.

*New in version 3.5.3.*

*Changed in version 3.5.1:* 'ssl_object' info was added to SSL sockets.

18.5.4.1.2. ReadTransport

class asyncio.ReadTransport
Interface for read-only transports.

is_reading()
Return True if the transport is receiving new data.

*New in version 3.7.*
pause_reading()

Pause the receiving end of the transport. No data will be passed to the protocol's data_received() method until resume_reading() is called.

*Changed in version 3.7:* The method is idempotent, i.e. it can be called when the transport is already paused or closed.

resume_reading()

Resume the receiving end. The protocol’s data_received() method will be called once again if some data is available for reading.

*Changed in version 3.7:* The method is idempotent, i.e. it can be called when the transport is already reading.

18.5.4.1.3. WriteTransport

class asyncio.WriteTransport

Interface for write-only transports.

abort()

Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's connection_lost() method will eventually be called with None as its argument.

can_write_eof()

Return True if the transport supports write_eof(), False if not.

get_write_buffer_size()
Return the current size of the output buffer used by the transport.

**get_write_buffer_limits()**
Get the high- and low-water limits for write flow control. Return a tuple \((\text{low}, \text{high})\) where \text{low} and \text{high} are positive number of bytes.

Use **set_write_buffer_limits()** to set the limits.

*New in version 3.4.2.*

**set_write_buffer_limits**(high=None, low=None)
Set the high- and low-water limits for write flow control.

These two values (measured in number of bytes) control when the protocol's pause_writing() and resume_writing() methods are called. If specified, the low-water limit must be less than or equal to the high-water limit. Neither high nor low can be negative.

pause_writing() is called when the buffer size becomes greater than or equal to the high value. If writing has been paused, resume_writing() is called when the buffer size becomes less than or equal to the low value.

The defaults are implementation-specific. If only the high-water limit is given, the low-water limit defaults to an implementation-specific value less than or equal to the high-water limit. Setting high to zero forces low to zero as well, and causes pause_writing() to be called whenever the buffer becomes non-empty. Setting low to zero causes resume_writing() to be called only once the buffer is empty. Use of zero for either
limit is generally sub-optimal as it reduces opportunities for doing I/O and computation concurrently.

Use `get_write_buffer_limits()` to get the limits.

**write**(data)

Write some *data* bytes to the transport.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.

**writelines**(list_of_data)

Write a list (or any iterable) of data bytes to the transport. This is functionally equivalent to calling `write()` on each element yielded by the iterable, but may be implemented more efficiently.

**write_eof()**

Close the write end of the transport after flushing buffered data. Data may still be received.

This method can raise `NotImplementedError` if the transport (e.g. SSL) doesn’t support half-closes.

### 18.5.4.1.4. DatagramTransport

DatagramTransport. **sendto**(data, addr=None)

Send the *data* bytes to the remote peer given by *addr* (a transport-dependent target address). If *addr* is `None`, the data is sent to the target address given on transport creation.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.
DatagramTransport.\texttt{abort()}

Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's\texttt{connection\_lost()} method will eventually be called with \texttt{None} as its argument.

18.5.4.1.5. BaseSubprocessTransport

\texttt{class asyncio.BaseSubprocessTransport}

\texttt{get\_pid()}

Return the subprocess process id as an integer.

\texttt{get\_pipe\_transport(fd)}

Return the transport for the communication pipe corresponding to the integer file descriptor \texttt{fd}:

- \texttt{0}: readable streaming transport of the standard input (\texttt{stdin}), or \texttt{None} if the subprocess was not created with \texttt{stdin=PIPE}
- \texttt{1}: writable streaming transport of the standard output (\texttt{stdout}), or \texttt{None} if the subprocess was not created with \texttt{stdout=PIPE}
- \texttt{2}: writable streaming transport of the standard error (\texttt{stderr}), or \texttt{None} if the subprocess was not created with \texttt{stderr=PIPE}
- other \texttt{fd}: \texttt{None}

\texttt{get\_returncode()}  

Return the subprocess returncode as an integer or \texttt{None} if it hasn't returned, similarly to the \texttt{subprocess.Popen.returncode} attribute.
**kill()**

Kill the subprocess, as in `subprocess.Popen.kill()`.

On POSIX systems, the function sends SIGKILL to the subprocess. On Windows, this method is an alias for `terminate()`.

**send_signal(signal)**

Send the `signal` number to the subprocess, as in `subprocess.Popen.send_signal()`.

**terminate()**

Ask the subprocess to stop, as in `subprocess.Popen.terminate()`. This method is an alias for the `close()` method.

On POSIX systems, this method sends SIGTERM to the subprocess. On Windows, the Windows API function `TerminateProcess()` is called to stop the subprocess.

**close()**

Ask the subprocess to stop by calling the `terminate()` method if the subprocess hasn’t returned yet, and close transports of all pipes (`stdin`, `stdout` and `stderr`).
18.5.4.2. Protocols

**asyncio** provides base classes that you can subclass to implement your network protocols. Those classes are used in conjunction with transports (see below): the protocol parses incoming data and asks for the writing of outgoing data, while the transport is responsible for the actual I/O and buffering.

When subclassing a protocol class, it is recommended you override certain methods. Those methods are callbacks: they will be called by the transport on certain events (for example when some data is received); you shouldn’t call them yourself, unless you are implementing a transport.

**Note:** All callbacks have default implementations, which are empty. Therefore, you only need to implement the callbacks for the events in which you are interested.

18.5.4.2.1. Protocol classes

*class asyncio.**Protocol**

The base class for implementing streaming protocols (for use with e.g. TCP and SSL transports).

*class asyncio.**BufferedProtocol**

A base class for implementing streaming protocols with manual control of the receive buffer.

*New in version 3.7: Important:* this has been been added to asyncio in Python 3.7 on a provisional basis! Treat it as an experimental API that might be changed or removed in Python 3.8.
class asyncio.DatagramProtocol

The base class for implementing datagram protocols (for use with e.g. UDP transports).

class asyncio.SubprocessProtocol

The base class for implementing protocols communicating with child processes (through a set of unidirectional pipes).

18.5.4.2.2. Connection callbacks

These callbacks may be called on Protocol, DatagramProtocol and SubprocessProtocol instances:

BaseProtocol.connection_made(transport)

Called when a connection is made.

The transport argument is the transport representing the connection. You are responsible for storing it somewhere (e.g. as an attribute) if you need to.

BaseProtocol.connection_lost(exc)

Called when the connection is lost or closed.

The argument is either an exception object or None. The latter means a regular EOF is received, or the connection was aborted or closed by this side of the connection.

connection_made() and connection_lost() are called exactly once per successful connection. All other callbacks will be called between those two methods, which allows for easier resource management in your protocol implementation.

The following callbacks may be called only on
SubprocessProtocol instances:

SubprocessProtocol.pipe_data_received(fd, data)
Called when the child process writes data into its stdout or stderr pipe. fd is the integer file descriptor of the pipe. data is a non-empty bytes object containing the data.

SubprocessProtocol.pipe_connection_lost(fd, exc)
Called when one of the pipes communicating with the child process is closed. fd is the integer file descriptor that was closed.

SubprocessProtocol.process_exited()
Called when the child process has exited.

18.5.4.2.3. Streaming protocols

The following callbacks are called on Protocol instances:

Protocol.data_received(data)
Called when some data is received. data is a non-empty bytes object containing the incoming data.

Note: Whether the data is buffered, chunked or reassembled depends on the transport. In general, you shouldn’t rely on specific semantics and instead make your parsing generic and flexible enough. However, data is always received in the correct order.

Protocol.eof_received()
Called when the other end signals it won’t send any more data (for example by calling write_eof(), if the other end also uses asyncio).
This method may return a false value (including `None`), in which case the transport will close itself. Conversely, if this method returns a true value, closing the transport is up to the protocol. Since the default implementation returns `None`, it implicitly closes the connection.

**Note:** Some transports such as SSL don’t support half-closed connections, in which case returning true from this method will not prevent closing the connection.

data_received() can be called an arbitrary number of times during a connection. However, eof_received() is called at most once and, if called, data_received() won’t be called after it.

State machine:

```
start -> connection_made
       [-> data_received] *
       [-> eof_received] ?
-> connection_lost -> end
```

18.5.4.2.4. Streaming protocols with manual receive buffer control

*New in version 3.7:* **Important:** `BufferedProtocol` has been added to asyncio in Python 3.7 *on a provisional basis!* Consider it as an experimental API that might be changed or removed in Python 3.8.

Event methods, such as `AbstractEventLoop.create_server()` and `AbstractEventLoop.create_connection()`, accept factories that return protocols that implement this interface.
The idea of BufferedProtocol is that it allows to manually allocate and control the receive buffer. Event loops can then use the buffer provided by the protocol to avoid unnecessary data copies. This can result in noticeable performance improvement for protocols that receive big amounts of data. Sophisticated protocols can allocate the buffer only once at creation time.

The following callbacks are called on BufferedProtocol instances:

BufferedProtocol.get_buffer()
   Called to allocate a new receive buffer. Must return an object that implements the buffer protocol.

BufferedProtocol.buffer_updated(nbytes)
   Called when the buffer was updated with the received data.

   nbytes is the total number of bytes that were written to the buffer.

BufferedProtocol.eof_received()
   See the documentation of the Protocol.eof_received() method.

get_buffer() can be called an arbitrary number of times during a connection. However, eof_received() is called at most once and, if called, get_buffer() and buffer_updated() won't be called after it.

State machine:

\[
\text{start} \rightarrow \text{connection_made} \\
\quad [\rightarrow \text{get_buffer} \\
\quad \quad [\rightarrow \text{buffer_updated}]? \\
\quad ]^* \\
\quad [\rightarrow \text{eof_received}]?
\]
18.5.4.2.5. Datagram protocols

The following callbacks are called on `DatagramProtocol` instances.

`DatagramProtocol.datagram_received(data, addr)`

Called when a datagram is received. `data` is a bytes object containing the incoming data. `addr` is the address of the peer sending the data; the exact format depends on the transport.

`DatagramProtocol.error_received(exc)`

Called when a previous send or receive operation raises an `OSError`. `exc` is the `OSError` instance.

This method is called in rare conditions, when the transport (e.g. UDP) detects that a datagram couldn't be delivered to its recipient. In many conditions though, undeliverable datagrams will be silently dropped.

18.5.4.2.6. Flow control callbacks

These callbacks may be called on `Protocol`, `DatagramProtocol` and `SubprocessProtocol` instances:

`BaseProtocol.pause_writing()`

Called when the transport's buffer goes over the high-water mark.

`BaseProtocol.resume_writing()`

Called when the transport's buffer drains below the low-water mark.

`pause_writing()` and `resume_writing()` calls are paired –
pause_writing() is called once when the buffer goes strictly over the high-water mark (even if subsequent writes increases the buffer size even more), and eventually resume_writing() is called once when the buffer size reaches the low-water mark.

**Note:** If the buffer size equals the high-water mark, pause_writing() is not called – it must go strictly over. Conversely, resume_writing() is called when the buffer size is equal or lower than the low-water mark. These end conditions are important to ensure that things go as expected when either mark is zero.

**Note:** On BSD systems (OS X, FreeBSD, etc.) flow control is not supported for DatagramProtocol, because send failures caused by writing too many packets cannot be detected easily. The socket always appears ‘ready’ and excess packets are dropped; an OSError with errno set to errno.ENOBUFS may or may not be raised; if it is raised, it will be reported to DatagramProtocol.error_received() but otherwise ignored.

### 18.5.4.2.7. Coroutines and protocols

Coroutines can be scheduled in a protocol method using ensure_future(), but there is no guarantee made about the execution order. Protocols are not aware of coroutines created in protocol methods and so will not wait for them.

To have a reliable execution order, use stream objects in a coroutine with await. For example, the StreamWriter.drain() coroutine can be used to wait until the write buffer is flushed.
18.5.4.3. Protocol examples

18.5.4.3.1. TCP echo client protocol

TCP echo client using the AbstractEventLoop.create_connection() method, send data and wait until the connection is closed:

```python
import asyncio

class EchoClientProtocol(asyncio.Protocol):
    def __init__(self, message, loop):
        self.message = message
        self.loop = loop

    def connection_made(self, transport):
        transport.write(self.message.encode())
        print('Data sent: {!r}'.format(self.message))

    def data_received(self, data):
        print('Data received: {!r}'.format(data.decode()))

    def connection_lost(self, exc):
        print('The server closed the connection')
        print('Stop the event loop')
        self.loop.stop()

loop = asyncio.get_event_loop()
message = 'Hello World!'
coro = loop.create_connection(lambda: EchoClientProtocol('127.0.0.1', 8888))
loop.run_until_complete(coro)
loop.run_forever()
loop.close()
```
The event loop is running twice. The `run_until_complete()` method is preferred in this short example to raise an exception if the server is not listening, instead of having to write a short coroutine to handle the exception and stop the running loop. At `run_until_complete()` exit, the loop is no longer running, so there is no need to stop the loop in case of an error.

**See also:** The TCP echo client using streams example uses the `asyncio.open_connection()` function.

### 18.5.4.3.2. TCP echo server protocol

TCP echo server using the `AbstractEventLoop.create_server()` method, send back received data and close the connection:

```python
import asyncio

class EchoServerClientProtocol(asyncio.Protocol):
    def connection_made(self, transport):
        peername = transport.get_extra_info('peername')
        print('Connection from {}'.format(peername))
        self.transport = transport

    def data_received(self, data):
        message = data.decode()
        print('Data received: {!r}'.format(message))

        print('Send: {!r}'.format(message))
        self.transport.write(data)

        print('Close the client socket')
        self.transport.close()
```
```python
loop = asyncio.get_event_loop()
# Each client connection will create a new protocol
coro = loop.create_server(EchoServerClientProtocol, server = loop.run_until_complete(coro))

# Serve requests until Ctrl+C is pressed
print('Serving on {}' .format(serversockets[0].getsockname()))
try:
    loop.run_forever()
except KeyboardInterrupt:
    pass

# Close the server
server.close()
loop.run_until_complete(server.wait_closed())
loop.close()
```

Transport.close() can be called immediately after WriteTransport.write() even if data are not sent yet on the socket: both methods are asynchronous. `await` is not needed because these transport methods are not coroutines.

**See also:** The [TCP echo server using streams](https://docs.python.org/3/library/asyncio-stream.html#asyncio-stream) example uses the `asyncio.start_server()` function.

### 18.5.4.3.3. UDP echo client protocol

UDP echo client using the AbstractEventLoop.create_datagram_endpoint() method, send data and close the transport when we received the answer:

```python
import asyncio
```
class EchoClientProtocol:
    def __init__(self, message, loop):
        self.message = message
        self.loop = loop
        self.transport = None

    def connection_made(self, transport):
        self.transport = transport
        print('Send: ', self.message)
        self.transport.sendto(self.message.encode())

    def datagram_received(self, data, addr):
        print("Received:", data.decode())
        print("Close the socket")
        self.transport.close()

    def error_received(self, exc):
        print('Error received: ', exc)

    def connection_lost(self, exc):
        print("Socket closed, stop the event loop")
        loop = asyncio.get_event_loop()
        loop.stop()

loop = asyncio.get_event_loop()
message = "Hello World!"
connect = loop.create_datagram_endpoint(
    lambda: EchoClientProtocol(message, loop),
    remote_addr=('127.0.0.1', 9999))
transport, protocol = loop.run_until_complete(connect)
loop.run_forever()
transport.close()
loop.close()
UDP echo server using the `AbstractEventLoop.create_datagram_endpoint()` method, send back received data:

```python
import asyncio
class EchoServerProtocol:
    def connection_made(self, transport):
        self.transport = transport

    def datagram_received(self, self, data, addr):
        message = data.decode()
        print('Received %r from %s' % (message, addr))
        print('Send %r to %s' % (message, addr))
        self.transport.sendto(data, addr)

loop = asyncio.get_event_loop()
print("Starting UDP server")
# One protocol instance will be created to serve all
listen = loop.create_datagram_endpoint(
    EchoServerProtocol, local_addr=('127.0.0.1', 9999))

transport, protocol = loop.run_until_complete(listen)

try:
    loop.run_forever()
except KeyboardInterrupt:
    pass

transport.close()
loop.close()
```

18.5.4.3.5. Register an open socket to wait for data using a protocol
Wait until a socket receives data using the `AbstractEventLoop.create_connection()` method with a protocol, and then close the event loop.

```python
import asyncio
from socket import socketpair

# Create a pair of connected sockets
rsock, wsock = socketpair()
loop = asyncio.get_event_loop()

class MyProtocol(asyncio.Protocol):
    transport = None

    def connection_made(self, transport):
        self.transport = transport

    def data_received(self, data):
        print("Received:" , data.decode())

        # We are done: close the transport (it will close())
        self.transport.close()

    def connection_lost(self, exc):
        # The socket has been closed, stop the event loop.
        loop.stop()

# Register the socket to wait for data
connect_coro = loop.create_connection(MyProtocol, sckt, protocol = loop.run_until_complete(connect_coro))

# Simulate the reception of data from the network
loop.call_soon(wsock.send, 'abc'.encode())

# Run the event loop
loop.run_forever()
```
# We are done, close sockets and the event loop
rsock.close()
wsock.close()
loop.close()

See also: The watch a file descriptor for read events example uses the low-level AbstractEventLoop.add_reader() method to register the file descriptor of a socket.

The register an open socket to wait for data using streams example uses high-level streams created by the open_connection() function in a coroutine.
18.5.5. Streams (coroutine based API)

Source code: Lib/asyncioStreams.py
18.5.5.1. Stream functions

**Note:** The top-level functions in this module are meant as convenience wrappers only; there's really nothing special there, and if they don't do exactly what you want, feel free to copy their code.

coroutine asyncio.open_connection(host=None, port=None, *, loop=None, limit=None, **kwds)

A wrapper for create_connection() returning a (reader, writer) pair.

The reader returned is a StreamReader instance; the writer is a StreamWriter instance.

The arguments are all the usual arguments to AbstractEventLoop.create_connection() except protocol_factory; most common are positional host and port, with various optional keyword arguments following.

Additional optional keyword arguments are loop (to set the event loop instance to use) and limit (to set the buffer limit passed to the StreamReader).

This function is a coroutine.

coroutine asyncio.start_server(client_connected_cb, host=None, port=None, *, loop=None, limit=None, **kwds)

Start a socket server, with a callback for each client connected. The return value is the same as create_server().

The client_connected_cb parameter is called with two parameters: client_reader, client_writer. client_reader is a StreamReader.
object, while client_writer is a StreamWriter object. The client_connected_cb parameter can either be a plain callback function or a coroutine function; if it is a coroutine function, it will be automatically converted into a Task.

The rest of the arguments are all the usual arguments to create_server() except protocol_factory; most common are positional host and port, with various optional keyword arguments following.

Additional optional keyword arguments are loop (to set the event loop instance to use) and limit (to set the buffer limit passed to the StreamReader).

This function is a coroutine.

coroutine asyncio.open_unix_connection(path=None, *, loop=None, limit=None, **kwds)
A wrapper for create_unix_connection() returning a (reader, writer) pair.

See open_connection() for information about return value and other details.

This function is a coroutine.

Availability: UNIX.

coroutine asyncio.start_unix_server(client_connected_cb, path=None, *, loop=None, limit=None, **kwds)
Start a UNIX Domain Socket server, with a callback for each client connected.

See start_server() for information about return value and
other details.

This function is a coroutine.

Availability: UNIX.
18.5.5.2. StreamReader

class asyncio.StreamReader(limit=None, loop=None)
   This class is **not thread safe**.

   `exception()`
      Get the exception.

   `feed_eof()`
      Acknowledge the EOF.

   `feed_data(data)`
      Feed `data` bytes in the internal buffer. Any operations waiting for
      the data will be resumed.

   `set_exception(exc)`
      Set the exception.

   `set_transport(transport)`
      Set the transport.

   **coroutine** `read(n=-1)`
      Read up to `n` bytes. If `n` is not provided, or set to `-1`, read until
      EOF and return all read bytes.

      If the EOF was received and the internal buffer is empty, return
      an empty `bytes` object.

      This method is a **coroutine**.

   **coroutine** `readline()`
      Read one line, where “line” is a sequence of bytes ending with
If EOF is received, and \n was not found, the method will return the partial read bytes.

If the EOF was received and the internal buffer is empty, return an empty bytes object.

This method is a coroutine.

coroutine readexactly(n)
Read exactly n bytes. Raise an IncompleteReadError if the end of the stream is reached before n can be read, the IncompleteReadError.partial attribute of the exception contains the partial read bytes.

This method is a coroutine.

coroutine readuntil(separator=b'n')
Read data from the stream until separator is found.

On success, the data and separator will be removed from the internal buffer (consumed). Returned data will include the separator at the end.

Configured stream limit is used to check result. Limit sets the maximal length of data that can be returned, not counting the separator.

If an EOF occurs and the complete separator is still not found, an IncompleteReadError exception will be raised, and the internal buffer will be reset. The IncompleteReadError.partial attribute may contain the
separator partially.

If the data cannot be read because of over limit, a \texttt{LimitOverrunError} exception will be raised, and the data will be left in the internal buffer, so it can be read again.

\textit{New in version 3.5.2.}

\texttt{at_eof()}

Return \texttt{True} if the buffer is empty and \texttt{feed_eof()} was called.
18.5.5.3. StreamWriter

class asyncio.StreamWriter(transport, protocol, reader, loop)
Wraps a Transport.

This exposes write(), writelines(), can_write_eof(), write_eof(), get_extra_info() and close(). It adds drain() which returns an optional Future on which you can wait for flow control. It also adds a transport attribute which references the Transport directly.

This class is not thread safe.

transport
Transport.

can_write_eof()
Return True if the transport supports write_eof(), False if not. See WriteTransport.can_write_eof().

close()
Close the transport: see BaseTransport.close().

is_closing()
Return True if the writer is closing or is closed.

New in version 3.7.

coroutine wait_closed()
Wait until the writer is closed.

Should be called after close() to wait until the underlying
connection (and the associated transport/protocol pair) is closed.

New in version 3.7.

coroutine **drain()**

Let the write buffer of the underlying transport a chance to be flushed.

The intended use is to write:

```python
w.write(data)
await w.drain()
```

When the size of the transport buffer reaches the high-water limit (the protocol is paused), block until the size of the buffer is drained down to the low-water limit and the protocol is resumed. When there is nothing to wait for, the yield-from continues immediately.

Yielding from **drain()** gives the opportunity for the loop to schedule the write operation and flush the buffer. It should especially be used when a possibly large amount of data is written to the transport, and the coroutine does not yield-from between calls to **write()**.

This method is a **coroutine**.

**get_extra_info**(name, default=None)

Return optional transport information: see **BaseTransport.get_extra_info()**.

**write**(data)
Write some *data* bytes to the transport: see `WriteTransport.write()`.

**writelines(data)**

Write a list (or any iterable) of data bytes to the transport: see `WriteTransport.writelines()`.

**write_eof()**

Close the write end of the transport after flushing buffered data: see `WriteTransport.write_eof()`.
18.5.5.4. StreamReaderProtocol

class asyncio.StreamReaderProtocol(stream_reader, client_connected_cb=None, loop=None)

Trivial helper class to adapt between Protocol and StreamReader. Subclass of Protocol.

stream_reader is a StreamReader instance, client_connected_cb is an optional function called with (stream_reader, stream_writer) when a connection is made, loop is the event loop instance to use.

(This is a helper class instead of making StreamReader itself a Protocol subclass, because the StreamReader has other potential uses, and to prevent the user of the StreamReader from accidentally calling inappropriate methods of the protocol.)
18.5.5.5. IncompleteReadError

(exception asyncio.IncompleteReadError)

Incomplete read error, subclass of EOFError.

expected
Total number of expected bytes (int).

partial
Read bytes string before the end of stream was reached (bytes).
18.5.5.6. LimitOverrunError

*exception* asyncio.*LimitOverrunError*

Reached the buffer limit while looking for a separator.

**consumed**

Total number of to be consumed bytes.
18.5.5.7. Stream examples

18.5.5.7.1. TCP echo client using streams

TCP echo client using the `asyncio.open_connection()` function:

```python
import asyncio

async def tcp_echo_client(message, loop):
    reader, writer = await asyncio.open_connection('127.0.0.1', loop=loop)

    print('Send: %r' % message)
    writer.write(message.encode())

    data = await reader.read(100)
    print('Received: %r' % data.decode())

    print('Close the socket')
    writer.close()

message = 'Hello World!'
loop = asyncio.get_event_loop()
loop.run_until_complete(tcp_echo_client(message, loop))
loop.close()
```

See also: The TCP echo client protocol example uses the `AbstractEventLoop.create_connection()` method.

18.5.5.7.2. TCP echo server using streams

TCP echo server using the `asyncio.start_server()` function:
import asyncio

async def handle_echo(reader, writer):
    data = await reader.read(100)
    message = data.decode()
    addr = writer.get_extra_info('peername')
    print("Received %r from %r" % (message, addr))

    print("Send: %r" % message)
    writer.write(data)
    await writer.drain()

    print("Close the client socket")
    writer.close()

loop = asyncio.get_event_loop()
coro = asyncio.start_server(handle_echo, '127.0.0.1')
server = loop.run_until_complete(coro)

# Serve requests until Ctrl+C is pressed
print('Serving on {}').format(server.sockets[0].getsockname())
try:
    loop.run_forever()
except KeyboardInterrupt:
    pass

# Close the server
server.close()
loop.run_until_complete(server.wait_closed())
loop.close()

See also: The TCP echo server protocol example uses the AbstractEventLoop.create_server() method.

18.5.5.7.3. Get HTTP headers
Simple example querying HTTP headers of the URL passed on the command line:

```python
import asyncio
import urllib.parse
import sys

@asyncio.coroutine
def print_http_headers(url):
    url = urllib.parse.urlsplit(url)
    if url.scheme == 'https':
        connect = asyncio.open_connection(url.hostname)
    else:
        connect = asyncio.open_connection(url.hostname)
    reader, writer = await connect
    query = ('HEAD {path} HTTP/1.0\r\n
    Host: {hostname}\r\n
    \r\n').format(path=url.path or '/', hostname=url.hostname)
    writer.write(query.encode('latin-1'))
    while True:
        line = await reader.readline()
        if not line:
            break
        line = line.decode('latin1').rstrip()
        if line:
            print('HTTP header> %s' % line)

    # Ignore the body, close the socket
    writer.close()

url = sys.argv[1]
loop = asyncio.get_event_loop()
task = asyncio.ensure_future(print_http_headers(url))
loop.run_until_complete(task)
loop.close()
```
Usage:

```
python example.py http://example.com/path/page.html
```

or with HTTPS:

```
python example.py https://example.com/path/page.html
```

18.5.5.7.4. Register an open socket to wait for data using streams

Coroutine waiting until a socket receives data using the `open_connection()` function:

```python
import asyncio
from socket import socketpair

async def wait_for_data(loop):
    # Create a pair of connected sockets
    rsock, wsock = socketpair()

    # Register the open socket to wait for data
    reader, writer = await asyncio.open_connection(sock=rsock)

    # Simulate the reception of data from the network
    loop.call_soon(wsock.send, 'abc'.encode())

    # Wait for data
    data = await reader.read(100)

    # Got data, we are done: close the socket
    print("Received:", data.decode())
    writer.close()
```
# Close the second socket

```python
close()
```

```python
loop = asyncio.get_event_loop()
loop.run_until_complete(wait_for_data(loop))
loop.close()
```

**See also:** The register an open socket to wait for data using a protocol example uses a low-level protocol created by the `AbstractEventLoop.create_connection()` method.

The watch a file descriptor for read events example uses the low-level `AbstractEventLoop.add_reader()` method to register the file descriptor of a socket.
18.5. asyncio — Asynchronous I/O, event loop, coroutines and tasks
18.5.6. Subprocess

Source code: Lib/asyncio/subprocess.py
18.5.6.1. Windows event loop

On Windows, the default event loop is `SelectorEventLoop` which does not support subprocesses. `ProactorEventLoop` should be used instead. Example to use it on Windows:

```python
import asyncio, sys

if sys.platform == 'win32':
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
```

See also: [Available event loops](#) and [Platform support](#).
18.5.6.2. Create a subprocess: high-level API using Process

**coroutine** asyncio.**create_subprocess_exec**(*args, stdin=None, stdout=None, stderr=None, loop=None, limit=None, **kwds)

Create a subprocess.

The `limit` parameter sets the buffer limit passed to the `StreamReader`. See `AbstractEventLoop.subprocess_exec()` for other parameters.

Return a `Process` instance.

This function is a **coroutine**.

**coroutine** asyncio.**create_subprocess_shell**(cmd, stdin=None, stdout=None, stderr=None, loop=None, limit=None, **kwds)

Run the shell command `cmd`.

The `limit` parameter sets the buffer limit passed to the `StreamReader`. See `AbstractEventLoop.subprocess_shell()` for other parameters.

Return a `Process` instance.

It is the application's responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid **shell injection** vulnerabilities. The `shlex.quote()` function can be
used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.

This function is a coroutine.

Use the `AbstractEventLoop.connect_read_pipe()` and `AbstractEventLoop.connect_write_pipe()` methods to connect pipes.
18.5.6.3. Create a subprocess: low-level API using subprocess.Popen

Run subprocesses asynchronously using the `subprocess` module.

Coroutine

AbstractEventLoop.subprocess_exec(protocol_factory, *args, stdin=subprocess.PIPE, stdout=subprocess.PIPE, stderr=subprocess.PIPE, **kwargs)

Create a subprocess from one or more string arguments (character strings or bytes strings encoded to the filesystem encoding), where the first string specifies the program to execute, and the remaining strings specify the program’s arguments. (Thus, together the string arguments form the `sys.argv` value of the program, assuming it is a Python script.) This is similar to the standard library `subprocess.Popen` class called with `shell=False` and the list of strings passed as the first argument; however, where `Popen` takes a single argument which is list of strings, `subprocess_exec()` takes multiple string arguments.

The `protocol_factory` must instantiate a subclass of the `asyncio.SubprocessProtocol` class.

Other parameters:

- `stdin`: Either a file-like object representing the pipe to be connected to the subprocess’s standard input stream using `connect_write_pipe()`, or the constant `subprocess.PIPE` (the default). By default a new pipe will be created and connected.
- `stdout`: Either a file-like object representing the pipe to be connected to the subprocess’s standard output stream using
connect_read_pipe(), or the constant 
subprocess.PIPE (the default). By default a new pipe will 
be created and connected.

- stderr: Either a file-like object representing the pipe to be 
connected to the subprocess's standard error stream using 
connect_read_pipe(), or one of the constants 
subprocess.PIPE (the default) or subprocess.STDOUT. 
By default a new pipe will be created and connected. When 
subprocess.STDOUT is specified, the subprocess's standard 
error stream will be connected to the same pipe as the 
standard output stream.

- All other keyword arguments are passed to 
subprocess.Popen without interpretation, except for 
bufsize, universal_newlines and shell, which should not be 
specified at all.

Returns a pair of (transport, protocol), where transport is 
an instance of BaseSubprocessTransport.

This method is a coroutine.

See the constructor of the subprocess.Popen class for 
parameters.

coroutine 
AbstractEventLoop.subprocess_shell(protocol_factory, 
cmd, *, stdin=subprocess.PIPE, stdout=subprocess.PIPE, 
stderr=subprocess.PIPE, **kwargs)

Create a subprocess from cmd, which is a character string or a 
bytes string encoded to the filesystem encoding, using the 
platform's “shell” syntax. This is similar to the standard library 
subprocess.Popen class called with shell=True.

The protocol_factory must instantiate a subclass of the
asyncio.SubprocessProtocol class.

See subprocess_exec() for more details about the remaining arguments.

Returns a pair of (transport, protocol), where transport is an instance of BaseSubprocessTransport.

It is the application’s responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid shell injection vulnerabilities. The shlex.quote() function can be used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.

This method is a coroutine.

See also: The AbstractEventLoop.connect_read_pipe() and AbstractEventLoop.connect_write_pipe() methods.
18.5.6.4. Constants

**asyncio.subprocess.PIPE**
Special value that can be used as the *stdin, stdout* or *stderr* argument to *create_subprocess_shell()* and *create_subprocess_exec()* and indicates that a pipe to the standard stream should be opened.

**asyncio.subprocess.STDOUT**
Special value that can be used as the *stderr* argument to *create_subprocess_shell()* and *create_subprocess_exec()* and indicates that standard error should go into the same handle as standard output.

**asyncio.subprocess.DEVNULL**
Special value that can be used as the *stdin, stdout* or *stderr* argument to *create_subprocess_shell()* and *create_subprocess_exec()* and indicates that the special file *os.devnull* will be used.
18.5.6.5. Process

class asyncio.subprocess.Process

A subprocess created by the create_subprocess_exec() or the create_subprocess_shell() function.

The API of the Process class was designed to be close to the API of the subprocess.Popen class, but there are some differences:

- There is no explicit poll() method
- The communicate() and wait() methods don’t take a timeout parameter: use the wait_for() function
- The universal_newlines parameter is not supported (only bytes strings are supported)
- The wait() method of the Process class is asynchronous whereas the wait() method of the Popen class is implemented as a busy loop.

This class is not thread safe. See also the Subprocess and threads section.

coroutine wait()

Wait for child process to terminate. Set and return returncode attribute.

This method is a coroutine.

Note: This will deadlock when using stdout=PIPE or stderr=PIPE and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use the communicate() method when using pipes to avoid that.
**coroutine** `communicate(input=None)`

Interact with process: Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate. The optional `input` argument should be data to be sent to the child process, or None, if no data should be sent to the child. The type of `input` must be bytes.

`communicate()` returns a tuple `(stdout_data, stderr_data)`.

If a `BrokenPipeError` or `ConnectionResetError` exception is raised when writing `input` into stdin, the exception is ignored. It occurs when the process exits before all data are written into stdin.

Note that if you want to send data to the process's stdin, you need to create the Process object with `stdin=PIPE`. Similarly, to get anything other than None in the result tuple, you need to give `stdout=PIPE` and/or `stderr=PIPE` too.

This method is a coroutine.

**Note:** The data read is buffered in memory, so do not use this method if the data size is large or unlimited.

*Changed in version 3.4.2:* The method now ignores `BrokenPipeError` and `ConnectionResetError`.

**send_signal(signal)**

Sends the signal `signal` to the child process.

**Note:** On Windows, SIGTERM is an alias for `terminate()`.
CTRL_C_EVENT and CTRL_BREAK_EVENT can be sent to processes started with a `creationflags` parameter which includes CREATE_NEW_PROCESS_GROUP.

**terminate()**
Stop the child. On Posix OSs the method sends `signal.SIGTERM` to the child. On Windows the Win32 API function `TerminateProcess()` is called to stop the child.

**kill()**
Kills the child. On Posix OSs the function sends SIGKILL to the child. On Windows `kill()` is an alias for `terminate()`.

**stdin**
Standard input stream (`StreamWriter`), `None` if the process was created with `stdin=None`.

**stdout**
Standard output stream (`StreamReader`), `None` if the process was created with `stdout=None`.

**stderr**
Standard error stream (`StreamReader`), `None` if the process was created with `stderr=None`.

**Warning:** Use the `communicate()` method rather than `.stdin.write`, `.stdout.read` or `.stderr.read` to avoid deadlocks due to streams pausing reading or writing and blocking the child process.

**pid**
The identifier of the process.
Note that for processes created by the `create_subprocess_shell()` function, this attribute is the process identifier of the spawned shell.

**returncode**

Return code of the process when it exited. A `None` value indicates that the process has not terminated yet.

A negative value `-N` indicates that the child was terminated by signal `N` (Unix only).
18.5.6.6. Subprocess and threads

asyncio supports running subprocesses from different threads, but there are limits:

- An event loop must run in the main thread
- The child watcher must be instantiated in the main thread, before executing subprocesses from other threads. Call the `get_child_watcher()` function in the main thread to instantiate the child watcher.

The `asyncio.subprocess.Process` class is not thread safe.

See also: The Concurrency and multithreading in asyncio section.
18.5.6.7. Subprocess examples

18.5.6.7.1. Subprocess using transport and protocol

Example of a subprocess protocol using to get the output of a subprocess and to wait for the subprocess exit. The subprocess is created by the `AbstractEventLoop.subprocess_exec()` method:

```python
import asyncio
import sys

class DateProtocol(asyncio.SubprocessProtocol):
    def __init__(self, exit_future):
        self.exit_future = exit_future
        self.output = bytearray()

    def pipe_data_received(self, fd, data):
        self.output.extend(data)

    def process_exited(self):
        self.exit_future.set_result(True)

async def get_date(loop):
    code = 'import datetime; print(datetime.datetime.now())

    exit_future = asyncio.Future(loop=loop)

    # Create the subprocess controlled by the protocol
    # redirect the standard output into a pipe
    transport, protocol = await loop.subprocess_exec(
        lambda: DateProtocol(exit_future),
        sys.executable, '-c', code,
        stdin=None, stderr=None)
```

# Wait for the subprocess exit using the process of the protocol
await exit_future

# Close the stdout pipe
transport.close()

# Read the output which was collected by the pipe method of the protocol
data = bytes(protocol.output)
return data.decode('ascii').rstrip()

if sys.platform == "win32":
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
else:
    loop = asyncio.get_event_loop()

date = loop.run_until_complete(get_date(loop))
print("Current date: %s" % date)
loop.close()

18.5.6.7.2. Subprocess using streams

Example using the Process class to control the subprocess and the StreamReader class to read from the standard output. The subprocess is created by the create_subprocess_exec() function:

import asyncio.subprocess
import sys

@asyncio.coroutine
def get_date():
    code = 'import datetime; print(datetime.datetime.now())
    # Create the subprocess, redirect the standard output into a pipe
    proc = await asyncio.create_subprocess_exec(sys.executable, '-c', code, stdout=asyncio.subprocess.PIPE)
    # Read one line of output
    data = await proc.stdout.readline()
    line = data.decode('ascii').rstrip()
    # Wait for the subprocess exit
    await proc.wait()
    return line

if sys.platform == "win32":
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
else:
    loop = asyncio.get_event_loop()

date = loop.run_until_complete(get_date())
print("Current date: %s" % date)
loop.close()
asyncio — Asynchronous I/O, event loop, coroutines and tasks
18.5.7. Synchronization primitives

Source code: Lib/asyncio/locks.py

Locks:

- Lock
- Event
- Condition

Semaphores:

- Semaphore
- BoundedSemaphore

asyncio lock API was designed to be close to classes of the threading module (Lock, Event, Condition, Semaphore, BoundedSemaphore), but it has no timeout parameter. The asyncio.wait_for() function can be used to cancel a task after a timeout.
18.5.7.1. Lock

class asyncio.Lock(*, loop=None)

Primitive lock objects.

A primitive lock is a synchronization primitive that is not owned by a particular coroutine when locked. A primitive lock is in one of two states, ‘locked’ or ‘unlocked’.

The lock is created in the unlocked state. It has two basic methods, `acquire()` and `release()`. When the state is unlocked, `acquire()` changes the state to locked and returns immediately. When the state is locked, `acquire()` blocks until a call to `release()` in another coroutine changes it to unlocked, then the `acquire()` call resets it to locked and returns. The `release()` method should only be called in the locked state; it changes the state to unlocked and returns immediately. If an attempt is made to release an unlocked lock, a `RuntimeError` will be raised.

When more than one coroutine is blocked in `acquire()` waiting for the state to turn to unlocked, only one coroutine proceeds when a `release()` call resets the state to unlocked; first coroutine which is blocked in `acquire()` is being processed.

`acquire()` is a coroutine and should be called with `await`.

Locks support the context management protocol.

This class is not thread safe.

`locked()`

Return `True` if the lock is acquired.
**coroutine acquire()**

Acquire a lock.

This method blocks until the lock is unlocked, then sets it to locked and returns `True`.

This method is a coroutine.

**release()**

Release a lock.

When the lock is locked, reset it to unlocked, and return. If any other coroutines are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

When invoked on an unlocked lock, a `RuntimeError` is raised.

There is no return value.
18.5.7.2. Event

class asyncio.Event(*, loop=None)
    An Event implementation, asynchronous equivalent to threading.Event.

Class implementing event objects. An event manages a flag that can be set to true with the set() method and reset to false with the clear() method. The wait() method blocks until the flag is true. The flag is initially false.

This class is not thread safe.

clear()
    Reset the internal flag to false. Subsequently, coroutines calling wait() will block until set() is called to set the internal flag to true again.

is_set()
    Return True if and only if the internal flag is true.

set()
    Set the internal flag to true. All coroutines waiting for it to become true are awakened. Coroutine that call wait() once the flag is true will not block at all.

coroutine wait()
    Block until the internal flag is true.

    If the internal flag is true on entry, return True immediately. Otherwise, block until another coroutine calls set() to set the
flag to true, then return True.

This method is a coroutine.
class asyncio.Condition(lock=None, *, loop=None)

A Condition implementation, asynchronous equivalent to threading.Condition.

This class implements condition variable objects. A condition variable allows one or more coroutines to wait until they are notified by another coroutine.

If the lock argument is given and not None, it must be a Lock object, and it is used as the underlying lock. Otherwise, a new Lock object is created and used as the underlying lock.

Conditions support the context management protocol.

This class is not thread safe.

coroutine acquire()

Acquire the underlying lock.

This method blocks until the lock is unlocked, then sets it to locked and returns True.

This method is a coroutine.

notify(n=1)

By default, wake up one coroutine waiting on this condition, if any. If the calling coroutine has not acquired the lock when this method is called, a RuntimeError is raised.

This method wakes up at most n of the coroutines waiting for the condition variable; it is a no-op if no coroutines are waiting.
Note: An awakened coroutine does not actually return from its `wait()` call until it can reacquire the lock. Since `notify()` does not release the lock, its caller should.

**locked()**
Return `True` if the underlying lock is acquired.

**notify_all()**
Wake up all coroutines waiting on this condition. This method acts like `notify()`, but wakes up all waiting coroutines instead of one. If the calling coroutine has not acquired the lock when this method is called, a `RuntimeError` is raised.

**release()**
Release the underlying lock.

When the lock is locked, reset it to unlocked, and return. If any other coroutines are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

When invoked on an unlocked lock, a `RuntimeError` is raised.

There is no return value.

**coroutine wait()**
Wait until notified.

If the calling coroutine has not acquired the lock when this method is called, a `RuntimeError` is raised.

This method releases the underlying lock, and then blocks until it is awakened by a `notify()` or `notify_all()` call for the
same condition variable in another coroutine. Once awakened, it re-acquires the lock and returns \texttt{True}.

This method is a \texttt{coroutine}.

\textit{coroutine} \texttt{wait\_for}(\textit{predicate})

Wait until a predicate becomes true.

The predicate should be a callable which result will be interpreted as a boolean value. The final predicate value is the return value.

This method is a \texttt{coroutine}. 
18.5.7.4. Semaphore

class asyncio.Semaphore(value=1, *, loop=None)
    A Semaphore implementation.

A semaphore manages an internal counter which is decremented by each `acquire()` call and incremented by each `release()` call. The counter can never go below zero; when `acquire()` finds that it is zero, it blocks, waiting until some other coroutine calls `release()`.

The optional argument gives the initial value for the internal counter; it defaults to 1. If the value given is less than 0, `ValueError` is raised.

Semaphores support the context management protocol.

This class is not thread safe.

coroutine `acquire()`
    Acquire a semaphore.

    If the internal counter is larger than zero on entry, decrement it by one and return True immediately. If it is zero on entry, block, waiting until some other coroutine has called `release()` to make it larger than 0, and then return True.

    This method is a coroutine.

`locked()`
    Returns True if semaphore can not be acquired immediately.
**release()**

Release a semaphore, incrementing the internal counter by one. When it was zero on entry and another coroutine is waiting for it to become larger than zero again, wake up that coroutine.
18.5.7.5. BoundedSemaphore

class asyncio.BoundedSemaphore\(value=1, *, loop=None\)

A bounded semaphore implementation. Inherit from Semaphore.

This raises ValueError in release() if it would increase the value above the initial value.

Bounded semaphores support the context management protocol.

This class is not thread safe.
18.5.7.6. Using locks, conditions and semaphores in the `async with` statement

Lock, Condition, Semaphore, and BoundedSemaphore objects can be used in `async with` statements.

The acquire() method will be called when the block is entered, and release() will be called when the block is exited. Hence, the following snippet:

```python
async with lock:
    # do something...
```

is equivalent to:

```python
await lock.acquire()
try:
    # do something...
finally:
    lock.release()
```

*Deprecated since version 3.7:* Lock acquiring using `await lock` or `yield from lock` and `with` statement (with `await lock`, with (yield from lock)) are deprecated.
18.5. asyncio — Asynchronous I/O, event loop, coroutines and tasks
18.5.8. Queues

Source code: Lib/asyncio/queues.py

Queues:

- Queue
- PriorityQueue
- LifoQueue

asyncio queue API was designed to be close to classes of the queue module (Queue, PriorityQueue, LifoQueue), but it has no timeout parameter. The asyncio.wait_for() function can be used to cancel a task after a timeout.
18.5.8.1. Queue

class asyncio.Queue(maxsize=0, *, loop=None)

A queue, useful for coordinating producer and consumer coroutines.

If maxsize is less than or equal to zero, the queue size is infinite. If it is an integer greater than 0, then \texttt{await put()} will block when the queue reaches \texttt{maxsize}, until an item is removed by \texttt{get()}.

Unlike the standard library \texttt{queue}, you can reliably know this Queue's size with \texttt{qsize()}, since your single-threaded asyncio application won't be interrupted between calling \texttt{qsize()} and doing an operation on the Queue.

This class is \texttt{not thread safe}.

\textit{Changed in version 3.4.4}: New \texttt{join()} and \texttt{task_done()} methods.

\texttt{empty()}

Return \texttt{True} if the queue is empty, \texttt{False} otherwise.

\texttt{full()}

Return \texttt{True} if there are \texttt{maxsize} items in the queue.

\textbf{Note}: If the Queue was initialized with \texttt{maxsize=0} (the default), then \texttt{full()} is never \texttt{True}.

\texttt{coroutine get()}

Remove and return an item from the queue. If queue is empty,
wait until an item is available.

This method is a coroutine.

**See also:** The `empty()` method.

get_nowait()

Remove and return an item from the queue.

Return an item if one is immediately available, else raise `QueueEmpty`.

coroutine join()

Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls `task_done()` to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, `join()` unblocks.

This method is a coroutine.

*New in version 3.4.4.*

coroutine put(item)

Put an item into the queue. If the queue is full, wait until a free slot is available before adding item.

This method is a coroutine.

**See also:** The `full()` method.
**put_nowait**(*item*)

Put an item into the queue without blocking.

If no free slot is immediately available, raise `QueueFull`.

**qsize()**

Number of items in the queue.

**task_done()**

Indicate that a formerly enqueued task is complete.

Used by queue consumers. For each `get()` used to fetch a task, a subsequent call to `task_done()` tells the queue that the processing on the task is complete.

If a `join()` is currently blocking, it will resume when all items have been processed (meaning that a `task_done()` call was received for every item that had been `put()` into the queue).

Raises `ValueError` if called more times than there were items placed in the queue.

*New in version 3.4.4.*

**maxsize**

Number of items allowed in the queue.
18.5.8.2. PriorityQueue

class asyncio.PriorityQueue

A subclass of Queue; retrieves entries in priority order (lowest first).

Entries are typically tuples of the form: (priority number, data).
18.5.8.3. LifoQueue

class asyncio.LifoQueue

A subclass of Queue that retrieves most recently added entries first.

18.5.8.3.1. Exceptions

exception asyncio.QueueEmpty

Exception raised when the get_nowait() method is called on a Queue object which is empty.

exception asyncio.QueueFull

Exception raised when the put_nowait() method is called on a Queue object which is full.
asyncio — Asynchronous I/O, event loop, coroutines and tasks
Asynchronous programming is different than classical “sequential” programming. This page lists common traps and explains how to avoid them.
18.5.9.1. Debug mode of asyncio

The implementation of asyncio has been written for performance. In order to ease the development of asynchronous code, you may wish to enable debug mode.

To enable all debug checks for an application:

- Enable the asyncio debug mode globally by setting the environment variable PYTHONASYNCIODEBUG to 1, using -X dev command line option (see the -X option), or by calling AbstractEventLoop.set_debug().
- Set the log level of the asyncio logger to logging.DEBUG. For example, call logging.basicConfig(level=logging.DEBUG) at startup.
- Configure the warnings module to display ResourceWarning warnings. For example, use the -Wdefault command line option of Python to display them.

Examples debug checks:

- Log coroutines defined but never “yielded from”
- call_soon() and call_at() methods raise an exception if they are called from the wrong thread.
- Log the execution time of the selector
- Log callbacks taking more than 100 ms to be executed. The AbstractEventLoop.slow_callback_duration attribute is the minimum duration in seconds of “slow” callbacks.
- ResourceWarning warnings are emitted when transports and event loops are not closed explicitly.

Changed in version 3.7: The new -X dev command line option can now also be used to enable the debug mode.
See also: The `AbstractEventLoop.set_debug()` method and the `asyncio logger`.
18.5.9.2. Cancellation

Cancellation of tasks is not common in classic programming. In asynchronous programming, not only is it something common, but you have to prepare your code to handle it.

Futures and tasks can be cancelled explicitly with their `Future.cancel()` method. The `wait_for()` function cancels the waited task when the timeout occurs. There are many other cases where a task can be cancelled indirectly.

Don't call `set_result()` or `set_exception()` method of `Future` if the future is cancelled: it would fail with an exception. For example, write:

```python
if not fut.cancelled():
    fut.set_result('done')
```

Don't schedule directly a call to the `set_result()` or the `set_exception()` method of a future with `AbstractEventLoop.call_soon()`: the future can be cancelled before its method is called.

If you wait for a future, you should check early if the future was cancelled to avoid useless operations. Example:

```python
async def slow_operation(fut):
    if fut.cancelled():
        return  # ... slow computation ...
    await fut
    # ...
```
The `shield()` function can also be used to ignore cancellation.
18.5.9.3. Concurrency and multithreading

An event loop runs in a thread and executes all callbacks and tasks in the same thread. While a task is running in the event loop, no other task is running in the same thread. But when the task uses `await`, the task is suspended and the event loop executes the next task.

To schedule a callback from a different thread, the `AbstractEventLoop.call_soon_threadsafe()` method should be used. Example:

```python
loop.call_soon_threadsafe(callback, *args)
```

Most asyncio objects are not thread safe. You should only worry if you access objects outside the event loop. For example, to cancel a future, don’t call directly its `Future.cancel()` method, but:

```python
loop.call_soon_threadsafe(fut.cancel)
```

To handle signals and to execute subprocesses, the event loop must be run in the main thread.

To schedule a coroutine object from a different thread, the `run_coroutine_threadsafe()` function should be used. It returns a `concurrent.futures.Future` to access the result:

```python
future = asyncio.run_coroutine_threadsafe(coro_func(), loop)  # Wait for the result
result = future.result(timeout)  # Wait for the result
```

The `AbstractEventLoop.run_in_executor()` method can be used with a thread pool executor to execute a callback in different
thread to not block the thread of the event loop.

**See also:** The *Synchronization primitives* section describes ways to synchronize tasks.

The *Subprocess and threads* section lists asyncio limitations to run subprocesses from different threads.
18.5.9.4. Handle blocking functions correctly

Blocking functions should not be called directly. For example, if a function blocks for 1 second, other tasks are delayed by 1 second which can have an important impact on reactivity.

For networking and subprocesses, the asyncio module provides high-level APIs like protocols.

An executor can be used to run a task in a different thread or even in a different process, to not block the thread of the event loop. See the AbstractEventLoop.run_in_executor() method.

See also: The Delayed calls section details how the event loop handles time.
18.5.9.5. Logging

The `asyncio` module logs information with the `logging` module in the logger `'asyncio'`.

The default log level for the `asyncio` module is `logging.INFO`. For those not wanting such verbosity from `asyncio` the log level can be changed. For example, to change the level to `logging.WARNING`:

```
logging.getLogger('asyncio').setLevel(logging.WARNING)
```
18.5.9.6. Detect coroutine objects never scheduled

When a coroutine function is called and its result is not passed to `ensure_future()` or to the `AbstractEventLoop.create_task()` method, the execution of the coroutine object will never be scheduled which is probably a bug. Enable the debug mode of asyncio to log a warning to detect it.

Example with the bug:

```python
import asyncio

async def test():
    print("never scheduled")

test()
```

Output in debug mode:

```
Coroutine test() at test.py:3 was never yielded from
Coroutine object created at (most recent call last):
  File "test.py", line 7, in <module>
    test()
```

The fix is to call the `ensure_future()` function or the `AbstractEventLoop.create_task()` method with the coroutine object.

See also: Pending task destroyed.
18.5.9.7. Detect exceptions never consumed

Python usually calls `sys.excepthook()` on unhandled exceptions. If `Future.set_exception()` is called, but the exception is never consumed, `sys.excepthook()` is not called. Instead, a log is emitted when the future is deleted by the garbage collector, with the traceback where the exception was raised.

Example of unhandled exception:

```python
import asyncio

@asyncio.coroutine
def bug():
    raise Exception("not consumed")

loop = asyncio.get_event_loop()
asyncio.ensure_future(bug())
loop.run_forever()
loop.close()
```

Output:

```
Task exception was never retrieved
future: <Task finished coro=<coro() done, defined at
Traceback (most recent call last):
  File "asyncio/tasks.py", line 237, in _step
    result = next(coro)
  File "asyncio/coroutines.py", line 141, in coro
    res = func(*args, **kw)
  File "test.py", line 5, in bug
    raise Exception("not consumed")
Exception: not consumed
```
Enable the debug mode of asyncio to get the traceback where the task was created. Output in debug mode:

```
Task exception was never retrieved
future: <Task finished coro=<bug() done, defined at
source_traceback: Object created at (most recent cal
File "test.py", line 8, in <module>
    asyncio.ensure_future(bug())
Traceback (most recent call last):
  File "asyncio/tasks.py", line 237, in _step
    result = next(coro)
  File "asyncio/coroutines.py", line 79, in __next__
    return next(self.gen)
  File "asyncio/coroutines.py", line 141, in coro
    res = func(*args, **kw)
  File "test.py", line 5, in bug
    raise Exception("not consumed")
Exception: not consumed
```

There are different options to fix this issue. The first option is to chain the coroutine in another coroutine and use classic try/except:

```
async def handle_exception():
    try:
        await bug()
    except Exception:
        print("exception consumed")

loop = asyncio.get_event_loop()
asyncio.ensure_future(handle_exception())
loop.run_forever()
loop.close()
```

Another option is to use the
AbstractEventLoop.run_until_complete() function:

```python
import asyncio

bug = ...

task = asyncio.ensure_future(bug())
try:
    loop.run_until_complete(task)
except Exception:
    print("exception consumed")
```

See also: The `Future.exception()` method.
18.5.9.8. Chain coroutines correctly

When a coroutine function calls other coroutine functions and tasks, they should be chained explicitly with `await`. Otherwise, the execution is not guaranteed to be sequential.

Example with different bugs using `asyncio.sleep()` to simulate slow operations:

```python
import asyncio

async def create():
    await asyncio.sleep(3.0)
    print("(1) create file")

async def write():
    await asyncio.sleep(1.0)
    print("(2) write into file")

async def close():
    print("(3) close file")

async def test():
    asyncio.ensure_future(create())
    asyncio.ensure_future(write())
    asyncio.ensure_future(close())
    await asyncio.sleep(2.0)
    loop.stop()

loop = asyncio.get_event_loop()
asyncio.ensure_future(test())
loop.run_forever()
print("Pending tasks at exit: %s" % asyncio.Task.all_tasks)
loop.close()
```
Expected output:

```
(1) create file
(2) write into file
(3) close file
Pending tasks at exit: set()
```

Actual output:

```
(3) close file
(2) write into file
Pending tasks at exit: {<Task pending create() at test.py:7 wait_for=<Future pending cb=[Task._wakeup()]>}
Task was destroyed but it is pending!
task: <Task pending create() done at test.py:5 wait_for=<Future pending cb=[Task._wakeup()]>}
```

The loop stopped before the `create()` finished, `close()` has been called before `write()`, whereas coroutine functions were called in this order: `create()`, `write()`, `close()`.

To fix the example, tasks must be marked with `await`:

```python
async def test():
    await asyncio.ensure_future(create())
    await asyncio.ensure_future(write())
    await asyncio.ensure_future(close())
    await asyncio.sleep(2.0)
    loop.stop()
```

Or without `asyncio.ensure_future()`:

```python
async def test():
    await create()
    await write()
    await close()
```
await asyncio.sleep(2.0)
loop.stop()
18.5.9.9. Pending task destroyed

If a pending task is destroyed, the execution of its wrapped coroutine did not complete. It is probably a bug and so a warning is logged.

Example of log:

```
Task was destroyed but it is pending!
task: <Task pending coro=<kill_me() done, defined at test.py:5> wait_for=<Future pending cb=[Task._wakeup()]>>
```

Enable the debug mode of asyncio to get the traceback where the task was created. Example of log in debug mode:

```
Task was destroyed but it is pending!
source_traceback: Object created at (most recent call last):
  File "test.py", line 15, in <module>
      task = asyncio.ensure_future(coro, loop=loop)
task: <Task pending coro=<kill_me() done, defined at test.py:5> wait_for=<Future pending cb=[Task._wakeup()]> created at test.py:15>
```

See also: Detect coroutine objects never scheduled.
18.5.9.10. Close transports and event loops

When a transport is no more needed, call its `close()` method to release resources. Event loops must also be closed explicitly.

If a transport or an event loop is not closed explicitly, a `ResourceWarning` warning will be emitted in its destructor. By default, `ResourceWarning` warnings are ignored. The Debug mode of asyncio section explains how to display them.
18.6. asyncore — Asynchronous socket handler

Source code: Lib/asyncore.py

Deprecated since version 3.6: Please use asyncio instead.

Note: This module exists for backwards compatibility only. For new code we recommend using asyncio.

This module provides the basic infrastructure for writing asynchronous socket service clients and servers.

There are only two ways to have a program on a single processor do "more than one thing at a time." Multi-threaded programming is the simplest and most popular way to do it, but there is another very different technique, that lets you have nearly all the advantages of multi-threading, without actually using multiple threads. It's really only practical if your program is largely I/O bound. If your program is processor bound, then pre-emptive scheduled threads are probably what you really need. Network servers are rarely processor bound, however.

If your operating system supports the select() system call in its I/O library (and nearly all do), then you can use it to juggle multiple communication channels at once; doing other work while your I/O is taking place in the "background." Although this strategy can seem strange and complex, especially at first, it is in many ways easier to understand and control than multi-threaded programming. The asyncore module solves many of the difficult problems for you,
making the task of building sophisticated high-performance network servers and clients a snap. For “conversational” applications and protocols the companion asynchat module is invaluable.

The basic idea behind both modules is to create one or more network channels, instances of class asyncore.dispatcher and asynchat.async_chat. Creating the channels adds them to a global map, used by the loop() function if you do not provide it with your own map.

Once the initial channel(s) is(are) created, calling the loop() function activates channel service, which continues until the last channel (including any that have been added to the map during asynchronous service) is closed.

asyncore.loop([timeout[, use_poll[, map[, count]]]])

Enter a polling loop that terminates after count passes or all open channels have been closed. All arguments are optional. The count parameter defaults to None, resulting in the loop terminating only when all channels have been closed. The timeout argument sets the timeout parameter for the appropriate select() or poll() call, measured in seconds; the default is 30 seconds. The use_poll parameter, if true, indicates that poll() should be used in preference to select() (the default is False).

The map parameter is a dictionary whose items are the channels to watch. As channels are closed they are deleted from their map. If map is omitted, a global map is used. Channels (instances of asyncore.dispatcher, asynchat.async_chat and subclasses thereof) can freely be mixed in the map.

class asyncore.dispatcher
The *dispatcher* class is a thin wrapper around a low-level socket object. To make it more useful, it has a few methods for event-handling which are called from the asynchronous loop. Otherwise, it can be treated as a normal non-blocking socket object.

The firing of low-level events at certain times or in certain connection states tells the asynchronous loop that certain higher-level events have taken place. For example, if we have asked for a socket to connect to another host, we know that the connection has been made when the socket becomes writable for the first time (at this point you know that you may write to it with the expectation of success). The implied higher-level events are:

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle_connect()</td>
<td>Implied by the first read or write event</td>
</tr>
<tr>
<td>handle_close()</td>
<td>Implied by a read event with no data available</td>
</tr>
<tr>
<td>handle_accepted()</td>
<td>Implied by a read event on a listening socket</td>
</tr>
</tbody>
</table>

During asynchronous processing, each mapped channel's `readable()` and `writable()` methods are used to determine whether the channel's socket should be added to the list of channels `select()`ed or `poll()`ed for read and write events.

Thus, the set of channel events is larger than the basic socket events. The full set of methods that can be overridden in your subclass follows:

**handle_read()**

Called when the asynchronous loop detects that a `read()` call
on the channel’s socket will succeed.

**handle_write()**

Called when the asynchronous loop detects that a writable socket can be written. Often this method will implement the necessary buffering for performance. For example:

```python
def handle_write(self):
    sent = self.send(self.buffer)
    self.buffer = self.buffer[:sent]
```

**handle_expt()**

Called when there is out of band (OOB) data for a socket connection. This will almost never happen, as OOB is tenuously supported and rarely used.

**handle_connect()**

Called when the active opener’s socket actually makes a connection. Might send a “welcome” banner, or initiate a protocol negotiation with the remote endpoint, for example.

**handle_close()**

Called when the socket is closed.

**handle_error()**

Called when an exception is raised and not otherwise handled. The default version prints a condensed traceback.

**handle_accept()**

Called on listening channels (passive openers) when a connection can be established with a new remote endpoint that has issued a `connect()` call for the local endpoint. Deprecated in version 3.2; use `handle_accepted()` instead.
Deprecated since version 3.2.

**handle_accepted**(sock, addr)
Called on listening channels (passive openers) when a connection has been established with a new remote endpoint that has issued a `connect()` call for the local endpoint. `sock` is a new socket object usable to send and receive data on the connection, and `addr` is the address bound to the socket on the other end of the connection.

New in version 3.2.

**readable()**
Called each time around the asynchronous loop to determine whether a channel’s socket should be added to the list on which read events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in read events.

**writable()**
Called each time around the asynchronous loop to determine whether a channel’s socket should be added to the list on which write events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in write events.

In addition, each channel delegates or extends many of the socket methods. Most of these are nearly identical to their socket partners.

**create_socket**(family=socket.AF_INET,
                 type=socket.SOCK_STREAM)
This is identical to the creation of a normal socket, and will use the same options for creation. Refer to the `socket`
documentation for information on creating sockets.

*Changed in version 3.3: family and type arguments can be omitted.*

**connect**(*address*)
As with the normal socket object, *address* is a tuple with the first element the host to connect to, and the second the port number.

**send**(*data*)
Send *data* to the remote end-point of the socket.

**recv**(*buffer_size*)
Read at most *buffer_size* bytes from the socket's remote end-point. An empty bytes object implies that the channel has been closed from the other end.

Note that **recv()** may raise **BlockingIOError**, even though **select.select()** or **select.poll()** has reported the socket ready for reading.

**listen**(*backlog*)
Listen for connections made to the socket. The *backlog* argument specifies the maximum number of queued connections and should be at least 1; the maximum value is system-dependent (usually 5).

**bind**(*address*)
Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family — refer to the socket documentation for more information.) To mark the socket as re-usable (setting the SO_REUSEADDR
option), call the dispatcher object's set_reuse_addr() method.

accept()
Accept a connection. The socket must be bound to an address and listening for connections. The return value can be either None or a pair (conn, address) where conn is a new socket object usable to send and receive data on the connection, and address is the address bound to the socket on the other end of the connection. When None is returned it means the connection didn't take place, in which case the server should just ignore this event and keep listening for further incoming connections.

close()
Close the socket. All future operations on the socket object will fail. The remote end-point will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

class asyncore.dispatcher_with_send
A dispatcher subclass which adds simple buffered output capability, useful for simple clients. For more sophisticated usage use asyncchat.async_chat.

class asyncore.file_dispatcher
A file_dispatcher takes a file descriptor or file object along with an optional map argument and wraps it for use with the poll() or loop() functions. If provided a file object or anything with a fileno() method, that method will be called and passed to the file_wrapper constructor. Availability: UNIX.
class asyncore.file_wrapper

A file_wrapper takes an integer file descriptor and calls os.dup() to duplicate the handle so that the original handle may be closed independently of the file_wrapper. This class implements sufficient methods to emulate a socket for use by the file_dispatcher class. Availability: UNIX.
18.6.1. asyncore Example basic HTTP client

Here is a very basic HTTP client that uses the `dispatcher` class to implement its socket handling:

```python
import asyncore

class HTTPClient(asyncore.dispatcher):
    def __init__(self, host, path):
        asyncore.dispatcher.__init__(self)
        self.create_socket()
        self.connect((host, 80))
        self.buffer = bytes('GET %s HTTP/1.0\r\nHost: %s\n' % (path, host), 'ascii')

    def handle_connect(self):
        pass

    def handle_close(self):
        self.close()

    def handle_read(self):
        print(self.recv(8192))

    def writable(self):
        return (len(self.buffer) > 0)

    def handle_write(self):
        sent = self.send(self.buffer)
        self.buffer = self.buffer[sent:]

client = HTTPClient('www.python.org', '/')
```
asyncore.loop()
18.6.2. asyncore Example basic echo server

Here is a basic echo server that uses the `dispatcher` class to accept connections and dispatches the incoming connections to a handler:

```python
import asyncore

class EchoHandler(asyncore.dispatcher_with_send):
    def handle_read(self):
        data = self.recv(8192)
        if data:
            self.send(data)

class EchoServer(asyncore.dispatcher):
    def __init__(self, host, port):
        asyncore.dispatcher.__init__(self)
        self.create_socket()
        self.set_reuse_addr()
        self.bind((host, port))
        self.listen(5)

    def handle_accepted(self, sock, addr):
        print('Incoming connection from %s' % repr(addr)
        handler = EchoHandler(sock)

server = EchoServer('localhost', 8080)
asyncore.loop()
```
18.7. **asynchat** — Asynchronous socket command/response handler

**Source code:** Lib/asynchat.py

*Deprecated since version 3.6: Please use asyncio instead.*

---

**Note:** This module exists for backwards compatibility only. For new code we recommend using asyncio.

This module builds on the asyncore infrastructure, simplifying asynchronous clients and servers and making it easier to handle protocols whose elements are terminated by arbitrary strings, or are of variable length. asynchat defines the abstract class async_chat that you subclass, providing implementations of the collect_incoming_data() and found_terminator() methods. It uses the same asynchronous loop as asyncore, and the two types of channel, asyncore.dispatcher and asynchat.async_chat, can freely be mixed in the channel map. Typically an asyncore.dispatcher server channel generates new asynchat.async_chat channel objects as it receives incoming connection requests.

```python
class asynchat.async_chat
```

This class is an abstract subclass of asyncore.dispatcher. To make practical use of the code you must subclass async_chat, providing meaningful collect_incoming_data() and found_terminator() methods. The asyncore.dispatcher methods can be used, although not all make sense in a
Like `asyncore.dispatcher`, `async_chat` defines a set of events that are generated by an analysis of socket conditions after a `select()` call. Once the polling loop has been started the `async_chat` object's methods are called by the event-processing framework with no action on the part of the programmer.

Two class attributes can be modified, to improve performance, or possibly even to conserve memory.

**ac_in_buffer_size**

The asynchronous input buffer size (default 4096).

**ac_out_buffer_size**

The asynchronous output buffer size (default 4096).

Unlike `asyncore.dispatcher`, `async_chat` allows you to define a **FIFO queue of producers**. A producer need have only one method, `more()`, which should return data to be transmitted on the channel. The producer indicates exhaustion (i.e. that it contains no more data) by having its `more()` method return the empty bytes object. At this point the `async_chat` object removes the producer from the queue and starts using the next producer, if any. When the producer queue is empty the `handle_write()` method does nothing. You use the channel object's `set_terminator()` method to describe how to recognize the end of, or an important breakpoint in, an incoming transmission from the remote endpoint.

To build a functioning `async_chat` subclass your input methods `collect_incoming_data()` and `found_terminator()` must handle the data that the channel receives asynchronously. The
methods are described below.

**async_chat.close_when_done()**

Pushes a `None` on to the producer queue. When this producer is popped off the queue it causes the channel to be closed.

**async_chat.collect_incoming_data(data)**

Called with `data` holding an arbitrary amount of received data. The default method, which must be overridden, raises a `NotImplementedError` exception.

**async_chat.discard_buffers()**

In emergencies this method will discard any data held in the input and/or output buffers and the producer queue.

**async_chat.found_terminator()**

Called when the incoming data stream matches the termination condition set by `set_terminator()`. The default method, which must be overridden, raises a `NotImplementedError` exception. The buffered input data should be available via an instance attribute.

**async_chat.get_terminator()**

Returns the current terminator for the channel.

**async_chat.push(data)**

Pushes data on to the channel’s queue to ensure its transmission. This is all you need to do to have the channel write the data out to the network, although it is possible to use your own producers in more complex schemes to implement encryption and chunking, for example.
**async_chat.push_with_producer(producer)**

Takes a producer object and adds it to the producer queue associated with the channel. When all currently-pushed producers have been exhausted the channel will consume this producer’s data by calling its `more()` method and send the data to the remote endpoint.

**async_chat.set_terminator(term)**

Sets the terminating condition to be recognized on the channel. `term` may be any of three types of value, corresponding to three different ways to handle incoming protocol data.

<table>
<thead>
<tr>
<th>term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>Will call <code>found_terminator()</code> when the string is found in the input stream</td>
</tr>
<tr>
<td>integer</td>
<td>Will call <code>found_terminator()</code> when the indicated number of characters have been received</td>
</tr>
<tr>
<td>None</td>
<td>The channel continues to collect data forever</td>
</tr>
</tbody>
</table>

Note that any data following the terminator will be available for reading by the channel after `found_terminator()` is called.
18.7.1. asynchat Example

The following partial example shows how HTTP requests can be read with `async_chat`. A web server might create an `http_request_handler` object for each incoming client connection. Notice that initially the channel terminator is set to match the blank line at the end of the HTTP headers, and a flag indicates that the headers are being read.

Once the headers have been read, if the request is of type POST (indicating that further data are present in the input stream) then the `Content-Length:` header is used to set a numeric terminator to read the right amount of data from the channel.

The `handle_request()` method is called once all relevant input has been marshalled, after setting the channel terminator to `None` to ensure that any extraneous data sent by the web client are ignored.

```python
import asynchat

class http_request_handler(asynchat.async_chat):
    def __init__(self, sock, addr, sessions, log):
        asynchat.async_chat.__init__(self, sock=sock)
        self.addr = addr
        self.sessions = sessions
        self.ibuffer = []
        self.obuffer = b"
        self.set_terminator(b"\r\n\r\n")
        self.reading_headers = True
        self.handling = False
        self.cgi_data = None
        self.log = log
```
def collect_incoming_data(self, data):
    """Buffer the data""
    self.ibuffer.append(data)

def found_terminator(self):
    if self.reading_headers:
        self.reading_headers = False
        self.parse_headers(b"".join(self.ibuffer)
        self.ibuffer = []
    if self.op.upper() == b"POST":
        clen = self.headers.getheader("content-length")
        self.set_terminator(int(clen))
    else:
        self.handling = True
        self.set_terminator(None)
        self.handle_request()
    elif not self.handling:
        self.set_terminator(None)  # browsers sometimes over-send
        self.cgi_data = parse(self.headers, b"
        self.handling = True
        self.ibuffer = []
        self.handle_request()
18.8. signal — Set handlers for asynchronous events

This module provides mechanisms to use signal handlers in Python.
18.8.1. General rules

The `signal.signal()` function allows defining custom handlers to be executed when a signal is received. A small number of default handlers are installed: SIGPIPE is ignored (so write errors on pipes and sockets can be reported as ordinary Python exceptions) and SIGINT is translated into a `KeyboardInterrupt` exception.

A handler for a particular signal, once set, remains installed until it is explicitly reset (Python emulates the BSD style interface regardless of the underlying implementation), with the exception of the handler for SIGCHLD, which follows the underlying implementation.

18.8.1.1. Execution of Python signal handlers

A Python signal handler does not get executed inside the low-level (C) signal handler. Instead, the low-level signal handler sets a flag which tells the virtual machine to execute the corresponding Python signal handler at a later point (for example at the next bytecode instruction). This has consequences:

- It makes little sense to catch synchronous errors like SIGFPE or SIGSEGV that are caused by an invalid operation in C code. Python will return from the signal handler to the C code, which is likely to raise the same signal again, causing Python to apparently hang. From Python 3.3 onwards, you can use the `faulthandler` module to report on synchronous errors.
- A long-running calculation implemented purely in C (such as regular expression matching on a large body of text) may run uninterrupted for an arbitrary amount of time, regardless of any signals received. The Python signal handlers will be called when
18.8.1.2. Signals and threads

Python signal handlers are always executed in the main Python thread, even if the signal was received in another thread. This means that signals can’t be used as a means of inter-thread communication. You can use the synchronization primitives from the `threading` module instead.

Besides, only the main thread is allowed to set a new signal handler.
18.8.2. Module contents

Changed in version 3.5: signal (SIG*), handler (SIG_DFL, SIG_IGN) and sigmask (SIG_BLOCK, SIG_UNBLOCK, SIG_SETMASK) related constants listed below were turned into enums. getsignal(), pthread_sigmask(), sigpending() and sigwait() functions return human-readable enums.

The variables defined in the signal module are:

signal.SIG_DFL
This is one of two standard signal handling options; it will simply perform the default function for the signal. For example, on most systems the default action for SIGQUIT is to dump core and exit, while the default action for SIGCHLD is to simply ignore it.

signal.SIG_IGN
This is another standard signal handler, which will simply ignore the given signal.

SIG*
All the signal numbers are defined symbolically. For example, the hangup signal is defined as signal.SIGHUP; the variable names are identical to the names used in C programs, as found in <signal.h>. The Unix man page for ‘signal()’ lists the existing signals (on some systems this is signal(2), on others the list is in signal(7)). Note that not all systems define the same set of signal names; only those names defined by the system are defined by this module.

signal.CTRL_C_EVENT
The signal corresponding to the Ctrl+C keystroke event. This signal can only be used with os.kill().

Availability: Windows.

New in version 3.2.

signal. **CTRL_BREAK_EVENT**
The signal corresponding to the Ctrl+Break keystroke event. This signal can only be used with os.kill().

Availability: Windows.

New in version 3.2.

signal. **NSIG**
One more than the number of the highest signal number.

signal. **ITIMER_REAL**
Decrements interval timer in real time, and delivers SIGALRM upon expiration.

signal. **ITIMER_VIRTUAL**
Decrements interval timer only when the process is executing, and delivers SIGVTALRM upon expiration.

signal. **ITIMER_PROF**
Decrements interval timer both when the process executes and when the system is executing on behalf of the process. Coupled with ITIMER_VIRTUAL, this timer is usually used to profile the time spent by the application in user and kernel space. SIGPROF is delivered upon expiration.

signal. **SIG_BLOCK**
A possible value for the `how` parameter to `pthread_sigmask()` indicating that signals are to be blocked.

*New in version 3.3.*

**signal.SIG_UNBLOCK**

A possible value for the `how` parameter to `pthread_sigmask()` indicating that signals are to be unblocked.

*New in version 3.3.*

**signal.SIG_SETMASK**

A possible value for the `how` parameter to `pthread_sigmask()` indicating that the signal mask is to be replaced.

*New in version 3.3.*

The `signal` module defines one exception:

**exception signal.ItimerError**

Raised to signal an error from the underlying `setitimer()` or `getitimer()` implementation. Expect this error if an invalid interval timer or a negative time is passed to `setitimer()`. This error is a subtype of `OSError`.

*New in version 3.3:* This error used to be a subtype of `IOError`, which is now an alias of `OSError`.

The `signal` module defines the following functions:

**signal.alarm(time)**

If `time` is non-zero, this function requests that a SIGALRM signal be sent to the process in `time` seconds. Any previously scheduled
alarm is canceled (only one alarm can be scheduled at any time). The returned value is then the number of seconds before any previously set alarm was to have been delivered. If time is zero, no alarm is scheduled, and any scheduled alarm is canceled. If the return value is zero, no alarm is currently scheduled. (See the Unix man page alarm(2).) Availability: Unix.

signal.getsignal(signalnum)

Return the current signal handler for the signal signalnum. The returned value may be a callable Python object, or one of the special values signal.SIG_IGN, signal.SIG_DFL or None. Here, signal.SIG_IGN means that the signal was previously ignored, signal.SIG_DFL means that the default way of handling the signal was previously in use, and None means that the previous signal handler was not installed from Python.

signal.pause()

Cause the process to sleep until a signal is received; the appropriate handler will then be called. Returns nothing. Not on Windows. (See the Unix man page signal(2).)

See also sigwait(), sigwaitinfo(), sigtimedwait() and sigpending().

signal.pthread_kill(thread_id, signalnum)

Send the signal signalnum to the thread thread_id, another thread in the same process as the caller. The target thread can be executing any code (Python or not). However, if the target thread is executing the Python interpreter, the Python signal handlers will be executed by the main thread. Therefore, the only point of sending a signal to a particular Python thread would be to force a running system call to fail with InterruptedError.
Use `threading.get_ident()` or the `ident` attribute of `threading.Thread` objects to get a suitable value for `thread_id`.

If `signalnum` is 0, then no signal is sent, but error checking is still performed; this can be used to check if the target thread is still running.

Availability: Unix (see the man page `pthread_kill(3)` for further information).

See also `os.kill()`.

*New in version 3.3.*

`signal.pthread_sigmask`(how, mask)

Fetch and/or change the signal mask of the calling thread. The signal mask is the set of signals whose delivery is currently blocked for the caller. Return the old signal mask as a set of signals.

The behavior of the call is dependent on the value of `how`, as follows.

- **SIG_BLOCK**: The set of blocked signals is the union of the current set and the `mask` argument.
- **SIG_UNBLOCK**: The signals in `mask` are removed from the current set of blocked signals. It is permissible to attempt to unblock a signal which is not blocked.
- **SIG_SETMASK**: The set of blocked signals is set to the `mask` argument.

`mask` is a set of signal numbers (e.g. `{signal.SIGINT, signal.SIGTERM}`). Use `range(1, signal.NSIG)` for a full mask including all signals.
For example, `signal.pthread_sigmask(signal.SIG_BLOCK, [])` reads the signal mask of the calling thread.

Availability: Unix. See the man page `sigprocmask(3)` and `pthread_sigmask(3)` for further information.

See also `pause()`, `sigpending()` and `sigwait()`.

*New in version 3.3.*

```python
signal.setitimer(which, seconds, interval=0.0)
```

Sets given interval timer (one of `signal.ITIMER_REAL`, `signal.ITIMER_VIRTUAL` or `signal.ITIMER_PROF`) specified by `which` to fire after `seconds` (float is accepted, different from `alarm()`) and after that every `interval` seconds (if `interval` is non-zero). The interval timer specified by `which` can be cleared by setting `seconds` to zero.

When an interval timer fires, a signal is sent to the process. The signal sent is dependent on the timer being used; `signal.ITIMER_REAL` will deliver `SIGALRM`, `signal.ITIMER_VIRTUAL` sends `SIGVTALRM`, and `signal.ITIMER_PROF` will deliver `SIGPROF`.

The old values are returned as a tuple: (delay, interval).

Attempting to pass an invalid interval timer will cause an `ItimerError`. Availability: Unix.

```python
signal.getitimer(which)
```

Returns current value of a given interval timer specified by `which`. Availability: Unix.
The function `signal.set_wakeup_fd(fd, *, warn_on_full_buffer=True)`

Set the wakeup file descriptor to `fd`. When a signal is received, the signal number is written as a single byte into the fd. This can be used by a library to wakeup a poll or select call, allowing the signal to be fully processed.

The old wakeup fd is returned (or -1 if file descriptor wakeup was not enabled). If `fd` is -1, file descriptor wakeup is disabled. If not -1, `fd` must be non-blocking. It is up to the library to remove any bytes from `fd` before calling poll or select again.

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a `ValueError` exception to be raised.

There are two common ways to use this function. In both approaches, you use the fd to wake up when a signal arrives, but then they differ in how they determine which signal or signals have arrived.

In the first approach, we read the data out of the fd’s buffer, and the byte values give you the signal numbers. This is simple, but in rare cases it can run into a problem: generally the fd will have a limited amount of buffer space, and if too many signals arrive too quickly, then the buffer may become full, and some signals may be lost. If you use this approach, then you should set `warn_on_full_buffer=True`, which will at least cause a warning to be printed to stderr when signals are lost.

In the second approach, we use the wakeup fd only for wakeups, and ignore the actual byte values. In this case, all we care about is whether the fd’s buffer is empty or non-empty; a full buffer doesn’t indicate a problem at all. If you use this approach, then you should
set `warn_on_full_buffer=False`, so that your users are not confused by spurious warning messages.

*Changed in version 3.5:* On Windows, the function now also supports socket handles.

*Changed in version 3.7:* Added `warn_on_full_buffer` parameter.

```python
signal.siginterrupt(signalnum, flag)
```
Change system call restart behaviour: if `flag` is `False`, system calls will be restarted when interrupted by signal `signalnum`, otherwise system calls will be interrupted. Returns nothing. Availability: Unix (see the man page `siginterrupt(3)` for further information).

Note that installing a signal handler with `signal()` will reset the restart behaviour to interruptible by implicitly calling `siginterrupt()` with a true `flag` value for the given signal.

```python
signal.signal(signalnum, handler)
```
Set the handler for signal `signalnum` to the function `handler`. `handler` can be a callable Python object taking two arguments (see below), or one of the special values `signal.SIG_IGN` or `signal.SIG_DFL`. The previous signal handler will be returned (see the description of `getsignal()` above). (See the Unix man page `signal(2)`.)

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a `ValueError` exception to be raised.

The `handler` is called with two arguments: the signal number and
the current stack frame (None or a frame object; for a description of frame objects, see the description in the type hierarchy or see the attribute descriptions in the inspect module).

On Windows, signal() can only be called with SIGABRT, SIGFPE, SIGILL, SIGINT, SIGSEGV, SIGTERM, or SIGBREAK. A ValueError will be raised in any other case. Note that not all systems define the same set of signal names; an AttributeError will be raised if a signal name is not defined as SIG* module level constant.

signal. sigpending()
Examine the set of signals that are pending for delivery to the calling thread (i.e., the signals which have been raised while blocked). Return the set of the pending signals.

Availability: Unix (see the man page sigpending(2) for further information).

See also pause(), pthread_sigmask() and sigwait().

New in version 3.3.

signal. sigwait(sigset)
Suspend execution of the calling thread until the delivery of one of the signals specified in the signal set sigset. The function accepts the signal (removes it from the pending list of signals), and returns the signal number.

Availability: Unix (see the man page sigwait(3) for further information).

See also pause(), pthread_sigmask(), sigpending(),

sigwaitinfo() and sigtimedwait().

New in version 3.3.

**signal. sigwaitinfo(sigset)**

Suspend execution of the calling thread until the delivery of one of the signals specified in the signal set `sigset`. The function accepts the signal and removes it from the pending list of signals. If one of the signals in `sigset` is already pending for the calling thread, the function will return immediately with information about that signal. The signal handler is not called for the delivered signal. The function raises an `InterruptedError` if it is interrupted by a signal that is not in `sigset`.

The return value is an object representing the data contained in the `siginfo_t` structure, namely: `si_signo`, `si_code`, `si_errno`, `si_pid`, `si_uid`, `si_status`, `si_band`.

Availability: Unix (see the man page `sigwaitinfo(2)` for further information).

See also `pause()`, `sigwait()` and `sigtimedwait()`.

New in version 3.3.

Changed in version 3.5: The function is now retried if interrupted by a signal not in `sigset` and the signal handler does not raise an exception (see PEP 475 for the rationale).

**signal. sigtimedwait(sigset, timeout)**

Like `sigwaitinfo()`, but takes an additional `timeout` argument specifying a timeout. If `timeout` is specified as 0, a poll is performed. Returns `None` if a timeout occurs.
Availability: Unix (see the man page `sigtimedwait(2)` for further information).

See also `pause()`, `sigwait()` and `sigwaitinfo()`.

*New in version 3.3.*

*Changed in version 3.5:* The function is now retried with the recomputed `timeout` if interrupted by a signal not in `sigset` and the signal handler does not raise an exception (see [PEP 475](https://www.python.org/dev/peps/pep-0475/) for the rationale).
18.8.3. Example

Here is a minimal example program. It uses the `alarm()` function to limit the time spent waiting to open a file; this is useful if the file is for a serial device that may not be turned on, which would normally cause the `os.open()` to hang indefinitely. The solution is to set a 5-second alarm before opening the file; if the operation takes too long, the alarm signal will be sent, and the handler raises an exception.

```python
import signal, os

def handler(signum, frame):
    print('Signal handler called with signal', signum)
    raise OSError("Couldn't open device!")

# Set the signal handler and a 5-second alarm
signal.signal(signal.SIGALRM, handler)
signal.alarm(5)

# This open() may hang indefinitely
fd = os.open('/dev/ttyS0', os.O_RDWR)

signal.alarm(0)  # Disable the alarm
```

Memory-mapped file objects behave like both `bytearray` and like `file objects`. You can use mmap objects in most places where `bytearray` are expected; for example, you can use the `re` module to search through a memory-mapped file. You can also change a single byte by doing `obj[index] = 97`, or change a subsequence by assigning to a slice: `obj[i1:i2] = b'...'`. You can also read and write data starting at the current file position, and `seek()` through the file to different positions.

A memory-mapped file is created by the `mmap` constructor, which is different on Unix and on Windows. In either case you must provide a file descriptor for a file opened for update. If you wish to map an existing Python file object, use its `fileno()` method to obtain the correct value for the `fileno` parameter. Otherwise, you can open the file using the `os.open()` function, which returns a file descriptor directly (the file still needs to be closed when done).

**Note:** If you want to create a memory-mapping for a writable, buffered file, you should `flush()` the file first. This is necessary to ensure that local modifications to the buffers are actually available to the mapping.

For both the Unix and Windows versions of the constructor, `access` may be specified as an optional keyword parameter. `access` accepts one of four values: `ACCESS_READ`, `ACCESS_WRITE`, or `ACCESS_COPY` to specify read-only, write-through or copy-on-write.
memory respectively, or ACCESS_DEFAULT to defer to prot. access can be used on both Unix and Windows. If access is not specified, Windows mmap returns a write-through mapping. The initial memory values for all three access types are taken from the specified file. Assignment to an ACCESS_READ memory map raises a TypeError exception. Assignment to an ACCESS_WRITE memory map affects both memory and the underlying file. Assignment to an ACCESS_COPY memory map affects memory but does not update the underlying file.

*Changed in version 3.7:* Added ACCESS_DEFAULT constant.

To map anonymous memory, -1 should be passed as the fileno along with the length.

```python
class mmap.mmap(fileno, length, tagname=None, access=ACCESS_DEFAULT[, offset])
```

*(Windows version)* Maps length bytes from the file specified by the file handle fileno, and creates a mmap object. If length is larger than the current size of the file, the file is extended to contain length bytes. If length is 0, the maximum length of the map is the current size of the file, except that if the file is empty Windows raises an exception (you cannot create an empty mapping on Windows).

*tagname*, if specified and not None, is a string giving a tag name for the mapping. Windows allows you to have many different mappings against the same file. If you specify the name of an existing tag, that tag is opened, otherwise a new tag of this name is created. If this parameter is omitted or None, the mapping is created without a name. Avoiding the use of the tag parameter will assist in keeping your code portable between Unix and Windows.
offset may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the file. offset defaults to 0. offset must be a multiple of the ALLOCATIONGRANULARITY.

```python
class mmap:
    mmap(fileno, length, flags=MAP_SHARED,
         prot=PROT_WRITE|PROT_READ, access=ACCESS_DEFAULT[
            offset])
```

(Unix version) Maps length bytes from the file specified by the file descriptor fileno, and returns a mmap object. If length is 0, the maximum length of the map will be the current size of the file when mmap is called.

flags specifies the nature of the mapping. MAP_PRIVATE creates a private copy-on-write mapping, so changes to the contents of the mmap object will be private to this process, and MAP_SHARED creates a mapping that's shared with all other processes mapping the same areas of the file. The default value is MAP_SHARED.

prot, if specified, gives the desired memory protection; the two most useful values are PROT_READ and PROT_WRITE, to specify that the pages may be read or written. prot defaults to PROT_READ | PROT_WRITE.

access may be specified in lieu of flags and prot as an optional keyword parameter. It is an error to specify both flags, prot and access. See the description of access above for information on how to use this parameter.

offset may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the file. offset defaults to 0. offset must be a multiple of the PAGESIZE.
or ALLOCATIONGRANULARITY.

To ensure validity of the created memory mapping the file specified by the descriptor fileno is internally automatically synchronized with physical backing store on Mac OS X and OpenVMS.

This example shows a simple way of using mmap:

```python
import mmap

# write a simple example file
with open("hello.txt", "wb") as f:
    f.write(b"Hello Python!\n")

with open("hello.txt", "r+b") as f:
    # memory-map the file, size 0 means whole file
    mm = mmap.mmap(f.fileno(), 0)
    # read content via standard file methods
    print(mm.readline())  # prints b"Hello Python"
    # read content via slice notation
    print(mm[:5])  # prints b"Hello"
    # update content using slice notation;
    # note that new content must have same size
    mm[6:] = b" world!\n"
    # ... and read again using standard file methods
    mm.seek(0)
    print(mm.readline())  # prints b"Hello world"

# close the map
mm.close()
```

mmap can also be used as a context manager in a with statement:
with mmap.mmap(-1, 13) as mm:
    mm.write(b"Hello world!")

New in version 3.2: Context manager support.

The next example demonstrates how to create an anonymous map and exchange data between the parent and child processes:

```
import mmap
import os

mm = mmap.mmap(-1, 13)
mm.write(b"Hello world!"

pid = os.fork()

if pid == 0:  # In a child process
    mm.seek(0)
    print(mm.readline())

    mm.close()
```

Memory-mapped file objects support the following methods:

**close()**

Closes the mmap. Subsequent calls to other methods of the object will result in a ValueError exception being raised. This will not close the open file.

**closed**

True if the file is closed.

New in version 3.2.

**find(sub[, start[, end]]))**
Returns the lowest index in the object where the subsequence `sub` is found, such that `sub` is contained in the range `[start, end]`. Optional arguments `start` and `end` are interpreted as in slice notation. Returns `-1` on failure.

*Changed in version 3.5:* Writable bytes-like object is now accepted.

**flush**([`offset`, `size`])

Flushes changes made to the in-memory copy of a file back to disk. Without use of this call there is no guarantee that changes are written back before the object is destroyed. If `offset` and `size` are specified, only changes to the given range of bytes will be flushed to disk; otherwise, the whole extent of the mapping is flushed.

*(Windows version)* A nonzero value returned indicates success; zero indicates failure.

*(Unix version)* A zero value is returned to indicate success. An exception is raised when the call failed.

**move**(dest, src, count)

Copy the `count` bytes starting at offset `src` to the destination index `dest`. If the mmap was created with ACCESS_READ, then calls to move will raise a `TypeError` exception.

**read**([`n`])

Return a `bytes` containing up to `n` bytes starting from the current file position. If the argument is omitted, `None` or negative, return all bytes from the current file position to the end of the mapping. The file position is updated to point after the
bytes that were returned.

*Changed in version 3.3:* Argument can be omitted or None.

**read_byte()**
Returns a byte at the current file position as an integer, and advances the file position by 1.

**readline()**
Returns a single line, starting at the current file position and up to the next newline.

**resize(newsize)**
Resizes the map and the underlying file, if any. If the mmap was created with ACCESS_READ or ACCESS_COPY, resizing the map will raise a TypeError exception.

**rfind(sub[, start[, end]])**
Returns the highest index in the object where the subsequence `sub` is found, such that `sub` is contained in the range `[start, end]`. Optional arguments `start` and `end` are interpreted as in slice notation. Returns -1 on failure.

*Changed in version 3.5:* Writable bytes-like object is now accepted.

**seek(pos[, whence])**
Set the file's current position. `whence` argument is optional and defaults to `os.SEEK_SET` or 0 (absolute file positioning); other values are `os.SEEK_CUR` or 1 (seek relative to the current position) and `os.SEEK_END` or 2 (seek relative to the file's end).
**size()**
Return the length of the file, which can be larger than the size of the memory-mapped area.

**tell()**
Returns the current position of the file pointer.

**write(bytes)**
Write the bytes in `bytes` into memory at the current position of the file pointer and return the number of bytes written (never less than `len(bytes)`), since if the write fails, a `ValueError` will be raised). The file position is updated to point after the bytes that were written. If the mmap was created with ACCESS_READ, then writing to it will raise a `TypeError` exception.

*Changed in version 3.5:* Writable bytes-like object is now accepted.

*Changed in version 3.6:* The number of bytes written is now returned.

**write_byte(byte)**
Write the integer `byte` into memory at the current position of the file pointer; the file position is advanced by 1. If the mmap was created with ACCESS_READ, then writing to it will raise a `TypeError` exception.

19. Internet Data Handling

This chapter describes modules which support handling data formats commonly used on the Internet.

- 19.1. email — An email and MIME handling package
  - 19.1.1. email.message: Representing an email message
  - 19.1.2. email.parser: Parsing email messages
    - 19.1.2.1. FeedParser API
    - 19.1.2.2. Parser API
    - 19.1.2.3. Additional notes
  - 19.1.3. email.generator: Generating MIME documents
  - 19.1.4. email.policy: Policy Objects
  - 19.1.5. email.errors: Exception and Defect classes
  - 19.1.6. email.headerregistry: Custom Header Objects
  - 19.1.7. email.contentmanager: Managing MIME Content
    - 19.1.7.1. Content Manager Instances
  - 19.1.8. email: Examples
  - 19.1.9. email.message.Message: Representing an email message using the compat32 API
  - 19.1.10. email.mime: Creating email and MIME objects from scratch
  - 19.1.11. email.header: Internationalized headers
  - 19.1.12. email.charset: Representing character sets
  - 19.1.13. email.encoders: Encoders
  - 19.1.14. email.utils: Miscellaneous utilities
  - 19.1.15. email.iterators: Iterators

- 19.2. json — JSON encoder and decoder
  - 19.2.1. Basic Usage
  - 19.2.2. Encoders and Decoders
  - 19.2.3. Exceptions
19.2.4. Standard Compliance and Interoperability
   - 19.2.4.1. Character Encodings
   - 19.2.4.2. Infinite and NaN Number Values
   - 19.2.4.3. Repeated Names Within an Object
   - 19.2.4.4. Top-level Non-Object, Non-Array Values
   - 19.2.4.5. Implementation Limitations

19.2.5. Command Line Interface
   - 19.2.5.1. Command line options

19.3. mailcap — Mailcap file handling

19.4. mailbox — Manipulate mailboxes in various formats
   - 19.4.1. Mailbox objects
     - 19.4.1.1. Maildir
     - 19.4.1.2. mbox
     - 19.4.1.3. MH
     - 19.4.1.4. Babyl
     - 19.4.1.5. MMDF
   - 19.4.2. Message objects
     - 19.4.2.1. MaildirMessage
     - 19.4.2.2. mboxMessage
     - 19.4.2.3. MHMessage
     - 19.4.2.4. BabylMessage
     - 19.4.2.5. MMDFMessage
   - 19.4.3. Exceptions
   - 19.4.4. Examples

19.5. mimetypes — Map filenames to MIME types
   - 19.5.1. MimeTypes Objects

19.6. base64 — Base16, Base32, Base64, Base85 Data Encodings

19.7. binhex — Encode and decode binhex4 files
   - 19.7.1. Notes

19.8. binascii — Convert between binary and ASCII

19.9. quopri — Encode and decode MIME quoted-printable data

19.10. uu — Encode and decode uuencode files
19.1. **email** — An email and MIME handling package

**Source code:** Lib/email/__init__.py

The `email` package is a library for managing email messages. It is specifically *not* designed to do any sending of email messages to SMTP (RFC 2821), NNTP, or other servers; those are functions of modules such as `smtplib` and `nntplib`. The `email` package attempts to be as RFC-compliant as possible, supporting RFC 5233 and RFC 6532, as well as such MIME-related RFCs as RFC 2045, RFC 2046, RFC 2047, RFC 2183, and RFC 2231.

The overall structure of the email package can be divided into three major components, plus a fourth component that controls the behavior of the other components.

The central component of the package is an “object model” that represents email messages. An application interacts with the package primarily through the object model interface defined in the `message` sub-module. The application can use this API to ask questions about an existing email, to construct a new email, or to add or remove email subcomponents that themselves use the same object model interface. That is, following the nature of email messages and their MIME subcomponents, the email object model is a tree structure of objects that all provide the `EmailMessage` API.

The other two major components of the package are the `parser` and the `generator`. The parser takes the serialized version of an email
message (a stream of bytes) and converts it into a tree of EmailMessage objects. The generator takes an EmailMessage and turns it back into a serialized byte stream. (The parser and generator also handle streams of text characters, but this usage is discouraged as it is too easy to end up with messages that are not valid in one way or another.)

The control component is the policy module. Every EmailMessage, every generator, and every parser has an associated policy object that controls its behavior. Usually an application only needs to specify the policy when an EmailMessage is created, either by directly instantiating an EmailMessage to create a new email, or by parsing an input stream using a parser. But the policy can be changed when the message is serialized using a generator. This allows, for example, a generic email message to be parsed from disk, but to serialize it using standard SMTP settings when sending it to an email server.

The email package does its best to hide the details of the various governing RFCs from the application. Conceptually the application should be able to treat the email message as a structured tree of unicode text and binary attachments, without having to worry about how these are represented when serialized. In practice, however, it is often necessary to be aware of at least some of the rules governing MIME messages and their structure, specifically the names and nature of the MIME “content types” and how they identify multipart documents. For the most part this knowledge should only be required for more complex applications, and even then it should only be the high level structure in question, and not the details of how those structures are represented. Since MIME content types are used widely in modern internet software (not just email), this will be a familiar concept to many programmers.
The following sections describe the functionality of the email package. We start with the message object model, which is the primary interface an application will use, and follow that with the parser and generator components. Then we cover the policy controls, which completes the treatment of the main components of the library.

The next three sections cover the exceptions the package may raise and the defects (non-compliance with the RFCs) that the parser may detect. Then we cover the headerregistry and the contentmanager sub-components, which provide tools for doing more detailed manipulation of headers and payloads, respectively. Both of these components contain features relevant to consuming and producing non-trivial messages, but also document their extensibility APIs, which will be of interest to advanced applications.

Following those is a set of examples of using the fundamental parts of the APIs covered in the preceding sections.

The forgoing represent the modern (unicode friendly) API of the email package. The remaining sections, starting with the Message class, cover the legacy compat32 API that deals much more directly with the details of how email messages are represented. The compat32 API does not hide the details of the RFCs from the application, but for applications that need to operate at that level, they can be useful tools. This documentation is also relevant for applications that are still using the compat32 API for backward compatibility reasons.

*Changed in version 3.6:* Docs reorganized and rewritten to promote the new EmailMessage/EmailPolicy API.

Contents of the email package documentation:
19.1.1. email.message: Representing an email message
19.1.2. email.parser: Parsing email messages
   - 19.1.2.1. FeedParser API
   - 19.1.2.2. Parser API
   - 19.1.2.3. Additional notes
19.1.3. email.generator: Generating MIME documents
19.1.4. email.policy: Policy Objects
19.1.5. email.errors: Exception and Defect classes
19.1.6. email.headerregistry: Custom Header Objects
19.1.7. email.contentmanager: Managing MIME Content
   - 19.1.7.1. Content Manager Instances
19.1.8. email: Examples

Legacy API:

19.1.9. email.message.Message: Representing an email message using the compat32 API
19.1.10. email.mime: Creating email and MIME objects from scratch
19.1.11. email.header: Internationalized headers
19.1.12. email.charset: Representing character sets
19.1.13. email.encoders: Encoders
19.1.14. email.utils: Miscellaneous utilities
19.1.15. email.iterators: Iterators

See also:

Module smtplib
   SMTP (Simple Mail Transport Protocol) client
Module poplib
   POP (Post Office Protocol) client
Module imaplib
IMAP (Internet Message Access Protocol) client

**Module** nntplib

NNTP (Net News Transport Protocol) client

**Module** mailbox

Tools for creating, reading, and managing collections of messages on disk using a variety standard formats.

**Module** smtpd

SMTP server framework (primarily useful for testing)
19.1. email — An email and MIME handling package
19.1.1. **email.message:** Representing an email message

**Source code:** Lib/email/message.py

*New in version 3.6:* [1]

The central class in the `email` package is the `EmailMessage` class, imported from the `email.message` module. It is the base class for the `email` object model. `EmailMessage` provides the core functionality for setting and querying header fields, for accessing message bodies, and for creating or modifying structured messages.

An email message consists of *headers* and a *payload* (which is also referred to as the *content*). Headers are RFC 5322 or RFC 6532 style field names and values, where the field name and value are separated by a colon. The colon is not part of either the field name or the field value. The payload may be a simple text message, or a binary object, or a structured sequence of sub-messages each with their own set of headers and their own payload. The latter type of payload is indicated by the message having a MIME type such as `multipart/*` or `message/rfc822`.

The conceptual model provided by an `EmailMessage` object is that of an ordered dictionary of headers coupled with a *payload* that represents the RFC 5322 body of the message, which might be a list of sub-`EmailMessage` objects. In addition to the normal dictionary methods for accessing the header names and values, there are methods for accessing specialized information from the headers (for example the MIME content type), for operating on the payload, for
generating a serialized version of the message, and for recursively walking over the object tree.

The `EmailMessage` dictionary-like interface is indexed by the header names, which must be ASCII values. The values of the dictionary are strings with some extra methods. Headers are stored and returned in case-preserving form, but field names are matched case-insensitively. Unlike a real dict, there is an ordering to the keys, and there can be duplicate keys. Additional methods are provided for working with headers that have duplicate keys.

The `payload` is either a string or bytes object, in the case of simple message objects, or a list of `EmailMessage` objects, for MIME container documents such as `multipart/*` and `message/rfc822` message objects.

```python
class email.message.EmailMessage(policy=default)
```

If `policy` is specified use the rules it specifies to update and serialize the representation of the message. If `policy` is not set, use the `default` policy, which follows the rules of the email RFCs except for line endings (instead of the RFC mandated `
`, it uses the Python standard `
` line endings). For more information see the `policy` documentation.

```python
as_string(unixfrom=False, maxheaderlen=None, policy=None)
```

Return the entire message flattened as a string. When optional `unixfrom` is true, the envelope header is included in the returned string. `unixfrom` defaults to `False`. For backward compatibility with the base `Message` class `maxheaderlen` is accepted, but defaults to `None`, which means that by default the line length is controlled by the `max_line_length` of the policy. The `policy`
argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified policy will be passed to the Generator.

Flattening the message may trigger changes to the EmailMessage if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not be the most useful way to serialize messages in your application, especially if you are dealing with multiple messages. See email.generator.Generator for a more flexible API for serializing messages. Note also that this method is restricted to producing messages serialized as “7 bit clean” when utf8 is False, which is the default.

Changed in version 3.6: the default behavior when maxheaderlen is not specified was changed from defaulting to 0 to defaulting to the value of max_line_length from the policy.

```
__str__(self)
```

Equivalent to `as_string(policy=self.policy.clone(utf8=True))`. Allows `str(msg)` to produce a string containing the serialized message in a readable format.

Changed in version 3.4: the method was changed to use utf8=True, thus producing an RFC 6531-like message representation, instead of being a direct alias for `as_string()`.

```
as_bytes(self, unixfrom=False, policy=None)
```
Return the entire message flattened as a bytes object. When optional `unixfrom` is true, the envelope header is included in the returned string. `unixfrom` defaults to False. The `policy` argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified `policy` will be passed to the `BytesGenerator`.

Flattening the message may trigger changes to the `EmailMessage` if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not be the most useful way to serialize messages in your application, especially if you are dealing with multiple messages. See `email.generator.BytesGenerator` for a more flexible API for serializing messages.

```
__bytes__()
```

Equivalent to `as_bytes()`. Allows `bytes(msg)` to produce a bytes object containing the serialized message.

```
is_multipart()
```

Return `True` if the message's payload is a list of sub-`EmailMessage` objects, otherwise return `False`. When `is_multipart()` returns `False`, the payload should be a string object (which might be a CTE encoded binary payload). Note that `is_multipart()` returning `True` does not necessarily mean that “`msg.get_content_maintype() == 'multipart'" will return the True. For example, `is_multipart` will return `True` when the `EmailMessage` is of type
message/rfc822.

**set_unixfrom**(unixfrom)

Set the message's envelope header to `unixfrom`, which should be a string. (See `mboxMessage` for a brief description of this header.)

**get_unixfrom()**

Return the message’s envelope header. Defaults to `None` if the envelope header was never set.

The following methods implement the mapping-like interface for accessing the message’s headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by `keys()`, but in an `EmailMessage` object, headers are always returned in the order they appeared in the original message, or in which they were added to the message later. Any header deleted and then re-added is always appended to the end of the header list.

These semantic differences are intentional and are biased toward convenience in the most common use cases.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

**__len__()**

Return the total number of headers, including duplicates.

**__contains__(name)**
Return true if the message object has a field named `name`. Matching is done without regard to case and `name` does not include the trailing colon. Used for the `in` operator. For example:

```python
if 'message-id' in myMessage:
    print('Message-ID:', myMessage['message-id'])
```

__getitem__(name)

Return the value of the named header field. `name` does not include the colon field separator. If the header is missing, `None` is returned; a `KeyError` is never raised.

Note that if the named field appears more than once in the message's headers, exactly which of those field values will be returned is undefined. Use the `get_all()` method to get the values of all the extant headers named `name`.

Using the standard (non-compat32) policies, the returned value is an instance of a subclass of `email.headerregistry.BaseHeader`.

__setitem__(name, val)

Add a header to the message with field name `name` and value `val`. The field is appended to the end of the message's existing headers.

Note that this does not overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name `name`, delete the field first, e.g.:
del msg['subject']
msg['subject'] = 'Python roolz!'

If the policy defines certain headers to be unique (as the standard policies do), this method may raise a ValueError when an attempt is made to assign a value to such a header when one already exists. This behavior is intentional for consistency's sake, but do not depend on it as we may choose to make such assignments do an automatic deletion of the existing header in the future.

__delitem__(name)
Delete all occurrences of the field with name name from the message's headers. No exception is raised if the named field isn't present in the headers.

keys()
Return a list of all the message's header field names.

values()
Return a list of all the message's field values.

items()
Return a list of 2-tuples containing all the message's field headers and values.

get(name, failobj=None)
Return the value of the named header field. This is identical to __getitem__() except that optional failobj is returned if the named header is missing (failobj defaults to None).

Here are some additional useful header related methods:
**get_all**(*name*, *failobj=None*)

Return a list of all the values for the field named *name*. If there are no such named headers in the message, *failobj* is returned (defaults to None).

**add_header**(*_name*, *_value*, **_params*)

Extended header setting. This method is similar to **__setitem__()** except that additional header parameters can be provided as keyword arguments. *_name* is the header field to add and *_value* is the primary value for the header.

For each item in the keyword argument dictionary **_params**, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as key="value" unless the value is None, in which case only the key will be added.

If the value contains non-ASCII characters, the charset and language may be explicitly controlled by specifying the value as a three tuple in the format (CHARSET, LANGUAGE, VALUE), where CHARSET is a string naming the charset to be used to encode the value, LANGUAGE can usually be set to None or the empty string (see RFC 2231 for other possibilities), and VALUE is the string value containing non-ASCII code points. If a three tuple is not passed and the value contains non-ASCII characters, it is automatically encoded in RFC 2231 format using a CHARSET of utf-8 and a LANGUAGE of None.

Here is an example:

```python
msg.add_header('Content-Disposition', 'attachment')
```
This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.
```

An example of the extended interface with non-ASCII characters:

```
msg.add_header('Content-Disposition', 'attachment', filename=('iso-8859-1', '', 'Fußballer.ppt'))
```

**replace_header**(_name,_value)

Replace a header. Replace the first header found in the message that matches _name, retaining header order and field name case of the original header. If no matching header is found, raise a KeyError.

**get_content_type()**

Return the message’s content type, coerced to lower case of the form maintype/subtype. If there is no Content-Type header in the message return the value returned by get_default_type(). If the Content-Type header is invalid, return text/plain.

(According to **RFC 2045**, messages always have a default type, get_content_type() will always return a value. **RFC 2045** defines a message’s default type to be text/plain unless it appears inside a multipart/digest container, in which case it would be message/rfc822. If the Content-Type header has an invalid type specification, **RFC 2045** mandates that the default type be text/plain.)
get_content_maintype()
Return the message’s main content type. This is the maintype part of the string returned by get_content_type().

get_content_subtype()
Return the message’s sub-content type. This is the subtype part of the string returned by get_content_type().

get_default_type()
Return the default content type. Most messages have a default content type of text/plain, except for messages that are subparts of multipart/digest containers. Such subparts have a default content type of message/rfc822.

set_default_type(ctype)
Set the default content type. ctype should either be text/plain or message/rfc822, although this is not enforced. The default content type is not stored in the Content-Type header, so it only affects the return value of the get_content_type methods when no Content-Type header is present in the message.

set_param(param, value, header='Content-Type', requote=True, charset=None, language='', replace=False)
Set a parameter in the Content-Type header. If the parameter already exists in the header, replace its value with value. When header is Content-Type (the default) and the header does not yet exist in the message, add it, set its value to text/plain, and append the new parameter value. Optional header specifies an alternative header to Content-Type.

If the value contains non-ASCII characters, the charset and language may be explicitly specified using the optional charset
and `language` parameters. Optional `language` specifies the RFC 2231 language, defaulting to the empty string. Both `charset` and `language` should be strings. The default is to use the `utf8` `charset` and `None` for the `language`.

If `replace` is `False` (the default) the header is moved to the end of the list of headers. If `replace` is `True`, the header will be updated in place.

Use of the `requote` parameter with `EmailMessage` objects is deprecated.

Note that existing parameter values of headers may be accessed through the `params` attribute of the header value (for example, `msg['Content-Type'].params['charset']`).

*Changed in version 3.4:* replace keyword was added.

```
def del_param(param, header='content-type', requote=True)
    Remove the given parameter completely from the Content-Type header. The header will be re-written in place without the parameter or its value. Optional header specifies an alternative to Content-Type.
```

Use of the `requote` parameter with `EmailMessage` objects is deprecated.

```
def get_filename(failobj=None)
    Return the value of the filename parameter of the Content-Disposition header of the message. If the header does not have a filename parameter, this method falls back to looking for the name parameter on the Content-Type header. If neither is found, or the header is missing, then failobj is returned. The
returned string will always be unquoted as per `email.utils.unquote()`.

**get_boundary** *(failobj=None)*
Return the value of the `boundary` parameter of the `Content-Type` header of the message, or `failobj` if either the header is missing, or has no `boundary` parameter. The returned string will always be unquoted as per `email.utils.unquote()`.

**set_boundary** *(boundary)*
Set the `boundary` parameter of the `Content-Type` header to `boundary`. `set_boundary()` will always quote `boundary` if necessary. A `HeaderParseError` is raised if the message object has no `Content-Type` header.

Note that using this method is subtly different from deleting the old `Content-Type` header and adding a new one with the new boundary via `add_header()`, because `set_boundary()` preserves the order of the `Content-Type` header in the list of headers.

**get_content_charset** *(failobj=None)*
Return the `charset` parameter of the `Content-Type` header, coerced to lower case. If there is no `Content-Type` header, or if that header has no `charset` parameter, `failobj` is returned.

**getCharsets** *(failobj=None)*
Return a list containing the character set names in the message. If the message is a `multipart`, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.
Each item in the list will be a string which is the value of the \texttt{charset} parameter in the \texttt{Content-Type} header for the represented subpart. If the subpart has no \texttt{Content-Type} header, no \texttt{charset} parameter, or is not of the \texttt{text} main MIME type, then that item in the returned list will be \texttt{failobj}.

\textbf{is\_attachment()}

Return \texttt{True} if there is a \texttt{Content-Disposition} header and its (case insensitive) value is \texttt{attachment}, \texttt{False} otherwise.

\textit{Changed in version 3.4.2:} \texttt{is\_attachment} is now a method instead of a property, for consistency with \texttt{is\_multipart()}.  

\textbf{get\_content\_disposition()}

Return the lowercased value (without parameters) of the message’s \texttt{Content-Disposition} header if it has one, or \texttt{None}. The possible values for this method are \texttt{inline}, \texttt{attachment} or \texttt{None} if the message follows \texttt{RFC 2183}.

\textit{New in version 3.5.}

The following methods relate to interrogating and manipulating the content (payload) of the message.

\textbf{walk()}

The \texttt{walk()} method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use \texttt{walk()} as the iterator in a \texttt{for} loop; each iteration returns the next subpart.

Here's an example that prints the MIME type of every part of a multipart message structure:
>>> for part in msg.walk():
...    print(part.get_content_type())
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
text/plain

walk iterates over the subparts of any part where is_multipart() returns True, even though msg.get_content_maintype() == 'multipart' may return False. We can see this in our example by making use of the _structure debug helper function:

>>> for part in msg.walk():
...    print(part.get_content_maintype() == 'multipart')
...    part.is_multipart())
True True
False False
False True
False False
False False
False True
False False
>>> _structure(msg)
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
text/plain
Here the message parts are not multipearts, but they do contain subparts. `is_multipart()` returns `True` and `walk` descends into the subparts.

**get_body** *(`preferencelist=('related', 'html', 'plain')`)*  
Return the MIME part that is the best candidate to be the “body” of the message.

`preferencelist` must be a sequence of strings from the set `related`, `html`, and `plain`, and indicates the order of preference for the content type of the part returned.

Start looking for candidate matches with the object on which the `get_body` method is called.

If `related` is not included in `preferencelist`, consider the root part (or subpart of the root part) of any related encountered as a candidate if the (sub-)part matches a preference.

When encountering a `multipart/related`, check the `start` parameter and if a part with a matching `Content-ID` is found, consider only it when looking for candidate matches. Otherwise consider only the first (default root) part of the `multipart/related`.

If a part has a `Content-Disposition` header, only consider the part a candidate match if the value of the header is `inline`.

If none of the candidates matches any of the preferences in `preferencelist`, return `None`.

Notes: (1) For most applications the only `preferencelist` combinations that really make sense are `('plain',)`,
('html', 'plain'), and the default ('related', 'html', 'plain'). (2) Because matching starts with the object on which get_body is called, calling get_body on a multipart/related will return the object itself unless preferencelist has a non-default value. (3) Messages (or message parts) that do not specify a Content-Type or whose Content-Type header is invalid will be treated as if they are of type text/plain, which may occasionally cause get_body to return unexpected results.

iter_attachments()

Return an iterator over all of the immediate sub-parts of the message that are not candidate “body” parts. That is, skip the first occurrence of each of text/plain, text/html, multipart/related, or multipart/alternative (unless they are explicitly marked as attachments via Content-Disposition: attachment), and return all remaining parts. When applied directly to a multipart/related, return an iterator over the all the related parts except the root part (ie: the part pointed to by the start parameter, or the first part if there is no start parameter or the start parameter doesn’t match the Content-ID of any of the parts). When applied directly to a multipart/alternative or a non-multipart, return an empty iterator.

iter_parts()

Return an iterator over all of the immediate sub-parts of the message, which will be empty for a non-multipart. (See also walk().)

get_content(*args, content_manager=None, **kw)
Call the \texttt{get\_content()} method of the \texttt{content\_manager}, passing self as the message object, and passing along any other arguments or keywords as additional arguments. If \texttt{content\_manager} is not specified, use the \texttt{content\_manager} specified by the current \texttt{policy}.

\texttt{set\_content(*args, content\_manager=None, **kw)}

Call the \texttt{set\_content()} method of the \texttt{content\_manager}, passing self as the message object, and passing along any other arguments or keywords as additional arguments. If \texttt{content\_manager} is not specified, use the \texttt{content\_manager} specified by the current \texttt{policy}.

\texttt{make\_related(boundary=None)}

Convert a non-multipart message into a multipart/related message, moving any existing \texttt{Content-headers} and payload into a (new) first part of the multipart. If \texttt{boundary} is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

\texttt{make\_alternative(boundary=None)}

Convert a non-multipart or a multipart/related into a multipart/alternative, moving any existing \texttt{Content-headers} and payload into a (new) first part of the multipart. If \texttt{boundary} is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).
**make_mixed**(boundary=None)

Convert a non-multipart, a multipart/related, or a multipart-alternative into a multipart/mixed, moving any existing *Content*-headers and payload into a (new) first part of the multipart. If `boundary` is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

**add_related**(args, content_manager=None, **kw)

If the message is a multipart/related, create a new message object, pass all of the arguments to its `set_content()` method, and `attach()` it to the multipart. If the message is a non-multipart, call `make_related()` and then proceed as above. If the message is any other type of multipart, raise a `TypeError`. If `content_manager` is not specified, use the `content_manager` specified by the current policy. If the added part has no `Content-Disposition` header, add one with the value `inline`.

**add_alternative**(args, content_manager=None, **kw)

If the message is a multipart/alternative, create a new message object, pass all of the arguments to its `set_content()` method, and `attach()` it to the multipart. If the message is a non-multipart or multipart/related, call `make_alternative()` and then proceed as above. If the message is any other type of multipart, raise a `TypeError`. If `content_manager` is not specified, use the `content_manager` specified by the current policy.
add_attachment(*args, content_manager=None, **kw)

If the message is a multipart/mixed, create a new message object, pass all of the arguments to its set_content() method, and attach() it to the multipart. If the message is a non-multipart, multipart/related, or multipart/alternative, call make_mixed() and then proceed as above. If content_manager is not specified, use the content_manager specified by the current policy. If the added part has no Content-Disposition header, add one with the value attachment. This method can be used both for explicit attachments (Content-Disposition: attachment and inline attachments (Content-Disposition: inline), by passing appropriate options to the content_manager.

clear()

Remove the payload and all of the headers.

clear_content()

Remove the payload and all of the Content- headers, leaving all other headers intact and in their original order.

EmailMessage objects have the following instance attributes:

preamble

The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this
text can become visible.

The *preamble* attribute contains this leading extra-armor text for MIME documents. When the *Parser* discovers some text after the headers but before the first boundary string, it assigns this text to the message's *preamble* attribute. When the *Generator* is writing out the plain text representation of a MIME message, and it finds the message has a *preamble* attribute, it will write this text in the area between the headers and the first boundary. See `email.parser` and `email.generator` for details.

Note that if the message object has no preamble, the *preamble* attribute will be `None`.

**epilogue**

The *epilogue* attribute acts the same way as the *preamble* attribute, except that it contains text that appears between the last boundary and the end of the message. As with the *preamble*, if there is no epilog text this attribute will be `None`.

**defects**

The *defects* attribute contains a list of all the problems found when parsing this message. See `email.errors` for a detailed description of the possible parsing defects.

class email.message.MIMEPart(policy=default)

This class represents a subpart of a MIME message. It is identical to `EmailMessage`, except that no *MIME-Version* headers are added when `set_content()` is called, since sub-parts do not need their own *MIME-Version* headers.
Footnotes

Originally added in 3.4 as a provisional module. Docs for legacy message class moved to email.message.Message: Representing an email message using the compat32 API.

[1]
19.1.2. `email.parser`: Parsing email messages

Source code: Lib/email/parser.py

Message object structures can be created in one of two ways: they can be created from whole cloth by creating an `EmailMessage` object, adding headers using the dictionary interface, and adding payload(s) using `set_content()` and related methods, or they can be created by parsing a serialized representation of the email message.

The `email` package provides a standard parser that understands most email document structures, including MIME documents. You can pass the parser a bytes, string or file object, and the parser will return to you the root `EmailMessage` instance of the object structure. For simple, non-MIME messages the payload of this root object will likely be a string containing the text of the message. For MIME messages, the root object will return `True` from its `is_multipart()` method, and the subparts can be accessed via the payload manipulation methods, such as `get_body()`, `iter_parts()`, and `walk()`.

There are actually two parser interfaces available for use, the `Parser` API and the incremental `FeedParser` API. The `Parser` API is most useful if you have the entire text of the message in memory, or if the entire message lives in a file on the file system. `FeedParser` is more appropriate when you are reading the message from a stream which might block waiting for more input (such as reading an email message from a socket). The `FeedParser` can consume and parse the
message incrementally, and only returns the root object when you close the parser.

Note that the parser can be extended in limited ways, and of course you can implement your own parser completely from scratch. All of the logic that connects the `email` package's bundled parser and the `EmailMessage` class is embodied in the policy class, so a custom parser can create message object trees any way it finds necessary by implementing custom versions of the appropriate policy methods.
19.1.2.1. FeedParser API

The BytesFeedParser, imported from the email.feedparser module, provides an API that is conducive to incremental parsing of email messages, such as would be necessary when reading the text of an email message from a source that can block (such as a socket). The BytesFeedParser can of course be used to parse an email message fully contained in a bytes-like object, string, or file, but the BytesParser API may be more convenient for such use cases. The semantics and results of the two parser APIs are identical.

The BytesFeedParser’s API is simple; you create an instance, feed it a bunch of bytes until there’s no more to feed it, then close the parser to retrieve the root message object. The BytesFeedParser is extremely accurate when parsing standards-compliant messages, and it does a very good job of parsing non-compliant messages, providing information about how a message was deemed broken. It will populate a message object’s defects attribute with a list of any problems it found in a message. See the email.errors module for the list of defects that it can find.

Here is the API for the BytesFeedParser:

```python
class email.parser.BytesFeedParser(_factory=None, *, policy=policy.compat32)
    Create a BytesFeedParser instance. Optional _factory is a no-
    argument callable; if not specified use the message_factory
    from the policy. Call _factory whenever a new message object is
    needed.

    If policy is specified use the rules it specifies to update the
```
representation of the message. If policy is not set, use the compat32 policy, which maintains backward compatibility with the Python 3.2 version of the email package and provides Message as the default factory. All other policies provide EmailMessage as the default _factory. For more information on what else policy controls, see the policy documentation.

Note: The policy keyword should always be specified; The default will change to email.policy.default in a future version of Python.

New in version 3.2.

Changed in version 3.3: Added the policy keyword.

Changed in version 3.6: _factory defaults to the policy message_factory.

**feed**(data)

Feed the parser some more data. data should be a bytes-like object containing one or more lines. The lines can be partial and the parser will stitch such partial lines together properly. The lines can have any of the three common line endings: carriage return, newline, or carriage return and newline (they can even be mixed).

**close()**

Complete the parsing of all previously fed data and return the root message object. It is undefined what happens if feed() is called after this method has been called.

class email.parser.FeedParser(_factory=None, *, policy=policy.compat32)
Works like `BytesFeedParser` except that the input to the `feed()` method must be a string. This is of limited utility, since the only way for such a message to be valid is for it to contain only ASCII text or, if `utf8` is `True`, no binary attachments.

*Changed in version 3.3:* Added the `policy` keyword.
19.1.2.2. Parser API

The `BytesParser` class, imported from the `email.parser` module, provides an API that can be used to parse a message when the complete contents of the message are available in a bytes-like object or file. The `email.parser` module also provides `Parser` for parsing strings, and header-only parsers, `BytesHeaderParser` and `HeaderParser`, which can be used if you're only interested in the headers of the message. `BytesHeaderParser` and `HeaderParser` can be much faster in these situations, since they do not attempt to parse the message body, instead setting the payload to the raw body.

```python
class email.parser.BytesParser(_class=None, *, policy=policy.compat32)
    Create a BytesParser instance. The _class and policy arguments have the same meaning and semantics as the _factory and policy arguments of BytesFeedParser.

    Note: The policy keyword should always be specified; The default will change to email.policy.default in a future version of Python.

    Changed in version 3.3: Removed the strict argument that was deprecated in 2.4. Added the policy keyword.

    Changed in version 3.6: _class defaults to the policy message_factory.

    parse(fp, headersonly=False)
    Read all the data from the binary file-like object fp, parse the resulting bytes, and return the message object. fp must support
both the \texttt{readline()} and the \texttt{read()} methods.

The bytes contained in \textit{fp} must be formatted as a block of RFC 5322 (or, if utf8 is True, RFC 6532) style headers and header continuation lines, optionally preceded by an envelope header. The header block is terminated either by the end of the data or by a blank line. Following the header block is the body of the message (which may contain MIME-encoded subparts, including subparts with a \textit{Content-Transfer-Encoding} of 8bit).

Optional \textit{headersonly} is a flag specifying whether to stop parsing after reading the headers or not. The default is \texttt{False}, meaning it parses the entire contents of the file.

\texttt{parsebytes(bytes, headersonly=False)}

Similar to the \texttt{parse()} method, except it takes a bytes-like object instead of a file-like object. Calling this method on a bytes-like object is equivalent to wrapping \textit{bytes} in a \texttt{BytesIO} instance first and calling \texttt{parse()}.

Optional \textit{headersonly} is as with the \texttt{parse()} method.

\textit{New in version 3.2.}

$\texttt{class email.parser.\texttt{BytesHeaderParser(_class=None,*,policy=policy.compat32)}}$

Exactly like \texttt{BytesParser}, except that \textit{headersonly} defaults to \texttt{True}.

\textit{New in version 3.3.}

$\texttt{class email.parser.\texttt{Parser(_class=None,*,policy=policy.compat32)}}$
This class is parallel to `BytesParser`, but handles string input.

*Changed in version 3.3:* Removed the `strict` argument. Added the `policy` keyword.

*Changed in version 3.6:* `_class` defaults to the policy `message_factory`.

**parse** *(fp, headersonly=False)*

Read all the data from the text-mode file-like object `fp`, parse the resulting text, and return the root message object. `fp` must support both the `readline()` and the `read()` methods on file-like objects.

Other than the text mode requirement, this method operates like `BytesParser.parse()`.

**parsestr** *(text, headersonly=False)*

Similar to the `parse()` method, except it takes a string object instead of a file-like object. Calling this method on a string is equivalent to wrapping `text` in a `StringIO` instance first and calling `parse()`.

Optional `headersonly` is as with the `parse()` method.

```
class email.parser.HeaderParser(_class=None, *,
policy=policy.compat32)
```

Exactly like `Parser`, except that `headersonly` defaults to `True`.

Since creating a message object structure from a string or a file object is such a common task, four functions are provided as a convenience. They are available in the top-level `email` package namespace.
email.message_from_bytes(s, _class=None, *,
policy=policy.compat32)

Return a message object structure from a bytes-like object. This is equivalent to BytesParser().parsebytes(s). Optional _class and strict are interpreted as with the BytesParser class constructor.

New in version 3.2.

Changed in version 3.3: Removed the strict argument. Added the policy keyword.

message_from_binary_file(fp, _class=None, *,
policy=policy.compat32)

Return a message object structure tree from an open binary file object. This is equivalent to BytesParser().parse(fp). _class and policy are interpreted as with the BytesParser class constructor.

New in version 3.2.

Changed in version 3.3: Removed the strict argument. Added the policy keyword.

email.message_from_string(s, _class=None, *,
policy=policy.compat32)

Return a message object structure from a string. This is equivalent to Parser().parsestr(s). _class and policy are interpreted as with the Parser class constructor.

Changed in version 3.3: Removed the strict argument. Added the policy keyword.
**email.message_from_file**(*fp, _class=None, *, policy=policy.compat32*)

Return a message object structure tree from an open file object. This is equivalent to `Parser().parse(fp)`. _class and policy are interpreted as with the `Parser` class constructor.

*Changed in version 3.3:* Removed the strict argument. Added the policy keyword.

*Changed in version 3.6:* _class defaults to the policy message_factory.

Here’s an example of how you might use `message_from_bytes()` at an interactive Python prompt:

```python
>>> import email
>>> msg = email.message_from_bytes(myBytes)
```
19.1.2.3. Additional notes

Here are some notes on the parsing semantics:

- Most non-multipart type messages are parsed as a single message object with a string payload. These objects will return False for is_multipart(), and iter_parts() will yield an empty list.

- All multipart type messages will be parsed as a container message object with a list of sub-message objects for their payload. The outer container message will return True for is_multipart(), and iter_parts() will yield a list of subparts.

- Most messages with a content type of message/* (such as message/delivery-status and message/rfc822) will also be parsed as container object containing a list payload of length 1. Their is_multipart() method will return True. The single element yielded by iter_parts() will be a sub-message object.

- Some non-standards-compliant messages may not be internally consistent about their multipart-edness. Such messages may have a Content-Type header of type multipart, but their is_multipart() method may return False. If such messages were parsed with the FeedParser, they will have an instance of the MultipartInvariantViolationDefect class in their defects attribute list. See email.errors for details.
19.1. email — An email and MIME handling package
19.1.3. **email.generator**: Generating MIME documents

**Source code:** Lib/email/generator.py

One of the most common tasks is to generate the flat (serialized) version of the email message represented by a message object structure. You will need to do this if you want to send your message via `smtplib.SMTP.sendmail()` or the `nntplib` module, or print the message on the console. Taking a message object structure and producing a serialized representation is the job of the generator classes.

As with the `email.parser` module, you aren’t limited to the functionality of the bundled generator; you could write one from scratch yourself. However the bundled generator knows how to generate most email in a standards-compliant way, should handle MIME and non-MIME email messages just fine, and is designed so that the bytes-oriented parsing and generation operations are inverses, assuming the same non-transforming policy is used for both. That is, parsing the serialized byte stream via the `BytesParser` class and then regenerating the serialized byte stream using `BytesGenerator` should produce output identical to the input [1]. (On the other hand, using the generator on an `EmailMessage` constructed by program may result in changes to the `EmailMessage` object as defaults are filled in.)

The **Generator** class can be used to flatten a message into a text (as opposed to binary) serialized representation, but since Unicode
cannot represent binary data directly, the message is of necessity transformed into something that contains only ASCII characters, using the standard email RFC Content Transfer Encoding techniques for encoding email messages for transport over channels that are not “8 bit clean”.

```
class email.generator.BytesGenerator(outfp,
    mangle_from_=None, maxheaderlen=None, *, policy=None)
    Return a BytesGenerator object that will write any message provided to the flatten() method, or any surrogateescape encoded text provided to the write() method, to the file-like object outfp. outfp must support a write method that accepts binary data.

    If optional mangle_from_ is True, put a > character in front of any line in the body that starts with the exact string "From ", that is From followed by a space at the beginning of a line. mangle_from_ defaults to the value of the mangle_from_ setting of the policy (which is True for the compat32 policy and False for all others). mangle_from_ is intended for use when messages are stored in unix mbox format (see mailbox and WHY THE CONTENT-LENGTH FORMAT IS BAD).

    If maxheaderlen is not None, refold any header lines that are longer than maxheaderlen, or if 0, do not rewrap any headers. If maxheaderlen is None (the default), wrap headers and other message lines according to the policy settings.

    If policy is specified, use that policy to control message generation. If policy is None (the default), use the policy associated with the Message or EmailMessage object passed to flatten to control the message generation. See email.policy for details on what
policy controls.

New in version 3.2.

Changed in version 3.3: Added the policy keyword.

Changed in version 3.6: The default behavior of the mangle_from_ and maxheaderlen parameters is to follow the policy.

flatten(msg, unixfrom=False, linesep=None)

Print the textual representation of the message object structure rooted at msg to the output file specified when the BytesGenerator instance was created.

If the policy option cte_type is 8bit (the default), copy any headers in the original parsed message that have not been modified to the output with any bytes with the high bit set reproduced as in the original, and preserve the non-ASCII Content-Transfer-Encoding of any body parts that have them. If cte_type is 7bit, convert the bytes with the high bit set as needed using an ASCII-compatible Content-Transfer-Encoding. That is, transform parts with non-ASCII Content-Transfer-Encoding (Content-Transfer-Encoding: 8bit) to an ASCII compatible Content-Transfer-Encoding, and encode RFC-invalid non-ASCII bytes in headers using the MIME unknown-8bit character set, thus rendering them RFC-compliant.

If unixfrom is True, print the envelope header delimiter used by the Unix mailbox format (see mailbox) before the first of the RFC 5322 headers of the root message object. If the root object has no envelope header, craft a standard one. The default is False. Note that for subparts, no envelope header is ever printed.
If `linesep` is not `None`, use it as the separator character between all the lines of the flattened message. If `linesep` is `None` (the default), use the value specified in the `policy`.

**clone(fp)**

Return an independent clone of this `BytesGenerator` instance with the exact same option settings, and `fp` as the new `outfp`.

**write(s)**

Encode `s` using the ASCII codec and the surrogateescape error handler, and pass it to the `write` method of the `outfp` passed to the `BytesGenerator`'s constructor.

As a convenience, `EmailMessage` provides the methods `as_bytes()` and `byte(aMessage)` (a.k.a. `__bytes__()`), which simplify the generation of a serialized binary representation of a message object. For more detail, see `email.message`.

Because strings cannot represent binary data, the `Generator` class must convert any binary data in any message it flattens to an ASCII compatible format, by converting them to an ASCII compatible `Content-Transfer_Encoding`. Using the terminology of the email RFCs, you can think of this as `Generator` serializing to an I/O stream that is not “8 bit clean”. In other words, most applications will want to be using `BytesGenerator`, and not `Generator`.

**class email.generator.**

```python
Generator(outfp,
        mangle_from_=None, maxheaderlen=None, *, policy=None)
```

Return a `Generator` object that will write any message provided to the `flatten()` method, or any text provided to the `write()` method, to the file-like object `outfp`. `outfp` must support a write
method that accepts string data.

If optional `mangle_from_` is True, put a > character in front of any line in the body that starts with the exact string "From", that is From followed by a space at the beginning of a line. `mangle_from_` defaults to the value of the `mangle_from_` setting of the `policy` (which is True for the `compat32` policy and False for all others). `mangle_from_` is intended for use when messages are stored in unix mbox format (see `mailbox` and `WHY THE CONTENT-LENGTH FORMAT IS BAD`).

If `maxheaderlen` is not None, refold any header lines that are longer than `maxheaderlen`, or if 0, do not rewrap any headers. If `manheaderlen` is None (the default), wrap headers and other message lines according to the `policy` settings.

If `policy` is specified, use that policy to control message generation. If `policy` is None (the default), use the policy associated with the `Message` or `EmailMessage` object passed to `flatten` to control the message generation. See `email.policy` for details on what `policy` controls.

**Changed in version 3.3:** Added the `policy` keyword.

**Changed in version 3.6:** The default behavior of the `mangle_from_` and `maxheaderlen` parameters is to follow the policy.

`flatten(msg, unixfrom=False, linesep=None)`

Print the textual representation of the message object structure rooted at `msg` to the output file specified when the `Generator` instance was created.

If the `policy` option `cte_type` is 8bit, generate the
message as if the option were set to 7bit. (This is required because strings cannot represent non-ASCII bytes.) Convert any bytes with the high bit set as needed using an ASCII-compatible Content-Transfer-Encoding. That is, transform parts with non-ASCII Content-Transfer-Encoding (Content-Transfer-Encoding: 8bit) to an ASCII compatible Content-Transfer-Encoding, and encode RFC-invalid non-ASCII bytes in headers using the MIME unknown-8bit character set, thus rendering them RFC-compliant.

If unixfrom is True, print the envelope header delimiter used by the Unix mailbox format (see mailbox) before the first of the RFC 5322 headers of the root message object. If the root object has no envelope header, craft a standard one. The default is False. Note that for subparts, no envelope header is ever printed.

If linesep is not None, use it as the separator character between all the lines of the flattened message. If linesep is None (the default), use the value specified in the policy.

*Changed in version 3.2: Added support for re-encoding 8bit message bodies, and the linesep argument.*

**clone**(fp)

Return an independent clone of this Generator instance with the exact same options, and fp as the new outfp.

**write**(s)

Write s to the write method of the outfp passed to the Generator’s constructor. This provides just enough file-like API for Generator instances to be used in the print()
function.

As a convenience, EmailMessage provides the methods as_string() and str(aMessage) (a.k.a. __str__()), which simplify the generation of a formatted string representation of a message object. For more detail, see email.message.

The email.generator module also provides a derived class, DecodedGenerator, which is like the Generator base class, except that non-text parts are not serialized, but are instead represented in the output stream by a string derived from a template filled in with information about the part.

class email.generator. DecodedGenerator(outfp, mangle_from_=None, maxheaderlen=None, fmt=None, *, policy=None)

Act like Generator, except that for any subpart of the message passed to Generator.flatten(), if the subpart is of main type text, print the decoded payload of the subpart, and if the main type is not text, instead of printing it fill in the string fmt using information from the part and print the resulting filled-in string.

To fill in fmt, execute fmt % part_info, where part_info is a dictionary composed of the following keys and values:

- **type** – Full MIME type of the non-text part
- **maintype** – Main MIME type of the non-text part
- **subtype** – Sub-MIME type of the non-text part
- **filename** – Filename of the non-text part
- **description** – Description associated with the non-text part
- **encoding** – Content transfer encoding of the non-text part

If fmt is None, use the following default fmt:
“[Non-text (%(type)s) part of message omitted, filename % (filename)s]”

Optional _mangle_from_ and maxheaderlen are as with the Generator base class.

Footnotes

This statement assumes that you use the appropriate setting for unixfrom, and that there are no policy settings calling for automatic adjustments (for example, refold_source must be none, which is not the default). It is also not 100% true, since if the message does not conform to the RFC standards occasionally information about the exact original text is lost during parsing error recovery. It is a goal to fix these latter edge cases when possible.

[1]
19.1.4. `email.policy`: Policy Objects

*New in version 3.3.*

**Source code:** Lib/email/policy.py

The `email` package's prime focus is the handling of email messages as described by the various email and MIME RFCs. However, the general format of email messages (a block of header fields each consisting of a name followed by a colon followed by a value, the whole block followed by a blank line and an arbitrary ‘body’), is a format that has found utility outside of the realm of email. Some of these uses conform fairly closely to the main email RFCs, some do not. Even when working with email, there are times when it is desirable to break strict compliance with the RFCs, such as generating emails that interoperate with email servers that do not themselves follow the standards, or that implement extensions you want to use in ways that violate the standards.

Policy objects give the email package the flexibility to handle all these disparate use cases.

A `Policy` object encapsulates a set of attributes and methods that control the behavior of various components of the email package during use. `Policy` instances can be passed to various classes and methods in the email package to alter the default behavior. The settable values and their defaults are described below.

There is a default policy used by all classes in the email package. For
all of the parser classes and the related convenience functions, and for the Message class, this is the Compat32 policy, via its corresponding pre-defined instance compat32. This policy provides for complete backward compatibility (in some cases, including bug compatibility) with the pre-Python3.3 version of the email package.

This default value for the policy keyword to EmailMessage is the EmailPolicy policy, via its pre-defined instance default.

When a Message or EmailMessage object is created, it acquires a policy. If the message is created by a parser, a policy passed to the parser will be the policy used by the message it creates. If the message is created by the program, then the policy can be specified when it is created. When a message is passed to a generator, the generator uses the policy from the message by default, but you can also pass a specific policy to the generator that will override the one stored on the message object.

The default value for the policy keyword for the email.parser classes and the parser convenience functions will be changing in a future version of Python. Therefore you should always specify explicitly which policy you want to use when calling any of the classes and functions described in the parser module.

The first part of this documentation covers the features of Policy, an abstract base class that defines the features that are common to all policy objects, including compat32. This includes certain hook methods that are called internally by the email package, which a custom policy could override to obtain different behavior. The second part describes the concrete classes EmailPolicy and Compat32, which implement the hooks that provide the standard behavior and the backward compatible behavior and features, respectively.
Policy instances are immutable, but they can be cloned, accepting the same keyword arguments as the class constructor and returning a new Policy instance that is a copy of the original but with the specified attributes values changed.

As an example, the following code could be used to read an email message from a file on disk and pass it to the system sendmail program on a Unix system:

```python
>>> from email import message_from_binary_file
>>> from email.generator import BytesGenerator
>>> from email import policy
>>> from subprocess import Popen, PIPE

with open('mymsg.txt', 'rb') as f:
    msg = message_from_binary_file(f, policy=policy)

p = Popen(['sendmail', msg['To'].addresses[0]],
          stdin=PIPE)

g = BytesGenerator(p.stdin, policy=msg.policy.clone)
g.flatten(msg)
p.stdin.close()
rc = p.wait()
```

Here we are telling BytesGenerator to use the RFC correct line separator characters when creating the binary string to feed into sendmail's stdin, where the default policy would use \n line separators.

Some email package methods accept a policy keyword argument, allowing the policy to be overridden for that method. For example, the following code uses the as_bytes() method of the msg object from the previous example and writes the message to a file using the native line separators for the platform on which it is running:

```python
>>> import os
```
Policy objects can also be combined using the addition operator, producing a policy object whose settings are a combination of the non-default values of the summed objects:

```python
>>> compat_SMTP = policy.compat32.clone(linesep='\r
',
>>> compat_strict = policy.compat32.clone(raise_on_defect=False)
>>> compat_strict_SMTP = compat_SMTP + compat_strict
```

This operation is not commutative; that is, the order in which the objects are added matters. To illustrate:

```python
>>> policy100 = policy.compat32.clone(max_line_length=100)
>>> policy80 = policy.compat32.clone(max_line_length=80)
>>> apolicy = policy100 + policy80
>>> apolicy.max_line_length
80
>>> apolicy = policy80 + policy100
>>> apolicy.max_line_length
100
```

```python
class email.policy.Policy(**kw)
```

This is the abstract base class for all policy classes. It provides default implementations for a couple of trivial methods, as well as the implementation of the immutability property, the `clone()` method, and the constructor semantics.

The constructor of a policy class can be passed various keyword arguments. The arguments that may be specified are any non-
method properties on this class, plus any additional non-method properties on the concrete class. A value specified in the constructor will override the default value for the corresponding attribute.

This class defines the following properties, and thus values for the following may be passed in the constructor of any policy class:

**max_line_length**

The maximum length of any line in the serialized output, not counting the end of line character(s). Default is 78, per RFC 5322. A value of 0 or None indicates that no line wrapping should be done at all.

**linesep**

The string to be used to terminate lines in serialized output. The default is \n because that’s the internal end-of-line discipline used by Python, though \r\n is required by the RFCs.

**cte_type**

Controls the type of Content Transfer Encodings that may be or are required to be used. The possible values are:

<table>
<thead>
<tr>
<th>7bit</th>
<th>all data must be “7 bit clean” (ASCII-only). This means that where necessary data will be encoded using either quoted-printable or base64 encoding.</th>
</tr>
</thead>
<tbody>
<tr>
<td>8bit</td>
<td>data is not constrained to be 7 bit clean. Data in headers is still required to be ASCII-only and so will be encoded (see fold_binary() and utf8 below for exceptions), but body parts may use the 8bit CTE.</td>
</tr>
</tbody>
</table>

A cte_type value of 8bit only works with BytesGenerator, not Generator, because strings cannot
contain binary data. If a `Generator` is operating under a policy that specifies `cte_type=8bit`, it will act as if `cte_type` is `7bit`.

**raise_on_defect**

If `True`, any defects encountered will be raised as errors. If `False` (the default), defects will be passed to the `register_defect()` method.

**mangle_from_**

If `True`, lines starting with “From “ in the body are escaped by putting a `>` in front of them. This parameter is used when the message is being serialized by a generator. Default: `False`.

*New in version 3.5:* The `mangle_from_` parameter.

**message_factory**

A factory function for constructing a new empty message object. Used by the parser when building messages. Defaults to `None`, in which case `Message` is used.

*New in version 3.6.*

The following `Policy` method is intended to be called by code using the email library to create policy instances with custom settings:

**clone(**\*kw\*)**

Return a new `Policy` instance whose attributes have the same values as the current instance, except where those attributes are given new values by the keyword arguments.

The remaining `Policy` methods are called by the email package.
code, and are not intended to be called by an application using the email package. A custom policy must implement all of these methods.

**handle_defect**(obj, defect)

Handle a *defect* found on *obj*. When the email package calls this method, *defect* will always be a subclass of Defect.

The default implementation checks the *raise_on_defect* flag. If it is True, *defect* is raised as an exception. If it is False (the default), *obj* and *defect* are passed to *register_defect*().

**register_defect**(obj, defect)

Register a *defect* on *obj*. In the email package, *defect* will always be a subclass of Defect.

The default implementation calls the *append* method of the *defects* attribute of *obj*. When the email package calls *handle_defect*, *obj* will normally have a *defects* attribute that has an *append* method. Custom object types used with the email package (for example, custom *Message* objects) should also provide such an attribute, otherwise defects in parsed messages will raise unexpected errors.

**header_max_count**(name)

Return the maximum allowed number of headers named *name*.

Called when a header is added to an *EmailMessage* or *Message* object. If the returned value is not 0 or None, and there are already a number of headers with the name *name* greater than or equal to the value returned, a *ValueError* is
Because the default behavior of `Message.__setitem__` is to append the value to the list of headers, it is easy to create duplicate headers without realizing it. This method allows certain headers to be limited in the number of instances of that header that may be added to a `Message` programmatically. (The limit is not observed by the parser, which will faithfully produce as many headers as exist in the message being parsed.)

The default implementation returns `None` for all header names.

**header_source_parse** *(sourcelines)*

The email package calls this method with a list of strings, each string ending with the line separation characters found in the source being parsed. The first line includes the field header name and separator. All whitespace in the source is preserved. The method should return the `(name, value)` tuple that is to be stored in the `Message` to represent the parsed header.

If an implementation wishes to retain compatibility with the existing email package policies, `name` should be the case preserved name (all characters up to the `:` separator), while `value` should be the unfolded value (all line separator characters removed, but whitespace kept intact), stripped of leading whitespace.

`sourcelines` may contain surrogate escaped binary data.

There is no default implementation

**header_store_parse** *(name, value)*
The email package calls this method with the name and value provided by the application program when the application program is modifying a Message programmatically (as opposed to a Message created by a parser). The method should return the (name, value) tuple that is to be stored in the Message to represent the header.

If an implementation wishes to retain compatibility with the existing email package policies, the name and value should be strings or string subclasses that do not change the content of the passed in arguments.

There is no default implementation

**header_fetch_parse**(name, value)

The email package calls this method with the name and value currently stored in the Message when that header is requested by the application program, and whatever the method returns is what is passed back to the application as the value of the header being retrieved. Note that there may be more than one header with the same name stored in the Message; the method is passed the specific name and value of the header destined to be returned to the application.

value may contain surrogateescaped binary data. There should be no surrogateescaped binary data in the value returned by the method.

There is no default implementation

**fold**(name, value)

The email package calls this method with the name and value currently stored in the Message for a given header. The
method should return a string that represents that header “folded” correctly (according to the policy settings) by composing the name with the value and inserting linesep characters at the appropriate places. See RFC 5322 for a discussion of the rules for folding email headers.

value may contain surrogateescaped binary data. There should be no surrogateescaped binary data in the string returned by the method.

fold_binary(name, value)
The same as fold(), except that the returned value should be a bytes object rather than a string.

value may contain surrogateescaped binary data. These could be converted back into binary data in the returned bytes object.

class email.policy>EmailPolicy(**kw)
This concrete Policy provides behavior that is intended to be fully compliant with the current email RFCs. These include (but are not limited to) RFC 5322, RFC 2047, and the current MIME RFCs.

This policy adds new header parsing and folding algorithms. Instead of simple strings, headers are str subclasses with attributes that depend on the type of the field. The parsing and folding algorithm fully implement RFC 2047 and RFC 5322.

The default value for the message_factory attribute is EmailMessage.

In addition to the settable attributes listed above that apply to all policies, this policy adds the following additional attributes:
New in version 3.6: [1]

utf8

If False, follow RFC 5322, supporting non-ASCII characters in headers by encoding them as “encoded words”. If True, follow RFC 6532 and use utf-8 encoding for headers. Messages formatted in this way may be passed to SMTP servers that support the SMTPUTF8 extension (RFC 6531).

refold_source

If the value for a header in the Message object originated from a parser (as opposed to being set by a program), this attribute indicates whether or not a generator should refold that value when transforming the message back into serialized form. The possible values are:

<table>
<thead>
<tr>
<th>none</th>
<th>all source values use original folding</th>
</tr>
</thead>
<tbody>
<tr>
<td>long</td>
<td>source values that have any line that is longer than max_line_length will be refolded</td>
</tr>
<tr>
<td>all</td>
<td>all values are refolded.</td>
</tr>
</tbody>
</table>

The default is long.

header_factory

A callable that takes two arguments, name and value, where name is a header field name and value is an unfolded header field value, and returns a string subclass that represents that header. A default header_factory (see headerregistry) is provided that supports custom parsing for the various address and date RFC 5322 header field types, and the major MIME header field stypes. Support for additional custom parsing will be added in the future.
**content_manager**

An object with at least two methods: `get_content` and `set_content`. When the `get_content()` or `set_content()` method of an `EmailMessage` object is called, it calls the corresponding method of this object, passing it the message object as its first argument, and any arguments or keywords that were passed to it as additional arguments. By default `content_manager` is set to `raw_data_manager`.

*New in version 3.4.*

The class provides the following concrete implementations of the abstract methods of `Policy`:

**header_max_count**(name)

Returns the value of the `max_count` attribute of the specialized class used to represent the header with the given name.

**header_source_parse**(sourcelines)

The name is parsed as everything up to the `:` and returned unmodified. The value is determined by stripping leading whitespace off the remainder of the first line, joining all subsequent lines together, and stripping any trailing carriage return or linefeed characters.

**header_store_parse**(name, value)

The name is returned unchanged. If the input value has a `name` attribute and it matches `name` ignoring case, the value is returned unchanged. Otherwise the `name` and `value` are passed to `header_factory`, and the resulting header object is returned as the value. In this case a `ValueError` is raised if the input value contains CR or LF characters.
header_fetch_parse(name, value)
If the value has a name attribute, it is returned to unmodified. Otherwise the name, and the value with any CR or LF characters removed, are passed to the header_factory, and the resulting header object is returned. Any surrogateescaped bytes get turned into the unicode unknown-character glyph.

fold(name, value)
Header folding is controlled by the refold_source policy setting. A value is considered to be a ‘source value’ if and only if it does not have a name attribute (having a name attribute means it is a header object of some sort). If a source value needs to be refolded according to the policy, it is converted into a header object by passing the name and the value with any CR and LF characters removed to the header_factory. Folding of a header object is done by calling its fold method with the current policy.

Source values are split into lines using splitlines(). If the value is not to be refolded, the lines are rejoined using the linesep from the policy and returned. The exception is lines containing non-ascii binary data. In that case the value is refolded regardless of the refold_source setting, which causes the binary data to be CTE encoded using the unknown-8bit charset.

fold_binary(name, value)
The same as fold() if cte_type is 7bit, except that the returned value is bytes.

If cte_type is 8bit, non-ASCII binary data is converted back into bytes. Headers with binary data are not refolded,
regardless of the refold_header setting, since there is no way to know whether the binary data consists of single byte characters or multibyte characters.

The following instances of EmailPolicy provide defaults suitable for specific application domains. Note that in the future the behavior of these instances (in particular the HTTP instance) may be adjusted to conform even more closely to the RFCs relevant to their domains.

**email.policy.default**

An instance of EmailPolicy with all defaults unchanged. This policy uses the standard Python `\n` line endings rather than the RFC-correct `\r\n`.

**email.policy.SMTP**

Suitable for serializing messages in conformance with the email RFCs. Like default, but with linesep set to `\r\n`, which is RFC compliant.

**email.policy.SMTPUTF8**

The same as SMTP except that utf8 is True. Useful for serializing messages to a message store without using encoded words in the headers. Should only be used for SMTP transmission if the sender or recipient addresses have non-ASCII characters (the smtplib.SMTP.send_message() method handles this automatically).

**email.policy.HTTP**

Suitable for serializing headers with for use in HTTP traffic. Like SMTP except that max_line_length is set to None (unlimited).

**email.policy.strict**
Convenience instance. The same as `default` except that `raise_on_defect` is set to `True`. This allows any policy to be made strict by writing:

```
somepolicy + policy.strict
```

With all of these `EmailPolicies`, the effective API of the email package is changed from the Python 3.2 API in the following ways:

- Setting a header on a `Message` results in that header being parsed and a header object created.
- Fetching a header value from a `Message` results in that header being parsed and a header object created and returned.
- Any header object, or any header that is refolded due to the policy settings, is folded using an algorithm that fully implements the RFC folding algorithms, including knowing where encoded words are required and allowed.

From the application view, this means that any header obtained through the `EmailMessage` is a header object with extra attributes, whose string value is the fully decoded unicode value of the header. Likewise, a header may be assigned a new value, or a new header created, using a unicode string, and the policy will take care of converting the unicode string into the correct RFC encoded form.

The header objects and their attributes are described in `headerregistry`.

```python
class email.policyCompat32(**kw)
```

This concrete `Policy` is the backward compatibility policy. It replicates the behavior of the email package in Python 3.2. The `policy` module also defines an instance of this class, `compat32`,...
that is used as the default policy. Thus the default behavior of the email package is to maintain compatibility with Python 3.2.

The following attributes have values that are different from the Policy default:

**mangle_from_**

The default is True.

The class provides the following concrete implementations of the abstract methods of Policy:

**header_source_parse**(sourcelines)

The name is parsed as everything up to the `:` and returned unmodified. The value is determined by stripping leading whitespace off the remainder of the first line, joining all subsequent lines together, and stripping any trailing carriage return or linefeed characters.

**header_store_parse**(name, value)

The name and value are returned unmodified.

**header_fetch_parse**(name, value)

If the value contains binary data, it is converted into a Header object using the unknown-8bit charset. Otherwise it is returned unmodified.

**fold**(name, value)

Headers are folded using the Header folding algorithm, which preserves existing line breaks in the value, and wraps each resulting line to the max_line_length. Non-ASCII binary data are CTE encoded using the unknown-8bit charset.
fold_binary\texttt{(name, value)}

Headers are folded using the \texttt{Header} folding algorithm, which preserves existing line breaks in the value, and wraps each resulting line to the \texttt{max_line_length}. If \texttt{cte_type} is 7\texttt{bit}, non-ascii binary data is CTE encoded using the \texttt{unknown-8bit} charset. Otherwise the original source header is used, with its existing line breaks and any (RFC invalid) binary data it may contain.

email.policy.\texttt{compat32}

An instance of \texttt{Compat32}, providing backward compatibility with the behavior of the email package in Python 3.2.

Footnotes

[1] Originally added in 3.3 as a \texttt{provisional feature}.
19. Internet Data Handling

19.1. `email` — An email and MIME handling package

```python
from email import email
```

An email module in Python that supports M4E.
The following exception classes are defined in the `email.errors` module:

```python
exception email.errors.MessageError
    This is the base class for all exceptions that the `email` package can raise. It is derived from the standard `Exception` class and defines no additional methods.

exception email.errors.MessageParseError
    This is the base class for exceptions raised by the `Parser` class. It is derived from `MessageError`. This class is also used internally by the parser used by `headerregistry`.

exception email.errors.HeaderParseError
    Raised under some error conditions when parsing the RFC 5322 headers of a message, this class is derived from `MessageParseError`. The `set_boundary()` method will raise this error if the content type is unknown when the method is called. `Header` may raise this error for certain base64 decoding errors, and when an attempt is made to create a header that appears to contain an embedded header (that is, there is what is supposed to be a continuation line that has no leading whitespace and looks like a header).```
Exception `email.errors.BoundaryError`
Deprecated and no longer used.

Exception `email.errors.MultipartConversionError`
Raised when a payload is added to a `Message` object using `add_payload()`, but the payload is already a scalar and the message’s `Content-Type` main type is not either `multipart` or missing. `MultipartConversionError` multiply inherits from `MessageError` and the built-in `TypeError`.

Since `Message.add_payload()` is deprecated, this exception is rarely raised in practice. However the exception may also be raised if the `attach()` method is called on an instance of a class derived from `MIMENonMultipart` (e.g. `MIMEImage`).

Here is the list of the defects that the `FeedParser` can find while parsing messages. Note that the defects are added to the message where the problem was found, so for example, if a message nested inside a `multipart/alternative` had a malformed header, that nested message object would have a defect, but the containing messages would not.

All defect classes are subclassed from `email.errors.MessageDefect`.

- `NoBoundaryInMultipartDefect` – A message claimed to be a multipart, but had no `boundary` parameter.

- `StartBoundaryNotFoundDefect` – The start boundary claimed in the `Content-Type` header was never found.

- `CloseBoundaryNotFoundDefect` – A start boundary was found, but no corresponding close boundary was ever found.
New in version 3.3.

- **FirstHeaderLineIsContinuationDefect** – The message had a continuation line as its first header line.

- **MisplacedEnvelopeHeaderDefect** - A “Unix From” header was found in the middle of a header block.

- **MissingHeaderBodySeparatorDefect** - A line was found while parsing headers that had no leading white space but contained no ‘:’. Parsing continues assuming that the line represents the first line of the body.

New in version 3.3.

- **MalformedHeaderDefect** – A header was found that was missing a colon, or was otherwise malformed.

  *Deprecated since version 3.3:* This defect has not been used for several Python versions.

- **MultipartInvariantViolationDefect** – A message claimed to be a *multipart*, but no subparts were found. Note that when a message has this defect, its `is_multipart()` method may return false even though its content type claims to be *multipart*.

- **InvalidBase64PaddingDefect** – When decoding a block of base64 encoded bytes, the padding was not correct. Enough padding is added to perform the decode, but the resulting decoded bytes may be invalid.

- **InvalidBase64CharactersDefect** – When decoding a block of base64 encoded bytes, characters outside the base64 alphabet
were encountered. The characters are ignored, but the resulting decoded bytes may be invalid.
19.1. email — An email and MIME handling package
19.1.6. 
email.headerregistry: Custom Header Objects

Source code: Lib/email/headerregistry.py

New in version 3.6: [1]

Headers are represented by customized subclasses of str. The particular class used to represent a given header is determined by the header_factory of the policy in effect when the headers are created. This section documents the particular header_factory implemented by the email package for handling RFC 5322 compliant email messages, which not only provides customized header objects for various header types, but also provides an extension mechanism for applications to add their own custom header types.

When using any of the policy objects derived from EmailPolicy, all headers are produced by HeaderRegistry and have BaseHeader as their last base class. Each header class has an additional base class that is determined by the type of the header. For example, many headers have the class UnstructuredHeader as their other base class. The specialized second class for a header is determined by the name of the header, using a lookup table stored in the HeaderRegistry. All of this is managed transparently for the typical application program, but interfaces are provided for modifying the default behavior for use by more complex applications.

The sections below first document the header base classes and their
attributes, followed by the API for modifying the behavior of `HeaderRegistry`, and finally the support classes used to represent the data parsed from structured headers.

```python
class email.headerregistry.BaseHeader(name, value)
    name and value are passed to BaseHeader from the header_factory call. The string value of any header object is the value fully decoded to unicode.
```

This base class defines the following read-only properties:

**name**

The name of the header (the portion of the field before the ‘:’). This is exactly the value passed in the `header_factory` call for `name`; that is, case is preserved.

**defects**

A tuple of `HeaderDefect` instances reporting any RFC compliance problems found during parsing. The email package tries to be complete about detecting compliance issues. See the `errors` module for a discussion of the types of defects that may be reported.

**max_count**

The maximum number of headers of this type that can have the same `name`. A value of `None` means unlimited. The `BaseHeader` value for this attribute is `None`; it is expected that specialized header classes will override this value as needed.

`BaseHeader` also provides the following method, which is called by the email library code and should not in general be called by application programs:
fold(*, policy)

Return a string containing linesep characters as required to correctly fold the header according to policy. A cte_type of 8bit will be treated as if it were 7bit, since headers may not contain arbitrary binary data. If utf8 is False, non-ASCII data will be RFC 2047 encoded.

BaseHeader by itself cannot be used to create a header object. It defines a protocol that each specialized header cooperates with in order to produce the header object. Specifically, BaseHeader requires that the specialized class provide aclassmethod() named parse. This method is called as follows:

```
parse(string, kwds)
```

kwds is a dictionary containing one pre-initialized key, defects. defects is an empty list. The parse method should append any detected defects to this list. On return, the kwds dictionary must contain values for at least the keys decoded and defects. decoded should be the string value for the header (that is, the header value fully decoded to unicode). The parse method should assume that string may contain content-transfer-encoded parts, but should correctly handle all valid unicode characters as well so that it can parse un-encoded header values.

BaseHeader’s __new__ then creates the header instance, and calls its init method. The specialized class only needs to provide an init method if it wishes to set additional attributes beyond those provided by BaseHeader itself. Such an init method should look like this:
```python
def init(self, *args, **kw):
    self._myattr = kw.pop('myattr')
    super().init(*args, **kw)
```

That is, anything extra that the specialized class puts in to the `kwds` dictionary should be removed and handled, and the remaining contents of `kw` (and `args`) passed to the `BaseHeader init` method.

```python
class email.headerregistry.UnstructuredHeader
```

An “unstructured” header is the default type of header in RFC 5322. Any header that does not have a specified syntax is treated as unstructured. The classic example of an unstructured header is the `Subject` header.

In RFC 5322, an unstructured header is a run of arbitrary text in the ASCII character set. RFC 2047, however, has an RFC 5322 compatible mechanism for encoding non-ASCII text as ASCII characters within a header value. When a `value` containing encoded words is passed to the constructor, the `UnstructuredHeader` parser converts such encoded words into unicode, following the RFC 2047 rules for unstructured text. The parser uses heuristics to attempt to decode certain non-compliant encoded words. Defects are registered in such cases, as well as defects for issues such as invalid characters within the encoded words or the non-encoded text.

This header type provides no additional attributes.

```python
class email.headerregistry.DateHeader
```

RFC 5322 specifies a very specific format for dates within email headers. The `DateHeader` parser recognizes that date format, as well as recognizing a number of variant forms that are sometimes
found “in the wild”.

This header type provides the following additional attributes:

**datetime**

If the header value can be recognized as a valid date of one form or another, this attribute will contain a `datetime` instance representing that date. If the timezone of the input date is specified as -0000 (indicating it is in UTC but contains no information about the source timezone), then `datetime` will be a naive `datetime`. If a specific timezone offset is found (including +0000), then `datetime` will contain an aware `datetime` that uses `datetime.timezone` to record the timezone offset.

The decoded value of the header is determined by formatting the `datetime` according to the RFC 5322 rules; that is, it is set to:

```python
email.utils.format_datetime(self.datetime)
```

When creating a `DateHeader`, `value` may be `datetime` instance. This means, for example, that the following code is valid and does what one would expect:

```python
msg['Date'] = datetime(2011, 7, 15, 21)
```

Because this is a naive `datetime` it will be interpreted as a UTC timestamp, and the resulting value will have a timezone of -0000. Much more useful is to use the `localtime()` function from the `utils` module:

```python
msg['Date'] = utils.localtime()
```
This example sets the date header to the current time and date using the current timezone offset.

```python
class email.headerregistry.AddressHeader
```

Address headers are one of the most complex structured header types. The `AddressHeader` class provides a generic interface to any address header.

This header type provides the following additional attributes:

**groups**

A tuple of `Group` objects encoding the addresses and groups found in the header value. Addresses that are not part of a group are represented in this list as single-address `Groups` whose `display_name` is `None`.

**addresses**

A tuple of `Address` objects encoding all of the individual addresses from the header value. If the header value contains any groups, the individual addresses from the group are included in the list at the point where the group occurs in the value (that is, the list of addresses is “flattened” into a one dimensional list).

The decoded value of the header will have all encoded words decoded to unicode. `idna` encoded domain names are also decoded to unicode. The decoded value is set by joining the `str` value of the elements of the `groups` attribute with `', '`.

A list of `Address` and `Group` objects in any combination may be used to set the value of an address header. `Group` objects whose `display_name` is `None` will be interpreted as single addresses,
which allows an address list to be copied with groups intact by using the list obtained from the `groups` attribute of the source header.

```python
class email.headerregistry.SingleAddressHeader
```
A subclass of `AddressHeader` that adds one additional attribute:

```python
address
```
The single address encoded by the header value. If the header value actually contains more than one address (which would be a violation of the RFC under the default `policy`), accessing this attribute will result in a `ValueError`.

Many of the above classes also have a `Unique` variant (for example, `UniqueUnstructuredHeader`). The only difference is that in the `Unique` variant, `max_count` is set to 1.

```python
class email.headerregistry.MIMEVersionHeader
```
There is really only one valid value for the `MIME-Version` header, and that is 1.0. For future proofing, this header class supports other valid version numbers. If a version number has a valid value per RFC 2045, then the header object will have non-None values for the following attributes:

```python
version
```
The version number as a string, with any whitespace and/or comments removed.

```python
major
```
The major version number as an integer.

```python
minor
```
The minor version number as an integer.
**ParameterizedMIMEHeader**

MIME headers all start with the prefix ‘Content-‘. Each specific header has a certain value, described under the class for that header. Some can also take a list of supplemental parameters, which have a common format. This class serves as a base for all the MIME headers that take parameters.

**params**

A dictionary mapping parameter names to parameter values.

**ContentTypeHeader**

A ParameterizedMIMEHeader class that handles the Content-Type header.

**content_type**

The content type string, in the form maintype/subtype.

**maintype**

**subtype**

**ContentDispositionHeader**

A ParameterizedMIMEHeader class that handles the Content-Disposition header.

**content-disposition**

inline and attachment are the only valid values in common use.

**ContentTransferEncoding**

Handles the Content-Transfer-Encoding header.

**cte**
Valid values are 7bit, 8bit, base64, and quoted-printable. See RFC 2045 for more information.

class email.headerregistry/HeaderRegistry(base_class=BaseHeader, default_class=UnstructuredHeader, use_default_map=True)
This is the factory used by EmailPolicy by default. HeaderRegistry builds the class used to create a header instance dynamically, using base_class and a specialized class retrieved from a registry that it holds. When a given header name does not appear in the registry, the class specified by default_class is used as the specialized class. When use_default_map is True (the default), the standard mapping of header names to classes is copied in to the registry during initialization. base_class is always the last class in the generated class's __bases__ list.

The default mappings are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>subject</td>
<td>UniqueUnstructuredHeader</td>
</tr>
<tr>
<td>date</td>
<td>UniqueDateHeader</td>
</tr>
<tr>
<td>resent-date</td>
<td>DateHeader</td>
</tr>
<tr>
<td>orig-date</td>
<td>UniqueDateHeader</td>
</tr>
<tr>
<td>sender</td>
<td>UniqueSingleAddressHeader</td>
</tr>
<tr>
<td>resent-sender</td>
<td>SingleAddressHeader</td>
</tr>
<tr>
<td>to</td>
<td>UniqueAddressHeader</td>
</tr>
<tr>
<td>resent-to</td>
<td>AddressHeader</td>
</tr>
<tr>
<td>cc</td>
<td>UniqueAddressHeader</td>
</tr>
<tr>
<td>resent-cc</td>
<td>AddressHeader</td>
</tr>
<tr>
<td>from</td>
<td>UniqueAddressHeader</td>
</tr>
</tbody>
</table>
HeaderRegistry has the following methods:

**map_to_type**(*self, name, cls*)

*name* is the name of the header to be mapped. It will be converted to lower case in the registry. *cls* is the specialized class to be used, along with *base_class*, to create the class used to instantiate headers that match *name*.

**__getitem__**(name)

Construct and return a class to handle creating a *name* header.

**__call__**(name, value)

Retrieves the specialized header associated with *name* from the registry (using *default_class* if *name* does not appear in the registry) and composes it with *base_class* to produce a class, calls the constructed class’s constructor, passing it the same argument list, and finally returns the class instance created thereby.

The following classes are the classes used to represent data parsed from structured headers and can, in general, be used by an application program to construct structured values to assign to specific headers.

```python
class email.headerregistry.Address(display_name='', username='', domain='', addr_spec=None)
```

The class used to represent an email address. The general form of an address is:

```
[display_name] <username@domain>
```
or:

```plaintext
username@domain
```

where each part must conform to specific syntax rules spelled out in RFC 5322.

As a convenience `addr_spec` can be specified instead of `username` and `domain`, in which case `username` and `domain` will be parsed from the `addr_spec`. An `addr_spec` must be a properly RFC quoted string; if it is not `Address` will raise an error. Unicode characters are allowed and will be properly encoded when serialized. However, per the RFCs, unicode is *not* allowed in the username portion of the address.

**display_name**

The display name portion of the address, if any, with all quoting removed. If the address does not have a display name, this attribute will be an empty string.

**username**

The `username` portion of the address, with all quoting removed.

**domain**

The `domain` portion of the address.

**addr_spec**

The `username@domain` portion of the address, correctly quoted for use as a bare address (the second form shown above). This attribute is not mutable.

```python
__str__()
```
The `str` value of the object is the address quoted according to RFC 5322 rules, but with no Content Transfer Encoding of any non-ASCII characters.

To support SMTP (RFC 5321), Address handles one special case: if username and domain are both the empty string (or None), then the string value of the Address is <>.

```python
class email.headerregistry.Group:
    def __init__(self, display_name=None, addresses=None):
        self.display_name = display_name
        self.addresses = addresses

    def __str__(self):
        return self.display_name + ': [' + '; '.join(self.addresses) + '];
```

As a convenience for processing lists of addresses that consist of a mixture of groups and single addresses, a Group may also be used to represent single addresses that are not part of a group by setting `display_name` to None and providing a list of the single address as `addresses`.

**display_name**

The `display_name` of the group. If it is None and there is exactly one Address in `addresses`, then the Group represents a single address that is not in a group.

**addresses**

A possibly empty tuple of Address objects representing the addresses in the group.

__str__(self)

The `str` value of a Group is formatted according to RFC 5322,
but with no Content Transfer Encoding of any non-ASCII characters. If `display_name` is none and there is a single `Address` in the `addresses` list, the `str` value will be the same as the `str` of that single `Address`.

### Footnotes

[1] Originally added in 3.3 as a **provisional module**
19. Internet Data Handling

19.1. `email` — An email and MIME handling package
19.1.7. \texttt{email.contentmanager}: Managing MIME Content

Source code: Lib/email/contentmanager.py

\textit{New in version 3.6: }[1]

\texttt{class email.contentmanager.ContentManager}

Base class for content managers. Provides the standard registry mechanisms to register converters between MIME content and other representations, as well as the \texttt{get\_content} and \texttt{set\_content} dispatch methods.

\texttt{get\_content}(\texttt{msg}, *\texttt{args}, **\texttt{kw})

Look up a handler function based on the \texttt{mimetype} of \texttt{msg} (see next paragraph), call it, passing through all arguments, and return the result of the call. The expectation is that the handler will extract the payload from \texttt{msg} and return an object that encodes information about the extracted data.

To find the handler, look for the following keys in the registry, stopping with the first one found:

- the string representing the full MIME type (maintype/subtype)
- the string representing the maintype
- the empty string
If none of these keys produce a handler, raise a `KeyError` for the full MIME type.

**set_content**(msg, obj, *args, **kw)

If the maintype is `multipart`, raise a `TypeError`; otherwise look up a handler function based on the type of `obj` (see next paragraph), call `clear_content()` on the `msg`, and call the handler function, passing through all arguments. The expectation is that the handler will transform and store `obj` into `msg`, possibly making other changes to `msg` as well, such as adding various MIME headers to encode information needed to interpret the stored data.

To find the handler, obtain the type of `obj` (`typ = type(obj)`), and look for the following keys in the registry, stopping with the first one found:

- the type itself (`typ`)
- the type's fully qualified name (`typ.__module__ + '.' + typ.__qualname__`).
- the type's qualname (`typ.__qualname__`)
- the type's name (`typ.__name__`).

If none of the above match, repeat all of the checks above for each of the types in the MRO (`typ.__mro__`). Finally, if no other key yields a handler, check for a handler for the key `None`. If there is no handler for `None`, raise a `KeyError` for the fully qualified name of the type.

Also add a `MIME-Version` header if one is not present (see also `MIMEPart`).

**add_get_handler**(key, handler)
Record the function \textit{handler} as the handler for \textit{key}. For the possible values of \textit{key}, see \texttt{get\_content}().

\textbf{add\_set\_handler}(\texttt{typekey, handler})

Record \textit{handler} as the function to call when an object of a type matching \texttt{typekey} is passed to \texttt{set\_content}(). For the possible values of \texttt{typekey}, see \texttt{set\_content}().
19.1.7.1. Content Manager Instances

Currently the email package provides only one concrete content manager, `raw_data_manager`, although more may be added in the future. `raw_data_manager` is the `content_manager` provided by `EmailPolicy` and its derivatives.

`email.contentmanager.raw_data_manager`

This content manager provides only a minimum interface beyond that provided by `Message` itself: it deals only with text, raw byte strings, and `Message` objects. Nevertheless, it provides significant advantages compared to the base API: `get_content` on a text part will return a unicode string without the application needing to manually decode it, `set_content` provides a rich set of options for controlling the headers added to a part and controlling the content transfer encoding, and it enables the use of the various `add_` methods, thereby simplifying the creation of multipart messages.

`email.contentmanager.get_content(msg, errors='replace')`

Return the payload of the part as either a string (for text parts), an `EmailMessage` object (for `message/rfc822` parts), or a bytes object (for all other non-multipart types). Raise a `KeyError` if called on a multipart. If the part is a text part and `errors` is specified, use it as the error handler when decoding the payload to unicode. The default error handler is `replace`.

`email.contentmanager.set_content(msg, 
<str>,
subtype="plain", charset='utf-8' cte=None, disposition=None,
Add headers and payload to `msg`:

Add a `Content-Type` header with a `maintype/subtype` value.

- For `str`, set the MIME maintype to `text`, and set the subtype to `subtype` if it is specified, or `plain` if it is not.
- For `bytes`, use the specified `maintype` and `subtype`, or raise a `TypeError` if they are not specified.
- For `EmailMessage` objects, set the maintype to message, and set the subtype to `subtype` if it is specified or `rfc822` if it is not. If `subtype` is partial, raise an error (bytes objects must be used to construct `message/partial` parts).
- For `<list>`, which should be a list of `EmailMessage` objects, set the maintype to `multipart`, and the subtype to `subtype` if it is specified, and `mixed` if it is not. If the message parts in the `<list>` have `MIME-Version` headers, remove them.

If `charset` is provided (which is valid only for `str`), encode the string to bytes using the specified character set. The default is `utf-8`. If the specified `charset` is a known alias for a standard
MIME charset name, use the standard charset instead.

If `cte` is set, encode the payload using the specified content transfer encoding, and set the `Content-Transfer-Encoding` header to that value. Possible values for `cte` are `quoted-printable`, `base64`, `7bit`, `8bit`, and `binary`. If the input cannot be encoded in the specified encoding (for example, specifying a `cte` of `7bit` for an input that contains non-ASCII values), raise a `ValueError`.

- For `str` objects, if `cte` is not set use heuristics to determine the most compact encoding.
- For `EmailMessage`, per RFC 2046, raise an error if a `cte` of `quoted-printable` or `base64` is requested for `subtype rfc822`, and for any `cte` other than `7bit` for `subtype external-body`. For `message/rfc822`, use `8bit` if `cte` is not specified. For all other values of `subtype`, use `7bit`.

**Note:** A `cte` of `binary` does not actually work correctly yet. The `EmailMessage` object as modified by `set_content` is correct, but `BytesGenerator` does not serialize it correctly.

If `disposition` is set, use it as the value of the `Content-Disposition` header. If not specified, and `filename` is specified, add the header with the value `attachment`. If `disposition` is not specified and `filename` is also not specified, do not add the header. The only valid values for `disposition` are `attachment` and `inline`.

If `filename` is specified, use it as the value of the `filename` parameter of the `Content-Disposition` header.
If `cid` is specified, add a `Content-ID` header with `cid` as its value.

If `params` is specified, iterate its `items` method and use the resulting `(key, value)` pairs to set additional parameters on the `Content-Type` header.

If `headers` is specified and is a list of strings of the form `headername: headervalue` or a list of `header` objects (distinguished from strings by having a `name` attribute), add the headers to `msg`.

**Footnotes**

[1] Originally added in 3.4 as a provisional module
19.1. **email** — An email and MIME handling package

---

Python » 3.7.0b1 Documentation » The Python Standard Library » 19. Internet Data Handling » 19.1. email — An email and MIME handling package »
19.1.8. **email**: Examples

Here are a few examples of how to use the `email` package to read, write, and send simple email messages, as well as more complex MIME messages.

First, let's see how to create and send a simple text message (both the text content and the addresses may contain unicode characters):

```python
# Import smtplib for the actual sending function
import smtplib

# Import the email modules we'll need
from email.message import EmailMessage

# Open the plain text file whose name is in textfile
with open(textfile) as fp:
    # Create a text/plain message
    msg = EmailMessage()
    msg.set_content(fp.read())

# me == the sender's email address
# you == the recipient's email address
msg['Subject'] = 'The contents of %s' % textfile
msg['From'] = me
msg['To'] = you

# Send the message via our own SMTP server.
s = smtplib.SMTP('localhost')
s.send_message(msg)
s.quit()
```

Parsing RFC822 headers can easily be done by the using the classes
from the **parser** module:

```python
# Import the email modules we'll need
from email.parser import BytesParser, Parser
from email.policy import default

# If the e-mail headers are in a file, uncomment these two lines:
# with open(messagefile, 'rb') as fp:
#     headers = BytesParser(policy=default).parse(fp)

# Or for parsing headers in a string (this is an uncommon operation), use:
headers = Parser(policy=default).parsestr('From: Foo Bar <user@example.com>
  'To: <someone_else@example.com>
  'Subject: Test message
  '
  'Body would go here')

# Now the header items can be accessed as a dictionary:
print('To: {}'.format(headers['to']))
print('From: {}'.format(headers['from']))
print('Subject: {}'.format(headers['subject']))

# You can also access the parts of the addresses:
print('Recipient username: {}'.format(headers['to'][1]))
print('Sender name: {}'.format(headers['from'].addresses[0]))
```
Here are the email package modules we'll need:

```python
from email.message import EmailMessage
```

Create the container email message:

```python
msg = EmailMessage()
msg['Subject'] = 'Our family reunion'
```

me == the sender's email address

```python
msg['From'] = me
```

family = the list of all recipients' email addresses

```python
msg['To'] = ',', join(family)
```

```python
msg.preamble = 'Our family reunion'
```

Open the files in binary mode. Use imghdr to figure MIME subtype for each specific image:

```python
for file in pngfiles:
    with open(file, 'rb') as fp:
        img_data = fp.read()
        msg.add_attachment(img_data, maintype='image', subtype=imghdr.what)
```

Send the email via our own SMTP server:

```python
with smtplib.SMTP('localhost') as s:
    s.send_message(msg)
```

Here’s an example of how to send the entire contents of a directory as an email message: [1]
from argparse import ArgumentParser
from email.message import EmailMessage
from email.policy import SMTP

def main():
    parser = ArgumentParser(description="Send the contents of a directory as a MIME message. Unless the -o option is given, the email is sent by your local SMTP server, which then does the normal delivery process. Your local machine must be running an SMTP server.
"")
    parser.add_argument('-d', '--directory',
                        help="Mail the contents of the specified directory, otherwise use the current directory. Only the regular files in the directory are sent, and we don't recurse to subdirectories.
"")
    parser.add_argument('-o', '--output',
                        metavar='FILE',
                        help="Print the composed message to FILE instead of sending the message to the SMTP server.
"")
    parser.add_argument('-s', '--sender', required=True,
                        help='The value of the From: header (required)
"")
    parser.add_argument('-r', '--recipient', required=True,
                        action='append', metavar='RECIPIENT',
                        default=[], dest='recipients',
                        help='A To: header value (at least one required)
"")

    args = parser.parse_args()
directory = args.directory
    if not directory:
        directory = '.'
    # Create the message
    msg = EmailMessage()
    msg['Subject'] = 'Contents of directory %s' % os
    msg['To'] = ', '.join(args.recipients)
    msg['From'] = args.sender

if __name__ == '__main__':
    main()
'''Unpack a MIME message into a directory of files.'''

```python
import os
import email
import mimetypes

from email.policy import default

from argparse import ArgumentParser

def main():
    parser = ArgumentParser(description='''
Unpack a MIME message into a directory of files.
'''
    )
    parser.add_argument('-d', '--directory', required=True,
                        help='''Unpack the MIME message into the named directory, which will be created if it doesn't already exist.'''
                        )
    parser.add_argument('msgfile')
    args = parser.parse_args()

    with open(args.msgfile, 'rb') as fp:
        msg = email.message_from_binary_file(fp, policy=default)

    try:
        os.mkdir(args.directory)
    except FileExistsError:
        pass

    counter = 1
    for part in msg.walk():
        # multipart/* are just containers
        if part.get_content_maintype() == 'multipart'
            continue
        # Applications should really sanitize the given
```
Here's an example of how to create an HTML message with an alternative plain text version. To make things a bit more interesting, we include a related image in the html part, and we save a copy of what we are going to send to disk, as well as sending it.

```
#!/usr/bin/env python3

import smtplib
from email.message import EmailMessage
from email.headerregistry import Address
from email.utils import make_msgid

# Create the base text message.
msg = EmailMessage()
msg['Subject'] = "Ayons asperges pour le déjeuner"
msg['From'] = Address("Pepé Le Pew", "pepe", "example.com")
msg['To'] = (Address("Penelope Pussycat", "penelope"), Address("Fabrette Pussycat", "fabrette"))
msg.set_content("\n")
```

```python
#email message can't be used to overwrite if not filename:
    ext = mimetypes.guess_extension(part.get_content_type())
if not ext:
    # Use a generic bag-of-bits extension
    ext = '.bin'
filename = 'part-%03d%s' % (counter, ext)
counter += 1
with open(os.path.join(args.directory, filename)) as fp:
    fp.write(part.get_payload(decode=True))
```

```python
if __name__ == '__main__':
    main()
```
Salut!

--Pepé

""

# Add the html version. This converts the message into a multipart/alternative container, with the original text message as the first part and the html message as the second part.

asparagus_cid = make_msgid()

msg.add_alternative(""
<html>
<head></head>
<body>
<p>Salut!</p>
<p>Cela ressemble à un excellent recipie</p>
</body>
<img src="cid:{asparagus_cid}" />
</body>
</html>
"".format(asparagus_cid=asparagus_cid[1:-1]), subtype

# note that we needed to peel the <> off the msgid for use in the html.

# Now add the related image to the html part.

with open("roasted-asparagus.jpg", 'rb') as img:
    msg.get_payload()[1].add_related(img.read(), 'image', cid=asparagus_cid)

# Make a local copy of what we are going to send.

with open('outgoing.msg', 'wb') as f:
    f.write(bytes(msg))
Send the message via local SMTP server.

```python
with smtplib.SMTP('localhost') as s:
    s.send_message(msg)
```

If we were sent the message from the last example, here is one way we could process it:

```python
import os
import sys
import tempfile
import mimetypes
import webbrowser

# Import the email modules we'll need
from email import policy
from email.parser import BytesParser

# An imaginary module that would make this work and
from imaginary import magic_html_parser

# In a real program you'd get the filename from the
with open('outgoing.msg', 'rb') as fp:
    msg = BytesParser(policy=policy.default).parse(fp)

# Now the header items can be accessed as a dictionary,
# be converted to unicode:
print('To:', msg['to'])
print('From:', msg['from'])
print('Subject:', msg['subject'])

# If we want to print a preview of the message content
# the least formatted payload is and print the first
# if the message has no plain text part printing the
# is probably useless, but this is just a conceptual
simplest = msg.get_body(preferencelist=('plain', 'html'))
```
print()
print(''.join(simplest.get_content().splitlines(keepends=True)).join(["

ans = input("View full message?")
if ans.lower()[0] == 'n':
    sys.exit()

# We can extract the richest alternative in order to display it:
richest = msg.get_body()
partfiles = {}
if richest['content-type'].maintype == 'text':
    if richest['content-type'].subtype == 'plain':
        for line in richest.get_content().splitlines():
            print(line)
    sys.exit()
elif richest['content-type'].subtype == 'html':
    body = richest
else:
    print("Don't know how to display {}".format(richest))
    sys.exit()
elif richest['content-type'].content_type == 'multipart/related':
    body = richest.get_body(preferencelist=('[html]'))
for part in richest.iter_attachments():
    fn = part.get_filename()
    if fn:
        extension = os.path.splitext(part.get_filename())
    else:
        extension = mimetypes.guess_extension(part)
with tempfile.NamedTemporaryFile(suffix=extension, delete=False) as f:
    f.write(part.get_content())
    # again strip the <> to go from email for...
    partfiles[part['content-id'][1:-1]] = f
else:
    print("Don't know how to display {}".format(richest))
    sys.exit()

with tempfile.NamedTemporaryFile(mode='w', delete=False) as f:
    # The magic_html_parser has to rewrite the href="cid:...." attributes...
    
  
    
  
    
  
"

19.1.9.

email.message.Message: Representing an email message using the compat32 API

The Message class is very similar to the EmailMessage class, without the methods added by that class, and with the default behavior of certain other methods being slightly different. We also document here some methods that, while supported by the EmailMessage class, are not recommended unless you are dealing with legacy code.

The philosophy and structure of the two classes is otherwise the same.

This document describes the behavior under the default (for Message) policy Compat32. If you are going to use another policy, you should be using the EmailMessage class instead.

An email message consists of headers and a payload. Headers must be RFC 5233 style names and values, where the field name and value are separated by a colon. The colon is not part of either the field name or the field value. The payload may be a simple text message, or a binary object, or a structured sequence of sub-messages each with their own set of headers and their own payload. The latter type of payload is indicated by the message having a MIME type such as multipart/* or message/rfc822.

The conceptual model provided by a Message object is that of an ordered dictionary of headers with additional methods for accessing
both specialized information from the headers, for accessing the payload, for generating a serialized version of the message, and for recursively walking over the object tree. Note that duplicate headers are supported but special methods must be used to access them.

The Message pseudo-dictionary is indexed by the header names, which must be ASCII values. The values of the dictionary are strings that are supposed to contain only ASCII characters; there is some special handling for non-ASCII input, but it doesn’t always produce the correct results. Headers are stored and returned in case-preserving form, but field names are matched case-insensitively. There may also be a single envelope header, also known as the Unix-From header or the From header. The payload is either a string or bytes, in the case of simple message objects, or a list of Message objects, for MIME container documents (e.g. multipart/* and message/rfc822).

Here are the methods of the Message class:

class email.message.Message(policy=compat32)

If policy is specified (it must be an instance of a policy class) use the rules it specifies to update and serialize the representation of the message. If policy is not set, use the compat32 policy, which maintains backward compatibility with the Python 3.2 version of the email package. For more information see the policy documentation.

Changed in version 3.3: The policy keyword argument was added.

as_string(unixfrom=False, maxheaderlen=0, policy=None)

Return the entire message flattened as a string. When optional unixfrom is true, the envelope header is included in the returned string. unixfrom defaults to False. For backward compatibility
reasons, `maxheaderlen` defaults to 0, so if you want a different value you must override it explicitly (the value specified for `max_line_length` in the policy will be ignored by this method). The policy argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified `policy` will be passed to the `Generator`.

Flattening the message may trigger changes to the `Message` if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it does not do the mangling of lines that begin with `From` that is required by the unix mailbox format. For more flexibility, instantiate a `Generator` instance and use its `flatten()` method directly. For example:

```python
from io import StringIO
from email.generator import Generator
fp = StringIO()
g = Generator(fp, mangle_from_=True, maxheaderlen)
g.flatten(msg)
text = fp.getvalue()
```

If the message object contains binary data that is not encoded according to RFC standards, the non-compliant data will be replaced by unicode “unknown character” code points. (See also `as_bytes()` and `BytesGenerator`.)
Changed in version 3.4: the policy keyword argument was added.

```
__str__(
  Equivalent to as_string(). Allows str(msg) to produce a string containing the formatted message.

as_bytes(unixfrom=False, policy=None)
  Return the entire message flattened as a bytes object. When optional unixfrom is true, the envelope header is included in the returned string. unixfrom defaults to False. The policy argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified policy will be passed to the BytesGenerator.

  Flattening the message may trigger changes to the Message if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

  Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it does not do the mangling of lines that begin with From that is required by the unix mbox format. For more flexibility, instantiate a BytesGenerator instance and use its flatten() method directly. For example:
```

```python
from io import BytesIO
from email.generator import BytesGenerator
fp = BytesIO()
g = BytesGenerator(fp, mangle_from_=True, maxhe
```
text = fp.getvalue()

New in version 3.4.

_bytes__()
Equivalent to \texttt{as\_bytes()}\texttt{}. Allows \texttt{bytes(msg)} to produce a bytes object containing the formatted message.

New in version 3.4.

\texttt{is\_multipart}()
Return \texttt{True} if the message's payload is a list of \texttt{Message} objects, otherwise return \texttt{False}. When \texttt{is\_multipart()} returns \texttt{False}, the payload should be a string object (which might be a CTE encoded binary payload. (Note that \texttt{is\_multipart()} returning \texttt{True} does not necessarily mean that \texttt{msg.get\_content\_maintype()} == \texttt{'multipart'” will return the \texttt{True}. For example, \texttt{is\_multipart} will return \texttt{True} when the \texttt{Message} is of type message/rfc822.)

\texttt{set\_unixfrom}(\texttt{unixfrom})
Set the message's envelope header to \texttt{unixfrom}, which should be a string.

\texttt{get\_unixfrom}()
Return the message's envelope header. Defaults to \texttt{None} if the envelope header was never set.

\texttt{attach}(\texttt{payload})
Add the given \texttt{payload} to the current payload, which must be \texttt{None} or a list of \texttt{Message} objects before the call. After the call, the payload will always be a list of \texttt{Message} objects. If you
want to set the payload to a scalar object (e.g. a string), use \texttt{set\_payload()} instead.

This is a legacy method. On the \texttt{EmailMessage} class its functionality is replaced by \texttt{set\_content()} and the related \texttt{make} and \texttt{add} methods.

\textbf{get\_payload}(i=None, decode=False)

Return the current payload, which will be a list of \texttt{Message} objects when \texttt{is\_multipart()} is \texttt{True}, or a string when \texttt{is\_multipart()} is \texttt{False}. If the payload is a list and you mutate the list object, you modify the message's payload in place.

With optional argument \texttt{i}, \texttt{get\_payload()} will return the \texttt{i}-th element of the payload, counting from zero, if \texttt{is\_multipart()} is \texttt{True}. An \texttt{IndexError} will be raised if \texttt{i} is less than 0 or greater than or equal to the number of items in the payload. If the payload is a string (i.e. \texttt{is\_multipart()} is \texttt{False}) and \texttt{i} is given, a \texttt{TypeError} is raised.

Optional \texttt{decode} is a flag indicating whether the payload should be decoded or not, according to the \texttt{Content-Transfer-Encoding} header. When \texttt{True} and the message is not a multipart, the payload will be decoded if this header's value is \texttt{quoted-printable} or \texttt{base64}. If some other encoding is used, or \texttt{Content-Transfer-Encoding} header is missing, the payload is returned as-is (undecoded). In all cases the returned value is binary data. If the message is a multipart and the \texttt{decode} flag is \texttt{True}, then \texttt{None} is returned. If the payload is base64 and it was not perfectly formed (missing padding, characters outside the base64 alphabet), then an appropriate defect will be added.
to the message's defect property (InvalidBase64PaddingDefect or InvalidBase64CharactersDefect, respectively).

When `decode` is False (the default) the body is returned as a string without decoding the `Content-Transfer-Encoding`. However, for a `Content-Transfer-Encoding` of 8bit, an attempt is made to decode the original bytes using the `charset` specified by the `Content-Type` header, using the `replace` error handler. If no `charset` is specified, or if the `charset` given is not recognized by the email package, the body is decoded using the default ASCII charset.

This is a legacy method. On the `EmailMessage` class its functionality is replaced by `get_content()` and `iter_parts()`.

**set_payload**(payload, charset=None)

Set the entire message object's payload to `payload`. It is the client's responsibility to ensure the payload invariants. Optional `charset` sets the message's default character set; see `set_charset()` for details.

This is a legacy method. On the `EmailMessage` class its functionality is replaced by `set_content()`.

**set_charset**(charset)

Set the character set of the payload to `charset`, which can either be a `Charset` instance (see `email.charset`), a string naming a character set, or None. If it is a string, it will be converted to a `Charset` instance. If `charset` is None, the `charset` parameter will be removed from the `Content-Type`
header (the message will not be otherwise modified). Anything else will generate a `TypeError`.

If there is no existing `MIME-Version` header one will be added. If there is no existing `Content-Type` header, one will be added with a value of `text/plain`. Whether the `Content-Type` header already exists or not, its `charset` parameter will be set to `charset.output_charset`. If `charset.input_charset` and `charset.output_charset` differ, the payload will be re-encoded to the `output_charset`. If there is no existing `Content-Transfer-Encoding` header, then the payload will be transfer-encoded, if needed, using the specified `Charset`, and a header with the appropriate value will be added. If a `Content-Transfer-Encoding` header already exists, the payload is assumed to already be correctly encoded using that `Content-Transfer-Encoding` and is not modified.

This is a legacy method. On the `EmailMessage` class its functionality is replaced by the `charset` parameter of the `email.emailmessage.EmailMessage.set_content()` method.

`get_charset()`

Return the `Charset` instance associated with the message’s payload.

This is a legacy method. On the `EmailMessage` class it always returns `None`.

The following methods implement a mapping-like interface for accessing the message’s `RFC 2822` headers. Note that there are some semantic differences between these methods and a normal
mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by `keys()`, but in a `Message` object, headers are always returned in the order they appeared in the original message, or were added to the message later. Any header deleted and then re-added are always appended to the end of the header list.

These semantic differences are intentional and are biased toward maximal convenience.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

In a model generated from bytes, any header values that (in contravention of the RFCs) contain non-ASCII bytes will, when retrieved through this interface, be represented as `Header` objects with a charset of `unknown-8bit`.

`__len__()`

Return the total number of headers, including duplicates.

`__contains__(name)`

Return true if the message object has a field named `name`. Matching is done case-insensitively and `name` should not include the trailing colon. Used for the `in` operator, e.g.:

```python
if 'message-id' in myMessage:
    print('Message-ID:', myMessage['message-id'])
```

`__getitem__(name)`
Return the value of the named header field. *name* should not include the colon field separator. If the header is missing, None is returned; a *KeyError* is never raised.

Note that if the named field appears more than once in the message’s headers, exactly which of those field values will be returned is undefined. Use the *get_all()* method to get the values of all the extant named headers.

**__setitem__**(name, val)

Add a header to the message with field name *name* and value *val*. The field is appended to the end of the message’s existing fields.

Note that this does *not* overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name *name*, delete the field first, e.g.:

```python
del msg['subject']
msg['subject'] = 'Python roolz!'```

**__delitem__**(name)

Delete all occurrences of the field with name *name* from the message’s headers. No exception is raised if the named field isn’t present in the headers.

**keys()**

Return a list of all the message’s header field names.

**values()**

Return a list of all the message’s field values.
items()
Return a list of 2-tuples containing all the message's field headers and values.

get(name, failobj=None)
Return the value of the named header field. This is identical to __getitem__() except that optional failobj is returned if the named header is missing (defaults to None).

Here are some additional useful methods:

get_all(name, failobj=None)
Return a list of all the values for the field named name. If there are no such named headers in the message, failobj is returned (defaults to None).

add_header(_name, _value, **_params)
Extended header setting. This method is similar to __setitem__() except that additional header parameters can be provided as keyword arguments. _name is the header field to add and _value is the primary value for the header.

For each item in the keyword argument dictionary _params, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as key="value" unless the value is None, in which case only the key will be added. If the value contains non-ASCII characters, it can be specified as a three tuple in the format (CHARSET, LANGUAGE, VALUE), where CHARSET is a string naming the charset to be used to encode the value, LANGUAGE can usually be set to None or the empty string (see RFC 2231
for other possibilities), and VALUE is the string value containing non-ASCII code points. If a three tuple is not passed and the value contains non-ASCII characters, it is automatically encoded in RFC 2231 format using a CHARSET of utf-8 and a LANGUAGE of None.

Here's an example:

```python
gmail_msg.add_header('Content-Disposition', 'attachment', filename='bud.gif')
```

This will add a header that looks like

```text
Content-Disposition: attachment; filename="bud.gif"
```

An example with non-ASCII characters:

```python
gmail_msg.add_header('Content-Disposition', 'attachment', filename=('iso-8859-1', '', 'Fußballer.ppt'))
```

Which produces

```text
Content-Disposition: attachment; filename*="iso-8859-1''Fu%DFballer.ppt"
```

**replace_header**(_name,_value)

Replace a header. Replace the first header found in the message that matches _name, retaining header order and field name case. If no matching header was found, a **KeyError** is raised.

**get_content_type()**

Return the message's content type. The returned string is
coerced to lower case of the form maintype/subtype. If there was no Content-Type header in the message the default type as given by get_default_type() will be returned. Since according to RFC 2045, messages always have a default type, get_content_type() will always return a value.

RFC 2045 defines a message’s default type to be text/plain unless it appears inside a multipart/digest container, in which case it would be message/rfc822. If the Content-Type header has an invalid type specification, RFC 2045 mandates that the default type be text/plain.

get_content_maintype()
Return the message’s main content type. This is the maintype part of the string returned by get_content_type().

get_content_subtype()
Return the message’s sub-content type. This is the subtype part of the string returned by get_content_type().

get_default_type()
Return the default content type. Most messages have a default content type of text/plain, except for messages that are subparts of multipart/digest containers. Such subparts have a default content type of message/rfc822.

set_default_type(ctype)
Set the default content type. ctype should either be text/plain or message/rfc822, although this is not enforced. The default content type is not stored in the Content-Type header.

get_params(failobj=None, header='content-type', unquote=True)
Return the message's **Content-Type** parameters, as a list. The elements of the returned list are 2-tuples of key/value pairs, as split on the '==' sign. The left hand side of the '==' is the key, while the right hand side is the value. If there is no '==' sign in the parameter the value is the empty string, otherwise the value is as described in `get_param()` and is unquoted if optional `unquote` is `True` (the default).

Optional `failobj` is the object to return if there is no **Content-Type** header. Optional `header` is the header to search instead of **Content-Type**.

This is a legacy method. On the `EmailMessage` class its functionality is replaced by the `params` property of the individual header objects returned by the header access methods.

```python
get_param(param, failobj=None, header='content-type', unquote=True)
```

Return the value of the **Content-Type** header's parameter `param` as a string. If the message has no **Content-Type** header or if there is no such parameter, then `failobj` is returned (defaults to `None`).

Optional `header` if given, specifies the message header to use instead of **Content-Type**.

Parameter values are always compared case insensitivity. The return value can either be a string, or a 3-tuple if the parameter was **RFC 2231** encoded. When it's a 3-tuple, the elements of the value are of the form `(CHARSET, LANGUAGE, VALUE)`. Note that both CHARSET and LANGUAGE can be `None`, in which case you should consider VALUE to be encoded in the us-
ascii charset. You can usually ignore LANGUAGE.

If your application doesn’t care whether the parameter was encoded as in RFC 2231, you can collapse the parameter value by calling email.utils.collapse_rfc2231_value(), passing in the return value from get_param(). This will return a suitably decoded Unicode string when the value is a tuple, or the original string unquoted if it isn’t. For example:

```
rawparam = msg.get_param('foo')
param = email.utils.collapse_rfc2231_value(rawparam)
```

In any case, the parameter value (either the returned string, or the VALUE item in the 3-tuple) is always unquoted, unless unquote is set to False.

This is a legacy method. On the EmailMessage class its functionality is replaced by the params property of the individual header objects returned by the header access methods.

```
def set_param(self, param, value, header='Content-Type', requote=True, charset=None, language='', replace=False):
    '''Set a parameter in the Content-Type header. If the parameter already exists in the header, its value will be replaced with value. If the Content-Type header as not yet been defined for this message, it will be set to text/plain and the new parameter value will be appended as per RFC 2045.

    Optional header specifies an alternative header to Content-Type, and all parameters will be quoted as necessary unless optional requote is False (the default is True).'''
```

If optional \texttt{charset} is specified, the parameter will be encoded according to \texttt{RFC 2231}. Optional \texttt{language} specifies the RFC 2231 language, defaulting to the empty string. Both \texttt{charset} and \texttt{language} should be strings.

If \texttt{replace} is \texttt{False} (the default) the header is moved to the end of the list of headers. If \texttt{replace} is \texttt{True}, the header will be updated in place.

\textit{Changed in version 3.4:} \texttt{replace} keyword was added.

\textbf{del\_param}(\texttt{param}, \texttt{header='content-type'}, \texttt{requote=True})

Remove the given parameter completely from the \texttt{Content-Type} header. The header will be re-written in place without the parameter or its value. All values will be quoted as necessary unless \texttt{requote} is \texttt{False} (the default is \texttt{True}). Optional \texttt{header} specifies an alternative to \texttt{Content-Type}.

\textbf{set\_type}(\texttt{type}, \texttt{header='Content-Type'}, \texttt{requote=True})

Set the main type and subtype for the \texttt{Content-Type} header. \texttt{type} must be a string in the form \texttt{maintype/subtype}, otherwise a \texttt{ValueError} is raised.

This method replaces the \texttt{Content-Type} header, keeping all the parameters in place. If \texttt{requote} is \texttt{False}, this leaves the existing header’s quoting as is, otherwise the parameters will be quoted (the default).

An alternative header can be specified in the \texttt{header} argument. When the \texttt{Content-Type} header is set a \texttt{MIME-Version} header is also added.

This is a legacy method. On the \texttt{EmailMessage} class its
functionality is replaced by the make_ and add_ methods.

**get_filename**(failobj=None)

Return the value of the filename parameter of the Content-Disposition header of the message. If the header does not have a filename parameter, this method falls back to looking for the name parameter on the Content-Type header. If neither is found, or the header is missing, then failobj is returned. The returned string will always be unquoted as per email.utils.unquote().

**get_boundary**(failobj=None)

Return the value of the boundary parameter of the Content-Type header of the message, or failobj if either the header is missing, or has no boundary parameter. The returned string will always be unquoted as per email.utils.unquote().

**set_boundary**(boundary)

Set the boundary parameter of the Content-Type header to boundary. set_boundary() will always quote boundary if necessary. A HeaderParseError is raised if the message object has no Content-Type header.

Note that using this method is subtly different than deleting the old Content-Type header and adding a new one with the new boundary via add_header(), because set_boundary() preserves the order of the Content-Type header in the list of headers. However, it does not preserve any continuation lines which may have been present in the original Content-Type header.

**get_content_charset**(failobj=None)
Return the `charset` parameter of the `Content-Type` header, coerced to lower case. If there is no `Content-Type` header, or if that header has no `charset` parameter, `failobj` is returned.

Note that this method differs from `get_charset()` which returns the `Charset` instance for the default encoding of the message body.

**get_charsets**(failobj=None)

Return a list containing the character set names in the message. If the message is a `multipart`, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the `charset` parameter in the `Content-Type` header for the represented subpart. However, if the subpart has no `Content-Type` header, no `charset` parameter, or is not of the `text` main MIME type, then that item in the returned list will be `failobj`.

**get_content_disposition()**

Return the lowercased value (without parameters) of the message's `Content-Disposition` header if it has one, or `None`. The possible values for this method are `inline`, `attachment` or `None` if the message follows RFC 2183.

*New in version 3.5.*

**walk()**

The `walk()` method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use
walk() as the iterator in a for loop; each iteration returns the next subpart.

Here's an example that prints the MIME type of every part of a multipart message structure:

```python
>>> for part in msg.walk():
...     print(part.get_content_type())
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
text/plain
walk iterates over the subparts of any part where is_multipart() returns True, even though msg.get_content_maintype() == 'multipart' may return False. We can see this in our example by making use of the _structure debug helper function:

```python
>>> for part in msg.walk():
...     print(part.get_content_maintype() == 'multipart' == part.is_multipart())
True True
False False
False True
False False
False False
False True
False False
>>> _structure(msg)
multipart/report
text/plain```
Here the message parts are not multipart, but they do contain subparts. is_multipart() returns True and walk descends into the subparts.

Message objects can also optionally contain two instance attributes, which can be used when generating the plain text of a MIME message.

**preamble**

The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this text can become visible.

The preamble attribute contains this leading extra-armor text for MIME documents. When the Parser discovers some text after the headers but before the first boundary string, it assigns this text to the message’s preamble attribute. When the Generator is writing out the plain text representation of a MIME message, and it finds the message has a preamble attribute, it will write this text in the area between the headers and the first boundary. See email.parser and email.generator for details.
Note that if the message object has no preamble, the `preamble` attribute will be `None`.

**epilogue**

The `epilogue` attribute acts the same way as the `preamble` attribute, except that it contains text that appears between the last boundary and the end of the message.

You do not need to set the epilogue to the empty string in order for the `Generator` to print a newline at the end of the file.

**defects**

The `defects` attribute contains a list of all the problems found when parsing this message. See `email.errors` for a detailed description of the possible parsing defects.
19.1. email — An email and MIME handling package
19.1.10. **email.mime**: Creating email and MIME objects from scratch

**Source code**: Lib/email.mime/

This module is part of the legacy ([Compat32](#)) email API. Its functionality is partially replaced by the [contentmanager](#) in the new API, but in certain applications these classes may still be useful, even in non-legacy code.

Ordinarily, you get a message object structure by passing a file or some text to a parser, which parses the text and returns the root message object. However you can also build a complete message structure from scratch, or even individual [Message](#) objects by hand. In fact, you can also take an existing structure and add new [Message](#) objects, move them around, etc. This makes a very convenient interface for slicing-and-dicing MIME messages.

You can create a new object structure by creating [Message](#) instances, adding attachments and all the appropriate headers manually. For MIME messages though, the [email](#) package provides some convenient subclasses to make things easier.

Here are the classes:

```python
class email.mime.base.MIMEBase(_maintype, _subtype, *,
    policy=compat32, **params)
    Module: email.mime.base
```
This is the base class for all the MIME-specific subclasses of \texttt{Message}. Ordinarily you won't create instances specifically of \texttt{MIMEBase}, although you could. \texttt{MIMEBase} is provided primarily as a convenient base class for more specific MIME-aware subclasses.

\_\_maintype is the \texttt{Content-Type} major type (e.g. \texttt{text} or \texttt{image}), and \_\_subtype is the \texttt{Content-Type} minor type (e.g. \texttt{plain} or \texttt{gif}). \_\_params is a parameter key/value dictionary and is passed directly to \texttt{Message.add\_header}.

If \texttt{policy} is specified, (defaults to the \texttt{compat32} policy) it will be passed to \texttt{Message}.

The \texttt{MIMEBase} class always adds a \texttt{Content-Type} header (based on \_\_maintype, \_\_subtype, and \_\_params), and a \texttt{MIME-Version} header (always set to 1.0).

\textit{Changed in version 3.6:} Added \texttt{policy} keyword-only parameter.

\begin{verbatim}
class email.mime.multipart.MIMENonMultipart
    Module: email.mime.multipart

A subclass of \texttt{MIMEBase}, this is an intermediate base class for MIME messages that are not \texttt{multipart}. The primary purpose of this class is to prevent the use of the \texttt{attach()} method, which only makes sense for \texttt{multipart} messages. If \texttt{attach()} is called, a \texttt{MultipartConversionError} exception is raised.

\begin{verbatim}
class email.mime.multipart.MIMEMultipart(_subtype='mixed',
boundary=None,_subparts=None, *, policy=compat32, **_params)
    Module: email.mime.multipart
\end{verbatim}
\end{verbatim}
A subclass of `MIMEBase`, this is an intermediate base class for MIME messages that are `multipart`. Optional `_subtype` defaults to `mixed`, but can be used to specify the subtype of the message. A `Content-Type` header of `multipart/_subtype` will be added to the message object. A `MIME-Version` header will also be added.

Optional `boundary` is the multipart boundary string. When `None` (the default), the boundary is calculated when needed (for example, when the message is serialized).

 `_subparts` is a sequence of initial subparts for the payload. It must be possible to convert this sequence to a list. You can always attach new subparts to the message by using the `Message.attach` method.

Optional `policy` argument defaults to `compat32`.

Additional parameters for the `Content-Type` header are taken from the keyword arguments, or passed into the `_params` argument, which is a keyword dictionary.

`Changed in version 3.6: Added policy keyword-only parameter.`

class email.mime.application.MIMEApplication(_data, _subtype='octet-stream', _encoder=email.encoders.encode_base64, *, policy=compat32, **_params)

Module: email.mime.application

A subclass of `MIMENonMultipart`, the `MIMEApplication` class is used to represent MIME message objects of major type `application`. `_data` is a string containing the raw byte data. Optional `_subtype` specifies the MIME subtype and defaults to `octet-stream`.

Optional `_encoder` is a callable (i.e. function) which will perform the
actual encoding of the data for transport. This callable takes one argument, which is the `MIMEApplication` instance. It should use `get_payload()` and `set_payload()` to change the payload to encoded form. It should also add any `Content-Transfer-Encoding` or other headers to the message object as necessary. The default encoding is base64. See the `email.encoders` module for a list of the built-in encoders.

Optional `policy` argument defaults to `compat32`.

_`params` are passed straight through to the base class constructor.

*Changed in version 3.6:* Added `policy` keyword-only parameter.

class email.mime.audio.MIMEAudio(_audiodata, _subtype=None, _encoder=email.encoders.encode_base64, *, policy=compat32, **_params)

Module: email.mime.audio

A subclass of `MIMENonMultipart`, the `MIMEAudio` class is used to create MIME message objects of major type `audio`. `_audiodata` is a string containing the raw audio data. If this data can be decoded by the standard Python module `sndhdr`, then the subtype will be automatically included in the `Content-Type` header. Otherwise you can explicitly specify the audio subtype via the `_subtype` argument. If the minor type could not be guessed and `_subtype` was not given, then `TypeError` is raised.

Optional `_encoder` is a callable (i.e. function) which will perform the actual encoding of the audio data for transport. This callable takes one argument, which is the `MIMEAudio` instance. It should use `get_payload()` and `set_payload()` to change the payload to encoded form. It should also add any `Content-Transfer-Encoding` or
other headers to the message object as necessary. The default encoding is base64. See the email.encoders module for a list of the built-in encoders.

Optional policy argument defaults to compat32.

__params are passed straight through to the base class constructor.

Changed in version 3.6: Added policy keyword-only parameter.

class email.mime.image.MIMEImage(_imagedata, _subtype=None, _encoder=email.encoders.encode_base64, *, policy=compat32, **__params)

Module: email.mime.image

A subclass of MIMENonMultipart, the MIMEImage class is used to create MIME message objects of major type image. _imagedata is a string containing the raw image data. If this data can be decoded by the standard Python module imghdr, then the subtype will be automatically included in the Content-Type header. Otherwise you can explicitly specify the image subtype via the _subtype argument. If the minor type could not be guessed and _subtype was not given, then TypeError is raised.

Optional _encoder is a callable (i.e. function) which will perform the actual encoding of the image data for transport. This callable takes one argument, which is the MIMEImage instance. It should use get_payload() and set_payload() to change the payload to encoded form. It should also add any Content-Transfer-Encoding or other headers to the message object as necessary. The default encoding is base64. See the email.encoders module for a list of the built-in encoders.
Optional *policy* argument defaults to *compat32*.

`_params` are passed straight through to the *MIMEBase* constructor.

*Changed in version 3.6:* Added *policy* keyword-only parameter.

```python
class email.mime.message.MIMEMessage(_msg, _subtype='rfc822', *, policy=compat32)

Module: email.mime.message
```

A subclass of *MIMENonMultipart*, the *MIMEMessage* class is used to create MIME objects of main type *message*. `_msg` is used as the payload, and must be an instance of class *Message* (or a subclass thereof), otherwise a *TypeError* is raised.

Optional `_subtype` sets the subtype of the message; it defaults to *rfc822*.

Optional *policy* argument defaults to *compat32*.

*Changed in version 3.6:* Added *policy* keyword-only parameter.

```python
class email.mime.text.MIMEText(_text, _subtype='plain', _charset=None, *, policy=compat32)

Module: email.mime.text
```

A subclass of *MIMENonMultipart*, the *MIMEText* class is used to create MIME objects of major type *text*. `_text` is the string for the payload. `_subtype` is the minor type and defaults to *plain*. `_charset` is the character set of the text and is passed as an argument to the *MIMENonMultipart* constructor; it defaults to *us-ascii* if the string contains only *ascii* code points, and *utf-8* otherwise. The `_charset` parameter accepts either a string or a *Charset* instance.
Unless the \_charset argument is explicitly set to None, the MIMEText object created will have both a Content-Type header with a charset parameter, and a Content-Transfer-Encoding header. This means that a subsequent set\_payload call will not result in an encoded payload, even if a charset is passed in the set\_payload command. You can “reset” this behavior by deleting the Content-Transfer-Encoding header, after which a set\_payload call will automatically encode the new payload (and add a new Content-Transfer-Encoding header).

Optional policy argument defaults to compat\_32.

*Changed in version 3.5:* \_charset also accepts Charset instances.

*Changed in version 3.6:* Added policy keyword-only parameter.
19.1. **email** — An email and MIME handling package
19.1.11. **email.header:** Internationalized headers

**Source code:** Lib/email/header.py

This module is part of the legacy (Compat32) email API. In the current API encoding and decoding of headers is handled transparently by the dictionary-like API of the EmailMessage class. In addition to uses in legacy code, this module can be useful in applications that need to completely control the character sets used when encoding headers.

The remaining text in this section is the original documentation of the module.

**RFC 2822** is the base standard that describes the format of email messages. It derives from the older **RFC 822** standard which came into widespread use at a time when most email was composed of ASCII characters only. **RFC 2822** is a specification written assuming email contains only 7-bit ASCII characters.

Of course, as email has been deployed worldwide, it has become internationalized, such that language specific character sets can now be used in email messages. The base standard still requires email messages to be transferred using only 7-bit ASCII characters, so a slew of RFCs have been written describing how to encode email containing non-ASCII characters into **RFC 2822**-compliant format. These RFCs include **RFC 2045**, **RFC 2046**, **RFC 2047**, and **RFC 2231**. The email package supports these standards in its email.header and email.charset modules.
If you want to include non-ASCII characters in your email headers, say in the Subject or To fields, you should use the Header class and assign the field in the Message object to an instance of Header instead of using a string for the header value. Import the Header class from the email.header module. For example:

```python
>>> from email.message import Message
>>> from email.header import Header
>>> msg = Message()
>>> h = Header('p\xf6stal', 'iso-8859-1')
>>> msg['Subject'] = h
>>> msg.as_string()
'Subject: =?iso-8859-1?q?p=F6stal?=\n\n'
```

Notice here how we wanted the Subject field to contain a non-ASCII character? We did this by creating a Header instance and passing in the character set that the byte string was encoded in. When the subsequent Message instance was flattened, the Subject field was properly RFC 2047 encoded. MIME-aware mail readers would show this header using the embedded ISO-8859-1 character.

Here is the Header class description:

```python
class email.header.Header(s=None, charset=None, maxlinelen=None, header_name=None, continuation_ws=' ', errors='strict')
```

Create a MIME-compliant header that can contain strings in different character sets.

Optional s is the initial header value. If None (the default), the initial header value is not set. You can later append to the header with append() method calls. s may be an instance of bytes or str, but see the append() documentation for semantics.
Optional `charset` serves two purposes: it has the same meaning as the `charset` argument to the `append()` method. It also sets the default character set for all subsequent `append()` calls that omit the `charset` argument. If `charset` is not provided in the constructor (the default), the `us-ascii` character set is used both as s’s initial charset and as the default for subsequent `append()` calls.

The maximum line length can be specified explicitly via `maxlinelen`. For splitting the first line to a shorter value (to account for the field header which isn’t included in s, e.g. `Subject`) pass in the name of the field in `header_name`. The default `maxlinelen` is 76, and the default value for `header_name` is `None`, meaning it is not taken into account for the first line of a long, split header.

Optional `continuation_ws` must be RFC 2822-compliant folding whitespace, and is usually either a space or a hard tab character. This character will be prepended to continuation lines. `continuation_ws` defaults to a single space character.

Optional `errors` is passed straight through to the `append()` method.

```python
append(s, charset=None, errors='strict')
```

Append the string s to the MIME header.

Optional `charset`, if given, should be a `Charset` instance (see `email.charset`) or the name of a character set, which will be converted to a `Charset` instance. A value of `None` (the default) means that the `charset` given in the constructor is used.

`s` may be an instance of `bytes` or `str`. If it is an instance of `bytes`, then `charset` is the encoding of that byte string, and a
UnicodeError will be raised if the string cannot be decoded with that character set.

If $s$ is an instance of str, then charset is a hint specifying the character set of the characters in the string.

In either case, when producing an RFC 2822-compliant header using RFC 2047 rules, the string will be encoded using the output codec of the charset. If the string cannot be encoded using the output codec, a UnicodeError will be raised.

Optional errors is passed as the errors argument to the decode call if $s$ is a byte string.

```python
encode(splitchars=‘;’, \t, maxlinelen=None, linesep=‘\n’)
```

Encode a message header into an RFC-compliant format, possibly wrapping long lines and encapsulating non-ASCII parts in base64 or quoted-printable encodings.

Optional splitchars is a string containing characters which should be given extra weight by the splitting algorithm during normal header wrapping. This is in very rough support of RFC 2822’s ‘higher level syntactic breaks’: split points preceded by a splitchar are preferred during line splitting, with the characters preferred in the order in which they appear in the string. Space and tab may be included in the string to indicate whether preference should be given to one over the other as a split point when other split chars do not appear in the line being split. Splitchars does not affect RFC 2047 encoded lines.

maxlinelen, if given, overrides the instance’s value for the maximum line length.
linesep specifies the characters used to separate the lines of the folded header. It defaults to the most useful value for Python application code (\n), but \r\n can be specified in order to produce headers with RFC-compliant line separators.

*Changed in version 3.2: Added the linesep argument.*

The Header class also provides a number of methods to support standard operators and built-in functions.

__str__()  
Returns an approximation of the Header as a string, using an unlimited line length. All pieces are converted to unicode using the specified encoding and joined together appropriately. Any pieces with a charset of 'unknown-8bit' are decoded as ASCII using the 'replace' error handler.

*Changed in version 3.2: Added handling for the 'unknown-8bit' charset.*

__eq__(other)  
This method allows you to compare two Header instances for equality.

__ne__(other)  
This method allows you to compare two Header instances for inequality.

The email.header module also provides the following convenient functions.

email.header.decode_header(header)  
Decode a message header value without converting the character
set. The header value is in header.
This function returns a list of (decoded_string, charset)
pairs containing each of the decoded parts of the header. charset is
None for non-encoded parts of the header, otherwise a lower case
string containing the name of the character set specified in the
encoded string.
Here’s an example:
>>> from email.header import decode_header
[(b'p\xf6stal', 'iso-8859-1')]
email.header. make_header(decoded_seq, maxlinelen=None,
header_name=None, continuation_ws=' ')
Create a Header instance from a sequence of pairs as returned by
decode_header().
decode_header() takes a header value string and returns a
sequence of pairs of the format (decoded_string, charset)
where charset is the name of the character set.
This function takes one of those sequence of pairs and returns a
Header instance. Optional maxlinelen, header_name, and
continuation_ws are as in the Header constructor.

19.1.12. **email.charset**: Representing character sets

**Source code**: Lib/email/charset.py

This module is part of the legacy (Compat32) email API. In the new API only the aliases table is used.

The remaining text in this section is the original documentation of the module.

This module provides a class `Charset` for representing character sets and character set conversions in email messages, as well as a character set registry and several convenience methods for manipulating this registry. Instances of `Charset` are used in several other modules within the `email` package.

Import this class from the `email.charset` module.

```python
class email.charsetCharset(input_charset=DEFAULT_CHARSET)
    Map character sets to their email properties.

    This class provides information about the requirements imposed on email for a specific character set. It also provides convenience routines for converting between character sets, given the availability of the applicable codecs. Given a character set, it will do its best to provide information on how to use that character set in an email message in an RFC-compliant way.
```
Certain character sets must be encoded with quoted-printable or base64 when used in email headers or bodies. Certain character sets must be converted outright, and are not allowed in email.

Optional *input_charset* is as described below; it is always coerced to lower case. After being alias normalized it is also used as a lookup into the registry of character sets to find out the header encoding, body encoding, and output conversion codec to be used for the character set. For example, if *inputcharset* is iso-8859-1, then headers and bodies will be encoded using quoted-printable and no output conversion codec is necessary. If *input_charset* is euc-jp, then headers will be encoded with base64, bodies will not be encoded, but output text will be converted from the euc-jp character set to the iso-2022-jp character set.

*Charset* instances have the following data attributes:

**input_charset**

The initial character set specified. Common aliases are converted to their *official* email names (e.g. latin_1 is converted to iso-8859-1). Defaults to 7-bit us-ascii.

**header_encoding**

If the character set must be encoded before it can be used in an email header, this attribute will be set to *Charset.QP* (for quoted-printable), *Charset.BASE64* (for base64 encoding), or *Charset.SHORTEST* for the shortest of QP or BASE64 encoding. Otherwise, it will be *None*.

**body_encoding**

Same as *header_encoding*, but describes the encoding for the mail message's body, which indeed may be different than the
header encoding. `Charset.SHORTEST` is not allowed for `body_encoding`.

**output_charset**
Some character sets must be converted before they can be used in email headers or bodies. If the `input_charset` is one of them, this attribute will contain the name of the character set output will be converted to. Otherwise, it will be `None`.

**input_codec**
The name of the Python codec used to convert the `input_charset` to Unicode. If no conversion codec is necessary, this attribute will be `None`.

**output_codec**
The name of the Python codec used to convert Unicode to the `output_charset`. If no conversion codec is necessary, this attribute will have the same value as the `input_codec`.

`Charset` instances also have the following methods:

**get_body_encoding()**
Return the content transfer encoding used for body encoding.

This is either the string `quoted-printable` or `base64` depending on the encoding used, or it is a function, in which case you should call the function with a single argument, the Message object being encoded. The function should then set the `Content-Transfer-Encoding` header itself to whatever is appropriate.

Returns the string `quoted-printable` if `body_encoding` is `QP`, returns the string `base64` if `body_encoding` is `BASE64`,
and returns the string 7bit otherwise.

**get_output_charset()**
Return the output character set.

This is the output_charset attribute if that is not None, otherwise it is input_charset.

**header_encode**(string)
Header-encode the string string.

The type of encoding (base64 or quoted-printable) will be based on the header_encoding attribute.

**header_encode_lines**(string, maxlengths)
Header-encode a string by converting it first to bytes.

This is similar to header_encode() except that the string is fit into maximum line lengths as given by the argument maxlengths, which must be an iterator: each element returned from this iterator will provide the next maximum line length.

**body_encode**(string)
Body-encode the string string.

The type of encoding (base64 or quoted-printable) will be based on the body_encoding attribute.

The Charset class also provides a number of methods to support standard operations and built-in functions.

**__str__**( )
Returns input_charset as a string coerced to lower case.
```python
__repr__() is an alias for __str__().

__eq__(other)
This method allows you to compare two Charset instances for equality.

__ne__(other)
This method allows you to compare two Charset instances for inequality.
```

The `email.charset` module also provides the following functions for adding new entries to the global character set, alias, and codec registries:

```python
email.charset.add charset(charset, header_enc=None, body_enc=None, output_charset=None)
Add character properties to the global registry.
```

`charset` is the input character set, and must be the canonical name of a character set.

Optional `header_enc` and `body_enc` is either `Charset.QP` for quoted-printable, `Charset.BASE64` for base64 encoding, `Charset.SHORTEST` for the shortest of quoted-printable or base64 encoding, or `None` for no encoding. `SHORTEST` is only valid for `header_enc`. The default is `None` for no encoding.

Optional `output_charset` is the character set that the output should be in. Conversions will proceed from input charset, to Unicode, to the output charset when the method `Charset.convert()` is called. The default is to output in the same character set as the input.
Both *input_charset* and *output_charset* must have Unicode codec entries in the module's character set-to-codec mapping; use `add_codec()` to add codecs the module does not know about. See the *codecs* module's documentation for more information.

The global character set registry is kept in the module global dictionary `CHARSETS`.

```python
email.charset.add_alias(alias, canonical)
```

Add a character set alias. *alias* is the alias name, e.g. `latin-1`. *canonical* is the character set's canonical name, e.g. `iso-8859-1`.

The global charset alias registry is kept in the module global dictionary `ALIASES`.

```python
email.charset.add_codec(charset, codecname)
```

Add a codec that map characters in the given character set to and from Unicode.

*charset* is the canonical name of a character set. *codecname* is the name of a Python codec, as appropriate for the second argument to the `str`'s `encode()` method.
19.1.13. **email.encoders**: Encoders

**Source code:** Lib/email/encoders.py

This module is part of the legacy (Compat32) email API. In the new API the functionality is provided by the *cte* parameter of the `set_content()` method.

The remaining text in this section is the original documentation of the module.

When creating `Message` objects from scratch, you often need to encode the payloads for transport through compliant mail servers. This is especially true for `image/*` and `text/*` type messages containing binary data.

The `email` package provides some convenient encodings in its `encoders` module. These encoders are actually used by the `MIMEAudio` and `MIMEImage` class constructors to provide default encodings. All encoder functions take exactly one argument, the message object to encode. They usually extract the payload, encode it, and reset the payload to this newly encoded value. They should also set the `Content-Transfer-Encoding` header as appropriate.

Note that these functions are not meaningful for a multipart message. They must be applied to individual subparts instead, and will raise a `TypeError` if passed a message whose type is multipart.

Here are the encoding functions provided:
email.encoders.**encode_quopri**(msg)

Encodes the payload into quoted-printable form and sets the `Content-Transfer-Encoding` header to `quoted-printable` [1]. This is a good encoding to use when most of your payload is normal printable data, but contains a few unprintable characters.

def encode_base64(msg)

Encodes the payload into base64 form and sets the `Content-Transfer-Encoding` header to `base64`. This is a good encoding to use when most of your payload is unprintable data since it is a more compact form than quoted-printable. The drawback of base64 encoding is that it renders the text non-human readable.

def encode_7or8bit(msg)

This doesn’t actually modify the message’s payload, but it does set the `Content-Transfer-Encoding` header to either `7bit` or `8bit` as appropriate, based on the payload data.

def encode_noop(msg)

This does nothing; it doesn’t even set the `Content-Transfer-Encoding` header.

Footnotes

[1] Note that encoding with `encode_quopri()` also encodes all tabs and space characters in the data.
19.1.14. **email.utils**: Miscellaneous utilities

**Source code:** Lib/email/utils.py

There are a couple of useful utilities provided in the `email.utils` module:

**email.utils.localtime**(*dt=None*)

Return local time as an aware datetime object. If called without arguments, return current time. Otherwise `dt` argument should be a `datetime` instance, and it is converted to the local time zone according to the system time zone database. If `dt` is naive (that is, `dt.tzinfo` is `None`), it is assumed to be in local time. In this case, a positive or zero value for `isdst` causes `localtime` to presume initially that summer time (for example, Daylight Saving Time) is or is not (respectively) in effect for the specified time. A negative value for `isdst` causes the `localtime` to attempt to divine whether summer time is in effect for the specified time.

*New in version 3.3.*

**email.utils.make_msgid**(*idstring=None, domain=None*)

Returns a string suitable for an RFC 2822-compliant `Message-ID` header. Optional `idstring` if given, is a string used to strengthen the uniqueness of the message id. Optional `domain` if given provides the portion of the msgid after the ‘@’. The default is the local hostname. It is not normally necessary to override this default, but may be useful certain cases, such as a constructing distributed
system that uses a consistent domain name across multiple hosts.

*Changed in version 3.2:* Added the *domain* keyword.

The remaining functions are part of the legacy (Compat32) email API. There is no need to directly use these with the new API, since the parsing and formatting they provide is done automatically by the header parsing machinery of the new API.

**email.utils.quote**(str)

Return a new string with backslashes in *str* replaced by two backslashes, and double quotes replaced by backslash-double quote.

**email.utils.unquote**(str)

Return a new string which is an *unquoted* version of *str*. If *str* ends and begins with double quotes, they are stripped off. Likewise if *str* ends and begins with angle brackets, they are stripped off.

**email.utils.parseaddr**(address)

Parse address – which should be the value of some address-containing field such as *To* or *Cc* – into its constituent *realname* and *email address* parts. Returns a tuple of that information, unless the parse fails, in which case a 2-tuple of ('', '') is returned.

**email.utils.formataddr**(pair, charset='utf-8')

The inverse of parseaddr(), this takes a 2-tuple of the form (realname, email_address) and returns the string value suitable for a *To* or *Cc* header. If the first element of *pair* is false, then the second element is returned unmodified.

Optional *charset* is the character set that will be used in the *RFC 2047* encoding of the *realname* if the *realname* contains non-
ASCII characters. Can be an instance of `str` or a `Charset`. Defaults to `utf-8`.

*Changed in version 3.3:* Added the `charset` option.

**email.utils.getaddresses(fieldvalues)**

This method returns a list of 2-tuples of the form returned by `parseaddr()`. `fieldvalues` is a sequence of header field values as might be returned by `Message.get_all`. Here's a simple example that gets all the recipients of a message:

```python
from email.utils import getaddresses

tos = msg.get_all('to', [])
ccs = msg.get_all('cc', [])
resent_tos = msg.get_all('resent-to', [])
resent_ccs = msg.get_all('resent-cc', [])
all_recipients = getaddresses(tos + ccs + resent_tos + resent_ccs)
```

**email.utils.parsedate(date)**

Attempts to parse a date according to the rules in [RFC 2822](https://tools.ietf.org/html/rfc2822). However, some mailers don't follow that format as specified, so `parsedate()` tries to guess correctly in such cases. `date` is a string containing an [RFC 2822](https://tools.ietf.org/html/rfc2822) date, such as "Mon, 20 Nov 1995 19:12:08 -0500". If it succeeds in parsing the date, `parsedate()` returns a 9-tuple that can be passed directly to `time.mktime()`; otherwise `None` will be returned. Note that indexes 6, 7, and 8 of the result tuple are not usable.

**email.utils.parsedate_tz(date)**

Performs the same function as `parsedate()`, but returns either `None` or a 10-tuple; the first 9 elements make up a tuple that can
be passed directly to `time.mktime()`, and the tenth is the offset of the date's timezone from UTC (which is the official term for Greenwich Mean Time) [1]. If the input string has no timezone, the last element of the tuple returned is `None`. Note that indexes 6, 7, and 8 of the result tuple are not usable.

```python
email.utils.parsedate_to_datetime(date)
```

The inverse of `format_datetime()`. Performs the same function as `parsedate()`, but on success returns a `datetime`. If the input date has a timezone of `-0000`, the `datetime` will be a naive `datetime`, and if the date is conforming to the RFCs it will represent a time in UTC but with no indication of the actual source timezone of the message the date comes from. If the input date has any other valid timezone offset, the `datetime` will be an aware `datetime` with the corresponding a `timezone tzinfo`.

New in version 3.3.

```python
email.utils.mktime_tz(tuple)
```

Turn a 10-tuple as returned by `parsedate_tz()` into a UTC timestamp (seconds since the Epoch). If the timezone item in the tuple is `None`, assume local time.

```python
email.utils.formatdate(timeval=None, localtime=False, usegmt=False)
```

Returns a date string as per RFC 2822, e.g.:

```
Fri, 09 Nov 2001 01:08:47 -0000
```

Optional `timeval` if given is a floating point time value as accepted by `time.gmtime()` and `time.localtime()`, otherwise the current time is used.
Optional `localtime` is a flag that when `True`, interprets `timeval`, and returns a date relative to the local timezone instead of UTC, properly taking daylight savings time into account. The default is `False` meaning UTC is used.

Optional `usegmt` is a flag that when `True`, outputs a date string with the timezone as an ascii string `GMT`, rather than a numeric `-0000`. This is needed for some protocols (such as HTTP). This only applies when `localtime` is `False`. The default is `False`.

```
email.utils.format_datetime(dt, usegmt=False)
```

Like `formatdate`, but the input is a `datetime` instance. If it is a naive datetime, it is assumed to be “UTC with no information about the source timezone”, and the conventional `-0000` is used for the timezone. If it is an aware `datetime`, then the numeric timezone offset is used. If it is an aware timezone with offset zero, then `usegmt` may be set to `True`, in which case the string `GMT` is used instead of the numeric timezone offset. This provides a way to generate standards conformant HTTP date headers.

`New in version 3.3.`

```
email.utils.decode_rfc2231(s)
```

Decode the string `s` according to RFC 2231.

```
email.utils.encode_rfc2231(s, charset=None, language=None)
```

Encode the string `s` according to RFC 2231. Optional `charset` and `language`, if given is the character set name and language name to use. If neither is given, `s` is returned as-is. If `charset` is given but `language` is not, the string is encoded using the empty string for `language`.
email.utils.collapse_rfc2231_value(value, errors='replace', fallback_charset='us-ascii')

When a header parameter is encoded in RFC 2231 format, Message.get_param may return a 3-tuple containing the character set, language, and value. collapse_rfc2231_value() turns this into a unicode string. Optional errors is passed to the errors argument of str's encode() method; it defaults to replace. Optional fallback_charset specifies the character set to use if the one in the RFC 2231 header is not known by Python; it defaults to us-ascii.

For convenience, if the value passed to collapse_rfc2231_value() is not a tuple, it should be a string and it is returned unquoted.

eemail.utils.decode_params(params)

Decode parameters list according to RFC 2231. params is a sequence of 2-tuples containing elements of the form (content-type, string-value).

Footnotes

[1] Note that the sign of the timezone offset is the opposite of the sign of the time.timezone variable for the same timezone; the latter variable follows the POSIX standard while this module follows RFC 2822.
19.1.15. **email.iterators:** Iterators

Source code: Lib/email/iterators.py

Iterating over a message object tree is fairly easy with the `Message.walk` method. The `email.iterators` module provides some useful higher level iterations over message object trees.

```python
e-mail.iterators.body_line_iterator(msg, decode=False)
```

This iterates over all the payloads in all the subparts of `msg`, returning the string payloads line-by-line. It skips over all the subpart headers, and it skips over any subpart with a payload that isn’t a Python string. This is somewhat equivalent to reading the flat text representation of the message from a file using `readline()`, skipping over all the intervening headers.

Optional `decode` is passed through to `Message.get_payload`.

```python
e-mail.iterators.typed_subpart_iterator(msg, maintype='text', subtype=None)
```

This iterates over all the subparts of `msg`, returning only those subparts that match the MIME type specified by `maintype` and `subtype`.

Note that `subtype` is optional; if omitted, then subpart MIME type matching is done only with the main type. `maintype` is optional too; it defaults to `text`. 
Thus, by default `typed_subpart_iterator()` returns each subpart that has a MIME type of `text/*`.

The following function has been added as a useful debugging tool. It should not be considered part of the supported public interface for the package.

```python
email.iterators._structure(msg, fp=None, level=0, include_default=False)
```

Prints an indented representation of the content types of the message object structure. For example:

```python
>>> msg = email.message_from_file(somefile)
>>> _structure(msg)
multipart/mixed
  text/plain
  text/plain
multipart/digest
  message/rfc822
    text/plain
  message/rfc822
    text/plain
  message/rfc822
    text/plain
  message/rfc822
    text/plain
  message/rfc822
    text/plain
text/plain
```

Optional `fp` is a file-like object to print the output to. It must be suitable for Python's `print()` function. `level` is used internally. `include_default`, if true, prints the default type as well.
19.2. json — JSON encoder and decoder

**Source code:** Lib/json/__init__.py

JSON (JavaScript Object Notation), specified by RFC 7159 (which obsoletes RFC 4627) and by ECMA-404, is a lightweight data interchange format inspired by JavaScript object literal syntax (although it is not a strict subset of JavaScript [1]).

json exposes an API familiar to users of the standard library marshal and pickle modules.

Encoding basic Python object hierarchies:

```python
>>> import json
>>> json.dumps(['foo', {'bar': ('baz', None, 1.0, 2)}, [
    'foo', {'bar': ['baz', None, 1.0, 2]}]])
'"foo",
    {"bar": ["baz", null, 1.0, 2]}}

>>> print(json.dumps("\"foo\bar\"))
"foo\bar"

>>> print(json.dumps('\u1234'))
\u1234

>>> print(json.dumps('\\'))
\\

>>> print(json.dumps({'c': 0, 'b': 0, 'a': 0}, sort_keys=True))
{"a": 0, "b": 0, "c": 0}

>>> from io import StringIO
>>> io = StringIO()
>>> json.dump(['streaming API'], io)
>>> io.getvalue()
'[, ["streaming API"]]
```
Compact encoding:
>>> import json
>>> json.dumps([1, 2, 3, {'4': 5, '6': 7}], separators
'[1,2,3,{"4":5,"6":7}]'

Pretty printing:
>>> import json
>>> print(json.dumps({'4': 5, '6': 7}, sort_keys=True
{
"4": 5,
"6": 7
}

Decoding JSON:
>>> import json
>>> json.loads('["foo", {"bar":["baz", null, 1.0, 2]}]'
['foo', {'bar': ['baz', None, 1.0, 2]}]
>>> json.loads('"\\"foo\\bar"')
'"foo\x08ar'
>>> from io import StringIO
>>> io = StringIO('["streaming API"]')
>>> json.load(io)
['streaming API']

Specializing JSON object decoding:
>>> import json
>>> def as_complex(dct):
...
if '__complex__' in dct:
...
return complex(dct['real'], dct['imag'])
...
return dct


Extending **JSONEncoder**:

```python
>>> import json
>>> class ComplexEncoder(json.JSONEncoder):
...     def default(self, obj):
...         if isinstance(obj, complex):
...             return [obj.real, obj.imag]
...         # Let the base class default method raise
...         return json.JSONEncoder.default(self, obj)

>>> json.dumps(2 + 1j, cls=ComplexEncoder)
'[2.0, 1.0]'
>>> ComplexEncoder().encode(2 + 1j)
'[2.0, 1.0]'
>>> list(ComplexEncoder().iterencode(2 + 1j))
[['2.0', ',', '1.0', ',']]
```

Using **json.tool** from the shell to validate and pretty-print:

```
$ echo '{"json":"obj"}' | python -m json.tool
{
  "json": "obj"
}
$ echo '{1.2:3.4}' | python -m json.tool
Expecting property name enclosed in double quotes: 1
```
See Command Line Interface for detailed documentation.

**Note:** JSON is a subset of YAML 1.2. The JSON produced by this module’s default settings (in particular, the default `separators` value) is also a subset of YAML 1.0 and 1.1. This module can thus also be used as a YAML serializer.
19.2.1. Basic Usage

```python
json.dump(obj, fp, *, skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True, cls=None, indent=None, separators=None, default=None, sort_keys=False, **kw)
```

Serialize `obj` as a JSON formatted stream to `fp` (a supporting file-like object) using this conversion table.

If `skipkeys` is true (default: False), then dict keys that are not of a basic type (`str`, `int`, `float`, `bool`, None) will be skipped instead of raising a `TypeError`.

The `json` module always produces `str` objects, not `bytes` objects. Therefore, `fp.write()` must support `str` input.

If `ensure_ascii` is true (the default), the output is guaranteed to have all incoming non-ASCII characters escaped. If `ensure_ascii` is false, these characters will be output as-is.

If `check_circular` is false (default: True), then the circular reference check for container types will be skipped and a circular reference will result in an `OverflowError` (or worse).

If `allow_nan` is false (default: True), then it will be a `ValueError` to serialize out of range `float` values (`nan`, `inf`, `-inf`) in strict compliance of the JSON specification. If `allow_nan` is true, their JavaScript equivalents (`NaN`, `Infinity`, `-Infinity`) will be used.

If `indent` is a non-negative integer or string, then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0, negative, or `""` will only insert newlines.
None (the default) selects the most compact representation. Using a positive integer indent indents that many spaces per level. If `indent` is a string (such as "\t"), that string is used to indent each level.

*Changed in version 3.2:* Allow strings for `indent` in addition to integers.

If specified, `separators` should be an `(item_separator, key_separator)` tuple. The default is `(',', ':')` if `indent` is `None` and `(',', ',', '':')` otherwise. To get the most compact JSON representation, you should specify `(',', ',', '':')` to eliminate whitespace.

*Changed in version 3.4:* Use `(',', ',', '':')` as default if `indent` is not `None`.

If specified, `default` should be a function that gets called for objects that can’t otherwise be serialized. It should return a JSON encodable version of the object or raise a `TypeError`. If not specified, `TypeError` is raised.

If `sort_keys` is true (default: `False`), then the output of dictionaries will be sorted by key.

To use a custom `JSONEncoder` subclass (e.g. one that overrides the `default()` method to serialize additional types), specify it with the `cls` kwarg; otherwise `JSONEncoder` is used.

*Changed in version 3.6:* All optional parameters are now keyword-only.

```
json.dumps(obj, *, skipkeys=False, ensure_ascii=True,
```
check_circular=True, allow_nan=True, cls=None, indent=None, separators=None, default=None, sort_keys=False, **kw)

Serialize `obj` to a JSON formatted `str` using this conversion table. The arguments have the same meaning as in `dump()`.

**Note:** Unlike `pickle` and `marshal`, JSON is not a framed protocol, so trying to serialize multiple objects with repeated calls to `dump()` using the same `fp` will result in an invalid JSON file.

**Note:** Keys in key/value pairs of JSON are always of the type `str`. When a dictionary is converted into JSON, all the keys of the dictionary are coerced to strings. As a result of this, if a dictionary is converted into JSON and then back into a dictionary, the dictionary may not equal the original one. That is, `loads(dumps(x)) != x` if `x` has non-string keys.

`json.load(fp, *, cls=None, object_hook=None, parse_float=None, parse_int=None, parse_constant=None, object_pairs_hook=None, **kw)`

Deserialize `fp` (a `.read()`-supporting file-like object containing a JSON document) to a Python object using this conversion table.

`object_hook` is an optional function that will be called with the result of any object literal decoded (a `dict`). The return value of `object_hook` will be used instead of the `dict`. This feature can be used to implement custom decoders (e.g. JSON-RPC class hinting).

`object_pairs_hook` is an optional function that will be called with the result of any object literal decoded with an ordered list of pairs. The return value of `object_pairs_hook` will be used instead of the `dict`. This feature can be used to implement custom decoders that rely
on the order that the key and value pairs are decoded (for example, `collections.OrderedDict()` will remember the order of insertion). If `object_hook` is also defined, the `object_pairs_hook` takes priority.

*Changed in version 3.1:* Added support for `object_pairs_hook`.

`parse_float`, if specified, will be called with the string of every JSON float to be decoded. By default, this is equivalent to `float(num_str)`. This can be used to use another datatype or parser for JSON floats (e.g. `decimal.Decimal`).

`parse_int`, if specified, will be called with the string of every JSON int to be decoded. By default, this is equivalent to `int(num_str)`. This can be used to use another datatype or parser for JSON integers (e.g. `float`).

`parse_constant`, if specified, will be called with one of the following strings: `'Infinity'`, `'Infinity'`, `'NaN'`. This can be used to raise an exception if invalid JSON numbers are encountered.

*Changed in version 3.1:* `parse_constant` doesn’t get called on ‘null’, ‘true’, ‘false’ anymore.

To use a custom `JSONDecoder` subclass, specify it with the `cls` kwarg; otherwise `JSONDecoder` is used. Additional keyword arguments will be passed to the constructor of the class.

If the data being deserialized is not a valid JSON document, a `JSONDecodeError` will be raised.

*Changed in version 3.6:* All optional parameters are now keyword-only.
json. **loads**(*s*, *, **encoding=None, cls=None, object_hook=None, parse_float=None, parse_int=None, parse_constant=None, object_pairs_hook=None, **kw*)

Deserialize *s* (a `str`, `bytes` or `bytearray` instance containing a JSON document) to a Python object using this conversion table.

The other arguments have the same meaning as in `load()`, except `encoding` which is ignored and deprecated.

If the data being deserialized is not a valid JSON document, a `JSONDecodeError` will be raised.

*Changed in version 3.6:* *s* can now be of type `bytes` or `bytearray`. The input encoding should be UTF-8, UTF-16 or UTF-32.
19.2.2. Encoders and Decoders

```python
class json.JSONDecoder(*, object_hook=None, parse_float=None, parse_int=None, parse_constant=None, strict=True, object_pairs_hook=None)
```

Simple JSON decoder.

Performs the following translations in decoding by default:

<table>
<thead>
<tr>
<th>JSON</th>
<th>Python</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>dict</td>
</tr>
<tr>
<td>array</td>
<td>list</td>
</tr>
<tr>
<td>string</td>
<td>str</td>
</tr>
<tr>
<td>number (int)</td>
<td>int</td>
</tr>
<tr>
<td>number (real)</td>
<td>float</td>
</tr>
<tr>
<td>true</td>
<td>True</td>
</tr>
<tr>
<td>false</td>
<td>False</td>
</tr>
<tr>
<td>null</td>
<td>None</td>
</tr>
</tbody>
</table>

It also understands `NaN`, `Infinity`, and `-Infinity` as their corresponding `float` values, which is outside the JSON spec.

`object_hook`, if specified, will be called with the result of every JSON object decoded and its return value will be used in place of the given `dict`. This can be used to provide custom deserializations (e.g. to support JSON-RPC class hinting).

`object_pairs_hook`, if specified will be called with the result of every JSON object decoded with an ordered list of pairs. The return value of `object_pairs_hook` will be used instead of the `dict`. This feature
can be used to implement custom decoders that rely on the order that the key and value pairs are decoded (for example, `collections.OrderedDict()` will remember the order of insertion). If `object_hook` is also defined, the `object_pairs_hook` takes priority.

*Changed in version 3.1:* Added support for `object_pairs_hook`.

`parse_float`, if specified, will be called with the string of every JSON float to be decoded. By default, this is equivalent to `float(num_str)`. This can be used to use another datatype or parser for JSON floats (e.g. `decimal.Decimal`).

`parse_int`, if specified, will be called with the string of every JSON int to be decoded. By default, this is equivalent to `int(num_str)`. This can be used to use another datatype or parser for JSON integers (e.g. `float`).

`parse_constant`, if specified, will be called with one of the following strings: `-Infinity`, `Infinity`, `NaN`. This can be used to raise an exception if invalid JSON numbers are encountered.

If `strict` is false (`True` is the default), then control characters will be allowed inside strings. Control characters in this context are those with character codes in the 0–31 range, including `\t` (tab), `\n`, `\r` and `\0`.

If the data being deserialized is not a valid JSON document, a `JSONDecodeError` will be raised.

*Changed in version 3.6:* All parameters are now **keyword-only**.

decode(s)
Return the Python representation of `s` (a `str` instance containing a JSON document).

`JSONDecodeError` will be raised if the given JSON document is not valid.

`raw_decode(s)`
Decode a JSON document from `s` (a `str` beginning with a JSON document) and return a 2-tuple of the Python representation and the index in `s` where the document ended.

This can be used to decode a JSON document from a string that may have extraneous data at the end.

```python
class json.JSONEncoder(*, skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True, sort_keys=False, indent=None, separators=None, default=None)
```
Extensible JSON encoder for Python data structures.

Supports the following objects and types by default:

<table>
<thead>
<tr>
<th>Python</th>
<th>JSON</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dict</code></td>
<td>object</td>
</tr>
<tr>
<td><code>list</code>, <code>tuple</code></td>
<td>array</td>
</tr>
<tr>
<td><code>str</code></td>
<td>string</td>
</tr>
<tr>
<td><code>int</code>, <code>float</code>, int- &amp; float-derived Enums</td>
<td>number</td>
</tr>
<tr>
<td><code>True</code></td>
<td>true</td>
</tr>
<tr>
<td><code>False</code></td>
<td>false</td>
</tr>
<tr>
<td><code>None</code></td>
<td>null</td>
</tr>
</tbody>
</table>

`Changed in version 3.4`: Added support for int- and float-derived
Enum classes.

To extend this to recognize other objects, subclass and implement a `default()` method with another method that returns a serializable object for `o` if possible, otherwise it should call the superclass implementation (to raise `TypeError`).

If `skipkeys` is false (the default), then it is a `TypeError` to attempt encoding of keys that are not `str`, `int`, `float` or `None`. If `skipkeys` is true, such items are simply skipped.

If `ensure_ascii` is true (the default), the output is guaranteed to have all incoming non-ASCII characters escaped. If `ensure_ascii` is false, these characters will be output as-is.

If `check_circular` is true (the default), then lists, dicts, and custom encoded objects will be checked for circular references during encoding to prevent an infinite recursion (which would cause an `OverflowError`). Otherwise, no such check takes place.

If `allow_nan` is true (the default), then `NaN`, `Infinity`, and `-Infinity` will be encoded as such. This behavior is not JSON specification compliant, but is consistent with most JavaScript based encoders and decoders. Otherwise, it will be a `ValueError` to encode such floats.

If `sort_keys` is true (default: `False`), then the output of dictionaries will be sorted by key; this is useful for regression tests to ensure that JSON serializations can be compared on a day-to-day basis.

If `indent` is a non-negative integer or string, then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0, negative, or `' ' will only insert newlines.
None (the default) selects the most compact representation. Using a positive integer indent indents that many spaces per level. If indent is a string (such as "\t"), that string is used to indent each level.

Changed in version 3.2: Allow strings for indent in addition to integers.

If specified, separators should be an (item_separator, key_separator) tuple. The default is (',', ':') if indent is None and (',', ':') otherwise. To get the most compact JSON representation, you should specify (',', ':') to eliminate whitespace.

Changed in version 3.4: Use (',', ':') as default if indent is not None.

If specified, default should be a function that gets called for objects that can’t otherwise be serialized. It should return a JSON encodable version of the object or raise a TypeError. If not specified, TypeError is raised.

Changed in version 3.6: All parameters are now keyword-only.

default(o)

Implement this method in a subclass such that it returns a serializable object for o, or calls the base implementation (to raise a TypeError).

For example, to support arbitrary iterators, you could implement default like this:

def default(self, o):
  pass
try:
    iterable = iter(o)
except TypeError:
    pass
else:
    return list(iterable)

# Let the base class default method raise the
return json.JSONEncoder.default(self, o)

**encode(o)**

Return a JSON string representation of a Python data structure, \( o \). For example:

```python
>>> json.JSONEncoder().encode({'foo': ['bar', '
    ']}
```

**iterencode(o)**

Encode the given object, \( o \), and yield each string representation as available. For example:

```python
for chunk in json.JSONEncoder().iterencode(big):
    mysocket.write(chunk)
```
19.2.3. Exceptions

```
exception json.JSONDecodeError(msg, doc, pos)
```

Subclass of `ValueError` with the following additional attributes:

- **msg**
  The unformatted error message.

- **doc**
  The JSON document being parsed.

- **pos**
  The start index of `doc` where parsing failed.

- **lineno**
  The line corresponding to `pos`.

- **colno**
  The column corresponding to `pos`.

*New in version 3.5.*
19.2.4. Standard Compliance and Interoperability

The JSON format is specified by RFC 7159 and by ECMA-404. This section details this module’s level of compliance with the RFC. For simplicity, JSONEncoder and JSONDecoder subclasses, and parameters other than those explicitly mentioned, are not considered.

This module does not comply with the RFC in a strict fashion, implementing some extensions that are valid JavaScript but not valid JSON. In particular:

- Infinite and NaN number values are accepted and output;
- Repeated names within an object are accepted, and only the value of the last name-value pair is used.

Since the RFC permits RFC-compliant parsers to accept input texts that are not RFC-compliant, this module’s deserializer is technically RFC-compliant under default settings.

19.2.4.1. Character Encodings

The RFC requires that JSON be represented using either UTF-8, UTF-16, or UTF-32, with UTF-8 being the recommended default for maximum interoperability.

As permitted, though not required, by the RFC, this module’s serializer sets ensure_ascii=True by default, thus escaping the output so that the resulting strings only contain ASCII characters.

Other than the ensure_ascii parameter, this module is defined strictly in terms of conversion between Python objects and Unicode
strings, and thus does not otherwise directly address the issue of character encodings.

The RFC prohibits adding a byte order mark (BOM) to the start of a JSON text, and this module's serializer does not add a BOM to its output. The RFC permits, but does not require, JSON deserializers to ignore an initial BOM in their input. This module's deserializer raises a ValueError when an initial BOM is present.

The RFC does not explicitly forbid JSON strings which contain byte sequences that don't correspond to valid Unicode characters (e.g. unpaired UTF-16 surrogates), but it does note that they may cause interoperability problems. By default, this module accepts and outputs (when present in the original str) code points for such sequences.

19.2.4.2. Infinite and NaN Number Values

The RFC does not permit the representation of infinite or NaN number values. Despite that, by default, this module accepts and outputs Infinity, -Infinity, and NaN as if they were valid JSON number literal values:

```python
>>> # Neither of these calls raises an exception, but
>>> json.dumps(float('-inf'))
'-Infinity'
>>> json.dumps(float('nan'))
'NaN'
>>> # Same when deserializing
>>> json.loads('-Infinity')
-inf
>>> json.loads('NaN')
nan
```
In the serializer, the `allow_nan` parameter can be used to alter this behavior. In the deserializer, the `parse_constant` parameter can be used to alter this behavior.

19.2.4.3. Repeated Names Within an Object

The RFC specifies that the names within a JSON object should be unique, but does not mandate how repeated names in JSON objects should be handled. By default, this module does not raise an exception; instead, it ignores all but the last name-value pair for a given name:

```python
>>> weird_json = '{"x": 1, "x": 2, "x": 3}'
>>> json.loads(weird_json)
{'x': 3}
```

The `object_pairs_hook` parameter can be used to alter this behavior.

19.2.4.4. Top-level Non-Object, Non-Array Values

The old version of JSON specified by the obsolete RFC 4627 required that the top-level value of a JSON text must be either a JSON object or array (Python `dict` or `list`), and could not be a JSON null, boolean, number, or string value. RFC 7159 removed that restriction, and this module does not and has never implemented that restriction in either its serializer or its deserializer.

Regardless, for maximum interoperability, you may wish to voluntarily adhere to the restriction yourself.

19.2.4.5. Implementation Limitations
Some JSON deserializer implementations may set limits on:

- the size of accepted JSON texts
- the maximum level of nesting of JSON objects and arrays
- the range and precision of JSON numbers
- the content and maximum length of JSON strings

This module does not impose any such limits beyond those of the relevant Python datatypes themselves or the Python interpreter itself.

When serializing to JSON, beware any such limitations in applications that may consume your JSON. In particular, it is common for JSON numbers to be deserialized into IEEE 754 double precision numbers and thus subject to that representation’s range and precision limitations. This is especially relevant when serializing Python `int` values of extremely large magnitude, or when serializing instances of “exotic” numerical types such as `decimal.Decimal`.
19.2.5. Command Line Interface

Source code: Lib/json/tool.py

The json.tool module provides a simple command line interface to validate and pretty-print JSON objects.

If the optional infile and outfile arguments are not specified, sys.stdin and sys.stdout will be used respectively:

```bash
$ echo '{"json": "obj"}' | python -m json.tool
{
    "json": "obj"
}
$ echo '{1.2:3.4}' | python -m json.tool
Expecting property name enclosed in double quotes: I
```

*Changed in version 3.5:* The output is now in the same order as the input. Use the `--sort-keys` option to sort the output of dictionaries alphabetically by key.

19.2.5.1. Command line options

**infile**

The JSON file to be validated or pretty-printed:

```bash
$ python -m json.tool mp_films.json
[
    {
        "title": "And Now for Something Completely Different",
        "year": 1971
```
If `infile` is not specified, read from `sys.stdin`.

**outfile**

Write the output of the `infile` to the given `outfile`. Otherwise, write it to `sys.stdout`.

**--sort-keys**

Sort the output of dictionaries alphabetically by key.

*New in version 3.5.*

**-h, --help**

Show the help message.

**Footnotes**

As noted in the errata for RFC 7159, JSON permits literal U+2028 (LINE SEPARATOR) and U+2029 (PARAGRAPH SEPARATOR) characters in strings, whereas JavaScript (as of ECMAScript Edition 5.1) does not.

[1]
Mailcap files are used to configure how MIME-aware applications such as mail readers and Web browsers react to files with different MIME types. (The name “mailcap” is derived from the phrase “mail capability”.) For example, a mailcap file might contain a line like `video/mpeg; xmpeg %s`. Then, if the user encounters an email message or Web document with the MIME type `video/mpeg`, `%s` will be replaced by a filename (usually one belonging to a temporary file) and the `xmpeg` program can be automatically started to view the file.

The mailcap format is documented in RFC 1524, “A User Agent Configuration Mechanism For Multimedia Mail Format Information,” but is not an Internet standard. However, mailcap files are supported on most Unix systems.

```python
mailcap.findmatch(caps, MIMEtype, key='view', filename='/dev/null', plist=[])  
```

Return a 2-tuple; the first element is a string containing the command line to be executed (which can be passed to `os.system()`), and the second element is the mailcap entry for a given MIME type. If no matching MIME type can be found, `(None, None)` is returned.

`key` is the name of the field desired, which represents the type of activity to be performed; the default value is ‘view’, since in the
most common case you simply want to view the body of the MIME-typed data. Other possible values might be 'compose' and 'edit', if you wanted to create a new body of the given MIME type or alter the existing body data. See RFC 1524 for a complete list of these fields.

*filename* is the filename to be substituted for %s in the command line; the default value is '/dev/null' which is almost certainly not what you want, so usually you'll override it by specifying a filename.

*plist* can be a list containing named parameters; the default value is simply an empty list. Each entry in the list must be a string containing the parameter name, an equals sign ('='), and the parameter's value. Mailcap entries can contain named parameters like %{foo}, which will be replaced by the value of the parameter named 'foo'. For example, if the command line `showpartial %{id} %{number} %{total}` was in a mailcap file, and *plist* was set to `['id=1', 'number=2', 'total=3']`, the resulting command line would be `showpartial 1 2 3`.

In a mailcap file, the “test” field can optionally be specified to test some external condition (such as the machine architecture, or the window system in use) to determine whether or not the mailcap line applies. `findmatch()` will automatically check such conditions and skip the entry if the check fails.

**mailcap.getcaps()**

Returns a dictionary mapping MIME types to a list of mailcap file entries. This dictionary must be passed to the `findmatch()` function. An entry is stored as a list of dictionaries, but it shouldn't be necessary to know the details of this representation.
The information is derived from all of the mailcap files found on the system. Settings in the user's mailcap file $HOME/.mailcap will override settings in the system mailcap files /etc/mailcap, /usr/etc/mailcap, and /usr/local/etc/mailcap.

An example usage:

```python
>>> import mailcap
>>> d = mailcap.getcaps()
>>> mailcap.findmatch(d, 'video/mpeg', filename='tmp
('xmpeg tmp1223', {'view': 'xmpeg %s'})
```
19.4. \texttt{mailbox} — Manipulate mailboxes in various formats

\textbf{Source code:} Lib/mailbox.py

This module defines two classes, \texttt{Mailbox} and \texttt{Message}, for accessing and manipulating on-disk mailboxes and the messages they contain. \texttt{Mailbox} offers a dictionary-like mapping from keys to messages. \texttt{Message} extends the \texttt{email.message} module's \texttt{Message} class with format-specific state and behavior. Supported mailbox formats are Maildir, mbox, MH, Babyl, and MMDF.

\textbf{See also:}

\textbf{Module email}

Represent and manipulate messages.
19.4.1. **Mailbox objects**

class mailbox.Mailbox

A mailbox, which may be inspected and modified.

The Mailbox class defines an interface and is not intended to be instantiated. Instead, format-specific subclasses should inherit from Mailbox and your code should instantiate a particular subclass.

The Mailbox interface is dictionary-like, with small keys corresponding to messages. Keys are issued by the Mailbox instance with which they will be used and are only meaningful to that Mailbox instance. A key continues to identify a message even if the corresponding message is modified, such as by replacing it with another message.

Messages may be added to a Mailbox instance using the set-like method add() and removed using a del statement or the set-like methods remove() and discard().

Mailbox interface semantics differ from dictionary semantics in some noteworthy ways. Each time a message is requested, a new representation (typically a Message instance) is generated based upon the current state of the mailbox. Similarly, when a message is added to a Mailbox instance, the provided message representation’s contents are copied. In neither case is a reference to the message representation kept by the Mailbox instance.

The default Mailbox iterator iterates over message representations, not keys as the default dictionary iterator does. Moreover, modification of a mailbox during iteration is safe and
well-defined. Messages added to the mailbox after an iterator is created will not be seen by the iterator. Messages removed from the mailbox before the iterator yields them will be silently skipped, though using a key from an iterator may result in a `KeyError` exception if the corresponding message is subsequently removed.

**Warning:** Be very cautious when modifying mailboxes that might be simultaneously changed by some other process. The safest mailbox format to use for such tasks is Maildir; try to avoid using single-file formats such as mbox for concurrent writing. If you’re modifying a mailbox, you must lock it by calling the `lock()` and `unlock()` methods before reading any messages in the file or making any changes by adding or deleting a message. Failing to lock the mailbox runs the risk of losing messages or corrupting the entire mailbox.

Mailbox instances have the following methods:

`add(message)`

Add `message` to the mailbox and return the key that has been assigned to it.

Parameter `message` may be a `Message` instance, an `email.message.Message` instance, a string, a byte string, or a file-like object (which should be open in binary mode). If `message` is an instance of the appropriate format-specific `Message` subclass (e.g., if it’s an `mboxMessage` instance and this is an `mbox` instance), its format-specific information is used. Otherwise, reasonable defaults for format-specific information are used.

*Changed in version 3.2:* Support for binary input was added.
**remove**(key)
**__delitem__**(key)
**discard**(key)

Delete the message corresponding to *key* from the mailbox.

If no such message exists, a **KeyError** exception is raised if the method was called as **remove()** or **__delitem__()** but no exception is raised if the method was called as **discard()**. The behavior of **discard()** may be preferred if the underlying mailbox format supports concurrent modification by other processes.

**__setitem__**(key, message)

Replace the message corresponding to *key* with *message*. Raise a **KeyError** exception if no message already corresponds to *key*.

As with **add()**, parameter *message* may be a **Message** instance, an **email.message.Message** instance, a string, a byte string, or a file-like object (which should be open in binary mode). If *message* is an instance of the appropriate format-specific **Message** subclass (e.g., if it’s an **mboxMessage** instance and this is an **mbox** instance), its format-specific information is used. Otherwise, the format-specific information of the message that currently corresponds to *key* is left unchanged.

**iterkeys()**
**keys()**

Return an iterator over all keys if called as **iterkeys()** or return a list of keys if called as **keys()**.
**itervalues()**
**__iter__()**
**values()**

Return an iterator over representations of all messages if called as `itervalues()` or `__iter__()` or return a list of such representations if called as `values()`. The messages are represented as instances of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

**Note:** The behavior of `__iter__()` is unlike that of dictionaries, which iterate over keys.

**iteritems()**
**items()**

Return an iterator over `(key, message)` pairs, where `key` is a key and `message` is a message representation, if called as `iteritems()` or return a list of such pairs if called as `items()`. The messages are represented as instances of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

**get(key, default=None)**
**__getitem__(key)**

Return a representation of the message corresponding to `key`. If no such message exists, `default` is returned if the method was called as `get()` and a `KeyError` exception is raised if the method was called as `__getitem__()`. The message is represented as an instance of the appropriate format-specific `Message` subclass unless a custom message factory was
specified when the Mailbox instance was initialized.

**get_message(key)**

Return a representation of the message corresponding to `key` as an instance of the appropriate format-specific `Message` subclass, or raise a `KeyError` exception if no such message exists.

**get_bytes(key)**

Return a byte representation of the message corresponding to `key`, or raise a `KeyError` exception if no such message exists.

*New in version 3.2.*

**get_string(key)**

Return a string representation of the message corresponding to `key`, or raise a `KeyError` exception if no such message exists. The message is processed through `email.message.Message` to convert it to a 7bit clean representation.

**get_file(key)**

Return a file-like representation of the message corresponding to `key`, or raise a `KeyError` exception if no such message exists. The file-like object behaves as if open in binary mode. This file should be closed once it is no longer needed.

*Changed in version 3.2:* The file object really is a binary file; previously it was incorrectly returned in text mode. Also, the file-like object now supports the context management protocol: you can use a `with` statement to automatically close it.
Note: Unlike other representations of messages, file-like representations are not necessarily independent of the Mailbox instance that created them or of the underlying mailbox. More specific documentation is provided by each subclass.

__contains__(key)
Return True if key corresponds to a message, False otherwise.

__len__()  
Return a count of messages in the mailbox.

clear()  
Delete all messages from the mailbox.

pop(key, default=None)
Return a representation of the message corresponding to key and delete the message. If no such message exists, return default. The message is represented as an instance of the appropriate format-specific Message subclass unless a custom message factory was specified when the Mailbox instance was initialized.

popitem()
Return an arbitrary (key, message) pair, where key is a key and message is a message representation, and delete the corresponding message. If the mailbox is empty, raise a KeyError exception. The message is represented as an instance of the appropriate format-specific Message subclass unless a custom message factory was specified when the
**Mailbox** instance was initialized.

**update**(arg)
Parameter *arg* should be a *key-to-message* mapping or an iterable of *(key, message)* pairs. Updates the mailbox so that, for each given *key* and *message*, the message corresponding to *key* is set to *message* as if by using **__setitem__**( ). As with **__setitem__**( ), each *key* must already correspond to a message in the mailbox or else a **KeyError** exception will be raised, so in general it is incorrect for *arg* to be a **Mailbox** instance.

**Note:** Unlike with dictionaries, keyword arguments are not supported.

**flush()**
Write any pending changes to the filesystem. For some **Mailbox** subclasses, changes are always written immediately and **flush**( ) does nothing, but you should still make a habit of calling this method.

**lock()**
Acquire an exclusive advisory lock on the mailbox so that other processes know not to modify it. An **External Clash Error** is raised if the lock is not available. The particular locking mechanisms used depend upon the mailbox format. You should *always* lock the mailbox before making any modifications to its contents.

**unlock()**
Release the lock on the mailbox, if any.
close()
Flush the mailbox, unlock it if necessary, and close any open files. For some Mailbox subclasses, this method does nothing.

19.4.1.1. Maildir

class mailbox. Maildir( dirname, factory=None, create=True )
A subclass of Mailbox for mailboxes in Maildir format. Parameter factory is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If factory is None, MaildirMessage is used as the default message representation. If create is True, the mailbox is created if it does not exist.

It is for historical reasons that dirname is named as such rather than path.

Maildir is a directory-based mailbox format invented for the qmail mail transfer agent and now widely supported by other programs. Messages in a Maildir mailbox are stored in separate files within a common directory structure. This design allows Maildir mailboxes to be accessed and modified by multiple unrelated programs without data corruption, so file locking is unnecessary.

Maildir mailboxes contain three subdirectories, namely: tmp, new, and cur. Messages are created momentarily in the tmp subdirectory and then moved to the new subdirectory to finalize delivery. A mail user agent may subsequently move the message to the cur subdirectory and store information about the state of the message in a special “info” section appended to its file name.
Folders of the style introduced by the Courier mail transfer agent are also supported. Any subdirectory of the main mailbox is considered a folder if '.' is the first character in its name. Folder names are represented by Maildir without the leading '. '. Each folder is itself a Maildir mailbox but should not contain other folders. Instead, a logical nesting is indicated using '.' to delimit levels, e.g., “Archived.2005.07”.

**Note:** The Maildir specification requires the use of a colon (':') in certain message file names. However, some operating systems do not permit this character in file names. If you wish to use a Maildir-like format on such an operating system, you should specify another character to use instead. The exclamation point ('!') is a popular choice. For example:

```
import mailbox
mailbox.Maildir.colon = '!!'
```

The colon attribute may also be set on a per-instance basis.

Maildir instances have all of the methods of Mailbox in addition to the following:

**list_folders()**

Return a list of the names of all folders.

**get_folder(folder)**

Return a Maildir instance representing the folder whose name is `folder`. A NoSuchMailboxError exception is raised if the folder does not exist.

**add_folder(folder)**

Create a folder whose name is `folder` and return a Maildir
instance representing it.

**remove_folder(folder)**
Delete the folder whose name is *folder*. If the folder contains any messages, a **NotEmptyError** exception will be raised and the folder will not be deleted.

**clean()**
Delete temporary files from the mailbox that have not been accessed in the last 36 hours. The Maildir specification says that mail-reading programs should do this occasionally.

Some **Mailbox** methods implemented by **Maildir** deserve special remarks:

**add(message)**
**__setitem__(key, message)**
**update(arg)**

**Warning:** These methods generate unique file names based upon the current process ID. When using multiple threads, undetected name clashes may occur and cause corruption of the mailbox unless threads are coordinated to avoid using these methods to manipulate the same mailbox simultaneously.

**flush()**
All changes to Maildir mailboxes are immediately applied, so this method does nothing.

**lock()**
**unlock()**
Maildir mailboxes do not support (or require) locking, so these
methods do nothing.

**close()**

*Maildir* instances do not keep any open files and the underlying mailboxes do not support locking, so this method does nothing.

**get_file(key)**

Depending upon the host platform, it may not be possible to modify or remove the underlying message while the returned file remains open.

---

### 19.4.1.2. **mbox**

`class mailbox.**mbox**(path, factory=None, create=True)`

A subclass of `Mailbox` for mailboxes in mbox format. Parameter `factory` is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If `factory` is `None`, `mboxMessage` is used as the default message representation. If `create` is `True`,
the mailbox is created if it does not exist.

The mbox format is the classic format for storing mail on Unix systems. All messages in an mbox mailbox are stored in a single file with the beginning of each message indicated by a line whose first five characters are “From “.

Several variations of the mbox format exist to address perceived shortcomings in the original. In the interest of compatibility, mbox implements the original format, which is sometimes referred to as mboxo. This means that the Content-Length header, if present, is ignored and that any occurrences of “From ” at the beginning of a line in a message body are transformed to “>From ” when storing the message, although occurrences of “>From ” are not transformed to “From ” when reading the message.

Some Mailbox methods implemented by mbox deserve special remarks:

get_file(key)

Using the file after calling flush() or close() on the mbox instance may yield unpredictable results or raise an exception.

lock()
unlock()

Three locking mechanisms are used—dot locking and, if available, the flock() and lockf() system calls.

mbox man page from qmail
A specification of the format and its variations.

mbox man page from tin
Another specification of the format, with details on locking.

**Configuring Netscape Mail on Unix: Why The Content-Length Format is Bad**

An argument for using the original mbox format rather than a variation.

“mbox” is a family of several mutually incompatible mailbox formats

A history of mbox variations.

19.4.1.3. **MH**

```python
class mailbox.MH(path, factory=None, create=True)
```

A subclass of Mailbox for mailboxes in MH format. Parameter `factory` is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If `factory` is `None`, `MHMessage` is used as the default message representation. If `create` is `True`, the mailbox is created if it does not exist.

MH is a directory-based mailbox format invented for the MH Message Handling System, a mail user agent. Each message in an MH mailbox resides in its own file. An MH mailbox may contain other MH mailboxes (called *folders*) in addition to messages. Folders may be nested indefinitely. MH mailboxes also support *sequences*, which are named lists used to logically group messages without moving them to sub-folders. Sequences are defined in a file called `.mh_sequences` in each folder.

The **MH** class manipulates MH mailboxes, but it does not attempt to emulate all of **mh**’s behaviors. In particular, it does not modify and is not affected by the context or `.mh_profile` files that are
used by `mh` to store its state and configuration.

MH instances have all of the methods of `Mailbox` in addition to the following:

**list_folders()**
Return a list of the names of all folders.

**get_folder(folder)**
Return an MH instance representing the folder whose name is `folder`. A `NoSuchMailboxError` exception is raised if the folder does not exist.

**add_folder(folder)**
Create a folder whose name is `folder` and return an MH instance representing it.

**remove_folder(folder)**
Delete the folder whose name is `folder`. If the folder contains any messages, a `NotEmptyError` exception will be raised and the folder will not be deleted.

**get_sequences()**
Return a dictionary of sequence names mapped to key lists. If there are no sequences, the empty dictionary is returned.

**set_sequences(sequences)**
Re-define the sequences that exist in the mailbox based upon `sequences`, a dictionary of names mapped to key lists, like returned by `get_sequences()`.

**pack()**
Rename messages in the mailbox as necessary to eliminate
gaps in numbering. Entries in the sequences list are updated correspondingly.

**Note:** Already-issued keys are invalidated by this operation and should not be subsequently used.

Some Mailbox methods implemented by MH deserve special remarks:

```python
remove(key)
__delitem__(key)
discard(key)
```

These methods immediately delete the message. The MH convention of marking a message for deletion by prepending a comma to its name is not used.

```python
lock()
unlock()
```

Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls. For MH mailboxes, locking the mailbox means locking the `.mh_sequences` file and, only for the duration of any operations that affect them, locking individual message files.

```python
get_file(key)
```

Depending upon the host platform, it may not be possible to remove the underlying message while the returned file remains open.

```python
flush()
```

All changes to MH mailboxes are immediately applied, so this method does nothing.
close()

MH instances do not keep any open files, so this method is equivalent to unlock().

MH & nmh: Email for Users & Programmers
    A GPL-licensed book on mh and nmh, with some information on the mailbox format.

19.4.1.4. Babyl

class mailbox. Babyl(path, factory=None, create=True)

A subclass of Mailbox for mailboxes in Babyl format. Parameter factory is a callble object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If factory is None, BabylMessage is used as the default message representation. If create is True, the mailbox is created if it does not exist.

Babyl is a single-file mailbox format used by the Rmail mail user agent included with Emacs. The beginning of a message is indicated by a line containing the two characters Control-Underscore (\037) and Control-L (\014). The end of a message is indicated by the start of the next message or, in the case of the last message, a line containing a Control-Underscore (\037) character.

Messages in a Babyl mailbox have two sets of headers, original
headers and so-called visible headers. Visible headers are typically a subset of the original headers that have been reformatted or abridged to be more attractive. Each message in a Babyl mailbox also has an accompanying list of labels, or short strings that record extra information about the message, and a list of all user-defined labels found in the mailbox is kept in the Babyl options section.

Babyl instances have all of the methods of Mailbox in addition to the following:

get_labels()
Return a list of the names of all user-defined labels used in the mailbox.

Note: The actual messages are inspected to determine which labels exist in the mailbox rather than consulting the list of labels in the Babyl options section, but the Babyl section is updated whenever the mailbox is modified.

Some Mailbox methods implemented by Babyl deserve special remarks:

get_file(key)
In Babyl mailboxes, the headers of a message are not stored contiguously with the body of the message. To generate a file-like representation, the headers and body are copied together into an io.BytesIO instance, which has an API identical to that of a file. As a result, the file-like object is truly independent of the underlying mailbox but does not save memory compared to a string representation.

lock()
unlock()

Three locking mechanisms are used—dot locking and, if available, the flock() and lockf() system calls.

See also:

Format of Version 5 Babyl Files
A specification of the Babyl format.

Reading Mail with Rmail
The Rmail manual, with some information on Babyl semantics.

19.4.1.5. MMDF

class mailbox. MMDF(path, factory=None, create=True)

A subclass of Mailbox for mailboxes in MMDF format. Parameter factory is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If factory is None, MMDFMessage is used as the default message representation. If create is True, the mailbox is created if it does not exist.

MMDF is a single-file mailbox format invented for the Multichannel Memorandum Distribution Facility, a mail transfer agent. Each message is in the same form as an mbox message but is bracketed before and after by lines containing four Control-A ('\001') characters. As with the mbox format, the beginning of each message is indicated by a line whose first five characters are “From “, but additional occurrences of “From ” are not transformed to “>From ” when storing messages because the extra message separator lines prevent mistaking such occurrences for the starts of subsequent messages.
Some Mailbox methods implemented by MMDF deserve special remarks:

**get_file**(key)

Using the file after calling flush() or close() on the MMDF instance may yield unpredictable results or raise an exception.

**lock()**

**unlock()**

Three locking mechanisms are used—dot locking and, if available, the flock() and lockf() system calls.

See also:

**mmdf man page from tin**

A specification of MMDF format from the documentation of tin, a newsreader.

**MMDF**

A Wikipedia article describing the Multichannel Memorandum Distribution Facility.
19.4.2. **Message** objects

```python
class mailbox.Message(message=None)
```

If `message` is omitted, the new instance is created in a default, empty state. If `message` is an `email.message.Message` instance, its contents are copied; furthermore, any format-specific information is converted insofar as possible if `message` is a `Message` instance. If `message` is a string, a byte string, or a file, it should contain an RFC 2822-compliant message, which is read and parsed. Files should be open in binary mode, but text mode files are accepted for backward compatibility.

The format-specific state and behaviors offered by subclasses vary, but in general it is only the properties that are not specific to a particular mailbox that are supported (although presumably the properties are specific to a particular mailbox format). For example, file offsets for single-file mailbox formats and file names for directory-based mailbox formats are not retained, because they are only applicable to the original mailbox. But state such as whether a message has been read by the user or marked as important is retained, because it applies to the message itself.

There is no requirement that `Message` instances be used to represent messages retrieved using `Mailbox` instances. In some situations, the time and memory required to generate `Message` representations might not be acceptable. For such situations, `Mailbox` instances also offer string and file-like representations,
and a custom message factory may be specified when a Mailbox instance is initialized.

### 19.4.2.1. MaildirMessage

**class** mailbox.MaildirMessage(*message=None*)

A message with Maildir-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

Typically, a mail user agent application moves all of the messages in the new subdirectory to the cur subdirectory after the first time the user opens and closes the mailbox, recording that the messages are old whether or not they’ve actually been read. Each message in cur has an “info” section added to its file name to store information about its state. (Some mail readers may also add an “info” section to messages in new.) The “info” section may take one of two forms: it may contain “2,” followed by a list of standardized flags (e.g., “2,FR”) or it may contain “1,” followed by so-called experimental information. Standard flags for Maildir messages are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Draft</td>
<td>Under composition</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>P</td>
<td>Passed</td>
<td>Forwarded, resent, or bounced</td>
</tr>
<tr>
<td>R</td>
<td>Replied</td>
<td>Replied to</td>
</tr>
<tr>
<td>S</td>
<td>Seen</td>
<td>Read</td>
</tr>
<tr>
<td>T</td>
<td>Trashed</td>
<td>Marked for subsequent deletion</td>
</tr>
</tbody>
</table>

MaildirMessage instances offer the following methods:
get_subdir()
Return either “new” (if the message should be stored in the new subdirectory) or “cur” (if the message should be stored in the cur subdirectory).

Note: A message is typically moved from new to cur after its mailbox has been accessed, whether or not the message is has been read. A message msg has been read if "S" in msg.get_flags() is True.

set_subdir(subdir)
Set the subdirectory the message should be stored in. Parameter subdir must be either “new” or “cur”.

get_flags()
Return a string specifying the flags that are currently set. If the message complies with the standard Maildir format, the result is the concatenation in alphabetical order of zero or one occurrence of each of 'D', 'F', 'P', 'R', 'S', and 'T'. The empty string is returned if no flags are set or if "info" contains experimental semantics.

set_flags(flags)
Set the flags specified by flags and unset all others.

add_flag(flag)
Set the flag(s) specified by flag without changing other flags. To add more than one flag at a time, flag may be a string of more than one character. The current “info” is overwritten whether or not it contains experimental information rather than flags.

remove_flag(flag)
Unset the flag(s) specified by flag without changing other flags. To remove more than one flag at a time, flag maybe a string of more than one character. If “info” contains experimental information rather than flags, the current “info” is not modified.

**get_date()**

Return the delivery date of the message as a floating-point number representing seconds since the epoch.

**set_date(date)**

Set the delivery date of the message to date, a floating-point number representing seconds since the epoch.

**get_info()**

Return a string containing the “info” for a message. This is useful for accessing and modifying “info” that is experimental (i.e., not a list of flags).

**set_info(info)**

Set “info” to info, which should be a string.

When a MaildirMessage instance is created based upon an mboxMessage or MMDFMessage instance, the Status and X-Status headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage or MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>O flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>R flag</td>
<td>A flag</td>
</tr>
<tr>
<td>S flag</td>
<td>R flag</td>
</tr>
<tr>
<td>T flag</td>
<td>D flag</td>
</tr>
</tbody>
</table>
When a `MaildirMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>“cur” subdirectory and S flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>R flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When a `MaildirMessage` instance is created based upon a `BabylMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>“cur” subdirectory and S flag</td>
<td>no “unseen” label</td>
</tr>
<tr>
<td>P flag</td>
<td>“forwarded” or “resent” label</td>
</tr>
<tr>
<td>R flag</td>
<td>“answered” label</td>
</tr>
<tr>
<td>T flag</td>
<td>“deleted” label</td>
</tr>
</tbody>
</table>

### 19.4.2.2. `mboxMessage`

```python
class mailbox.mboxMessage(message=None)
```

A message with mbox-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

Messages in an mbox mailbox are stored together in a single file. The sender’s envelope address and the time of delivery are typically stored in a line beginning with “From ” that is used to indicate the start of a message, though there is considerable
variation in the exact format of this data among mbox implementations. Flags that indicate the state of the message, such as whether it has been read or marked as important, are typically stored in Status and X-Status headers.

Conventional flags for mbox messages are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Read</td>
<td>Read</td>
</tr>
<tr>
<td>O</td>
<td>Old</td>
<td>Previously detected by MUA</td>
</tr>
<tr>
<td>D</td>
<td>Deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>A</td>
<td>Answered</td>
<td>Replied to</td>
</tr>
</tbody>
</table>

The “R” and “O” flags are stored in the Status header, and the “D”, “F”, and “A” flags are stored in the X-Status header. The flags and headers typically appear in the order mentioned.

mboxMessage instances offer the following methods:

**get_from()**

Return a string representing the “From ” line that marks the start of the message in an mbox mailbox. The leading “From ” and the trailing newline are excluded.

**set_from(from_, time_=None)**

Set the “From ” line to from_, which should be specified without a leading “From ” or trailing newline. For convenience, time_ may be specified and will be formatted appropriately and appended to from_. If time_ is specified, it should be a time.struct_time instance, a tuple suitable for passing to
time.strftime(), or True (to use time.gmtime()).

get_flags()
Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of 'R', 'O', 'D', 'F', and 'A'.

set_flags(flags)
Set the flags specified by flags and unset all others. Parameter flags should be the concatenation in any order of zero or more occurrences of each of 'R', 'O', 'D', 'F', and 'A'.

add_flag(flag)
Set the flag(s) specified by flag without changing other flags. To add more than one flag at a time, flag may be a string of more than one character.

remove_flag(flag)
Unset the flag(s) specified by flag without changing other flags. To remove more than one flag at a time, flag maybe a string of more than one character.

When an mboxMessage instance is created based upon a MaildirMessage instance, a “From ” line is generated based upon the MaildirMessage instance’s delivery date, and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>S flag</td>
</tr>
<tr>
<td>O flag</td>
<td>“cur” subdirectory</td>
</tr>
</tbody>
</table>
When an `mboxMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>A flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When an `mboxMessage` instance is created based upon a `BabylMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” label</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>D flag</td>
<td>“deleted” label</td>
</tr>
<tr>
<td>A flag</td>
<td>“answered” label</td>
</tr>
</tbody>
</table>

When a `Message` instance is created based upon an `MMDFMessage` instance, the “From ” line is copied and all flags directly correspond:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>R flag</td>
</tr>
<tr>
<td>O flag</td>
<td>O flag</td>
</tr>
<tr>
<td>Sequence</td>
<td>Explanation</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>unseen</td>
<td>Not read, but previously detected by MUA</td>
</tr>
<tr>
<td>replied</td>
<td>Replied to</td>
</tr>
<tr>
<td>flagged</td>
<td>Marked as important</td>
</tr>
</tbody>
</table>

19.4.2.3. **MHMessage**

class mailbox. **MHMessage**(message=None)

A message with MH-specific behaviors. Parameter *message* has the same meaning as with the **Message** constructor.

MH messages do not support marks or flags in the traditional sense, but they do support sequences, which are logical groupings of arbitrary messages. Some mail reading programs (although not the standard **mh** and **nmh**) use sequences in much the same way flags are used with other formats, as follows:

**MHMessage** instances offer the following methods:

**get_sequences()**

Return a list of the names of sequences that include this message.

**set_sequences(sequences)**

Set the list of sequences that include this message.

**add_sequence(sequence)**
Add \texttt{sequence} to the list of sequences that include this message.

\textbf{remove\_sequence}(\texttt{sequence})

Remove \texttt{sequence} from the list of sequences that include this message.

When an \texttt{MHMessage} instance is created based upon a \texttt{MaildirMessage} instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>no S flag</td>
</tr>
<tr>
<td>“replied” sequence</td>
<td>R flag</td>
</tr>
<tr>
<td>“flagged” sequence</td>
<td>F flag</td>
</tr>
</tbody>
</table>

When an \texttt{MHMessage} instance is created based upon an \texttt{mboxMessage} or \texttt{MMDFMessage} instance, the \texttt{Status} and \texttt{X-Status} headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage or MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>no R flag</td>
</tr>
<tr>
<td>“replied” sequence</td>
<td>A flag</td>
</tr>
<tr>
<td>“flagged” sequence</td>
<td>F flag</td>
</tr>
</tbody>
</table>

When an \texttt{MHMessage} instance is created based upon a \texttt{BabylMessage} instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>“unseen” label</td>
</tr>
</tbody>
</table>
“replied” sequence | “answered” label

19.4.2.4. **BabylMessage**

class mailbox. **BabylMessage**(message=None)

A message with Babyl-specific behaviors. Parameter *message* has the same meaning as with the **Message** constructor.

Certain message labels, called *attributes*, are defined by convention to have special meanings. The attributes are as follows:

<table>
<thead>
<tr>
<th>Label</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>unseen</td>
<td>Not read, but previously detected by MUA</td>
</tr>
<tr>
<td>deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>filed</td>
<td>Copied to another file or mailbox</td>
</tr>
<tr>
<td>answered</td>
<td>Replied to</td>
</tr>
<tr>
<td>forwarded</td>
<td>Forwarded</td>
</tr>
<tr>
<td>edited</td>
<td>Modified by the user</td>
</tr>
<tr>
<td>resent</td>
<td>Resent</td>
</tr>
</tbody>
</table>

By default, Rmail displays only visible headers. The **BabylMessage** class, though, uses the original headers because they are more complete. Visible headers may be accessed explicitly if desired.

**BabylMessage** instances offer the following methods:

**get_labels()**

Return a list of labels on the message.

**set_labels**(labels)
Set the list of labels on the message to labels.

add_label(label)
Add label to the list of labels on the message.

remove_label(label)
Remove label from the list of labels on the message.

get_visible()
Return an Message instance whose headers are the message’s visible headers and whose body is empty.

set_visible(visible)
Set the message’s visible headers to be the same as the headers in message. Parameter visible should be a Message instance, an email.message.Message instance, a string, or a file-like object (which should be open in text mode).

update_visible()
When a BabylMessage instance’s original headers are modified, the visible headers are not automatically modified to correspond. This method updates the visible headers as follows: each visible header with a corresponding original header is set to the value of the original header, each visible header without a corresponding original header is removed, and any of Date, From, Reply-To, To, CC, and Subject that are present in the original headers but not the visible headers are added to the visible headers.

When a BabylMessage instance is created based upon a MaildirMessage instance, the following conversions take place:
<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” label</td>
<td>no S flag</td>
</tr>
<tr>
<td>“deleted” label</td>
<td>T flag</td>
</tr>
<tr>
<td>“answered” label</td>
<td>R flag</td>
</tr>
<tr>
<td>“forwarded” label</td>
<td>P flag</td>
</tr>
</tbody>
</table>

When a `BabylMessage` instance is created based upon an `mboxMessage` or `MMDFMessage` instance, the `Status` and `X-Status` headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th><code>mboxMessage</code> or <code>MMDFMessage</code> state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” label</td>
<td>no R flag</td>
</tr>
<tr>
<td>“deleted” label</td>
<td>D flag</td>
</tr>
<tr>
<td>“answered” label</td>
<td>A flag</td>
</tr>
</tbody>
</table>

When a `BabylMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th><code>MHMessage</code> state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” label</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>“answered” label</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

19.4.2.5. **MMDFMessage**

```python
class mailbox.MMDFMessage(message=None)
```

A message with MMDF-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

As with message in an mbox mailbox, MMDF messages are stored
with the sender’s address and the delivery date in an initial line beginning with “From “. Likewise, flags that indicate the state of the message are typically stored in Status and X-Status headers.

Conventional flags for MMDF messages are identical to those of mbox message and are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Read</td>
<td>Read</td>
</tr>
<tr>
<td>O</td>
<td>Old</td>
<td>Previously detected by MUA</td>
</tr>
<tr>
<td>D</td>
<td>Deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>A</td>
<td>Answered</td>
<td>Replied to</td>
</tr>
</tbody>
</table>

The “R” and “O” flags are stored in the Status header, and the “D”, “F”, and “A” flags are stored in the X-Status header. The flags and headers typically appear in the order mentioned.

MMDFMessage instances offer the following methods, which are identical to those offered by mboxMessage:

```python
get_from()  # Return a string representing the “From ” line that marks the start of the message in an mbox mailbox. The leading “From ” and the trailing newline are excluded.

set_from(from_, time_=None)  # Set the “From ” line to from_, which should be specified without a leading “From ” or trailing newline. For convenience, time_ may be specified and will be formatted appropriately and appended to from_. If time_ is specified, it should be a
```
time.struct_time instance, a tuple suitable for passing to time.strftime(), or True (to use time.gmtime()).

**get_flags()**
Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of 'R', 'O', 'D', 'F', and 'A'.

**set.flags(flags)**
Set the flags specified by flags and unset all others. Parameter flags should be the concatenation in any order of zero or more occurrences of each of 'R', 'O', 'D', 'F', and 'A'.

**add_flag(flag)**
Set the flag(s) specified by flag without changing other flags. To add more than one flag at a time, flag may be a string of more than one character.

**remove_flag(flag)**
Unset the flag(s) specified by flag without changing other flags. To remove more than one flag at a time, flag maybe a string of more than one character.

When an MMDFMessage instance is created based upon a MaildirMessage instance, a “From ” line is generated based upon the MaildirMessage instance’s delivery date, and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>S flag</td>
</tr>
<tr>
<td>O flag</td>
<td>“cur” subdirectory</td>
</tr>
</tbody>
</table>
When an **MMDFMessage** instance is created based upon an **MHMessage** instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>A flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When an **MMDFMessage** instance is created based upon a **BabylMessage** instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” label</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>D flag</td>
<td>“deleted” label</td>
</tr>
<tr>
<td>A flag</td>
<td>“answered” label</td>
</tr>
</tbody>
</table>

When an **MMDFMessage** instance is created based upon an **mboxMessage** instance, the “From ” line is copied and all flags directly correspond:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>R flag</td>
</tr>
<tr>
<td>O flag</td>
<td>O flag</td>
</tr>
<tr>
<td>--------</td>
<td>--------</td>
</tr>
<tr>
<td>D flag</td>
<td>D flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>A flag</td>
<td>A flag</td>
</tr>
</tbody>
</table>
19.4.3. Exceptions

The following exception classes are defined in the `mailbox` module:

```python
exception mailbox.Error
    The base class for all other module-specific exceptions.

exception mailbox.NoSuchMailboxError
    Raised when a mailbox is expected but is not found, such as when instantiating a `Mailbox` subclass with a path that does not exist (and with the `create` parameter set to `False`), or when opening a folder that does not exist.

exception mailbox.NotEmptyError
    Raised when a mailbox is not empty but is expected to be, such as when deleting a folder that contains messages.

exception mailbox.ExternalClashError
    Raised when some mailbox-related condition beyond the control of the program causes it to be unable to proceed, such as when failing to acquire a lock that another program already holds a lock, or when a uniquely-generated file name already exists.

exception mailbox.FormatError
    Raised when the data in a file cannot be parsed, such as when an `MH` instance attempts to read a corrupted `.mh_sequences` file.
```
19.4.4. Examples

A simple example of printing the subjects of all messages in a mailbox that seem interesting:

```python
import mailbox
for message in mailbox.mbox('~/mbox'):
    subject = message['subject']  # Could possibly be None.
    if subject and 'python' in subject.lower():
        print(subject)
```

To copy all mail from a Babyl mailbox to an MH mailbox, converting all of the format-specific information that can be converted:

```python
import mailbox
destination = mailbox.MH('~/Mail')
destination.lock()
for message in mailbox.Babyl('~/RMAIL'):
    destination.add(mailbox.MHMessage(message))
destination.flush()
destination.unlock()
```

This example sorts mail from several mailing lists into different mailboxes, being careful to avoid mail corruption due to concurrent modification by other programs, mail loss due to interruption of the program, or premature termination due to malformed messages in the mailbox:

```python
import mailbox
import email.errors

list_names = ('python-list', 'python-dev', 'python-
```
boxes = {name: mailbox.mbox('~/email/%s' % name) for name in list_names}

for key in inbox.iterkeys():
    try:
        message = inbox[key]
    except email.errors.MessageParseError:
        continue  # The message is malformed.

for name in list_names:
    list_id = message['list-id']
    if list_id and name in list_id:
        # Get mailbox to use
        box = boxes[name]

        # Write copy to disk before removing original.
        # If there's a crash, you might duplicate that's better than losing a message completely.
        box.lock()
        box.add(message)
        box.flush()
        box.unlock()

        # Remove original message
        inbox.lock()
        inbox.discard(key)
        inbox.flush()
        inbox.unlock()
        break  # Found destination,

for box in boxes.itervalues():
    box.close()
19.5. **mimetypes** — Map filenames to MIME types

**Source code:** Lib/mimetypes.py

The **mimetypes** module converts between a filename or URL and the MIME type associated with the filename extension. Conversions are provided from filename to MIME type and from MIME type to filename extension; encodings are not supported for the latter conversion.

The module provides one class and a number of convenience functions. The functions are the normal interface to this module, but some applications may be interested in the class as well.

The functions described below provide the primary interface for this module. If the module has not been initialized, they will call `init()` if they rely on the information `init()` sets up.

**mimetypes.** `.guess_type(url, strict=True)`

Guess the type of a file based on its filename or URL, given by `url`. The return value is a tuple *(type, encoding)* where *type* is `None` if the type can’t be guessed (missing or unknown suffix) or a string of the form `'type/subtype'`, usable for a MIME `content-type` header.

*encoding* is `None` for no encoding or the name of the program used to encode (e.g. `compress` or `gzip`). The encoding is suitable for use as a `Content-Encoding` header, **not** as a `Content-Transfer-Encoding` header. The mappings are table driven. Encoding suffixes are case sensitive; type suffixes are first tried case
sensitively, then case insensitively.

The optional *strict* argument is a flag specifying whether the list of known MIME types is limited to only the official types registered with IANA. When *strict* is `True` (the default), only the IANA types are supported; when *strict* is `False`, some additional non-standard but commonly used MIME types are also recognized.

```
mimetypes.guess_all_extensions(type, strict=True)
```

Guess the extensions for a file based on its MIME type, given by *type*. The return value is a list of strings giving all possible filename extensions, including the leading dot (`'.'`). The extensions are not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type *type* by `guess_type()`.

The optional *strict* argument has the same meaning as with the `guess_type()` function.

```
mimetypes.guess_extension(type, strict=True)
```

Guess the extension for a file based on its MIME type, given by *type*. The return value is a string giving a filename extension, including the leading dot (`'.'`). The extension is not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type *type* by `guess_type()`. If no extension can be guessed for *type*, `None` is returned.

The optional *strict* argument has the same meaning as with the `guess_type()` function.

Some additional functions and data items are available for controlling the behavior of the module.
mimetypes.init(files=None)

Initialize the internal data structures. If given, files must be a sequence of file names which should be used to augment the default type map. If omitted, the file names to use are taken from knownfiles; on Windows, the current registry settings are loaded. Each file named in files or knownfiles takes precedence over those named before it. Calling init() repeatedly is allowed.

Specifying an empty list for files will prevent the system defaults from being applied: only the well-known values will be present from a built-in list.

*Changed in version 3.2:* Previously, Windows registry settings were ignored.

mimetypes.read_mime_types(filename)

Load the type map given in the file filename, if it exists. The type map is returned as a dictionary mapping filename extensions, including the leading dot ('.'), to strings of the form 'type/subtype'. If the file filename does not exist or cannot be read, None is returned.

mimetypes.add_type(type, ext, strict=True)

Add a mapping from the MIME type type to the extension ext. When the extension is already known, the new type will replace the old one. When the type is already known the extension will be added to the list of known extensions.

When strict is True (the default), the mapping will be added to the official MIME types, otherwise to the non-standard ones.
Flag indicating whether or not the global data structures have been initialized. This is set to True by `init()`.

`mimetypes.knownfiles`
List of type map file names commonly installed. These files are typically named `mime.types` and are installed in different locations by different packages.

`mimetypes.suffix_map`
Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately.

`mimetypes.encodings_map`
Dictionary mapping filename extensions to encoding types.

`mimetypes.types_map`
Dictionary mapping filename extensions to MIME types.

`mimetypes.common_types`
Dictionary mapping filename extensions to non-standard, but commonly found MIME types.

An example usage of the module:

```python
>>> import mimetypes
>>> mimetypes.init()
>>> mimetypes.knownfiles
['/etc/mime.types', '/etc/httpd/mime.types', ...
]  
>>> mimetypes.suffix_map['.tgz']
'.tar.gz'
>>> mimetypes.encodings_map['.gz']
```
19.5.1. MimeTypes Objects

The `MimeTypes` class may be useful for applications which may want more than one MIME-type database; it provides an interface similar to the one of the `mimetypes` module.

```python
class mimetypes.MimeTypes(filenames=(), strict=True)
```

This class represents a MIME-types database. By default, it provides access to the same database as the rest of this module. The initial database is a copy of that provided by the module, and may be extended by loading additional `mime.types`-style files into the database using the `read()` or `readfp()` methods. The mapping dictionaries may also be cleared before loading additional data if the default data is not desired.

The optional `filenames` parameter can be used to cause additional files to be loaded “on top” of the default database.

**suffix_map**

Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately. This is initially a copy of the global `suffix_map` defined in the module.

**encodings_map**

Dictionary mapping filename extensions to encoding types. This is initially a copy of the global `encodings_map` defined in the module.
**types_map**

Tuple containing two dictionaries, mapping filename extensions to MIME types: the first dictionary is for the non-standards types and the second one is for the standard types. They are initialized by `common_types` and `types_map`.

**types_map_inv**

Tuple containing two dictionaries, mapping MIME types to a list of filename extensions: the first dictionary is for the non-standards types and the second one is for the standard types. They are initialized by `common_types` and `types_map`.

**guess_extension**(type, strict=True)

Similar to the `guess_extension()` function, using the tables stored as part of the object.

**guess_type**(url, strict=True)

Similar to the `guess_type()` function, using the tables stored as part of the object.

**guess_all_extensions**(type, strict=True)

Similar to the `guess_all_extensions()` function, using the tables stored as part of the object.

**read**(filename, strict=True)

Load MIME information from a file named `filename`. This uses `readfp()` to parse the file.

If `strict` is `True`, information will be added to list of standard types, else to the list of non-standard types.

**readfp**(fp, strict=True)
Load MIME type information from an open file \texttt{fp}. The file must have the format of the standard \texttt{mime.types} files.

If \textit{strict} is \texttt{True}, information will be added to the list of standard types, else to the list of non-standard types.

\texttt{read\_windows\_registry(\textit{strict=\texttt{True}})}

Load MIME type information from the Windows registry. Availability: Windows.

If \textit{strict} is \texttt{True}, information will be added to the list of standard types, else to the list of non-standard types.

\textit{New in version 3.2.}
19.6. **base64** — Base16, Base32, Base64, Base85 Data Encodings

**Source code:** Lib/base64.py

This module provides functions for encoding binary data to printable ASCII characters and decoding such encodings back to binary data. It provides encoding and decoding functions for the encodings specified in [RFC 3548](https://tools.ietf.org/html/rfc3548), which defines the Base16, Base32, and Base64 algorithms, and for the de-facto standard Ascii85 and Base85 encodings.

The [RFC 3548](https://tools.ietf.org/html/rfc3548) encodings are suitable for encoding binary data so that it can safely sent by email, used as parts of URLs, or included as part of an HTTP POST request. The encoding algorithm is not the same as the uuencode program.

There are two interfaces provided by this module. The modern interface supports encoding `bytes-like objects` to ASCII `bytes`, and decoding `bytes-like objects` or strings containing ASCII to `bytes`. Both base-64 alphabets defined in [RFC 3548](https://tools.ietf.org/html/rfc3548) (normal, and URL- and filesystem-safe) are supported.

The legacy interface does not support decoding from strings, but it does provide functions for encoding and decoding to and from `file objects`. It only supports the Base64 standard alphabet, and it adds newlines every 76 characters as per [RFC 2045](https://tools.ietf.org/html/rfc2045). Note that if you are looking for [RFC 2045](https://tools.ietf.org/html/rfc2045) support you probably want to be looking at the `email` package instead.
*Changed in version 3.3:* ASCII-only Unicode strings are now accepted by the decoding functions of the modern interface.

*Changed in version 3.4:* Any bytes-like objects are now accepted by all encoding and decoding functions in this module. Ascii85/Base85 support added.

The modern interface provides:

```python
base64.b64encode(s, altchars=None)
```
Encode the bytes-like object `s` using Base64 and return the encoded bytes.

Optional `altchars` must be a bytes-like object of at least length 2 (additional characters are ignored) which specifies an alternative alphabet for the `+` and `/` characters. This allows an application to e.g. generate URL or filesystem safe Base64 strings. The default is `None`, for which the standard Base64 alphabet is used.

```python
base64.b64decode(s, altchars=None, validate=False)
```
Decode the Base64 encoded bytes-like object or ASCII string `s` and return the decoded bytes.

Optional `altchars` must be a bytes-like object or ASCII string of at least length 2 (additional characters are ignored) which specifies the alternative alphabet used instead of the `+` and `/` characters.

A `binascii.Error` exception is raised if `s` is incorrectly padded.

If `validate` is `False` (the default), characters that are neither in the normal base-64 alphabet nor the alternative alphabet are discarded prior to the padding check. If `validate` is `True`, these non-alphabet characters in the input result in a `binascii.Error`. 
base64. **standard_b64encode**(s)

Encode bytes-like object s using the standard Base64 alphabet and return the encoded bytes.

base64. **standard_b64decode**(s)

Decode bytes-like object or ASCII string s using the standard Base64 alphabet and return the decoded bytes.

base64. **urlsafe_b64encode**(s)

Encode bytes-like object s using the URL- and filesystem-safe alphabet, which substitutes - instead of + and _ instead of / in the standard Base64 alphabet, and return the encoded bytes. The result can still contain =.

base64. **urlsafe_b64decode**(s)

Decode bytes-like object or ASCII string s using the URL- and filesystem-safe alphabet, which substitutes - instead of + and _ instead of / in the standard Base64 alphabet, and return the decoded bytes.

base64. **b32encode**(s)

Encode the bytes-like object s using Base32 and return the encoded bytes.

base64. **b32decode**(s, casefold=False, map01=None)

Decode the Base32 encoded bytes-like object or ASCII string s and return the decoded bytes.

Optional casefold is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is False.

**RFC 3548** allows for optional mapping of the digit 0 (zero) to the
letter O (oh), and for optional mapping of the digit 1 (one) to either the letter I (eye) or letter L (el). The optional argument \texttt{map01} when not \texttt{None}, specifies which letter the digit 1 should be mapped to (when \texttt{map01} is not \texttt{None}, the digit 0 is always mapped to the letter O). For security purposes the default is \texttt{None}, so that 0 and 1 are not allowed in the input.

A \texttt{binascii.Error} is raised if \textit{s} is incorrectly padded or if there are non-alphabet characters present in the input.

\texttt{base64.b16encode(s)}

Encode the \texttt{bytes-like object} \textit{s} using Base16 and return the encoded \texttt{bytes}.

\texttt{base64.b16decode(s, casefold=False)}

Decode the Base16 encoded \texttt{bytes-like object} or ASCII string \textit{s} and return the decoded \texttt{bytes}.

Optional \texttt{casefold} is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is \texttt{False}.

A \texttt{binascii.Error} is raised if \textit{s} is incorrectly padded or if there are non-alphabet characters present in the input.

\texttt{base64.a85encode(b, *, foldspaces=False, wrapcol=0, pad=False, adobe=False)}

Encode the \texttt{bytes-like object} \textit{b} using Ascii85 and return the encoded \texttt{bytes}.

\texttt{foldspaces} is an optional flag that uses the special short sequence ‘y’ instead of 4 consecutive spaces (ASCII 0x20) as supported by ‘btoa’. This feature is not supported by the “standard” Ascii85 encoding.
`wrapcol` controls whether the output should have newline (b'\n') characters added to it. If this is non-zero, each output line will be at most this many characters long.

`pad` controls whether the input is padded to a multiple of 4 before encoding. Note that the `btoa` implementation always pads.

`adobe` controls whether the encoded byte sequence is framed with `<~` and `~>`, which is used by the Adobe implementation.

*New in version 3.4.*

`base64.a85decode(b, *, foldspaces=False, adobe=False, ignorechars=b'\t\n\\v')`  
Decode the Ascii85 encoded bytes-like object or ASCII string `b` and return the decoded `bytes`.

`foldspaces` is a flag that specifies whether the ‘y’ short sequence should be accepted as shorthand for 4 consecutive spaces (ASCII 0x20). This feature is not supported by the “standard” Ascii85 encoding.

`adobe` controls whether the input sequence is in Adobe Ascii85 format (i.e. is framed with `<~` and `~>`).

`ignorechars` should be a bytes-like object or ASCII string containing characters to ignore from the input. This should only contain whitespace characters, and by default contains all whitespace characters in ASCII.

*New in version 3.4.*

`base64.b85encode(b, pad=False)`  
Encode the bytes-like object `b` using base85 (as used in e.g. git-
style binary diffs) and return the encoded bytes.

If pad is true, the input is padded with b'\0' so its length is a multiple of 4 bytes before encoding.

*New in version 3.4.*

**base64. b85decode(b)**

Decode the base85-encoded bytes-like object or ASCII string b and return the decoded bytes. Padding is implicitly removed, if necessary.

*New in version 3.4.*

**Note:** Both Base85 and Ascii85 have an expansion factor of 5 to 4 (5 Base85 or Ascii85 characters can encode 4 binary bytes), while the better-known Base64 has an expansion factor of 6 to 4. They are therefore more efficient when space expensive. They differ by details such as the character map used for encoding.

The legacy interface:

**base64. decode(input, output)**

Decode the contents of the binary input file and write the resulting binary data to the output file. input and output must be file objects. input will be read until input.readline() returns an empty bytes object.

**base64. decodebytes(s)**

Decode the bytes-like object s, which must contain one or more lines of base64 encoded data, and return the decoded bytes.

*New in version 3.1.*
base64. `decodestring(s)`
 Deprecated alias of `decodebytes()`.

*Deprecated since version 3.1.*

base64. `encode(input, output)`
 Encode the contents of the binary `input` file and write the resulting base64 encoded data to the `output` file. `input` and `output` must be file objects. `input` will be read until `input.read()` returns an empty bytes object. `encode()` inserts a newline character (`b'\n'`) after every 76 bytes of the output, as well as ensuring that the output always ends with a newline, as per RFC 2045 (MIME).

base64. `encodebytes(s)`
 Encode the bytes-like object `s`, which can contain arbitrary binary data, and return bytes containing the base64-encoded data, with newlines (b'\n') inserted after every 76 bytes of output, and ensuring that there is a trailing newline, as per RFC 2045 (MIME).

*New in version 3.1.*

base64. `decodestring(s)`
 Deprecated alias of `encodebytes()`.

*Deprecated since version 3.1.*

An example usage of the module:

```python
>>> import base64
>>> encoded = base64.b64encode(b'data to be encoded')
>>> encoded
b'ZGF0YSB0byBiZSBlbmNvZGVk'
>>> data = base64.b64decode(encoded)
>>> data
```
See also:

**Module binascii**

Support module containing ASCII-to-binary and binary-to-ASCII conversions.

**RFC 1521 - MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies**

Section 5.2, “Base64 Content-Transfer-Encoding,” provides the definition of the base64 encoding.
19.7. **binhex** — Encode and decode binhex4 files

**Source code:** Lib/binhex.py

This module encodes and decodes files in binhex4 format, a format allowing representation of Macintosh files in ASCII. Only the data fork is handled.

The **binhex** module defines the following functions:

- **binhex.**binhex**(input, output)**
  Convert a binary file with filename `input` to binhex file `output`. The `output` parameter can either be a filename or a file-like object (any object supporting a `write()` and `close()` method).

- **binhex.**hexbin**(input, output)**
  Decode a binhex file `input`. `input` may be a filename or a file-like object supporting `read()` and `close()` methods. The resulting file is written to a file named `output`, unless the argument is `None` in which case the output filename is read from the binhex file.

The following exception is also defined:

- **exception** binhex.**Error**
  Exception raised when something can't be encoded using the binhex format (for example, a filename is too long to fit in the filename field), or when input is not properly encoded binhex data.

<tbody>
<tr>
<td></td>
<td>Support module containing ASCII-to-binary and binary-to-ASCII conversions.</td>
</tr>
</tbody>
</table>
19.7.1. Notes

There is an alternative, more powerful interface to the coder and decoder, see the source for details.

If you code or decode textfiles on non-Macintosh platforms they will still use the old Macintosh newline convention (carriage-return as end of line).
19.8. binascii — Convert between binary and ASCII

The **binascii** module contains a number of methods to convert between binary and various ASCII-encoded binary representations. Normally, you will not use these functions directly but use wrapper modules like **uu**, **base64**, or **binhex** instead. The **binascii** module contains low-level functions written in C for greater speed that are used by the higher-level modules.

**Note:** a2b_* functions accept Unicode strings containing only ASCII characters. Other functions only accept bytes-like objects (such as **bytes**, **bytearray** and other objects that support the buffer protocol).

*Changed in version 3.3:* ASCII-only unicode strings are now accepted by the a2b_* functions.

The **binascii** module defines the following functions:

**binascii. a2b_uu(string)**

Convert a single line of uuencoded data back to binary and return the binary data. Lines normally contain 45 (binary) bytes, except for the last line. Line data may be followed by whitespace.

**binascii. b2a_uu(data, *, backtick=False)**

Convert binary data to a line of ASCII characters, the return value is the converted line, including a newline char. The length of **data** should be at most 45. If **backtick** is true, zeros are represented by
instead of spaces.

*Changed in version 3.7:* Added the `backtick` parameter.

**binascii.```a2b_base64(string)```**

Convert a block of base64 data back to binary and return the binary data. More than one line may be passed at a time.

**binascii.```b2a_base64(data, *, newline=True)```**

Convert binary data to a line of ASCII characters in base64 coding. The return value is the converted line, including a newline char if `newline` is true. The output of this function conforms to *RFC 3548*.

*Changed in version 3.6:* Added the `newline` parameter.

**binascii.```a2b_qp(data, header=False)```**

Convert a block of quoted-printable data back to binary and return the binary data. More than one line may be passed at a time. If the optional argument `header` is present and true, underscores will be decoded as spaces.

**binascii.```b2a_qp(data, quotetabs=False, istext=True, header=False)```**

Convert binary data to a line(s) of ASCII characters in quoted-printable encoding. The return value is the converted line(s). If the optional argument `quotetabs` is present and true, all tabs and spaces will be encoded. If the optional argument `istext` is present and true, newlines are not encoded but trailing whitespace will be encoded. If the optional argument `header` is present and true, spaces will be encoded as underscores per RFC1522. If the optional argument `header` is present and false, newline characters will be encoded as well; otherwise linefeed conversion might corrupt the binary data stream.
binascii.a2b_hqx(string)
Convert binhex4 formatted ASCII data to binary, without doing RLE-decompression. The string should contain a complete number of binary bytes, or (in case of the last portion of the binhex4 data) have the remaining bits zero.

binascii.rledecode_hqx(data)
Perform RLE-decompression on the data, as per the binhex4 standard. The algorithm uses 0x90 after a byte as a repeat indicator, followed by a count. A count of 0 specifies a byte value of 0x90. The routine returns the decompressed data, unless data input data ends in an orphaned repeat indicator, in which case the Incomplete exception is raised.

*Changed in version 3.2:* Accept only bytestring or bytearray objects as input.

binascii.rlecode_hqx(data)
Perform binhex4 style RLE-compression on data and return the result.

binascii.b2a_hqx(data)
Perform hexbin4 binary-to-ASCII translation and return the resulting string. The argument should already be RLE-coded, and have a length divisible by 3 (except possibly the last fragment).

binascii.crc_hqx(data, value)
Compute a 16-bit CRC value of data, starting with value as the initial CRC, and return the result. This uses the CRC-CCITT polynomial $x^{16} + x^{12} + x^5 + 1$, often represented as 0x1021. This CRC is used in the binhex4 format.
binascii.crc32(data[, value])

Compute CRC-32, the 32-bit checksum of data, starting with an initial CRC of value. The default initial CRC is zero. The algorithm is consistent with the ZIP file checksum. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm. Use as follows:

```python
print(binascii.crc32(b"hello world"))
# Or, in two pieces:
crc = binascii.crc32(b"hello")
crc = binascii.crc32(b" world", crc)
print('crc32 = {:#010x}'.format(crc))
```

Changed in version 3.0: The result is always unsigned. To generate the same numeric value across all Python versions and platforms, use `crc32(data) & 0xffffffff`.

binascii.b2a_hex(data)

binascii.hexlify(data)

Return the hexadecimal representation of the binary data. Every byte of data is converted into the corresponding 2-digit hex representation. The returned bytes object is therefore twice as long as the length of data.

binascii.a2b_hex(hexstr)

binascii.unhexlify(hexstr)

Return the binary data represented by the hexadecimal string hexstr. This function is the inverse of `b2a_hex()`. hexstr must contain an even number of hexadecimal digits (which can be upper or lower case), otherwise an Error exception is raised.

exception binascii.Error
Exception raised on errors. These are usually programming errors.

```
exception binascii.Incomplete
```

Exception raised on incomplete data. These are usually not programming errors, but may be handled by reading a little more data and trying again.

---

**See also:**

- **Module** `base64`
  - Support for RFC compliant base64-style encoding in base 16, 32, 64, and 85.
- **Module** `binhex`
  - Support for the binhex format used on the Macintosh.
- **Module** `uu`
  - Support for UU encoding used on Unix.
- **Module** `quopri`
  - Support for quoted-printable encoding used in MIME email messages.
This module performs quoted-printable transport encoding and decoding, as defined in RFC 1521: “MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies”. The quoted-printable encoding is designed for data where there are relatively few nonprintable characters; the base64 encoding scheme available via the base64 module is more compact if there are many such characters, as when sending a graphics file.

**quopri.decode**(*input*, *output*, *header=False*)

Decode the contents of the *input* file and write the resulting decoded binary data to the *output* file. *input* and *output* must be binary file objects. If the optional argument *header* is present and true, underscore will be decoded as space. This is used to decode “Q”-encoded headers as described in RFC 1522: “MIME (Multipurpose Internet Mail Extensions) Part Two: Message Header Extensions for Non-ASCII Text”.

**quopri.encode**(*input*, *output*, *quotetabs*, *header=False*)

Encode the contents of the *input* file and write the resulting quoted-printable data to the *output* file. *input* and *output* must be binary file objects. *quotetabs*, a non-optional flag which controls whether to encode embedded spaces and tabs; when true it encodes such
embedded whitespace, and when false it leaves them unencoded. Note that spaces and tabs appearing at the end of lines are always encoded, as per RFC 1521. header is a flag which controls if spaces are encoded as underscores as per RFC 1522.

quopri.decodestring(s, header=False)
   Like decode(), except that it accepts a source bytes and returns the corresponding decoded bytes.

quopri.encodestring(s, quotetabs=False, header=False)
   Like encode(), except that it accepts a source bytes and returns the corresponding encoded bytes. By default, it sends a False value to quotetabs parameter of the encode() function.

See also:
Module base64
   Encode and decode MIME base64 data
19.10. **uu** — Encode and decode uuencode files

**Source code:** Lib/uu.py

This module encodes and decodes files in uuencode format, allowing arbitrary binary data to be transferred over ASCII-only connections. Wherever a file argument is expected, the methods accept a file-like object. For backwards compatibility, a string containing a pathname is also accepted, and the corresponding file will be opened for reading and writing; the pathname `'-'` is understood to mean the standard input or output. However, this interface is deprecated; it's better for the caller to open the file itself, and be sure that, when required, the mode is `'rb'` or `'wb'` on Windows.

This code was contributed by Lance Ellinghouse, and modified by Jack Jansen.

The **uu** module defines the following functions:

```python
uu.encode(in_file, out_file, name=None, mode=None, *, backtick=False)
```

Uuencode file `in_file` into file `out_file`. The uuencoded file will have the header specifying `name` and `mode` as the defaults for the results of decoding the file. The default defaults are taken from `in_file`, or `'- '` and `0o666` respectively. If `backtick` is true, zeros are represented by `'` instead of spaces.

*Changed in version 3.7:* Added the `backtick` parameter.
uu.decode(in_file, out_file=None, mode=None, quiet=False)

This call decodes uuencoded file in_file placing the result on file out_file. If out_file is a pathname, mode is used to set the permission bits if the file must be created. Defaults for out_file and mode are taken from the uuencode header. However, if the file specified in the header already exists, a uu.Error is raised.

decode() may print a warning to standard error if the input was produced by an incorrect uuencoder and Python could recover from that error. Setting quiet to a true value silences this warning.

exception uu.Error

Subclass of Exception, this can be raised by uu.decode() under various situations, such as described above, but also including a badly formatted header, or truncated input file.

20.1. **html** — HyperText Markup Language support

**Source code:** Lib/html/__init__.py

This module defines utilities to manipulate HTML.

**html.escape**(s, quote=True)

Convert the characters &, < and > in string s to HTML-safe sequences. Use this if you need to display text that might contain such characters in HTML. If the optional flag *quote* is true, the characters (") and (') are also translated; this helps for inclusion in an HTML attribute value delimited by quotes, as in `<a href="...">`.

*New in version 3.2.*

**html.unescape**(s)

Convert all named and numeric character references (e.g. &gt;, &amp;, &lt;,) in the string s to the corresponding unicode characters. This function uses the rules defined by the HTML 5 standard for both valid and invalid character references, and the list of HTML 5 named character references.

*New in version 3.4.*

Submodules in the **html** package are:

- **html.parser** – HTML/XHTML parser with lenient parsing mode
html.entities – HTML entity definitions
20.2. html.parser — Simple HTML and XHTML parser

Source code: Lib/html/parser.py

This module defines a class HTMLParser which serves as the basis for parsing text files formatted in HTML (HyperText Mark-up Language) and XHTML.

```python
class html.parser.HTMLParser(*, convert_charrefs=True)

Create a parser instance able to parse invalid markup.

If convert_charrefs is True (the default), all character references (except the ones in script/style elements) are automatically converted to the corresponding Unicode characters.

An HTMLParser instance is fed HTML data and calls handler methods when start tags, end tags, text, comments, and other markup elements are encountered. The user should subclass HTMLParser and override its methods to implement the desired behavior.

This parser does not check that end tags match start tags or call the end-tag handler for elements which are closed implicitly by closing an outer element.

Changed in version 3.4: convert_charrefs keyword argument added.

Changed in version 3.5: The default value for argument
convert_charrefs is now True.
20.2.1. Example HTML Parser Application

As a basic example, below is a simple HTML parser that uses the HTMLParser class to print out start tags, end tags, and data as they are encountered:

```python
from html.parser import HTMLParser

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print("Encountered a start tag:", tag)

    def handle_endtag(self, tag):
        print("Encountered an end tag:", tag)

    def handle_data(self, data):
        print("Encountered some data:", data)

parser = MyHTMLParser()
parser.feed('<html><head><title>Test</title></head>'
            '<body><h1>Parse me!</h1></body></html>

The output will then be:

Encountered a start tag: html
Encountered a start tag: head
Encountered a start tag: title
Encountered some data: Test
Encountered an end tag: title
Encountered an end tag: head
Encountered a start tag: body
Encountered a start tag: h1
Encountered some data: Parse me!
Encountered an end tag: h1
```
Encountered an end tag : body
Encountered an end tag : html
20.2.2. HTMLParser Methods

**HTMLParser** instances have the following methods:

**HTMLParser**.\texttt{feed}(\textit{data})

Feed some text to the parser. It is processed insofar as it consists of complete elements; incomplete data is buffered until more data is fed or \texttt{close()} is called. \textit{data} must be \texttt{str}.

**HTMLParser**.\texttt{close}()

Force processing of all buffered data as if it were followed by an end-of-file mark. This method may be redefined by a derived class to define additional processing at the end of the input, but the redefined version should always call the **HTMLParser** base class method \texttt{close}().

**HTMLParser**.\texttt{reset}()

Reset the instance. Loses all unprocessed data. This is called implicitly at instantiation time.

**HTMLParser**.\texttt{getpos}()

Return current line number and offset.

**HTMLParser**.\texttt{get_starttag_text}()

Return the text of the most recently opened start tag. This should not normally be needed for structured processing, but may be useful in dealing with HTML “as deployed” or for re-generating input with minimal changes (whitespace between attributes can be preserved, etc.).

The following methods are called when data or markup elements are
encountered and they are meant to be overridden in a subclass. The base class implementations do nothing (except for `handle_startendtag()`):

**HTMLParser.** `handle_starttag(tag, attrs)`

This method is called to handle the start of a tag (e.g. `<div id="main">`).

The `tag` argument is the name of the tag converted to lower case. The `attrs` argument is a list of `(name, value)` pairs containing the attributes found inside the tag's `<>` brackets. The `name` will be translated to lower case, and quotes in the `value` have been removed, and character and entity references have been replaced.

For instance, for the tag `<A HREF="https://www.cwi.nl/">`, this method would be called as `handle_starttag('a', [(['href', 'https://www.cwi.nl/'])])`.

All entity references from `html.entities` are replaced in the attribute values.

**HTMLParser.** `handle_endtag(tag)`

This method is called to handle the end tag of an element (e.g. `</div>`).

The `tag` argument is the name of the tag converted to lower case.

**HTMLParser.** `handle_startendtag(tag, attrs)`

Similar to `handle_starttag()`, but called when the parser encounters an XHTML-style empty tag (`<img ... />`). This method may be overridden by subclasses which require this particular lexical information; the default implementation simply
calls `handle_starttag()` and `handle_endtag()`.

**HTMLParser.** `handle_data(data)`

This method is called to process arbitrary data (e.g. text nodes and the content of `<script>...</script>` and `<style>...</style>`).

**HTMLParser.** `handle_entityref(name)`

This method is called to process a named character reference of the form `&name;` (e.g. `&gt;`), where `name` is a general entity reference (e.g. `'gt'`). This method is never called if `convert_charrefs` is `True`.

**HTMLParser.** `handle_charref(name)`

This method is called to process decimal and hexadecimal numeric character references of the form `&#NNN;` and `&#xNNN;`. For example, the decimal equivalent for `&gt;` is `&#62;`, whereas the hexadecimal is `&#x3E;`; in this case the method will receive '62' or 'x3E'. This method is never called if `convert_charrefs` is `True`.

**HTMLParser.** `handle_comment(data)`

This method is called when a comment is encountered (e.g. `<!-- comment-->`).

For example, the comment `<!-- comment -->` will cause this method to be called with the argument ' comment '.

The content of Internet Explorer conditional comments (condcoms) will also be sent to this method, so, for `<!--[if IE 9]>IE9-specific content<![endif]-->`, this method will receive ' [if IE 9]>IE9-specific content<![endif]'.
**HTMLParser**. **handle_decl**(decl)

This method is called to handle an HTML doctype declaration (e.g. `<!DOCTYPE html>`).

The *decl* parameter will be the entire contents of the declaration inside the `<!...>` markup (e.g. `'DOCTYPE html'`).

**HTMLParser**. **handle_pi**(data)

Method called when a processing instruction is encountered. The *data* parameter will contain the entire processing instruction. For example, for the processing instruction `<?proc color='red'>`, this method would be called as `handle_pi("proc color='red'")`. It is intended to be overridden by a derived class; the base class implementation does nothing.

**Note:** The **HTMLParser** class uses the SGML syntactic rules for processing instructions. An XHTML processing instruction using the trailing '?' will cause the '?' to be included in *data*.

**HTMLParser**. **unknown_decl**(data)

This method is called when an unrecognized declaration is read by the parser.

The *data* parameter will be the entire contents of the declaration inside the `<![...]>` markup. It is sometimes useful to be overridden by a derived class. The base class implementation does nothing.
20.2.3. Examples

The following class implements a parser that will be used to illustrate more examples:

```python
from html.parser import HTMLParser
from html.entities import name2codepoint

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print("Start tag:", tag)
        for attr in attrs:
            print("    attr:", attr)

    def handle_endtag(self, tag):
        print("End tag:", tag)

    def handle_data(self, data):
        print("Data:", data)

    def handle_comment(self, data):
        print("Comment:", data)

    def handle_entityref(self, name):
        c = chr(name2codepoint[name])
        print("Named ent:", c)

    def handle_charref(self, name):
        if name.startswith('x'):
            c = chr(int(name[1:], 16))
        else:
            c = chr(int(name))
        print("Num ent:", c)

    def handle_decl(self, data):
```

```python
def print("Decl : ", data)
parser = MyHTMLParser()

Parsing a doctype:

```
Parsing comments:

```python
>>> parser.feed('<!-- a comment -->
...
<!--[if IE 9]>IE-specific content<![endif]-->
Comment : a comment
Comment : [if IE 9]>IE-specific content<![endif]
```

Parsing named and numeric character references and converting them to the correct char (note: these 3 references are all equivalent to '>

```python
>>> parser.feed('&gt;&amp;#62;&amp;#x3E;')
Named ent: >
Num ent : >
Num ent : >
```

Feeding incomplete chunks to `feed()` works, but `handle_data()` might be called more than once (unless `convert_charrefs` is set to True):

```python
>>> for chunk in ['<sp', 'an>buff', ',  'ered ', ',  'text'</']
...     parser.feed(chunk)
...     Start tag: span
Data : buff
Data : ered
Data : text
End tag : span
```

Parsing invalid HTML (e.g. unquoted attributes) also works:
```python
>>> parser.feed('<p><a class=link href=#main>tag soup</a>
Start tag: p
Start tag: a
  attr: ('class', 'link')
  attr: ('href', '#main')
Data : tag soup
End tag : p
End tag : a
```
20.3. `html.entities` — Definitions of HTML general entities

**Source code:** `Lib/html/entities.py`

This module defines four dictionaries, `html5`, `name2codepoint`, `codepoint2name`, and `entitydefs`.

`html.entities.html5`
A dictionary that maps HTML5 named character references [1] to the equivalent Unicode character(s), e.g. `html5['gt;'] == '>'`. Note that the trailing semicolon is included in the name (e.g. 'gt;'), however some of the names are accepted by the standard even without the semicolon: in this case the name is present with and without the ';'. See also `html.unescape()`.

*New in version 3.3.*

`html.entities.entitydefs`
A dictionary mapping XHTML 1.0 entity definitions to their replacement text in ISO Latin-1.

`html.entities.name2codepoint`
A dictionary that maps HTML entity names to the Unicode code points.

`html.entities.codepoint2name`
A dictionary that maps Unicode code points to HTML entity names.
Footnotes

[1] See https://www.w3.org/TR/html5/syntax.html#named-character-references
20.4. XML Processing Modules

Source code: Lib/xml/

Python's interfaces for processing XML are grouped in the `xml` package.

**Warning:** The XML modules are not secure against erroneous or maliciously constructed data. If you need to parse untrusted or unauthenticated data see the XML vulnerabilities and The defusedxml and defusedexpat Packages sections.

It is important to note that modules in the `xml` package require that there be at least one SAX-compliant XML parser available. The Expat parser is included with Python, so the `xml.parsers.expat` module will always be available.

The documentation for the `xml.dom` and `xml.sax` packages are the definition of the Python bindings for the DOM and SAX interfaces.

The XML handling submodules are:

- `xml.etree.ElementTree`: the ElementTree API, a simple and lightweight XML processor
- `xml.dom`: the DOM API definition
- `xml.dom.minidom`: a minimal DOM implementation
- `xml.dom.pulldom`: support for building partial DOM trees
- `xml.sax`: SAX2 base classes and convenience functions
- `xml.parsers.expat`: the Expat parser binding
20.4.1. XML vulnerabilities

The XML processing modules are not secure against maliciously constructed data. An attacker can abuse XML features to carry out denial of service attacks, access local files, generate network connections to other machines, or circumvent firewalls.

The following table gives an overview of the known attacks and whether the various modules are vulnerable to them.

<table>
<thead>
<tr>
<th>kind</th>
<th>sax</th>
<th>etree</th>
<th>minidom</th>
<th>pulldom</th>
</tr>
</thead>
<tbody>
<tr>
<td>billion laughs</td>
<td>Vulnerable</td>
<td>Vulnerable</td>
<td>Vulnerable</td>
<td>Vulnerable</td>
</tr>
<tr>
<td>quadratic blowup</td>
<td>Vulnerable</td>
<td>Vulnerable</td>
<td>Vulnerable</td>
<td>Vulnerable</td>
</tr>
<tr>
<td>external entity expansion</td>
<td>Vulnerable</td>
<td>Safe (1)</td>
<td>Safe (2)</td>
<td>Vulnerable</td>

<tr>
<td>DTD retrieval</td>
<td>Vulnerable</td>
<td>Safe</td>
<td>Safe</td>
<td>Vulnerable</td>
</tr>
<tr>
<td>decompression bomb</td>
<td>Safe</td>
<td>Safe</td>
<td>Safe</td>
<td>Safe</td>
</tr>
</tbody>
</table>

1. `xml.etree.ElementTree` doesn’t expand external entities and raises a `ParserError` when an entity occurs.
2. `xml.dom.minidom` doesn’t expand external entities and simply returns the unexpanded entity verbatim.
3. `xmlrpcclient` doesn’t expand external entities and omits them.

billion laughs / exponential entity expansion

The Billion Laughs attack – also known as exponential entity expansion – uses multiple levels of nested entities. Each entity refers to another entity several times, and the final entity definition contains a small string. The exponential expansion results in
several gigabytes of text and consumes lots of memory and CPU time.

quadratic blowup entity expansion
A quadratic blowup attack is similar to a Billion Laughs attack; it abuses entity expansion, too. Instead of nested entities it repeats one large entity with a couple of thousand chars over and over again. The attack isn't as efficient as the exponential case but it avoids triggering parser countermeasures that forbid deeply-nested entities.

external entity expansion
Entity declarations can contain more than just text for replacement. They can also point to external resources or local files. The XML parser accesses the resource and embeds the content into the XML document.

DTD retrieval
Some XML libraries like Python’s xml.dom.pulldom retrieve document type definitions from remote or local locations. The feature has similar implications as the external entity expansion issue.

decompression bomb
Decompression bombs (aka ZIP bomb) apply to all XML libraries that can parse compressed XML streams such as gzipped HTTP streams or LZMA-compressed files. For an attacker it can reduce the amount of transmitted data by three magnitudes or more.

The documentation for defusedxml on PyPI has further information about all known attack vectors with examples and references.
20.4.2. The defusedxml and defusedexpat Packages

defusedxml is a pure Python package with modified subclasses of all stdlib XML parsers that prevent any potentially malicious operation. Use of this package is recommended for any server code that parses untrusted XML data. The package also ships with example exploits and extended documentation on more XML exploits such as XPath injection.

defusedexpat provides a modified libexpat and a patched pyexpat module that have countermeasures against entity expansion DoS attacks. The defusedexpat module still allows a sane and configurable amount of entity expansions. The modifications may be included in some future release of Python, but will not be included in any bugfix releases of Python because they break backward compatibility.
20.5. `xml.etree.ElementTree` — The ElementTree XML API

Source code: Lib/xml/etree/ElementTree.py

The `xml.etree.ElementTree` module implements a simple and efficient API for parsing and creating XML data.

*Changed in version 3.3:* This module will use a fast implementation whenever available. The `xml.etree.cElementTree` module is deprecated.

**Warning:** The `xml.etree.ElementTree` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see [XML vulnerabilities](#).
20.5.1. Tutorial

This is a short tutorial for using `xml.etree.ElementTree` (ET in short). The goal is to demonstrate some of the building blocks and basic concepts of the module.

20.5.1.1. XML tree and elements

XML is an inherently hierarchical data format, and the most natural way to represent it is with a tree. ET has two classes for this purpose - `ElementTree` represents the whole XML document as a tree, and `Element` represents a single node in this tree. Interactions with the whole document (reading and writing to/from files) are usually done on the `ElementTree` level. Interactions with a single XML element and its sub-elements are done on the `Element` level.

20.5.1.2. Parsing XML

We’ll be using the following XML document as the sample data for this section:

```xml
<?xml version="1.0"?>
<data>
  <country name="Liechtenstein">
    <rank>1</rank>
    <year>2008</year>
    <gdppc>141100</gdppc>
    <neighbor name="Austria" direction="E"/>
    <neighbor name="Switzerland" direction="W"/>
  </country>
  <country name="Singapore">
    <rank>4</rank>
  </country>
</data>
```
We can import this data by reading from a file:

```python
import xml.etree.ElementTree as ET
tree = ET.parse('country_data.xml')
root = tree.getroot()
```

Or directly from a string:

```python
root = ET.fromstring(country_data_as_string)
```

`fromstring()` parses XML from a string directly into an `Element`, which is the root element of the parsed tree. Other parsing functions may create an `ElementTree`. Check the documentation to be sure.

As an `Element`, `root` has a tag and a dictionary of attributes:

```python
>>> root.tag
'data'
>>> root.attrib
{}
```

It also has children nodes over which we can iterate:
Children are nested, and we can access specific child nodes by index:

```python
>>> root[0][1].text
'2008'
```

**Note:** Not all elements of the XML input will end up as elements of the parsed tree. Currently, this module skips over any XML comments, processing instructions, and document type declarations in the input. Nevertheless, trees built using this module's API rather than parsing from XML text can have comments and processing instructions in them; they will be included when generating XML output. A document type declaration may be accessed by passing a custom `TreeBuilder` instance to the `XMLParser` constructor.

### 20.5.1.3. Pull API for non-blocking parsing

Most parsing functions provided by this module require the whole document to be read at once before returning any result. It is possible to use an `XMLParser` and feed data into it incrementally, but it is a push API that calls methods on a callback target, which is too low-level and inconvenient for most needs. Sometimes what the user really wants is to be able to parse XML incrementally, without blocking operations, while enjoying the convenience of fully constructed `Element` objects.
The most powerful tool for doing this is `XMLPullParser`. It does not require a blocking read to obtain the XML data, and is instead fed with data incrementally with `XMLPullParser.feed()` calls. To get the parsed XML elements, call `XMLPullParser.read_events()`. Here is an example:

```python
>>> parser = ET.XMLPullParser(["start", "end"]) >>> parser.feed("<mytag>sometext")
>>> list(parser.read_events())
[("start", <Element 'mytag' at 0x7fa66db2be58>)] >>> parser.feed(' more text</mytag>')</dict> >>> for event, elem in parser.read_events(): ...	print(event) ...	print(elem.tag, 'text=', elem.text)
```

The obvious use case is applications that operate in a non-blocking fashion where the XML data is being received from a socket or read incrementally from some storage device. In such cases, blocking reads are unacceptable.

Because it's so flexible, `XMLPullParser` can be inconvenient to use for simpler use-cases. If you don't mind your application blocking on reading XML data but would still like to have incremental parsing capabilities, take a look at `iterparse()`. It can be useful when you're reading a large XML document and don't want to hold it wholly in memory.

### 20.5.1.4. Finding interesting elements

`Element` has some useful methods that help iterate recursively over all the sub-tree below it (its children, their children, and so on). For
example, `Element.iter()`:

```python
>>> for neighbor in root.iter('neighbor'):
...     print(neighbor.attrib)
...
{'name': 'Austria', 'direction': 'E'}
{'name': 'Switzerland', 'direction': 'W'}
{'name': 'Malaysia', 'direction': 'N'}
{'name': 'Costa Rica', 'direction': 'W'}
{'name': 'Colombia', 'direction': 'E'}
```

`Element.findall()` finds only elements with a tag which are direct children of the current element. `Element.find()` finds the first child with a particular tag, and `Element.text` accesses the element's text content. `Element.get()` accesses the element’s attributes:

```python
>>> for country in root.findall('country'):
...     rank = country.find('rank').text
...     name = country.get('name')
...     print(name, rank)
...     Liechtenstein 1
     Singapore 4
     Panama 68
```

More sophisticated specification of which elements to look for is possible by using XPath.

**20.5.1.5. Modifying an XML File**

`ElementTree` provides a simple way to build XML documents and write them to files. The `ElementTree.write()` method serves this purpose.
Once created, an `Element` object may be manipulated by directly changing its fields (such as `Element.text`), adding and modifying attributes (`Element.set()` method), as well as adding new children (for example with `Element.append()`).

Let's say we want to add one to each country's rank, and add an updated attribute to the rank element:

```python
>>> for rank in root.iter('rank'):
...    new_rank = int(rank.text) + 1
...    rank.text = str(new_rank)
...    rank.set('updated', 'yes')
...  
>>> tree.write('output.xml')
```

Our XML now looks like this:

```xml
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank updated="yes">2</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank updated="yes">5</rank>
        <year>2011</year>
        <gdppc>59900</gdppc>
        <neighbor name="Malaysia" direction="N"/>
    </country>
    <country name="Panama">
        <rank updated="yes">69</rank>
        <year>2011</year>
```
We can remove elements using `Element.remove()`. Let's say we want to remove all countries with a rank higher than 50:

```python
>>> for country in root.findall('country'):
...    rank = int(country.find('rank').text)
...    if rank > 50:
...        root.remove(country)
...>>> tree.write('output.xml')
```

Our XML now looks like this:

```xml
<?xml version="1.0"?>
<data>
  <country name="Liechtenstein">
    <rank updated="yes">2</rank>
    <year>2008</year>
    <gdppc>141100</gdppc>
    <neighbor name="Austria" direction="E"/>
    <neighbor name="Switzerland" direction="W"/>
  </country>
  <country name="Singapore">
    <rank updated="yes">5</rank>
    <year>2011</year>
    <gdppc>59900</gdppc>
    <neighbor name="Malaysia" direction="N"/>
  </country>
</data>
```
20.5.1.6. Building XML documents

The `SubElement()` function also provides a convenient way to create new sub-elements for a given element:

```python
>>> a = ET.Element('a')
>>> b = ET.SubElement(a, 'b')
>>> c = ET.SubElement(a, 'c')
>>> d = ET.SubElement(c, 'd')
>>> ET.dump(a)
<a><b /></c><d /></a>
```

20.5.1.7. Parsing XML with Namespaces

If the XML input has namespaces, tags and attributes with prefixes in the form `prefix:sometag` get expanded to `{uri}sometag` where the `prefix` is replaced by the full URI. Also, if there is a default namespace, that full URI gets prepended to all of the non-prefixed tags.

Here is an XML example that incorporates two namespaces, one with the prefix “fictional” and the other serving as the default namespace:

```xml
<?xml version="1.0"?>
<actors xmlns:fictional="http://characters.example.com" xmlns="http://people.example.com">
    <actor>
        <name>John Cleese</name>
        <fictional:character>Lancelot</fictional:character>
        <fictional:character>Archie Leach</fictional:character>
    </actor>
    <actor>
        <name>Eric Idle</name>
        <fictional:character>Sir Robin</fictional:character>
    </actor>
</actors>
```
One way to search and explore this XML example is to manually add the URI to every tag or attribute in the xpath of a `find()` or `findall()`:

```python
root = fromstring(xml_text)
for actor in root.findall('{http://people.example.com}actor'):
    name = actor.find('{http://people.example.com}name').text
    print(name.text)
    for char in actor.findall('{http://characters.example.com}character'):
        print('	|-->', char.text)
```

A better way to search the namespaced XML example is to create a dictionary with your own prefixes and use those in the search functions:

```python
ns = {'real_person': 'http://people.example.com',
     'role': 'http://characters.example.com'}

for actor in root.findall('real_person:actor', ns):
    name = actor.find('real_person:name', ns).text
    print(name.text)
    for char in actor.findall('role:character', ns):
        print('	|-->', char.text)
```

These two approaches both output:

```
John Cleese
|--> Lancelot
```
20.5.1.8. Additional resources

See http://effbot.org/zone/element-index.htm for tutorials and links to other docs.
20.5.2. XPath support

This module provides limited support for XPath expressions for locating elements in a tree. The goal is to support a small subset of the abbreviated syntax; a full XPath engine is outside the scope of the module.

20.5.2.1. Example

Here's an example that demonstrates some of the XPath capabilities of the module. We'll be using the `countrydata` XML document from the Parsing XML section:

```python
import xml.etree.ElementTree as ET
root = ET.fromstring(countrydata)

# Top-level elements
root.findall(".")

# All 'neighbor' grand-children of 'country' children elements
root.findall("./country/neighbor")

# Nodes with name='Singapore' that have a 'year' child node
root.findall("./year/..[@name='Singapore']")

# 'year' nodes that are children of nodes with name='Singapore'
root.findall("./*[@name='Singapore']/year")

# All 'neighbor' nodes that are the second child of their parent
root.findall("./neighbor[2]")
```
# 20.5.2.2. Supported XPath syntax

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>tag</td>
<td>Selects all child elements with the given tag. For example, spam selects all child elements named spam, and spam/egg selects all grandchildren named egg in all children named spam.</td>
</tr>
<tr>
<td>*</td>
<td>Selects all child elements. For example, */egg selects all grandchildren named egg.</td>
</tr>
<tr>
<td>.</td>
<td>Selects the current node. This is mostly useful at the beginning of the path, to indicate that it’s a relative path.</td>
</tr>
<tr>
<td>//</td>
<td>Selects all subelements, on all levels beneath the current element. For example, ../../../egg selects all egg elements in the entire tree.</td>
</tr>
<tr>
<td>..</td>
<td>Selects the parent element. Returns None if the path attempts to reach the ancestors of the start element (the element find was called on).</td>
</tr>
<tr>
<td>[@attrib]</td>
<td>Selects all elements that have the given attribute.</td>
</tr>
<tr>
<td>[@attrib='value']</td>
<td>Selects all elements for which the given attribute has the given value. The value cannot contain quotes.</td>
</tr>
<tr>
<td>[tag]</td>
<td>Selects all elements that have a child named tag. Only immediate children are supported.</td>
</tr>
<tr>
<td></td>
<td>Selects all elements whose complete text content, including descendants, equals</td>
</tr>
<tr>
<td>Predicate</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>[.='text']</code></td>
<td>Selects all elements that have a child named <code>tag</code> whose complete text content, including descendants, equals the given <code>text</code>. New in version 3.7.</td>
</tr>
<tr>
<td><code>[tag='text']</code></td>
<td>Selects all elements that are located at the given position. The position can be either an integer (1 is the first position), the expression <code>last()</code> (for the last position), or a position relative to the last position (e.g. <code>last()-1</code>).</td>
</tr>
</tbody>
</table>

Predicates (expressions within square brackets) must be preceded by a tag name, an asterisk, or another predicate. `position` predicates must be preceded by a tag name.
20.5.3. Reference

20.5.3.1. Functions

```python
xml.etree.ElementTree.Comment(text=None)
```

Comment element factory. This factory function creates a special element that will be serialized as an XML comment by the standard serializer. The comment string can be either a bytestring or a Unicode string. `text` is a string containing the comment string. Returns an element instance representing a comment.

Note that `XMLParser` skips over comments in the input instead of creating comment objects for them. An `ElementTree` will only contain comment nodes if they have been inserted into the tree using one of the `Element` methods.

```python
xml.etree.ElementTree.dump(elem)
```

Writes an element tree or element structure to `sys.stdout`. This function should be used for debugging only.

The exact output format is implementation dependent. In this version, it's written as an ordinary XML file.

`elem` is an element tree or an individual element.

```python
xml.etree.ElementTree.fromstring(text)
```

Parses an XML section from a string constant. Same as `XML()`.

`text` is a string containing XML data. Returns an `Element` instance.

```python
xml.etree.ElementTree.fromstringlist(sequence, parser=None)
```

Parses an XML document from a sequence of string fragments. sequence is a list or other sequence containing XML data fragments. parser is an optional parser instance. If not given, the standard XMLParser parser is used. Returns an Element instance.

New in version 3.2.

xml.etree.ElementTree.iselement(element)

Checks if an object appears to be a valid element object. element is an element instance. Returns a true value if this is an element object.

xml.etree.ElementTree.iterparse(source, events=None, parser=None)

Parses an XML section into an element tree incrementally, and reports what’s going on to the user. source is a filename or file object containing XML data. events is a sequence of events to report back. The supported events are the strings "start", "end", "start-ns" and "end-ns" (the “ns” events are used to get detailed namespace information). If events is omitted, only "end" events are reported. parser is an optional parser instance. If not given, the standard XMLParser parser is used. parser must be a subclass of XMLParser and can only use the default TreeBuilder as a target. Returns an iterator providing (event, elem) pairs.

Note that while iterparse() builds the tree incrementally, it issues blocking reads on source (or the file it names). As such, it’s unsuitable for applications where blocking reads can’t be made. For fully non-blocking parsing, see XMLPullParser.
**Note:** `iterparse()` only guarantees that it has seen the “>” character of a starting tag when it emits a “start” event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present.
If you need a fully populated element, look for “end” events instead.

*Deprecated since version 3.4:* The `parser` argument.

```python
xml.etree.ElementTree.parse(source, parser=None)
```

Parses an XML section into an element tree. `source` is a filename or file object containing XML data. `parser` is an optional parser instance. If not given, the standard `XMLParser` parser is used. Returns an `ElementTree` instance.

```python
xml.etree.ElementTree.ProcessingInstruction(target, text=None)
```

PI element factory. This factory function creates a special element that will be serialized as an XML processing instruction. `target` is a string containing the PI target. `text` is a string containing the PI contents, if given. Returns an element instance, representing a processing instruction.

Note that `XMLParser` skips over processing instructions in the input instead of creating comment objects for them. An `ElementTree` will only contain processing instruction nodes if they have been inserted into to the tree using one of the `Element` methods.

```python
xml.etree.ElementTree.register_namespace(prefix, uri)
```

Registers a namespace prefix. The registry is global, and any
existing mapping for either the given prefix or the namespace URI will be removed. *prefix* is a namespace prefix. *uri* is a namespace uri. Tags and attributes in this namespace will be serialized with the given prefix, if at all possible.

*New in version 3.2.*

```python
xml.etree.ElementTree.SubElement(parent, tag, attrib={}, **extra)
```

Subelement factory. This function creates an element instance, and appends it to an existing element.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. *parent* is the parent element. *tag* is the subelement name. *attrib* is an optional dictionary, containing element attributes. *extra* contains additional attributes, given as keyword arguments. Returns an element instance.

```python
xml.etree.ElementTree.tostring(element, encoding="us-ascii", method="xml", *, short_empty_elements=True)
```

Generates a string representation of an XML element, including all subelements. *element* is an `Element` instance. *encoding* [1] is the output encoding (default is US-ASCII). Use `encoding="unicode"` to generate a Unicode string (otherwise, a bytestring is generated). *method* is either "xml", "html" or "text" (default is "xml"). *short_empty_elements* has the same meaning as in `ElementTree.write()`. Returns an (optionally) encoded string containing the XML data.

*New in version 3.4*: The *short_empty_elements* parameter.

```python
xml.etree.ElementTree.tostringlist(element, encoding="us-ascii", method="xml", *, short_empty_elements=True)
```
Generates a string representation of an XML element, including all subelements. `element` is an `Element` instance. `encoding` [1] is the output encoding (default is US-ASCII). Use `encoding="unicode"` to generate a Unicode string (otherwise, a bytestring is generated). `method` is either "xml", "html" or "text" (default is "xml"). `short_empty_elements` has the same meaning as in `ElementTree.write()`. Returns a list of (optionally) encoded strings containing the XML data. It does not guarantee any specific sequence, except that `b"".join(tostringlist(element)) == tostring(element).

*New in version 3.2.*

*New in version 3.4:* The `short_empty_elements` parameter.

```
xml.etree.ElementTree.XML(text, parser=None)
```

Parses an XML section from a string constant. This function can be used to embed “XML literals” in Python code. `text` is a string containing XML data. `parser` is an optional parser instance. If not given, the standard `XMLParser` parser is used. Returns an `Element` instance.

```
xml.etree.ElementTree.XMLID(text, parser=None)
```

Parses an XML section from a string constant, and also returns a dictionary which maps from element id:s to elements. `text` is a string containing XML data. `parser` is an optional parser instance. If not given, the standard `XMLParser` parser is used. Returns a tuple containing an `Element` instance and a dictionary.

### 20.5.3.2. Element Objects
class xml.etree.ElementTree.Element(tag, attrib={}, **extra)
Element class. This class defines the Element interface, and provides a reference implementation of this interface.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. *tag* is the element name. *attrib* is an optional dictionary, containing element attributes. *extra* contains additional attributes, given as keyword arguments.

**tag**
A string identifying what kind of data this element represents (the element type, in other words).

**text**

**tail**
These attributes can be used to hold additional data associated with the element. Their values are usually strings but may be any application-specific object. If the element is created from an XML file, the *text* attribute holds either the text between the element’s start tag and its first child or end tag, or None, and the *tail* attribute holds either the text between the element’s end tag and the next tag, or None. For the XML data

```xml
<a><b>1<c>2<d/>3</c></b>4</a>
```

the *a* element has None for both *text* and *tail* attributes, the *b* element has *text"1"* and *tail"4"*, the *c* element has *text"2"* and *tail None*, and the *d* element has *text None* and *tail"3"*.

To collect the inner text of an element, see *iterertext()*, for example "".join(element.itertext()).

Applications may store arbitrary objects in these attributes.
**attrib**

A dictionary containing the element’s attributes. Note that while the `attrib` value is always a real mutable Python dictionary, an ElementTree implementation may choose to use another internal representation, and create the dictionary only if someone asks for it. To take advantage of such implementations, use the dictionary methods below whenever possible.

The following dictionary-like methods work on the element attributes.

**clear()**

Resets an element. This function removes all subelements, clears all attributes, and sets the text and tail attributes to `None`.

**get**(key, default=None)

Gets the element attribute named `key`.

Returns the attribute value, or `default` if the attribute was not found.

**items()**

Returns the element attributes as a sequence of (name, value) pairs. The attributes are returned in an arbitrary order.

**keys()**

Returns the elements attribute names as a list. The names are returned in an arbitrary order.

**set**(key, value)

Set the attribute `key` on the element to `value`. 
The following methods work on the element’s children (subelements).

**append(subelement)**

Adds the element `subelement` to the end of this element's internal list of subelements. Raises `TypeError` if `subelement` is not an `Element`.

**extend(subelements)**

Appends `subelements` from a sequence object with zero or more elements. Raises `TypeError` if a subelement is not an `Element`.

*New in version 3.2.*

**find(match, namespaces=None)**

Finds the first subelement matching `match`. `match` may be a tag name or a path. Returns an element instance or `None`. `namespaces` is an optional mapping from namespace prefix to full name.

**findall(match, namespaces=None)**

Finds all matching subelements, by tag name or path. Returns a list containing all matching elements in document order. `namespaces` is an optional mapping from namespace prefix to full name.

**findtext(match, default=None, namespaces=None)**

Finds text for the first subelement matching `match`. `match` may be a tag name or a path. Returns the text content of the first matching element, or `default` if no element was found. Note that if the matching element has no text content an empty string is
returned. namespaces is an optional mapping from namespace prefix to full name.

**getchildren()**

*Deprecated since version 3.2:* Use `list(elem)` or iteration.

**getiterator**(tag=None)

*Deprecated since version 3.2:* Use method `Element.iter()` instead.

**insert**(index, subelement)

Inserts subelement at the given position in this element. Raises `TypeError` if subelement is not an `Element`.

**iter**(tag=None)

Creates a tree iterator with the current element as the root. The iterator iterates over this element and all elements below it, in document (depth first) order. If tag is not `None` or `'*'`, only elements whose tag equals tag are returned from the iterator. If the tree structure is modified during iteration, the result is undefined.

*New in version 3.2.*

**iterfind**(match, namespaces=None)

Finds all matching subelements, by tag name or path. Returns an iterable yielding all matching elements in document order. namespaces is an optional mapping from namespace prefix to full name.

*New in version 3.2.*

**itertext()**
Creates a text iterator. The iterator loops over this element and all subelements, in document order, and returns all inner text.

*New in version 3.2.*

**makeelement**(tag, attrib)

Creates a new element object of the same type as this element. Do not call this method, use the `SubElement()` factory function instead.

**remove**(subelement)

Removes *subelement* from the element. Unlike the find* methods this method compares elements based on the instance identity, not on tag value or contents.

*Element* objects also support the following sequence type methods for working with subelements: `__delitem__()`, `__getitem__()`, `__setitem__()`, `__len__()`.  

Caution: Elements with no subelements will test as `False`. This behavior will change in future versions. Use specific `len(elem)` or `elem is None` test instead.

```python
element = root.find('foo')

if not element:  # careful!
    print("element not found, or element has no s

if element is None:
    print("element not found")
```

20.5.3.3. ElementTree Objects
class xml.etree.ElementTree.ElementTree

ElementTree wrapper class. This class represents an entire element hierarchy, and adds some extra support for serialization to and from standard XML.

`element` is the root element. The tree is initialized with the contents of the XML `file` if given.

```python
_def_setroot(element)
Replaces the root element for this tree. This discards the current contents of the tree, and replaces it with the given element. Use with care. `element` is an element instance.

`find(match, namespaces=None)`
Same as Element.find(), starting at the root of the tree.

`findall(match, namespaces=None)`
Same as Element.findall(), starting at the root of the tree.

`findtext(match, default=None, namespaces=None)`
Same as Element.findtext(), starting at the root of the tree.

`getiterator(tag=None)`
Deprecated since version 3.2: Use method ElementTree.iter() instead.

`getroot()`
Returns the root element for this tree.

`iter(tag=None)`
Creates and returns a tree iterator for the root element. The
iterator loops over all elements in this tree, in section order. tag is the tag to look for (default is to return all elements).

**iterfind**(match, namespaces=None)

Same as `Element.iterfind()`, starting at the root of the tree.

*New in version 3.2.*

**parse**(source, parser=None)

Loads an external XML section into this element tree. source is a file name or file object. parser is an optional parser instance. If not given, the standard `XMLParser` parser is used. Returns the section root element.

**write**(file, encoding="us-ascii", xml_declaration=None, default_namespace=None, method="xml", *, short_empty_elements=True)

Writes the element tree to a file, as XML. file is a file name, or a file object opened for writing. encoding [1] is the output encoding (default is US-ASCII). xml_declaration controls if an XML declaration should be added to the file. Use False for never, True for always, None for only if not US-ASCII or UTF-8 or Unicode (default is None). default_namespace sets the default XML namespace (for “xmlns”). method is either "xml", "html" or "text" (default is "xml"). The keyword-only short_empty_elements parameter controls the formatting of elements that contain no content. If True (the default), they are emitted as a single self-closed tag, otherwise they are emitted as a pair of start/end tags.

The output is either a string (str) or binary (bytes). This is
controlled by the encoding argument. If encoding is "unicode", the output is a string; otherwise, it's binary. Note that this may conflict with the type of file if it's an open file object; make sure you do not try to write a string to a binary stream and vice versa.

New in version 3.4: The short_empty_elements parameter.

This is the XML file that is going to be manipulated:

```xml
<html>
  <head>
    <title>Example page</title>
  </head>
  <body>
    <p>Moved to <a href="http://example.org/">example.org</a> or <a href="http://example.com/">example.com</a></p>
  </body>
</html>
```

Example of changing the attribute “target” of every link in first paragraph:

```python
>>> from xml.etree.ElementTree import ElementTree
>>> tree = ElementTree()
>>> tree.parse("index.xhtml")
<Element 'html' at 0xb77e6fac>  # Finds first occurrence
>>> p = tree.find("body/p")  # Finds first occurrence
>>> p
<Element 'p' at 0xb77ec26c>
>>> links = list(p.iter("a"))  # Returns list of all
>>> links
[<Element 'a' at 0xb77ec2ac>, <Element 'a' at 0xb77edc>]
>>> for i in links:  # Iterates through all
...    i.attrib["target"] = "blank"
```
20.5.3.4. QName Objects

class xml.etree.ElementTree.QName(text_or_uri, tag=None)

QName wrapper. This can be used to wrap a QName attribute value, in order to get proper namespace handling on output. 

text_or_uri is a string containing the QName value, in the form {uri}local, or, if the tag argument is given, the URI part of a QName. If tag is given, the first argument is interpreted as a URI, and this argument is interpreted as a local name. QName instances are opaque.

20.5.3.5. TreeBuilder Objects

class xml.etree.ElementTree.TreeBuilder(element_factory=None)

Generic element structure builder. This builder converts a sequence of start, data, and end method calls to a well-formed element structure. You can use this class to build an element structure using a custom XML parser, or a parser for some other XML-like format. element_factory, when given, must be a callable accepting two positional arguments: a tag and a dict of attributes. It is expected to return a new element instance.

close()

Flushes the builder buffers, and returns the toplevel document element. Returns an Element instance.

data(data)

Adds text to the current element. data is a string. This should be
either a bytestring, or a Unicode string.

**end**(tag)
Closes the current element. *tag* is the element name. Returns the closed element.

**start**(tag, attrs)
Opens a new element. *tag* is the element name. *attrs* is a dictionary containing element attributes. Returns the opened element.

In addition, a custom `TreeBuilder` object can provide the following method:

**doctype**(name, pubid, system)
Handles a doctype declaration. *name* is the doctype name. *pubid* is the public identifier. *system* is the system identifier. This method does not exist on the default `TreeBuilder` class.

*New in version 3.2.*

### 20.5.3.6. XMLParser Objects

**class** xml.etree.ElementTree.**XMLParser**(html=0,
  target=None, encoding=None)

This class is the low-level building block of the module. It uses `xml.parsers.expat` for efficient, event-based parsing of XML. It can be fed XML data incrementally with the `feed()` method, and parsing events are translated to a push API - by invoking callbacks on the `target` object. If `target` is omitted, the standard `TreeBuilder` is used. The `html` argument was historically used for backwards compatibility and is now deprecated. If `encoding` [1]
is given, the value overrides the encoding specified in the XML file.

*Deprecated since version 3.4:* The html argument. The remaining arguments should be passed via keyword to prepare for the removal of the html argument.

**close()**

Finishes feeding data to the parser. Returns the result of calling the close() method of the target passed during construction; by default, this is the toplevel document element.

**doctype**(*name, pubid, system*)

*Deprecated since version 3.2:* Define the TreeBuilder.doctype() method on a custom TreeBuilder target.

**feed**(*data*)

Feeds data to the parser. *data* is encoded data.

XMLParser.feed() calls target's start(tag, attrs_dict) method for each opening tag, its end(tag) method for each closing tag, and data is processed by method data(data). XMLParser.close() calls target's method close(). XMLParser can be used not only for building a tree structure. This is an example of counting the maximum depth of an XML file:

```python
>>> from xml.etree.ElementTree import XMLParser
>>> class MaxDepth:
...     # The target...     maxDepth = 0
...     depth = 0
...     def start(self, tag, attrib):  # Called
...         self.depth += 1
...         if self.depth > self.maxDepth:
```
```python
...     self.maxDepth = self.depth
...     def end(self, tag):  # Called
...         self.depth -= 1
...     def data(self, data):
...         pass  # We do not need to do anything with data.
...     def close(self):  # Called when all data has been parsed.
...         return self.maxDepth

>>> target = MaxDepth()
>>> parser = XMLPullParser(target=target)
>>> exampleXml = """
...     <a>
...         <b>
...             <c>
...                 <d/>
...             </c>
...         </b>
...     </b>
... </a>"""
>>> parser.feed(exampleXml)
>>> parser.close()
4
```

20.5.3.7. XMLPullParser Objects

class
xml.etree.ElementTree.**XMLPullParser**(events=None)

A pull parser suitable for non-blocking applications. Its input-side API is similar to that of **XMLParser**, but instead of pushing calls to a callback target, **XMLPullParser** collects an internal list of parsing events and lets the user read from it. **events** is a sequence of events to report back. The supported events are the strings
"start", "end", "start-ns" and "end-ns" (the “ns” events are used to get detailed namespace information). If events is omitted, only "end" events are reported.

**feed**(data)
Feed the given bytes data to the parser.

**close()**
Signal the parser that the data stream is terminated. Unlike `XMLParser.close()`, this method always returns `None`. Any events not yet retrieved when the parser is closed can still be read with `read_events()`.

**read_events()**
Return an iterator over the events which have been encountered in the data fed to the parser. The iterator yields (event, elem) pairs, where event is a string representing the type of event (e.g. "end") and elem is the encountered Element object.

Events provided in a previous call to `read_events()` will not be yielded again. Events are consumed from the internal queue only when they are retrieved from the iterator, so multiple readers iterating in parallel over iterators obtained from `read_events()` will have unpredictable results.

**Note:** `XMLPullParser` only guarantees that it has seen the “>” character of a starting tag when it emits a “start” event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present.
If you need a fully populated element, look for “end” events
New in version 3.4.

20.5.3.8. Exceptions

class xml.etree.ElementTree.ParseError
   XML parse error, raised by the various parsing methods in this module when parsing fails. The string representation of an instance of this exception will contain a user-friendly error message. In addition, it will have the following attributes available:

   code
   A numeric error code from the expat parser. See the documentation of xml.parsers.expat for the list of error codes and their meanings.

   position
   A tuple of line, column numbers, specifying where the error occurred.

Footnotes

(1, 2, 3, 4) The encoding string included in XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not. See https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and https://www.iana.org/assignments/character-sets/character-sets.xhtml.

[1]
The Document Object Model, or “DOM,” is a cross-language API from the World Wide Web Consortium (W3C) for accessing and modifying XML documents. A DOM implementation presents an XML document as a tree structure, or allows client code to build such a structure from scratch. It then gives access to the structure through a set of objects which provided well-known interfaces.

The DOM is extremely useful for random-access applications. SAX only allows you a view of one bit of the document at a time. If you are looking at one SAX element, you have no access to another. If you are looking at a text node, you have no access to a containing element. When you write a SAX application, you need to keep track of your program’s position in the document somewhere in your own code. SAX does not do it for you. Also, if you need to look ahead in the XML document, you are just out of luck.

Some applications are simply impossible in an event driven model with no access to a tree. Of course you could build some sort of tree yourself in SAX events, but the DOM allows you to avoid writing that code. The DOM is a standard tree representation for XML data.

The Document Object Model is being defined by the W3C in stages, or “levels” in their terminology. The Python mapping of the API is substantially based on the DOM Level 2 recommendation.
DOM applications typically start by parsing some XML into a DOM. How this is accomplished is not covered at all by DOM Level 1, and Level 2 provides only limited improvements: There is a DOMImplementation object class which provides access to Document creation methods, but no way to access an XML reader/parser/Document builder in an implementation-independent way. There is also no well-defined way to access these methods without an existing Document object. In Python, each DOM implementation will provide a function `getDOMImplementation()`. DOM Level 3 adds a Load/Store specification, which defines an interface to the reader, but this is not yet available in the Python standard library.

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification; this portion of the reference manual describes the interpretation of the specification in Python.

The specification provided by the W3C defines the DOM API for Java, ECMAScript, and OMG IDL. The Python mapping defined here is based in large part on the IDL version of the specification, but strict compliance is not required (though implementations are free to support the strict mapping from IDL). See section Conformance for a detailed discussion of mapping requirements.

See also:

**Document Object Model (DOM) Level 2 Specification**

The W3C recommendation upon which the Python DOM API is based.

**Document Object Model (DOM) Level 1 Specification**
The W3C recommendation for the DOM supported by xml.dom.minidom.

**Python Language Mapping Specification**
This specifies the mapping from OMG IDL to Python.
20.6.1. Module Contents

The `xml.dom` contains the following functions:

`xml.dom.registerDOMImplementation(name, factory)`

Register the `factory` function with the name `name`. The factory function should return an object which implements the DOMImplementation interface. The factory function can return the same object every time, or a new one for each call, as appropriate for the specific implementation (e.g. if that implementation supports some customization).

`xml.dom.getDOMImplementation(name=None, features=())`  

Return a suitable DOM implementation. The `name` is either well-known, the module name of a DOM implementation, or `None`. If it is not `None`, imports the corresponding module and returns a DOMImplementation object if the import succeeds. If no name is given, and if the environment variable PYTHON_DOM is set, this variable is used to find the implementation.

If name is not given, this examines the available implementations to find one with the required feature set. If no implementation can be found, raise an `ImportError`. The features list must be a sequence of `(feature, version)` pairs which are passed to the hasFeature() method on available DOMImplementation objects.

Some convenience constants are also provided:

`xml.dom.EMPTY_NAMESPACE`

The value used to indicate that no namespace is associated with a
node in the DOM. This is typically found as the namespaceURI of a node, or used as the namespaceURI parameter to a namespaces-specific method.

```python
xml.dom.XML_NAMESPACE
The namespace URI associated with the reserved prefix xml, as defined by Namespaces in XML (section 4).
```

```python
xml.dom.XMLNS_NAMESPACE
The namespace URI for namespace declarations, as defined by Document Object Model (DOM) Level 2 Core Specification (section 1.1.8).
```

```python
xml.dom.XHTML_NAMESPACE
The URI of the XHTML namespace as defined by XHTML 1.0: The Extensible HyperText Markup Language (section 3.1.1).
```

In addition, `xml.dom` contains a base Node class and the DOM exception classes. The Node class provided by this module does not implement any of the methods or attributes defined by the DOM specification; concrete DOM implementations must provide those. The Node class provided as part of this module does provide the constants used for the nodeType attribute on concrete Node objects; they are located within the class rather than at the module level to conform with the DOM specifications.
20.6.2. Objects in the DOM

The definitive documentation for the DOM is the DOM specification from the W3C.

Note that DOM attributes may also be manipulated as nodes instead of as simple strings. It is fairly rare that you must do this, however, so this usage is not yet documented.

### 20.6.2.1. DOMImplementation Objects

The DOMImplementation interface provides a way for applications to determine the availability of particular features in the DOM they are using. DOM Level 2 added the ability to create new Document and DocumentType objects using the DOMImplementation as well.

DOMImplementation. **hasFeature**(feature, version)

Return true if the feature identified by the pair of strings feature and version is implemented.

DOMImplementation. **createDocument**(namespaceUri, qualifiedName, doctype)
Return a new Document object (the root of the DOM), with a child Element object having the given namespaceUri and qualifiedName. The doctype must be a DocumentType object created by createDocumentType(), or None. In the Python DOM API, the first two arguments can also be None in order to indicate that no Element child is to be created.

DOMImplementation.createDocumentType(qualifiedName, publicId, systemId)
Return a new DocumentType object that encapsulates the given qualifiedName, publicId, and systemId strings, representing the information contained in an XML document type declaration.

20.6.2.2. Node Objects
All of the components of an XML document are subclasses of Node.

Node.nodeType
An integer representing the node type. Symbolic constants for the types are on the Node object: ELEMENT_NODE, ATTRIBUTE_NODE, TEXT_NODE, CDATA_SECTION_NODE, ENTITY_NODE, PROCESSING_INSTRUCTION_NODE, COMMENT_NODE, DOCUMENT_NODE, DOCUMENT_TYPE_NODE, NOTATION_NODE. This is a read-only attribute.

Node.parentNode
The parent of the current node, or None for the document node. The value is always a Node object or None. For Element nodes, this will be the parent element, except for the root element, in which case it will be the Document object. For Attr nodes, this is always None. This is a read-only attribute.
Node. **attributes**
   A NamedNodeMap of attribute objects. Only elements have actual values for this; others provide None for this attribute. This is a read-only attribute.

Node. **previousSibling**
   The node that immediately precedes this one with the same parent. For instance the element with an end-tag that comes just before the self element's start-tag. Of course, XML documents are made up of more than just elements so the previous sibling could be text, a comment, or something else. If this node is the first child of the parent, this attribute will be None. This is a read-only attribute.

Node. **nextSibling**
   The node that immediately follows this one with the same parent. See also previousSibling. If this is the last child of the parent, this attribute will be None. This is a read-only attribute.

Node. **childNodes**
   A list of nodes contained within this node. This is a read-only attribute.

Node. **firstChild**
   The first child of the node, if there are any, or None. This is a read-only attribute.

Node. **lastChild**
   The last child of the node, if there are any, or None. This is a read-only attribute.

Node. **localName**
   The part of the tagName following the colon if there is one, else
the entire tagName. The value is a string.

**Node. `prefix`**

The part of the tagName preceding the colon if there is one, else the empty string. The value is a string, or `None`.

**Node. `namespaceURI`**

The namespace associated with the element name. This will be a string or `None`. This is a read-only attribute.

**Node. `nodeName`**

This has a different meaning for each node type; see the DOM specification for details. You can always get the information you would get here from another property such as the `tagName` property for elements or the `name` property for attributes. For all node types, the value of this attribute will be either a string or `None`. This is a read-only attribute.

**Node. `nodeValue`**

This has a different meaning for each node type; see the DOM specification for details. The situation is similar to that with `nodeName`. The value is a string or `None`.

**Node. `hasAttributes()`**

Returns true if the node has any attributes.

**Node. `hasChildNodes()`**

Returns true if the node has any child nodes.

**Node. `isSameNode(other)`**

Returns true if `other` refers to the same node as this node. This is especially useful for DOM implementations which use any sort of
proxy architecture (because more than one object can refer to the same node).

Note: This is based on a proposed DOM Level 3 API which is still in the “working draft” stage, but this particular interface appears uncontroversial. Changes from the W3C will not necessarily affect this method in the Python DOM interface (though any new W3C API for this would also be supported).

Node. **appendChild**(newChild)

Add a new child node to this node at the end of the list of children, returning *newChild*. If the node was already in the tree, it is removed first.

Node. **insertBefore**(newChild, refChild)

Insert a new child node before an existing child. It must be the case that *refChild* is a child of this node; if not, *ValueError* is raised. *newChild* is returned. If *refChild* is None, it inserts *newChild* at the end of the children’s list.

Node. **removeChild**(oldChild)

Remove a child node. *oldChild* must be a child of this node; if not, *ValueError* is raised. *oldChild* is returned on success. If *oldChild* will not be used further, its *unlink()* method should be called.

Node. **replaceChild**(newChild, oldChild)

Replace an existing node with a new node. It must be the case that *oldChild* is a child of this node; if not, *ValueError* is raised.

Node. **normalize**()

Join adjacent text nodes so that all stretches of text are stored as single Text instances. This simplifies processing text from a DOM
tree for many applications.

Node. **cloneNode**(deep)

Clone this node. Setting *deep* means to clone all child nodes as well. This returns the clone.

### 20.6.2.3. NodeList Objects

A NodeList represents a sequence of nodes. These objects are used in two ways in the DOM Core recommendation: an Element object provides one as its list of child nodes, and the `getElementsByTagName()` and `getElementsByTagNameNS()` methods of Node return objects with this interface to represent query results.

The DOM Level 2 recommendation defines one method and one attribute for these objects:

**NodeList.item**(i)

Return the *i*th item from the sequence, if there is one, or None. The index *i* is not allowed to be less than zero or greater than or equal to the length of the sequence.

**NodeList.length**

The number of nodes in the sequence.

In addition, the Python DOM interface requires that some additional support is provided to allow NodeList objects to be used as Python sequences. All NodeList implementations must include support for `__len__()` and `__getitem__()`; this allows iteration over the NodeList in for statements and proper support for the `len()` built-in function.
If a DOM implementation supports modification of the document, the NodeList implementation must also support the __setitem__() and __delitem__() methods.

20.6.2.4. DocumentType Objects

Information about the notations and entities declared by a document (including the external subset if the parser uses it and can provide the information) is available from a DocumentType object. The DocumentType for a document is available from the Document object's doctype attribute; if there is no DOCTYPE declaration for the document, the document's doctype attribute will be set to None instead of an instance of this interface.

DocumentType is a specialization of Node, and adds the following attributes:

DocumentType.publicId
The public identifier for the external subset of the document type definition. This will be a string or None.

DocumentType.systemId
The system identifier for the external subset of the document type definition. This will be a URI as a string, or None.

DocumentType.internalSubset
A string giving the complete internal subset from the document. This does not include the brackets which enclose the subset. If the document has no internal subset, this should be None.

DocumentType.name
The name of the root element as given in the DOCTYPE
declaration, if present.

**DocumentType**. **entities**
This is a NamedNodeMap giving the definitions of external entities. For entity names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be None if the information is not provided by the parser, or if no entities are defined.

**DocumentType**. **notations**
This is a NamedNodeMap giving the definitions of notations. For notation names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be None if the information is not provided by the parser, or if no notations are defined.

### 20.6.2.5. Document Objects

A Document represents an entire XML document, including its constituent elements, attributes, processing instructions, comments etc. Remember that it inherits properties from Node.

**Document**. **documentElement**
The one and only root element of the document.

**Document**. **createElement**(*tagName*)
Create and return a new element node. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as insertBefore() or appendChild().

**Document**. **createElementNS**(*namespaceURI, tagName*)
Create and return a new element with a namespace. The `tagName` may have a prefix. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as `insertBefore()` or `appendChild()`.

**Document. `createTextNode(data)`**
Create and return a text node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

**Document. `createComment(data)`**
Create and return a comment node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

**Document. `createProcessingInstruction(target, data)`**
Create and return a processing instruction node containing the `target` and `data` passed as parameters. As with the other creation methods, this one does not insert the node into the tree.

**Document. `createAttribute(name)`**
Create and return an attribute node. This method does not associate the attribute node with any particular element. You must use `setAttributeNode()` on the appropriate `Element` object to use the newly created attribute instance.

**Document. `createAttributeNS(namespaceURI, qualifiedName)`**
Create and return an attribute node with a namespace. The `tagName` may have a prefix. This method does not associate the attribute node with any particular element. You must use `setAttributeNode()` on the appropriate `Element` object to
use the newly created attribute instance.

Document. **getElementsByTagName**(tagName)
Search for all descendants (direct children, children’s children, etc.) with a particular element type name.

Document. **getElementsByTagNameNS**(namespaceURI, localName)
Search for all descendants (direct children, children’s children, etc.) with a particular namespace URI and localname. The localname is the part of the namespace after the prefix.

**20.6.2.6. Element Objects**

Element is a subclass of Node, so inherits all the attributes of that class.

Element. **tagName**
The element type name. In a namespace-using document it may have colons in it. The value is a string.

Element. **getElementsByTagName**(tagName)
Same as equivalent method in the Document class.

Element. **getElementsByTagNameNS**(namespaceURI, localName)
Same as equivalent method in the Document class.

Element. **hasAttribute**(name)
Returns true if the element has an attribute named by name.

Element. **hasAttributeNS**(namespaceURI, localName)
Returns true if the element has an attribute named by `namespaceURI` and `localName`.

**Element.getAttribute(name)**

Return the value of the attribute named by `name` as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

**Element.getAttributeNode(attrname)**

Return the Attr node for the attribute named by `attrname`.

**Element.getAttributeNS(namespaceURI, localName)**

Return the value of the attribute named by `namespaceURI` and `localName` as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

**Element.getAttributeNodeNS(namespaceURI, localName)**

Return an attribute value as a node, given a `namespaceURI` and `localName`.

**Element.removeAttribute(name)**

Remove an attribute by name. If there is no matching attribute, a `NotFoundErr` is raised.

**Element.removeAttributeNode(oldAttr)**

Remove and return `oldAttr` from the attribute list, if present. If `oldAttr` is not present, `NotFoundErr` is raised.

**Element.removeAttributeNS(namespaceURI, localName)**

Remove an attribute by name. Note that it uses a `localName`, not a qname. No exception is raised if there is no matching attribute.

**Element.setAttribute(name, value)**
Set an attribute value from a string.

Element. `setAttributeNode(newAttr)`
Add a new attribute node to the element, replacing an existing attribute if necessary if the name attribute matches. If a replacement occurs, the old attribute node will be returned. If `newAttr` is already in use, `InuseAttributeErr` will be raised.

Element. `setAttributeNodeNS(newAttr)`
Add a new attribute node to the element, replacing an existing attribute if necessary if the namespaceURI and localName attributes match. If a replacement occurs, the old attribute node will be returned. If `newAttr` is already in use, `InuseAttributeErr` will be raised.

Element. `setAttributeNS(namespaceURI, qname, value)`
Set an attribute value from a string, given a `namespaceURI` and a `qname`. Note that a qname is the whole attribute name. This is different than above.

20.6.2.7. Attr Objects

Attr inherits from Node, so inherits all its attributes.

Attr. `name`
The attribute name. In a namespace-using document it may include a colon.

Attr. `localName`
The part of the name following the colon if there is one, else the entire name. This is a read-only attribute.
Attr. **prefix**

The part of the name preceding the colon if there is one, else the empty string.

Attr. **value**

The text value of the attribute. This is a synonym for the `nodeValue` attribute.

### 20.6.2.8. NamedNodeMap Objects

NamedNodeMap does not inherit from Node.

**NamedNodeMap.length**

The length of the attribute list.

**NamedNodeMap.item(index)**

Return an attribute with a particular index. The order you get the attributes in is arbitrary but will be consistent for the life of a DOM. Each item is an attribute node. Get its value with the `value` attribute.

There are also experimental methods that give this class more mapping behavior. You can use them or you can use the standardized `getAttribute*()` family of methods on the Element objects.

### 20.6.2.9. Comment Objects

Comment represents a comment in the XML document. It is a subclass of Node, but cannot have child nodes.

**Comment.data**

The content of the comment as a string. The attribute contains all
characters between the leading <!- -> and trailing - ->, but does not include them.

20.6.2.10. Text and CDATASection Objects

The Text interface represents text in the XML document. If the parser and DOM implementation support the DOM's XML extension, portions of the text enclosed in CDATA marked sections are stored in CDATASection objects. These two interfaces are identical, but provide different values for the nodeType attribute.

These interfaces extend the Node interface. They cannot have child nodes.

Text.data

The content of the text node as a string.

**Note:** The use of a CDATASection node does not indicate that the node represents a complete CDATA marked section, only that the content of the node was part of a CDATA section. A single CDATA section may be represented by more than one node in the document tree. There is no way to determine whether two adjacent CDATASection nodes represent different CDATA marked sections.

20.6.2.11. ProcessingInstruction Objects

Represents a processing instruction in the XML document; this inherits from the Node interface and cannot have child nodes.

ProcessingInstruction.target

The content of the processing instruction up to the first whitespace
character. This is a read-only attribute.

**ProcessingInstruction**. **data**

The content of the processing instruction following the first whitespace character.

### 20.6.2.12. Exceptions

The DOM Level 2 recommendation defines a single exception, **DOMException**, and a number of constants that allow applications to determine what sort of error occurred. **DOMException** instances carry a **code** attribute that provides the appropriate value for the specific exception.

The Python DOM interface provides the constants, but also expands the set of exceptions so that a specific exception exists for each of the exception codes defined by the DOM. The implementations must raise the appropriate specific exception, each of which carries the appropriate value for the **code** attribute.

**exception** **xml.dom.DOMException**

Base exception class used for all specific DOM exceptions. This exception class cannot be directly instantiated.

**exception** **xml.dom.DomstringSizeErr**

Raised when a specified range of text does not fit into a string. This is not known to be used in the Python DOM implementations, but may be received from DOM implementations not written in Python.

**exception** **xml.dom.HierarchyRequestErr**

Raised when an attempt is made to insert a node where the node type is not allowed.
**exception** `xml.dom.IndexSizeErr`  
Raised when an index or size parameter to a method is negative or exceeds the allowed values.

**exception** `xml.dom.InuseAttributeErr`  
Raised when an attempt is made to insert an Attr node that is already present elsewhere in the document.

**exception** `xml.dom.InvalidAccessErr`  
Raised if a parameter or an operation is not supported on the underlying object.

**exception** `xml.dom.InvalidCharacterErr`  
This exception is raised when a string parameter contains a character that is not permitted in the context it’s being used in by the XML 1.0 recommendation. For example, attempting to create an Element node with a space in the element type name will cause this error to be raised.

**exception** `xml.dom.InvalidModificationErr`  
Raised when an attempt is made to modify the type of a node.

**exception** `xml.dom.InvalidStateErr`  
Raised when an attempt is made to use an object that is not defined or is no longer usable.

**exception** `xml.dom.NamespaceErr`  
If an attempt is made to change any object in a way that is not permitted with regard to the Namespaces in XML recommendation, this exception is raised.

**exception** `xml.dom.NotFoundErr`  
Exception when a node does not exist in the referenced context.
For example, NamedNodeMap.removeNamedItem() will raise this if the node passed in does not exist in the map.

`exception xml.dom.NotSupportedErr`
Raised when the implementation does not support the requested type of object or operation.

`exception xml.dom.NoDataAllowedErr`
This is raised if data is specified for a node which does not support data.

`exception xml.dom.NoModificationAllowedErr`
Raised on attempts to modify an object where modifications are not allowed (such as for read-only nodes).

`exception xml.dom.SyntaxErr`
Raised when an invalid or illegal string is specified.

`exception xml.dom.WrongDocumentErr`
Raised when a node is inserted in a different document than it currently belongs to, and the implementation does not support migrating the node from one document to the other.

The exception codes defined in the DOM recommendation map to the exceptions described above according to this table:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOMSTRING_SIZE_ERR</td>
<td>DomstringSizeErr</td>
</tr>
<tr>
<td>HIERARCHY_REQUEST_ERR</td>
<td>HierarchyRequestErr</td>
</tr>
<tr>
<td>INDEX_SIZE_ERR</td>
<td>IndexSizeErr</td>
</tr>
<tr>
<td>INUSE_ATTRIBUTE_ERR</td>
<td>InuseAttributeErr</td>
</tr>
<tr>
<td>INVALID_ACCESS_ERR</td>
<td>InvalidAccessErr</td>
</tr>
<tr>
<td>Error Code</td>
<td>Error Name</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>INVALID_CHARACTER_ERR</td>
<td>InvalidCharacterErr</td>

</tbody>
</table>
20.6.3. Conformance

This section describes the conformance requirements and relationships between the Python DOM API, the W3C DOM recommendations, and the OMG IDL mapping for Python.

20.6.3.1. Type Mapping

The IDL types used in the DOM specification are mapped to Python types according to the following table.

<table>
<thead>
<tr>
<th>IDL Type</th>
<th>Python Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>bool or int</td>
</tr>
<tr>
<td>int</td>
<td>int</td>
</tr>
<tr>
<td>long int</td>
<td>int</td>
</tr>
<tr>
<td>unsigned int</td>
<td>int</td>
</tr>
<tr>
<td>DOMString</td>
<td>str or bytes</td>
</tr>
<tr>
<td>null</td>
<td>None</td>
</tr>
</tbody>
</table>

20.6.3.2. Accessor Methods

The mapping from OMG IDL to Python defines accessor functions for IDL attribute declarations in much the way the Java mapping does. Mapping the IDL declarations

```plaintext
readonly attribute string someValue;
attribute string anotherValue;
```

yields three accessor functions: a “get” method for someValue
(_get_someValue()), and “get” and “set” methods for anotherValue (_get_anotherValue() and _set_anotherValue()). The mapping, in particular, does not require that the IDL attributes are accessible as normal Python attributes: object.someValue is not required to work, and may raise an AttributeError.

The Python DOM API, however, does require that normal attribute access work. This means that the typical surrogates generated by Python IDL compilers are not likely to work, and wrapper objects may be needed on the client if the DOM objects are accessed via CORBA. While this does require some additional consideration for CORBA DOM clients, the implementers with experience using DOM over CORBA from Python do not consider this a problem. Attributes that are declared readonly may not restrict write access in all DOM implementations.

In the Python DOM API, accessor functions are not required. If provided, they should take the form defined by the Python IDL mapping, but these methods are considered unnecessary since the attributes are accessible directly from Python. “Set” accessors should never be provided for readonly attributes.

The IDL definitions do not fully embody the requirements of the W3C DOM API, such as the notion of certain objects, such as the return value of getElementsByTagName(), being “live”. The Python DOM API does not require implementations to enforce such requirements.
20.7. `xml.dom.minidom` — Minimal DOM implementation

Source code: Lib/xml/dom/minidom.py

`xml.dom.minidom` is a minimal implementation of the Document Object Model interface, with an API similar to that in other languages. It is intended to be simpler than the full DOM and also significantly smaller. Users who are not already proficient with the DOM should consider using the `xml.etree.ElementTree` module for their XML processing instead.

**Warning:** The `xml.dom.minidom` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

DOM applications typically start by parsing some XML into a DOM. With `xml.dom.minidom`, this is done through the parse functions:

```python
from xml.dom.minidom import parse, parseString

dom1 = parse('c:\temp\mydata.xml')  # parse an XML file

datasource = open('c:\temp\mydata.xml')
dom2 = parse(datasource)  # parse an open file

dom3 = parseString('<myxml>Some data<empty/> some more data</myxml>')</n```

The `parse()` function can take either a filename or an open file.
xml.dom.minidom.parse(filename_or_file, parser=None, bufsize=None)

Return a Document from the given input. filename_or_file may be either a file name, or a file-like object. parser, if given, must be a SAX2 parser object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the parseString() function instead:

xml.dom.minidom.parseString(string, parser=None)

Return a Document that represents the string. This method creates an io.StringIO object for the string and passes that on to parse().

Both functions return a Document object representing the content of the document.

What the parse() and parseString() functions do is connect an XML parser with a “DOM builder” that can accept parse events from any SAX parser and convert them into a DOM tree. The name of the functions are perhaps misleading, but are easy to grasp when learning the interfaces. The parsing of the document will be completed before these functions return; it’s simply that these functions do not provide a parser implementation themselves.

You can also create a Document by calling a method on a “DOM Implementation” object. You can get this object either by calling the
getDOMImplementation() function in the `xml.dom` package or the `xml.dom.minidom` module. Once you have a Document, you can add child nodes to it to populate the DOM:

```python
from xml.dom.minidom import getDOMImplementation

impl = getDOMImplementation()

newdoc = impl.createDocument(None, "some_tag", None)
top_element = newdoc.documentElement
text = newdoc.createTextNode('Some textual content.')
top_element.appendChild(text)
```

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification. The main property of the document object is the `documentElement` property. It gives you the main element in the XML document: the one that holds all others. Here is an example program:

```python
dom3 = parseString("<myxml>Some data</myxml>")
assert dom3.documentElement.tagName == "myxml"
```

When you are finished with a DOM tree, you may optionally call the `unlink()` method to encourage early cleanup of the now-unneeded objects. `unlink()` is an `xml.dom.minidom`-specific extension to the DOM API that renders the node and its descendants are essentially useless. Otherwise, Python's garbage collector will eventually take care of the objects in the tree.

**See also:**

*Document Object Model (DOM) Level 1 Specification*
The W3C recommendation for the DOM supported by xml.dom.minidom.
20.7.1. DOM Objects

The definition of the DOM API for Python is given as part of the xml.dom module documentation. This section lists the differences between the API and xml.dom.minidom.

Node. `unlink()`

Break internal references within the DOM so that it will be garbage collected on versions of Python without cyclic GC. Even when cyclic GC is available, using this can make large amounts of memory available sooner, so calling this on DOM objects as soon as they are no longer needed is good practice. This only needs to be called on the Document object, but may be called on child nodes to discard children of that node.

You can avoid calling this method explicitly by using the `with` statement. The following code will automatically unlink `dom` when the `with` block is exited:

```python
with xml.dom.minidom.parse(datasource) as dom:
    ... # Work with dom.
```

Node. `writexml(writer, indent="", addindent="", newl="")`

Write XML to the writer object. The writer should have a `write()` method which matches that of the file object interface. The `indent` parameter is the indentation of the current node. The `addindent` parameter is the incremental indentation to use for subnodes of the current one. The `newl` parameter specifies the string to use to terminate newlines.

For the Document node, an additional keyword argument
encoding can be used to specify the encoding field of the XML header.

**Node. `toxml(encoding=None)`**

Return a string or byte string containing the XML represented by the DOM node.

With an explicit encoding [1] argument, the result is a byte string in the specified encoding. With no encoding argument, the result is a Unicode string, and the XML declaration in the resulting string does not specify an encoding. Encoding this string in an encoding other than UTF-8 is likely incorrect, since UTF-8 is the default encoding of XML.

**Node. `toprettyxml(indent='', newl='', encoding='')`**

Return a pretty-printed version of the document. indent specifies the indentation string and defaults to a tabulator; newl specifies the string emitted at the end of each line and defaults to \n.

The encoding argument behaves like the corresponding argument of `toxml()`.
20.7.2. DOM Example

This example program is a fairly realistic example of a simple program. In this particular case, we do not take much advantage of the flexibility of the DOM.

```python
import xml.dom.minidom

document = """
<slideshow>
<title>Demo slideshow</title>
<slide><title>Slide title</title>
<point>This is a demo</point>
<point>Of a program for processing slides</point>
</slide>

<slide><title>Another demo slide</title>
<point>It is important</point>
<point>To have more than</point>
<point>one slide</point>
</slide>

""

dom = xml.dom.minidom.parseString(document)

def getText(nodelist):
    rc = []
    for node in nodelist:
        if node.nodeType == node.TEXT_NODE:
            rc.append(node.data)
    return ''.join(rc)

def handleSlideshow(slideshow):
    print("<html>")
```
handleSlideshowTitle(slideshow.getElementsByTagName("slide"))
slides = slideshow.getElementsByTagName("slide")
handleToc(slides)
handleSlides(slides)
print("</html>")

def handleSlides(slides):
    for slide in slides:
        handleSlide(slide)

def handleSlide(slide):
    handleSlideTitle(slide.getElementsByTagName("title"))
    handlePoints(slide.getElementsByTagName("point"))

def handleSlideTitle(title):
    print("<h2>%s</h2>" % getText(title.childNodes))

def handlePoints(points):
    print("<ul>"
    for point in points:
        handlePoint(point)
    print("</ul>")

def handlePoint(point):
    print("<li>%s</li>" % getText(point.childNodes))

def handleToc(slides):
    for slide in slides:
        title = slide.getElementsByTagName("title")
        print("<p>%s</p>" % getText(title.childNodes))

handleSlideshow(dom)
20.7.3. minidom and the DOM standard

The `xml.dom.minidom` module is essentially a DOM 1.0-compatible DOM with some DOM 2 features (primarily namespace features).

Usage of the DOM interface in Python is straight-forward. The following mapping rules apply:

- Interfaces are accessed through instance objects. Applications should not instantiate the classes themselves; they should use the creator functions available on the Document object. Derived interfaces support all operations (and attributes) from the base interfaces, plus any new operations.
- Operations are used as methods. Since the DOM uses only `in` parameters, the arguments are passed in normal order (from left to right). There are no optional arguments. `void` operations return `None`.
- IDL attributes map to instance attributes. For compatibility with the OMG IDL language mapping for Python, an attribute `foo` can also be accessed through accessor methods `_get_foo()` and `_set_foo()`. `readonly` attributes must not be changed; this is not enforced at runtime.
- The types `short`, `int`, `unsigned int`, `unsigned long`, and `boolean` all map to Python integer objects.
- The type `DOMString` maps to Python strings. `xml.dom.minidom` supports either bytes or strings, but will normally produce strings. Values of type `DOMString` may also be `None` where allowed to have the IDL `null` value by the DOM specification from the W3C.
- `const` declarations map to variables in their respective scope (e.g. `xml.dom.minidom.Node.PROCESSING_INSTRUCTION_NODE`).
they must not be changed.

- **DOMException** is currently not supported in `xml.dom.minidom`. Instead, `xml.dom.minidom` uses standard Python exceptions such as `TypeError` and `AttributeError`.
- NodeList objects are implemented using Python's built-in list type. These objects provide the interface defined in the DOM specification, but with earlier versions of Python they do not support the official API. They are, however, much more “Pythonic” than the interface defined in the W3C recommendations.

The following interfaces have no implementation in `xml.dom.minidom`:

- DOMTimeStamp
- DocumentType
- DOMImplementation
- CharacterData
- CDATASEction
- Notation
- Entity
- EntityReference
- DocumentFragment

Most of these reflect information in the XML document that is not of general utility to most DOM users.

**Footnotes**

The encoding name included in the XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not valid in an XML document’s declaration, even though Python accepts it as an encoding name. See [https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl](https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl) and [https://www.iana.org/assignments/character-](https://www.iana.org/assignments/character-)
20.8. `xml.dom.pulldom` — Support for building partial DOM trees

Source code: Lib/xml/dom/pulldom.py

The `xml.dom.pulldom` module provides a “pull parser” which can also be asked to produce DOM-accessible fragments of the document where necessary. The basic concept involves pulling “events” from a stream of incoming XML and processing them. In contrast to SAX which also employs an event-driven processing model together with callbacks, the user of a pull parser is responsible for explicitly pulling events from the stream, looping over those events until either processing is finished or an error condition occurs.

**Warning:** The `xml.dom.pulldom` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see [XML vulnerabilities](#).

Example:

```python
from xml.dom import pulldom

doc = pulldom.parse('sales_items.xml')
for event, node in doc:
    if event == pulldom.START_ELEMENT and node.tagName if int(node.getAttribute('price')) > 50:
        doc.expandNode(node)
        print(node.toxml())
```
event is a constant and can be one of:

- START_ELEMENT
- END_ELEMENT
- COMMENT
- START_DOCUMENT
- END_DOCUMENT
- CHARACTERS
- PROCESSING_INSTRUCTION
- IGNORABLE_WHITE_SPACE

node is an object of type xml.dom.minidom.Document, xml.dom.minidom.Element or xml.dom.minidom.Text.

Since the document is treated as a “flat” stream of events, the document “tree” is implicitly traversed and the desired elements are found regardless of their depth in the tree. In other words, one does not need to consider hierarchical issues such as recursive searching of the document nodes, although if the context of elements were important, one would either need to maintain some context-related state (i.e. remembering where one is in the document at any given point) or to make use of the DOMEventStream.expandNode() method and switch to DOM-related processing.

class xml.dom.pulldom.PullDom(documentFactory=None)
    Subclass of xml.sax.handler.ContentHandler.

class xml.dom.pulldom.SAX2DOM(documentFactory=None)
    Subclass of xml.sax.handler.ContentHandler.

xml.dom.pulldom.parse(stream_or_string, parser=None, bufsize=None)
Return a **DOMEventStream** from the given input. *stream_or_string* may be either a file name, or a file-like object. *parser*, if given, must be an **XMLReader** object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the **parseString()** function instead:

```
xml.dom.pulldom.parseString(string, parser=None)
```

Return a **DOMEventStream** that represents the (Unicode) *string*.

```
xml.dom.pulldom.default_bufsize
```

Default value for the *bufsize* parameter to **parse()**.

The value of this variable can be changed before calling **parse()** and the new value will take effect.
20.8.1. DOMEventStream Objects

class xml.dom.pulldom.DOMEventStream(stream, parser, bufsize)

getEvent()
Return a tuple containing event and the current node as
xml.dom.minidom.Document if event equals
START_DOCUMENT, xml.dom.minidom.Element if event
equals START_ELEMENT or END_ELEMENT or
xml.dom.minidom.Text if event equals CHARACTERS. The
current node does not contain information about its children,
unless expandNode() is called.

expandNode(node)
Expands all children of node into node. Example:

```python
from xml.dom import pulldom

xml = '<html><title>Foo</title> <p>Some text <div>and more</div></p>
for event, node in doc:
    if event == pulldom.START_ELEMENT and node:
        # Following statement only prints '<p/>
        print(node.toxml())
        doc.expandNode(node)
        # Following statement prints node with
        print(node.toxml())
```

reset()
20.9. **xml.sax** — Support for SAX2 parsers

**Source code:** Lib/xml/sax/__init__.py

The **xml.sax** package provides a number of modules which implement the Simple API for XML (SAX) interface for Python. The package itself provides the SAX exceptions and the convenience functions which will be most used by users of the SAX API.

**Warning:** The **xml.sax** module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see [XML vulnerabilities](#).

The convenience functions are:

**xml.sax.make_parser** *(parser_list=[])*

Create and return a SAX **XMLReader** object. The first parser found will be used. If *parser_list* is provided, it must be a sequence of strings which name modules that have a function named `create_parser()`. Modules listed in *parser_list* will be used before modules in the default list of parsers.

**xml.sax.parse** *(filename_or_stream, handler, error_handler=handler.ErrorHandler())*

Create a SAX parser and use it to parse a document. The document, passed in as *filename_or_stream*, can be a filename or a file object. The *handler* parameter needs to be a SAX **ContentHandler** instance. If *error_handler* is given, it must be a
SAX `ErrorHandler` instance; if omitted, `SAXParseException` will be raised on all errors. There is no return value; all work must be done by the `handler` passed in.

```python
def xml.sax.parseString(string, handler, error_handler=handler.ErrorHandler())
```

Similar to `parse()`, but parses from a buffer `string` received as a parameter. `string` must be a `str` instance or a bytes-like object.

*Changed in version 3.5:* Added support of `str` instances.

A typical SAX application uses three kinds of objects: readers, handlers and input sources. “Reader” in this context is another term for parser, i.e. some piece of code that reads the bytes or characters from the input source, and produces a sequence of events. The events then get distributed to the handler objects, i.e. the reader invokes a method on the handler. A SAX application must therefore obtain a reader object, create or open the input sources, create the handlers, and connect these objects all together. As the final step of preparation, the reader is called to parse the input. During parsing, methods on the handler objects are called based on structural and syntactic events from the input data.

For these objects, only the interfaces are relevant; they are normally not instantiated by the application itself. Since Python does not have an explicit notion of interface, they are formally introduced as classes, but applications may use implementations which do not inherit from the provided classes. The `InputSource`, `Locator`, `Attributes`, `AttributesNS`, and `XMLReader` interfaces are defined in the module `xml.sax.xmlreader`. The handler interfaces are defined in `xml.sax.handler`. For convenience, `InputSource` (which is often instantiated directly) and the handler classes are also available from
**xml.sax.** These interfaces are described below.

In addition to these classes, **xml.sax** provides the following exception classes.

```python
exception xml.sax.SAXException(msg, exception=None)
```

Encapsulate an XML error or warning. This class can contain basic error or warning information from either the XML parser or the application: it can be subclassed to provide additional functionality or to add localization. Note that although the handlers defined in the **ErrorHandler** interface receive instances of this exception, it is not required to actually raise the exception — it is also useful as a container for information.

When instantiated, `msg` should be a human-readable description of the error. The optional `exception` parameter, if given, should be `None` or an exception that was caught by the parsing code and is being passed along as information.

This is the base class for the other SAX exception classes.

```python
exception xml.sax.SAXParseException(msg, exception, locator)
```

Subclass of **SAXException** raised on parse errors. Instances of this class are passed to the methods of the SAX **ErrorHandler** interface to provide information about the parse error. This class supports the SAX **Locator** interface as well as the **SAXException** interface.

```python
exception xml.sax.SAXNotRecognizedException(msg, exception=None)
```

Subclass of **SAXException** raised when a SAX **XMLReader** is
confronted with an unrecognized feature or property. SAX applications and extensions may use this class for similar purposes.

```
exception xml.sax.SAXNotSupportedException(msg, exception=None)
```

Subclass of `SAXException` raised when a SAX `XMLReader` is asked to enable a feature that is not supported, or to set a property to a value that the implementation does not support. SAX applications and extensions may use this class for similar purposes.

**See also:**

**SAX: The Simple API for XML**

This site is the focal point for the definition of the SAX API. It provides a Java implementation and online documentation. Links to implementations and historical information are also available.

**Module `xml.sax.handler`**

Definitions of the interfaces for application-provided objects.

**Module `xml.sax.saxutils`**

Convenience functions for use in SAX applications.

**Module `xml.sax.xmlreader`**

Definitions of the interfaces for parser-provided objects.
20.9.1. SAXException Objects

The **SAXException** exception class supports the following methods:

SAXException.**getMessage**()

Return a human-readable message describing the error condition.

SAXException.**getException**()

Return an encapsulated exception object, or **None**.
20.10. **xml.sax.handler** —
Base classes for SAX handlers

**Source code:** Lib/xml/sax/handler.py

The SAX API defines four kinds of handlers: content handlers, DTD handlers, error handlers, and entity resolvers. Applications normally only need to implement those interfaces whose events they are interested in; they can implement the interfaces in a single object or in multiple objects. Handler implementations should inherit from the base classes provided in the module `xml.sax.handler`, so that all methods get default implementations.

```python
class xml.sax.handler.ContentHandler
    This is the main callback interface in SAX, and the one most important to applications. The order of events in this interface mirrors the order of the information in the document.

class xml.sax.handler/DTDHandler
    Handle DTD events.

    This interface specifies only those DTD events required for basic parsing (unparsed entities and attributes).

class xml.sax.handler.EntityResolver
    Basic interface for resolving entities. If you create an object implementing this interface, then register the object with your Parser, the parser will call the method in your object to resolve all external entities.
```
class xml.sax.handler.ErrorHandler

Interface used by the parser to present error and warning messages to the application. The methods of this object control whether errors are immediately converted to exceptions or are handled in some other way.

In addition to these classes, xml.sax.handler provides symbolic constants for the feature and property names.

xml.sax.handler.feature_namespaces

value: "http://xml.org/sax/features/namespaces"
true: Perform Namespace processing.
false: Optionally do not perform Namespace processing (implies namespace-prefixes; default).
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_namespace_prefixes

value: "http://xml.org/sax/features/namespace-prefixes"
true: Report the original prefixed names and attributes used for Namespace declarations.
false: Do not report attributes used for Namespace declarations, and optionally do not report original prefixed names (default).
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_string_interning

value: "http://xml.org/sax/features/string-interning"
true: All element names, prefixes, attribute names, Namespace URIs, and local names are interned using the built-in intern function.
false: Names are not necessarily interned, although they may be
xml.sax.handler.feature_validation

value: "http://xml.org/sax/features/validation"
true: Report all validation errors (implies external-general-entities and external-parameter-entities).
false: Do not report validation errors.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_external_ges

value: "http://xml.org/sax/features/external-general-entities"
true: Include all external general (text) entities.
false: Do not include external general entities.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_external_pes

value: "http://xml.org/sax/features/external-parameter-entities"
true: Include all external parameter entities, including the external DTD subset.
false: Do not include any external parameter entities, even the external DTD subset.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.all_features

List of all features.

xml.sax.handler.property_lexical_handler

value: "http://xml.org/sax/properties/lexical-handler"
data type: xml.sax.sax2lib.LexicalHandler (not supported in Python 2)
description: An optional extension handler for lexical events like comments.
access: read/write

xml.sax.handler.property_declaration_handler

value: "http://xml.org/sax/properties/declaration-handler"
data type: xml.sax.sax2lib.DeclHandler (not supported in Python 2)
description: An optional extension handler for DTD-related events other than notations and unparsed entities.
access: read/write

xml.sax.handler.property_dom_node

value: "http://xml.org/sax/properties/dom-node"
data type: org.w3c.dom.Node (not supported in Python 2)
description: When parsing, the current DOM node being visited if this is a DOM iterator; when not parsing, the root DOM node for iteration.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.property_xml_string

value: "http://xml.org/sax/properties/xml-string"
data type: String
description: The literal string of characters that was the source for the current event.
access: read-only

xml.sax.handler.all_properties
List of all known property names.
20.10.1. ContentHandler Objects

Users are expected to subclass `ContentHandler` to support their application. The following methods are called by the parser on the appropriate events in the input document:

**ContentHandler.** `setDocumentLocator(locator)`
- Called by the parser to give the application a locator for locating the origin of document events.

SAX parsers are strongly encouraged (though not absolutely required) to supply a locator: if it does so, it must supply the locator to the application by invoking this method before invoking any of the other methods in the DocumentHandler interface.

The locator allows the application to determine the end position of any document-related event, even if the parser is not reporting an error. Typically, the application will use this information for reporting its own errors (such as character content that does not match an application’s business rules). The information returned by the locator is probably not sufficient for use with a search engine.

Note that the locator will return correct information only during the invocation of the events in this interface. The application should not attempt to use it at any other time.

**ContentHandler.** `startDocument()`
- Receive notification of the beginning of a document.

The SAX parser will invoke this method only once, before any other methods in this interface or in DTDHandler (except for `setDocumentLocator()`).
ContentHandler.endDocument()

Receive notification of the end of a document.

The SAX parser will invoke this method only once, and it will be the last method invoked during the parse. The parser shall not invoke this method until it has either abandoned parsing (because of an unrecoverable error) or reached the end of input.

ContentHandler.startPrefixMapping(prefix, uri)

Begin the scope of a prefix-URI Namespace mapping.

The information from this event is not necessary for normal Namespace processing: the SAX XML reader will automatically replace prefixes for element and attribute names when the feature_namespaces feature is enabled (the default).

There are cases, however, when applications need to use prefixes in character data or in attribute values, where they cannot safely be expanded automatically; the startPrefixMapping() and endPrefixMapping() events supply the information to the application to expand prefixes in those contexts itself, if necessary.

Note that startPrefixMapping() and endPrefixMapping() events are not guaranteed to be properly nested relative to each-other: all startPrefixMapping() events will occur before the corresponding startElement() event, and all endPrefixMapping() events will occur after the corresponding endElement() event, but their order is not guaranteed.

ContentHandler.endPrefixMapping(prefix)

End the scope of a prefix-URI mapping.

See startPrefixMapping() for details. This event will always
occur after the corresponding \texttt{endElement()} event, but the order of \texttt{endPrefixMapping()} events is not otherwise guaranteed.

\texttt{ContentHandler.startElement(name, attrs)}

Signals the start of an element in non-namespace mode.

The \texttt{name} parameter contains the raw XML 1.0 name of the element type as a string and the \texttt{attrs} parameter holds an object of the \texttt{Attributes} interface (see \texttt{The Attributes Interface}) containing the attributes of the element. The object passed as \texttt{attrs} may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the \texttt{copy()} method of the \texttt{attrs} object.

\texttt{ContentHandler.endElement(name)}

Signals the end of an element in non-namespace mode.

The \texttt{name} parameter contains the name of the element type, just as with the \texttt{startElement()} event.

\texttt{ContentHandler.startElementNS(name, qname, attrs)}

Signals the start of an element in namespace mode.

The \texttt{name} parameter contains the name of the element type as a \texttt{(uri, localname)} tuple, the \texttt{qname} parameter contains the raw XML 1.0 name used in the source document, and the \texttt{attrs} parameter holds an instance of the \texttt{AttributesNS} interface (see \texttt{The AttributesNS Interface}) containing the attributes of the element. If no namespace is associated with the element, the \texttt{uri} component of \texttt{name} will be \texttt{None}. The object passed as \texttt{attrs} may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the
attributes, use the `copy()` method of the `attrs` object.

Parsers may set the `qname` parameter to `None`, unless the `feature_namespaces` feature is activated.

`ContentHandler.endElementNS(name, qname)`
Signals the end of an element in namespace mode.

The `name` parameter contains the name of the element type, just as with the `startElementNS()` method, likewise the `qname` parameter.

`ContentHandler.characters(content)`
Receive notification of character data.

The Parser will call this method to report each chunk of character data. SAX parsers may return all contiguous character data in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity so that the Locator provides useful information.

`content` may be a string or bytes instance; the `expat` reader module always produces strings.

**Note:** The earlier SAX 1 interface provided by the Python XML Special Interest Group used a more Java-like interface for this method. Since most parsers used from Python did not take advantage of the older interface, the simpler signature was chosen to replace it. To convert old code to the new interface, use `content` instead of slicing content with the old `offset` and `length` parameters.

`ContentHandler.ignorableWhitespace(whitespace)`
Receive notification of ignorable whitespace in element content.

Validating Parsers must use this method to report each chunk of ignorable whitespace (see the W3C XML 1.0 recommendation, section 2.10): non-validating parsers may also use this method if they are capable of parsing and using content models.

SAX parsers may return all contiguous whitespace in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity, so that the Locator provides useful information.

ContentHandler. **processingInstruction**(target, data)

Receive notification of a processing instruction.

The Parser will invoke this method once for each processing instruction found: note that processing instructions may occur before or after the main document element.

A SAX parser should never report an XML declaration (XML 1.0, section 2.8) or a text declaration (XML 1.0, section 4.3.1) using this method.

ContentHandler. **skippedEntity**(name)

Receive notification of a skipped entity.

The Parser will invoke this method once for each entity skipped. Non-validating processors may skip entities if they have not seen the declarations (because, for example, the entity was declared in an external DTD subset). All processors may skip external entities, depending on the values of the feature_external_ges and the feature_external_pes properties.
20.10.2. DTDHandler Objects

`DTDHandler` instances provide the following methods:

`DTDHandler.notationDecl(name, publicId, systemId)`
- Handle a notation declaration event.

`DTDHandler.unparsedEntityDecl(name, publicId, systemId, ndata)`
- Handle an unparsed entity declaration event.
20.10.3. EntityResolver Objects

EntityResolver. **resolveEntity**(publicId, systemId)

Resolve the system identifier of an entity and return either the system identifier to read from as a string, or an InputSource to read from. The default implementation returns systemId.
20.10.4. ErrorHandler Objects

Objects with this interface are used to receive error and warning information from the XMLReader. If you create an object that implements this interface, then register the object with your XMLReader, the parser will call the methods in your object to report all warnings and errors. There are three levels of errors available: warnings, (possibly) recoverable errors, and unrecoverable errors. All methods take a SAXParseException as the only parameter. Errors and warnings may be converted to an exception by raising the passed-in exception object.

ErrorHandler.error(exception)
Called when the parser encounters a recoverable error. If this method does not raise an exception, parsing may continue, but further document information should not be expected by the application. Allowing the parser to continue may allow additional errors to be discovered in the input document.

ErrorHandler.fatalError(exception)
Called when the parser encounters an error it cannot recover from; parsing is expected to terminate when this method returns.

ErrorHandler.warning(exception)
Called when the parser presents minor warning information to the application. Parsing is expected to continue when this method returns, and document information will continue to be passed to the application. Raising an exception in this method will cause parsing to end.
20.11. `xml.sax.saxutils` —
SAX Utilities

**Source code:** Lib/xml/sax/saxutils.py

The module `xml.sax.saxutils` contains a number of classes and functions that are commonly useful when creating SAX applications, either in direct use, or as base classes.

```python
xml.sax.saxutils.escape(data, entities={})
```

Escape `&`, `<`, and `>` in a string of data.

You can escape other strings of data by passing a dictionary as the optional `entities` parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. The characters `&`, `<` and `>` are always escaped, even if `entities` is provided.

```python
xml.sax.saxutils.unescape(data, entities={})
```

Unescape `&`amp;`, `&lt;`, and `&gt;` in a string of data.

You can unescape other strings of data by passing a dictionary as the optional `entities` parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. `&`, `<` and `>` are always unescaped, even if `entities` is provided.

```python
xml.sax.saxutils.quoteattr(data, entities={})
```

Similar to `escape()`, but also prepares `data` to be used as an attribute value. The return value is a quoted version of `data` with
any additional required replacements. quoteattr() will select a quote character based on the content of data, attempting to avoid encoding any quote characters in the string. If both single- and double-quote characters are already in data, the double-quote characters will be encoded and data will be wrapped in double-quotes. The resulting string can be used directly as an attribute value:

```python
>>> print("<element attr=\%s>" % quoteattr("ab ' cd \\\"ef")
<element attr="ab ' cd "ef">
```

This function is useful when generating attribute values for HTML or any SGML using the reference concrete syntax.

class xml.sax.saxutils.XMLGenerator(out=None, encoding='iso-8859-1', short_empty_elements=False)

This class implements the ContentHandler interface by writing SAX events back into an XML document. In other words, using an XMLGenerator as the content handler will reproduce the original document being parsed. out should be a file-like object which will default to sys.stdout. encoding is the encoding of the output stream which defaults to 'iso-8859-1'. short_empty_elements controls the formatting of elements that contain no content: if False (the default) they are emitted as a pair of start/end tags, if set to True they are emitted as a single self-closed tag.

*New in version 3.2:* The short_empty_elements parameter.

class xml.sax.saxutils.XMLFilterBase(base)

This class is designed to sit between an XMLReader and the client application's event handlers. By default, it does nothing but pass requests up to the reader and events on to the handlers
unmodified, but subclasses can override specific methods to modify the event stream or the configuration requests as they pass through.

```python
xml.sax.saxutils.prepare_input_source(source, base="")
```

This function takes an input source and an optional base URL and returns a fully resolved `InputSource` object ready for reading. The input source can be given as a string, a file-like object, or an `InputSource` object; parsers will use this function to implement the polymorphic `source` argument to their `parse()` method.
20.12. `xml.sax.xmlreader` — Interface for XML parsers

**Source code:** Lib/xml/sax/xmlreader.py

SAX parsers implement the `XMLReader` interface. They are implemented in a Python module, which must provide a function `create_parser()`. This function is invoked by `xml.sax.make_parser()` with no arguments to create a new parser object.

```python
class xml.sax.xmlreader.XMLReader
    Base class which can be inherited by SAX parsers.

class xml.sax.xmlreader.IncrementalParser
    In some cases, it is desirable not to parse an input source at once, but to feed chunks of the document as they get available. Note that the reader will normally not read the entire file, but read it in chunks as well; still `parse()` won't return until the entire document is processed. So these interfaces should be used if the blocking behaviour of `parse()` is not desirable.
```

When the parser is instantiated it is ready to begin accepting data from the feed method immediately. After parsing has been finished with a call to close the reset method must be called to make the parser ready to accept new data, either from feed or using the parse method.

Note that these methods must *not* be called during parsing, that is, after parse has been called and before it returns.
By default, the class also implements the parse method of the XMLReader interface using the feed, close and reset methods of the IncrementalParser interface as a convenience to SAX 2.0 driver writers.

**class xml.sax.xmlreader.Locator**

Interface for associating a SAX event with a document location. A locator object will return valid results only during calls to DocumentHandler methods; at any other time, the results are unpredictable. If information is not available, methods may return None.

**class xml.sax.xmlreader.InputSource**(*system_id=\text{None}*)

Encapsulation of the information needed by the XMLReader to read entities.

This class may include information about the public identifier, system identifier, byte stream (possibly with character encoding information) and/or the character stream of an entity.

Applications will create objects of this class for use in the `XMLReader.parse()` method and for returning from `EntityResolver.resolveEntity`.

An `InputSource` belongs to the application, the `XMLReader` is not allowed to modify `InputSource` objects passed to it from the application, although it may make copies and modify those.

**class xml.sax.xmlreader.AttributesImpl**(*attrs*)

This is an implementation of the Attributes interface (see section The Attributes Interface). This is a dictionary-like object which represents the element attributes in a `startElement()` call. In addition to the most useful dictionary operations, it supports
a number of other methods as described by the interface. Objects of this class should be instantiated by readers; `attrs` must be a dictionary-like object containing a mapping from attribute names to attribute values.

```python
class xml.sax.xmlreader.AttributesNSImpl(attrs, qnames)
```

Namespace-aware variant of `AttributesImpl`, which will be passed to `startElementNS()`. It is derived from `AttributesImpl`, but understands attribute names as two-tuples of `namespaceURI` and `localname`. In addition, it provides a number of methods expecting qualified names as they appear in the original document. This class implements the AttributesNS interface (see section The AttributesNS Interface).
20.12.1. XMLReader Objects

The XMLReader interface supports the following methods:

XMLReader.\texttt{parse}(source)

Process an input source, producing SAX events. The \texttt{source} object can be a system identifier (a string identifying the input source – typically a file name or a URL), a file-like object, or an \texttt{InputSource} object. When \texttt{parse()} returns, the input is completely processed, and the parser object can be discarded or reset.

\textit{Changed in version 3.5}: Added support of character streams.

XMLReader.\texttt{getContentHandler}()

Return the current \texttt{ContentHandler}.

XMLReader.\texttt{setContentHandler}(handler)

Set the current \texttt{ContentHandler}. If no \texttt{ContentHandler} is set, content events will be discarded.

XMLReader.\texttt{getDTDHandler}()

Return the current \texttt{DTDHandler}.

XMLReader.\texttt{setDTDHandler}(handler)

Set the current \texttt{DTDHandler}. If no \texttt{DTDHandler} is set, DTD events will be discarded.

XMLReader.\texttt{getEntityResolver}()

Return the current \texttt{EntityResolver}.

XMLReader.\texttt{setEntityResolver}(handler)
Set the current `EntityResolver`. If no `EntityResolver` is set, attempts to resolve an external entity will result in opening the system identifier for the entity, and fail if it is not available.

**XMLReader**. `getErrorHandler()`

Return the current `ErrorHandler`.

**XMLReader**. `setErrorHandler(handler)`

Set the current error handler. If no `ErrorHandler` is set, errors will be raised as exceptions, and warnings will be printed.

**XMLReader**. `setLocale(locale)`

Allow an application to set the locale for errors and warnings.

SAX parsers are not required to provide localization for errors and warnings; if they cannot support the requested locale, however, they must raise a SAX exception. Applications may request a locale change in the middle of a parse.

**XMLReader**. `getFeature(featurename)`

Return the current setting for feature `featurename`. If the feature is not recognized, `SAXNotRecognizedException` is raised. The well-known featurenames are listed in the module `xml.sax.handler`.

**XMLReader**. `setFeature(featurename, value)`

Set the `featurename` to `value`. If the feature is not recognized, `SAXNotRecognizedException` is raised. If the feature or its setting is not supported by the parser, `SAXNotSupportedException` is raised.

**XMLReader**. `getProperty(propertyname)`
Return the current setting for property *propertyname*. If the property is not recognized, a SAXNotRecognizedException is raised. The well-known property names are listed in the module `xml.sax.handler`.

**XMLReader. `setProperty(propertyname, value)`**

Set the *propertyname* to *value*. If the property is not recognized, SAXNotRecognizedException is raised. If the property or its setting is not supported by the parser, SAXNotSupportedException is raised.
20.12.2. IncrementalParser Objects

Instances of IncrementalParser offer the following additional methods:

IncrementalParser.feed(data)

Process a chunk of data.

IncrementalParser.close()

Assume the end of the document. That will check well-formedness conditions that can be checked only at the end, invoke handlers, and may clean up resources allocated during parsing.

IncrementalParser.reset()

This method is called after close has been called to reset the parser so that it is ready to parse new documents. The results of calling parse or feed after close without calling reset are undefined.
20.12.3. Locator Objects

Instances of `Locator` provide these methods:

- **Locator.getColumnNumber()**
  Return the column number where the current event begins.

- **Locator.getLineNumber()**
  Return the line number where the current event begins.

- **Locator.getPublicId()**
  Return the public identifier for the current event.

- **Locator.getSystemId()**
  Return the system identifier for the current event.
20.12.4. InputSource Objects

InputSource. `setPublicId(id)`
Sets the public identifier of this InputSource.

InputSource. `getPublicId()`
Returns the public identifier of this InputSource.

InputSource. `setSystemId(id)`
Sets the system identifier of this InputSource.

InputSource. `getSystemId()`
Returns the system identifier of this InputSource.

InputSource. `setEncoding(encoding)`
Sets the character encoding of this InputSource.

The encoding must be a string acceptable for an XML encoding declaration (see section 4.3.3 of the XML recommendation).

The encoding attribute of the InputSource is ignored if the InputSource also contains a character stream.

InputSource. `getEncoding()`
Get the character encoding of this InputSource.

InputSource. `setByteStream(bytefile)`
Set the byte stream (a binary file) for this input source.

The SAX parser will ignore this if there is also a character stream specified, but it will use a byte stream in preference to opening a URI connection itself.
If the application knows the character encoding of the byte stream, it should set it with the setEncoding method.

**InputSource**. **getBytesStream()**
Get the byte stream for this input source.

The getEncoding method will return the character encoding for this byte stream, or None if unknown.

**InputSource**. **setCharacterStream(charfile)**
Set the character stream (a text file) for this input source.

If there is a character stream specified, the SAX parser will ignore any byte stream and will not attempt to open a URI connection to the system identifier.

**InputSource**. **getCharacterStream()**
Get the character stream for this input source.
20.12.5. The Attributes Interface

Attributes objects implement a portion of the mapping protocol, including the methods copy(), get(), __contains__(), items(), keys(), and values(). The following methods are also provided:

**Attributes**. **getLength()**
Return the number of attributes.

**Attributes**. **getNames()**
Return the names of the attributes.

**Attributes**. **getType(name)**
Returns the type of the attribute name, which is normally 'CDATA'.

**Attributes**. **getValue(name)**
Return the value of attribute name.
20.12.6. The AttributesNS Interface

This interface is a subtype of the Attributes interface (see section The Attributes Interface). All methods supported by that interface are also available on AttributesNS objects.

The following methods are also available:

AttributesNS. `getValueByQName(name)`
    Return the value for a qualified name.

AttributesNS. `getNameByQName(name)`
    Return the (namespace, localname) pair for a qualified name.

AttributesNS. `getQNameByName(name)`
    Return the qualified name for a (namespace, localname) pair.

AttributesNS. `getQNames()`
    Return the qualified names of all attributes.
20.13. **xml.parsers.expat** — Fast XML parsing using Expat

**Warning:** The pyexpat module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see [XML vulnerabilities](#).

The `xml.parsers.expat` module is a Python interface to the Expat non-validating XML parser. The module provides a single extension type, `xmlparser`, that represents the current state of an XML parser. After an `xmlparser` object has been created, various attributes of the object can be set to handler functions. When an XML document is then fed to the parser, the handler functions are called for the character data and markup in the XML document.

This module uses the pyexpat module to provide access to the Expat parser. Direct use of the pyexpat module is deprecated.

This module provides one exception and one type object:

```python
exception xml.parsers.expat.ExpatError
    The exception raised when Expat reports an error. See section
    ExpatError Exceptions for more information on interpreting Expat
    errors.

exception xml.parsers.expat.error
    Alias for ExpatError.
```

```python
xml.parsers.expat.XMLParserType
    The type of the return values from the ParserCreate() function.
```
The `xml.parsers.expat` module contains two functions:

```python
xml.parsers.expat.ErrorString(errno)
```

Returns an explanatory string for a given error number `errno`.

```python
xml.parsers.expat.ParserCreate(encoding=None, namespace_separator=None)
```

Creates and returns a new xmlparser object. `encoding`, if specified, must be a string naming the encoding used by the XML data. Expat doesn’t support as many encodings as Python does, and its repertoire of encodings can’t be extended; it supports UTF-8, UTF-16, ISO-8859-1 (Latin1), and ASCII. If `encoding` [1] is given it will override the implicit or explicit encoding of the document.

Expat can optionally do XML namespace processing for you, enabled by providing a value for `namespace_separator`. The value must be a one-character string; a `ValueError` will be raised if the string has an illegal length (None is considered the same as omission). When namespace processing is enabled, element type names and attribute names that belong to a namespace will be expanded. The element name passed to the element handlers `StartElementHandler` and `EndElementHandler` will be the concatenation of the namespace URI, the namespace separator character, and the local part of the name. If the namespace separator is a zero byte (`chr(0)`) then the namespace URI and the local part will be concatenated without any separator.

For example, if `namespace_separator` is set to a space character (`' '`) and the following document is parsed:

```xml
<?xml version="1.0"?>
<root xmlns="http://default-namespace.org/"
     xmlns:py = "http://www.python.org/ns/">
```
StartElementHandler will receive the following strings for each element:

<table>
<thead>
<tr>
<th>String</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://www.python.org/ns/">http://www.python.org/ns/</a> elem1</td>
<td><a href="http://www.python.org/ns/">http://www.python.org/ns/</a> elem1</td>
</tr>
<tr>
<td>elem2</td>
<td>elem2</td>
</tr>
</tbody>
</table>

Due to limitations in the Expat library used by pyexpat, the xmlparser instance returned can only be used to parse a single XML document. Call `ParserCreate` for each document to provide unique parser instances.

**See also:**

**The Expat XML Parser**

Home page of the Expat project.
20.13.1. XMLParser Objects

xmlparser objects have the following methods:

xmlparser.\texttt{Parse}($data[, isfinal]$)

 Parses the contents of the string $data$, calling the appropriate handler functions to process the parsed data. $isfinal$ must be true on the final call to this method; it allows the parsing of a single file in fragments, not the submission of multiple files. $data$ can be the empty string at any time.

xmlparser.\texttt{ParseFile}($file$)

 Parse XML data reading from the object $file$. $file$ only needs to provide the \texttt{read(nbytes)} method, returning the empty string when there's no more data.

xmlparser.\texttt{SetBase}($base$)

 Sets the base to be used for resolving relative URIs in system identifiers in declarations. Resolving relative identifiers is left to the application: this value will be passed through as the $base$ argument to the \texttt{ExternalEntityRefHandler()}, \texttt{NotationDeclHandler()}, and \texttt{UnparsedEntityDeclHandler()} functions.

xmlparser.\texttt{GetBase}()

 Returns a string containing the base set by a previous call to \texttt{SetBase()}, or \texttt{None} if \texttt{SetBase()} hasn't been called.

xmlparser.\texttt{GetInputContext}()

 Returns the input data that generated the current event as a string. The data is in the encoding of the entity which contains the text.
When called while an event handler is not active, the return value is `None`.

```python
class xmlparser:
    ExternalEntityParserCreate(context[, encoding])
```

Create a “child” parser which can be used to parse an external parsed entity referred to by content parsed by the parent parser. The `context` parameter should be the string passed to the `ExternalEntityRefHandler()` handler function, described below. The child parser is created with the `ordered_attributes` and `specified_attributes` set to the values of this parser.

```python
class xmlparser:
    SetParamEntityParsing(flag)
```

Control parsing of parameter entities (including the external DTD subset). Possible `flag` values are `XML_PARAM_ENTITY_PARSING_NEVER`, `XML_PARAM_ENTITY_PARSING_UNLESS_STANDALONE` and `XML_PARAM_ENTITY_PARSING_ALWAYS`. Return true if setting the flag was successful.

```python
class xmlparser:
    UseForeignDTD([flag])
```

Calling this with a true value for `flag` (the default) will cause Expat to call the `ExternalEntityRefHandler` with `None` for all arguments to allow an alternate DTD to be loaded. If the document does not contain a document type declaration, the `ExternalEntityRefHandler` will still be called, but the `StartDoctypeDeclHandler` and `EndDoctypeDeclHandler` will not be called.

Passing a false value for `flag` will cancel a previous call that passed a true value, but otherwise has no effect.
This method can only be called before the `Parse()` or `ParseFile()` methods are called; calling it after either of those have been called causes `ExpatriError` to be raised with the `code` attribute set to `errors.codes[errors.XML_ERROR_CANT_CHANGE_FEATURE_`

xmlparser objects have the following attributes:

`xmlparser.buffer_size`
The size of the buffer used when `buffer_text` is true. A new buffer size can be set by assigning a new integer value to this attribute. When the size is changed, the buffer will be flushed.

`xmlparser.buffer_text`
Setting this to true causes the xmlparser object to buffer textual content returned by Expat to avoid multiple calls to the `CharacterDataHandler()` callback whenever possible. This can improve performance substantially since Expat normally breaks character data into chunks at every line ending. This attribute is false by default, and may be changed at any time.

`xmlparser.buffer_used`
If `buffer_text` is enabled, the number of bytes stored in the buffer. These bytes represent UTF-8 encoded text. This attribute has no meaningful interpretation when `buffer_text` is false.

`xmlparser.ordered_attributes`
Setting this attribute to a non-zero integer causes the attributes to be reported as a list rather than a dictionary. The attributes are presented in the order found in the document text. For each attribute, two list entries are presented: the attribute name and the attribute value. (Older versions of this module also used this
format.) By default, this attribute is false; it may be changed at any time.

**xmlparser.specified_attributes**

If set to a non-zero integer, the parser will report only those attributes which were specified in the document instance and not those which were derived from attribute declarations. Applications which set this need to be especially careful to use what additional information is available from the declarations as needed to comply with the standards for the behavior of XML processors. By default, this attribute is false; it may be changed at any time.

The following attributes contain values relating to the most recent error encountered by an xmlparser object, and will only have correct values once a call to Parse() or ParseFile() has raised an `xml.parsers.expat.ExpatError` exception.

**xmlparser.ErrorByteIndex**

Byte index at which an error occurred.

**xmlparser.ErrorCode**

Numeric code specifying the problem. This value can be passed to the `ErrorString()` function, or compared to one of the constants defined in the `errors` object.

**xmlparser.ErrorColumnNumber**

Column number at which an error occurred.

**xmlparser.ErrorLineNumber**

Line number at which an error occurred.

The following attributes contain values relating to the current parse location in an xmlparser object. During a callback reporting a parse...
event they indicate the location of the first of the sequence of characters that generated the event. When called outside of a callback, the position indicated will be just past the last parse event (regardless of whether there was an associated callback).

**xmlparser.CurrentByteIndex**
Current byte index in the parser input.

**xmlparser.CurrentColumnNumber**
Current column number in the parser input.

**xmlparser.CurrentLineNumber**
Current line number in the parser input.

Here is the list of handlers that can be set. To set a handler on an `xmlparser` object `o`, use `o.handlername = func`. `handlername` must be taken from the following list, and `func` must be a callable object accepting the correct number of arguments. The arguments are all strings, unless otherwise stated.

**xmlparser.XmlDeclHandler(version, encoding, standalone)**
Called when the XML declaration is parsed. The XML declaration is the (optional) declaration of the applicable version of the XML recommendation, the encoding of the document text, and an optional “standalone” declaration. `version` and `encoding` will be strings, and `standalone` will be 1 if the document is declared standalone, 0 if it is declared not to be standalone, or -1 if the standalone clause was omitted. This is only available with Expat version 1.95.0 or newer.

**xmlparser.StartDoctypeDeclHandler(doctypeName, systemId, publicId, has_internal_subset)**
Called when Expat begins parsing the document type declaration
(<!DOCTYPE ...). The doctypeName is provided exactly as presented. The systemId and publicId parameters give the system and public identifiers if specified, or None if omitted. has_internal_subset will be true if the document contains and internal document declaration subset. This requires Expat version 1.2 or newer.

xmlparser.EndDoctypeDeclHandler()

Called when Expat is done parsing the document type declaration. This requires Expat version 1.2 or newer.

xmlparser.ElementDeclHandler(name, model)

Called once for each element type declaration. name is the name of the element type, and model is a representation of the content model.

xmlparser.AttlistDeclHandler(elname, attname, type, default, required)

Called for each declared attribute for an element type. If an attribute list declaration declares three attributes, this handler is called three times, once for each attribute. elname is the name of the element to which the declaration applies and attname is the name of the attribute declared. The attribute type is a string passed as type; the possible values are 'CDATA', 'ID', 'IDREF', ... default gives the default value for the attribute used when the attribute is not specified by the document instance, or None if there is no default value (#IMPLIED values). If the attribute is required to be given in the document instance, required will be true. This requires Expat version 1.95.0 or newer.

xmlparser.StartElementHandler(name, attributes)

Called for the start of every element. name is a string containing
the element name, and *attributes* is the element attributes. If *ordered_attributes* is true, this is a list (see *ordered_attributes* for a full description). Otherwise it's a dictionary mapping names to values.

**xmlparser.EndElementHandler** *(name)*

Called for the end of every element.

**xmlparser.ProcessingInstructionHandler** *(target, data)*

Called for every processing instruction.

**xmlparser.CharacterDataHandler** *(data)*

Called for character data. This will be called for normal character data, CDATA marked content, and ignorable whitespace. Applications which must distinguish these cases can use the **StartCdataSectionHandler**, **EndCdataSectionHandler**, and **ElementDeclHandler** callbacks to collect the required information.

**xmlparser.UnparsedEntityDeclHandler** *(entityName, base, systemId, publicId, notationName)*

Called for unparsed (NDATA) entity declarations. This is only present for version 1.2 of the Expat library; for more recent versions, use **EntityDeclHandler** instead. (The underlying function in the Expat library has been declared obsolete.)

**xmlparser.EntityDeclHandler** *(entityName, is_parameter_entity, value, base, systemId, publicId, notationName)*

Called for all entity declarations. For parameter and internal entities, *value* will be a string giving the declared contents of the entity; this will be **None** for external entities. The *notationName*
The parameter will be `None` for parsed entities, and the name of the notation for unparsed entities. `is_parameter_entity` will be true if the entity is a parameter entity or false for general entities (most applications only need to be concerned with general entities). This is only available starting with version 1.95.0 of the Expat library.

```python
xmlparser.NotationDeclHandler(notationName, base, systemId, publicId)
```
Called for notation declarations. `notationName`, `base`, and `systemId`, and `publicId` are strings if given. If the public identifier is omitted, `publicId` will be `None`.

```python
xmlparser.StartNamespaceDeclHandler(prefix, uri)
```
Called when an element contains a namespace declaration. Namespace declarations are processed before the `StartElementHandler` is called for the element on which declarations are placed.

```python
xmlparser.EndNamespaceDeclHandler(prefix)
```
Called when the closing tag is reached for an element that contained a namespace declaration. This is called once for each namespace declaration on the element in the reverse of the order for which the `StartNamespaceDeclHandler` was called to indicate the start of each namespace declaration’s scope. Calls to this handler are made after the corresponding `EndElementHandler` for the end of the element.

```python
xmlparser.CommentHandler(data)
```
Called for comments. `data` is the text of the comment, excluding the leading `<!--` and trailing `-->`.

```python
xmlparser.StartCdataSectionHandler()
```
Called at the start of a CDATA section. This and `EndCdataSectionHandler` are needed to be able to identify the syntactical start and end for CDATA sections.

`xmlparser.EndCdataSectionHandler()`
Called at the end of a CDATA section.

`xmlparser.DefaultHandler(data)`
Called for any characters in the XML document for which no applicable handler has been specified. This means characters that are part of a construct which could be reported, but for which no handler has been supplied.

`xmlparser.DefaultHandlerExpand(data)`
This is the same as the `DefaultHandler()`, but doesn't inhibit expansion of internal entities. The entity reference will not be passed to the default handler.

`xmlparser.NotStandaloneHandler()`
Called if the XML document hasn't been declared as being a standalone document. This happens when there is an external subset or a reference to a parameter entity, but the XML declaration does not set standalone to `yes` in an XML declaration. If this handler returns `0`, then the parser will raise an `XML_ERROR_NOT_STANDALONE` error. If this handler is not set, no exception is raised by the parser for this condition.

`xmlparser.ExternalEntityRefHandler(context, base, systemId, publicId)`
Called for references to external entities. `base` is the current base, as set by a previous call to `SetBase()`. The public and system identifiers, `systemId` and `publicId`, are strings if given; if the public
identifier is not given, publicId will be None. The context value is opaque and should only be used as described below.

For external entities to be parsed, this handler must be implemented. It is responsible for creating the sub-parser using ExternalEntityParserCreate(context), initializing it with the appropriate callbacks, and parsing the entity. This handler should return an integer; if it returns 0, the parser will raise an XML_ERROR_EXTERNAL_ENTITY_HANDLING error, otherwise parsing will continue.

If this handler is not provided, external entities are reported by the DefaultHandler callback, if provided.
20.13.2. ExpatError Exceptions

**ExpatError** exceptions have a number of interesting attributes:

**ExpatError**.*code*

Expat's internal error number for the specific error. The **errors.messages** dictionary maps these error numbers to Expat's error messages. For example:

```python
from xml.parsers.expat import ParserCreate, ExpatError

p = ParserCreate()
try:
    p.Parse(some_xml_document)
except ExpatError as err:
    print("Error:", errors.messages[err.code])
```

The **errors** module also provides error message constants and a dictionary **codes** mapping these messages back to the error codes, see below.

**ExpatError**.*lineno*

Line number on which the error was detected. The first line is numbered 1.

**ExpatError**.*offset*

Character offset into the line where the error occurred. The first column is numbered 0.
20.13.3. Example

The following program defines three handlers that just print out their arguments.

```python
import xml.parsers.expat

# 3 handler functions
def start_element(name, attrs):
    print('Start element:', name, attrs)
def end_element(name):
    print('End element:', name)
def char_data(data):
    print('Character data:', repr(data))

p = xml.parsers.expat.ParserCreate()
p.StartElementHandler = start_element
p.EndElementHandler = end_element
p.CharacterDataHandler = char_data

p.Parse("""<?xml version="1.0"?>
<parent id="top"><child1 name="paul">Text goes here</child1>
<child2 name="fred">More text</child2>
</parent>""", 1)
```

The output from this program is:

```
Start element: parent {'id': 'top'}
Start element: child1 {'name': 'paul'}
Character data: 'Text goes here'
End element: child1
Character data: '
'
Start element: child2 {'name': 'fred'}
```
Character data: 'More text'
End element: child2
Character data: '\n'
End element: parent
20.13.4. Content Model Descriptions

Content models are described using nested tuples. Each tuple contains four values: the type, the quantifier, the name, and a tuple of children. Children are simply additional content model descriptions.

The values of the first two fields are constants defined in the `xml.parsers.expat.model` module. These constants can be collected in two groups: the model type group and the quantifier group.

The constants in the model type group are:

- `xml.parsers.expat.model.XML_CTYPE_ANY`
  The element named by the model name was declared to have a content model of ANY.

- `xml.parsers.expat.model.XML_CTYPE_CHOICE`
  The named element allows a choice from a number of options; this is used for content models such as `(A | B | C)`.

- `xml.parsers.expat.model.XML_CTYPE_EMPTY`
  Elements which are declared to be EMPTY have this model type.

- `xml.parsers.expat.model.XML_CTYPE_MIXED`

- `xml.parsers.expat.model.XML_CTYPE_NAME`

- `xml.parsers.expat.model.XML_CTYPE_SEQ`
  Models which represent a series of models which follow one after the other are indicated with this model type. This is used for models such as `(A, B, C)`.

The constants in the quantifier group are:
xml.parsers.expat.model.XML_CQUANT_NONE

No modifier is given, so it can appear exactly once, as for A.

xml.parsers.expat.model.XML_CQUANT_OPT

The model is optional: it can appear once or not at all, as for A?.

xml.parsers.expat.model.XML_CQUANT_PLUS

The model must occur one or more times (like A+).

xml.parsers.expat.model.XML_CQUANT_REP

The model must occur zero or more times, as for A*.
20.13.5. Expat error constants

The following constants are provided in the `xml.parsers.expat.errors` module. These constants are useful in interpreting some of the attributes of the ExpatError exception objects raised when an error has occurred. Since for backwards compatibility reasons, the constants' value is the error message and not the numeric error code, you do this by comparing its `code` attribute with `errors.codes[errors.XML_ERROR_CONSTANT_NAME]`.

The `errors` module has the following attributes:

- `xml.parsers.expat.errors.codes`  
  A dictionary mapping numeric error codes to their string descriptions.  
  
  *New in version 3.2.*

- `xml.parsers.expat.errors.messages`  
  A dictionary mapping string descriptions to their error codes.  
  
  *New in version 3.2.*

- `xml.parsers.expat.errors.XML_ERROR_ASYNC_ENTITY`  
  An entity reference in an attribute value referred to an external entity instead of an internal entity.

- `xml.parsers.expat.errors.XML_ERROR_ATTRIBUTE_EXTERNAL_ENTITY_REF`  
  A character reference referred to a character which is illegal in XML
(for example, character 0, or ‘&#0;’).

xml.parsers.expat.errors.XML_ERROR_BINARY_ENTITY_REF
An entity reference referred to an entity which was declared with a notation, so cannot be parsed.

xml.parsers.expat.errors.XML_ERROR_DUPLICATE_ATTRIBUTE
An attribute was used more than once in a start tag.

xml.parsers.expat.errors.XML_ERROR_INCORRECT_ENCODING
xml.parsers.expat.errors.XML_ERROR_INVALID_TOKEN
Raised when an input byte could not properly be assigned to a character; for example, a NUL byte (value 0) in a UTF-8 input stream.

xml.parsers.expat.errors.XML_ERROR_JUNK_AFTER_DOC_ELEMENT
Something other than whitespace occurred after the document element.

xml.parsers.expat.errors.XML_ERROR_MISPLACED_XML_PI
An XML declaration was found somewhere other than the start of the input data.

xml.parsers.expat.errors.XML_ERROR_NO_ELEMENTS
The document contains no elements (XML requires all documents to contain exactly one top-level element).

xml.parsers.expat.errors.XML_ERROR_NO_MEMORY
Expat was not able to allocate memory internally.

xml.parsers.expat.errors.XML_ERROR_PARAM_ENTITY_REF
A parameter entity reference was found where it was not allowed.
xml.parsers.expat.errors.XML_ERROR_PARTIAL_CHAR
An incomplete character was found in the input.

xml.parsers.expat.errors.XML_ERROR_RECURSIVE_ENT]
An entity reference contained another reference to the same entity; possibly via a different name, and possibly indirectly.

xml.parsers.expat.errors.XML_ERROR_SYNTAX
Some unspecified syntax error was encountered.

xml.parsers.expat.errors.XML_ERROR_TAG_MISMATCH
An end tag did not match the innermost open start tag.

xml.parsers.expat.errors.XML_ERROR_UNCLOSED_TOKEN
Some token (such as a start tag) was not closed before the end of the stream or the next token was encountered.

xml.parsers.expat.errors.XML_ERROR_UNDEFINED_ENT]
A reference was made to an entity which was not defined.

xml.parsers.expat.errors.XML_ERROR_UNKNOWN_ENCOD]
The document encoding is not supported by Expat.

xml.parsers.expat.errors.XML_ERROR_UNCLOSED_CDATA
A CDATA marked section was not closed.

xml.parsers.expat.errors.XML_ERROR_EXTERNAL_ENTI]
xml.parsers.expat.errors.XML_ERROR_NOT_STANDALONE
The parser determined that the document was not “standalone” though it declared itself to be in the XML declaration, and the NotStandaloneHandler was set and returned 0.

xml.parsers.expat.errors.XML_ERROR_UNEXPECTED_STA
xml.parsers.expat.errors.XML_ERROR_ENTITY_DECLARED_IN_PE

xml.parsers.expat.errors.XML_ERROR_FEATURE_REQUIRES_XML_DTD
An operation was requested that requires DTD support to be compiled in, but Expat was configured without DTD support. This should never be reported by a standard build of the xml.parsers.expat module.

xml.parsers.expat.errors.XML_ERROR_CANT_CHANGE_FEATURE_ONCE_PARSING
A behavioral change was requested after parsing started that can only be changed before parsing has started. This is (currently) only raised by UseForeignDTD().

xml.parsers.expat.errors.XML_ERROR_UNBOUND_PREFIX
An undeclared prefix was found when namespace processing was enabled.

xml.parsers.expat.errors.XML_ERROR_UNDECLARING_PREFIX
The document attempted to remove the namespace declaration associated with a prefix.

xml.parsers.expat.errors.XML_ERROR_INCOMPLETE_PE
A parameter entity contained incomplete markup.

xml.parsers.expat.errors.XML_ERROR_TEXT_DECL
There was an error parsing a text declaration in an external entity.

xml.parsers.expat.errors.XML_ERROR_PUBLICID
Characters were found in the public id that are not allowed.

xml.parsers.expat.errors.XML_ERROR_SUSPENDED
The requested operation was made on a suspended parser, but isn’t allowed. This includes attempts to provide additional input or to stop the parser.

```
xml.parsers.expat.errors.XML_ERROR_NOT_SUSPENDED
```

An attempt to resume the parser was made when the parser had not been suspended.

```
xml.parsers.expat.errors.XML_ERROR_ABORTED
```

This should not be reported to Python applications.

```
xml.parsers.expat.errors.XML_ERROR_FINISHED
```

The requested operation was made on a parser which was finished parsing input, but isn’t allowed. This includes attempts to provide additional input or to stop the parser.

```
xml.parsers.expat.errors.XML_ERROR_SUSPEND_PE
```

Footnotes

[1] The encoding string included in XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not. See https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and https://www.iana.org/assignments/character-sets/character-sets.xhtml.
21. Internet Protocols and Support

The modules described in this chapter implement Internet protocols and support for related technology. They are all implemented in Python. Most of these modules require the presence of the system-dependent module `socket`, which is currently supported on most popular platforms. Here is an overview:

- **21.1. webbrowser — Convenient Web-browser controller**
  - 21.1.1. Browser Controller Objects
- **21.2. cgi — Common Gateway Interface support**
  - 21.2.1. Introduction
  - 21.2.2. Using the cgi module
  - 21.2.3. Higher Level Interface
  - 21.2.4. Functions
  - 21.2.5. Caring about security
  - 21.2.6. Installing your CGI script on a Unix system
  - 21.2.7. Testing your CGI script
  - 21.2.8. Debugging CGI scripts
  - 21.2.9. Common problems and solutions
- **21.3. cgitb — Traceback manager for CGI scripts**
- **21.4. wsgiref — WSGI Utilities and Reference Implementation**
  - 21.4.1. wsgiref.util — WSGI environment utilities
  - 21.4.2. wsgiref.headers — WSGI response header tools
  - 21.4.3. wsgiref.simple_server — a simple WSGI HTTP server
  - 21.4.4. wsgiref.validate — WSGI conformance checker
  - 21.4.5. wsgiref.handlers — server/gateway base classes
  - 21.4.6. Examples
- **21.5. urllib — URL handling modules**
- **21.6. urllib.request — Extensible library for opening URLs**
  - 21.6.1. Request Objects
- 21.6.2. OpenerDirector Objects
- 21.6.3. BaseHandler Objects
- 21.6.4. HTTPRedirectHandler Objects
- 21.6.5. HTTPCookieProcessor Objects
- 21.6.6. ProxyHandler Objects
- 21.6.7. HTTPPasswordMgr Objects
- 21.6.8. HTTPPasswordMgrWithPriorAuth Objects
- 21.6.9. AbstractBasicAuthHandler Objects
- 21.6.10. HTTPBasicAuthHandler Objects
- 21.6.11. ProxyBasicAuthHandler Objects
- 21.6.13. HTTPDigestAuthHandler Objects
- 21.6.15. HTTPHandler Objects
- 21.6.16. HTTPSHandler Objects
- 21.6.17. FileHandler Objects
- 21.6.18. DataHandler Objects
- 21.6.19. FTPHandler Objects
- 21.6.20. CacheFTPHandler Objects
- 21.6.21. UnknownHandler Objects
- 21.6.22. HTTPErrorProcessor Objects
- 21.6.23. Examples
- 21.6.24. Legacy interface
- 21.6.25. urllib.request Restrictions

- 21.7. urllib.response — Response classes used by urllib
- 21.8. urllib.parse — Parse URLs into components
  - 21.8.1. URL Parsing
  - 21.8.2. Parsing ASCII Encoded Bytes
  - 21.8.3. Structured Parse Results
  - 21.8.4. URL Quoting
- 21.9. urllib.error — Exception classes raised by urllib.request
- 21.10. urllib.robotparser — Parser for robots.txt
- 21.11. http — HTTP modules
• 21.11.1. HTTP status codes
• 21.12. http.client — HTTP protocol client
  • 21.12.1. HTTPConnection Objects
  • 21.12.2. HTTPResponse Objects
  • 21.12.3. Examples
  • 21.12.4. HTTPMessage Objects
• 21.13. ftplib — FTP protocol client
  • 21.13.1. FTP Objects
  • 21.13.2. FTP_TLS Objects
• 21.14. poplib — POP3 protocol client
  • 21.14.1. POP3 Objects
  • 21.14.2. POP3 Example
• 21.15. imaplib — IMAP4 protocol client
  • 21.15.1. IMAP4 Objects
  • 21.15.2. IMAP4 Example
• 21.16. nntplib — NNTP protocol client
  • 21.16.1. NNTP Objects
    ■ 21.16.1.1. Attributes
    ■ 21.16.1.2. Methods
  • 21.16.2. Utility functions
• 21.17. smtplib — SMTP protocol client
  • 21.17.1. SMTP Objects
  • 21.17.2. SMTP Example
• 21.18. smtpd — SMTP Server
  • 21.18.1. SMTPServer Objects
  • 21.18.2. DebuggingServer Objects
  • 21.18.3. PureProxy Objects
  • 21.18.4. MailmanProxy Objects
  • 21.18.5. SMTPChannel Objects
• 21.19. telnetlib — Telnet client
  • 21.19.1. Telnet Objects
  • 21.19.2. Telnet Example
• 21.20. uuid — UUID objects according to RFC 4122
21.20.1. Example

21.21. socketserver — A framework for network servers
  21.21.1. Server Creation Notes
  21.21.2. Server Objects
  21.21.3. Request Handler Objects
  21.21.4. Examples
    ■ 21.21.4.1. socketserver.TCPServer Example
    ■ 21.21.4.2. socketserver.UDPServer Example
    ■ 21.21.4.3. Asynchronous Mixins

21.22. http.server — HTTP servers

21.23. http.cookies — HTTP state management
  21.23.1. Cookie Objects
  21.23.2. Morsel Objects
  21.23.3. Example

21.24. http.cookiejar — Cookie handling for HTTP clients
  21.24.2. FileCookieJar subclasses and co-operation with web browsers
  21.24.3. CookiePolicy Objects
  21.24.4. DefaultCookiePolicy Objects
  21.24.5. Cookie Objects
  21.24.6. Examples

21.25. xmlrpc — XMLRPC server and client modules

21.26. xmlrpc.client — XML-RPC client access
  21.26.2. DateTime Objects
  21.26.3. Binary Objects
  21.26.4. Fault Objects
  21.26.5. ProtocolError Objects
  21.26.6. MultiCall Objects
  21.26.7. Convenience Functions
  21.26.9. Example of Client and Server Usage
• 21.27. xmlrpc.server — Basic XML-RPC servers
  • 21.27.1. SimpleXMLRPCServer Objects
    ■ 21.27.1.1. SimpleXMLRPCServer Example
  • 21.27.2. CGIXMLRPCRequestHandler
  • 21.27.3. Documenting XMLRPC server
  • 21.27.4. DocXMLRPCServer Objects
  • 21.27.5. DocCGIXMLRPCRequestHandler
• 21.28. ipaddress — IPv4/IPv6 manipulation library
  • 21.28.1. Convenience factory functions
  • 21.28.2. IP Addresses
    ■ 21.28.2.1. Address objects
    ■ 21.28.2.2. Conversion to Strings and Integers
    ■ 21.28.2.3. Operators
      ■ 21.28.2.3.1. Comparison operators
      ■ 21.28.2.3.2. Arithmetic operators

    ■ 21.28.3.1. Prefix, net mask and host mask
    ■ 21.28.3.2. Network objects
    ■ 21.28.3.3. Operators
      ■ 21.28.3.3.1. Logical operators
      ■ 21.28.3.3.2. Iteration
      ■ 21.28.3.3.3. Networks as containers of addresses
  • 21.28.4. Interface objects
  • 21.28.5. Other Module Level Functions
  • 21.28.6. Custom Exceptions
21.1. webbrowser — Convenient Web-browser controller

Source code: Lib/webbrowser.py

The webbrowser module provides a high-level interface to allow displaying Web-based documents to users. Under most circumstances, simply calling the open() function from this module will do the right thing.

Under Unix, graphical browsers are preferred under X11, but text-mode browsers will be used if graphical browsers are not available or an X11 display isn’t available. If text-mode browsers are used, the calling process will block until the user exits the browser.

If the environment variable BROWSER exists, it is interpreted as the os.pathsep-separated list of browsers to try ahead of the platform defaults. When the value of a list part contains the string %s, then it is interpreted as a literal browser command line to be used with the argument URL substituted for %s; if the part does not contain %s, it is simply interpreted as the name of the browser to launch. [1]

For non-Unix platforms, or when a remote browser is available on Unix, the controlling process will not wait for the user to finish with the browser, but allow the remote browser to maintain its own windows on the display. If remote browsers are not available on Unix, the controlling process will launch a new browser and wait.

The script webbrowser can be used as a command-line interface for the module. It accepts a URL as the argument. It accepts the following
optional parameters: `-n` opens the URL in a new browser window, if possible; `-t` opens the URL in a new browser page ("tab"). The options are, naturally, mutually exclusive. Usage example:

```python
python -m webbrowser -t "http://www.python.org"
```

The following exception is defined:

```
exception webbrowser.Error
Exception raised when a browser control error occurs.
```

The following functions are defined:

```
webbrowser.open(url, new=0, autoraise=True)
Display url using the default browser. If new is 0, the url is opened in the same browser window if possible. If new is 1, a new browser window is opened if possible. If new is 2, a new browser page ("tab") is opened if possible. If autoraise is True, the window is raised if possible (note that under many window managers this will occur regardless of the setting of this variable).

Note that on some platforms, trying to open a filename using this function, may work and start the operating system's associated program. However, this is neither supported nor portable.
```

```
webbrowser.open_new(url)
Open url in a new window of the default browser, if possible, otherwise, open url in the only browser window.
```

```
webbrowser.open_new_tab(url)
Open url in a new page ("tab") of the default browser, if possible, otherwise equivalent to open_new().
```
webbrowser.get(using=None)

Return a controller object for the browser type using. If using is None, return a controller for a default browser appropriate to the caller's environment.

webbrowser.register(name, constructor, instance=None, *, preferred=False)

Register the browser type name. Once a browser type is registered, the get() function can return a controller for that browser type. If instance is not provided, or is None, constructor will be called without parameters to create an instance when needed. If instance is provided, constructor will never be called, and may be None.

Setting preferred to True makes this browser a preferred result for a get() call with no argument. Otherwise, this entry point is only useful if you plan to either set the BROWSER variable or call get() with a nonempty argument matching the name of a handler you declare.

*Changed in version 3.7:* preferred keyword-only parameter was added.

A number of browser types are predefined. This table gives the type names that may be passed to the get() function and the corresponding instantiations for the controller classes, all defined in this module.

<table>

<tr>
<td>'chromium-browser'</td>
<td>Chromium('chromium-browser')</td>
<td></td>
</tr>
</tbody>
</table>

Notes:
1. “Konqueror” is the file manager for the KDE desktop environment for Unix, and only makes sense to use if KDE is running. Some way of reliably detecting KDE would be nice; the KDEDIR variable is not sufficient. Note also that the name “kfm” is used even when using the konqueror command with KDE 2 — the implementation selects the best strategy for running Konqueror.

2. Only on Windows platforms.
3. Only on Mac OS X platform.

New in version 3.3: Support for Chrome/Chromium has been added.

Here are some simple examples:

```python
url = 'http://docs.python.org/

# Open URL in a new tab, if a browser window is already open.
webbrowser.open_new_tab(url)

# Open URL in new window, raising the window if possible.
webbrowser.open_new(url)
```
21.1.1. Browser Controller Objects

Browser controllers provide these methods which parallel three of the module-level convenience functions:

controller.\textbf{open}(url, new=0, autoraise=True)

Display $url$ using the browser handled by this controller. If $new$ is 1, a new browser window is opened if possible. If $new$ is 2, a new browser page ("tab") is opened if possible.

controller.\textbf{open}$_\textbf{\_\_}_\textbf{new}$(url)

Open $url$ in a new window of the browser handled by this controller, if possible, otherwise, open $url$ in the only browser window. Alias \texttt{open\_new()}.

controller.\textbf{open}$_\textbf{\_\_}_\textbf{new\_\_}\textbf{tab}$(url)

Open $url$ in a new page ("tab") of the browser handled by this controller, if possible, otherwise equivalent to \texttt{open\_\_new()}.  

Footnotes

[1] Executables named here without a full path will be searched in the directories given in the \texttt{PATH} environment variable.
21.2. **cgi** — Common Gateway Interface support

**Source code:** Lib/cgi.py

Support module for Common Gateway Interface (CGI) scripts.

This module defines a number of utilities for use by CGI scripts written in Python.
21.2.1. Introduction

A CGI script is invoked by an HTTP server, usually to process user input submitted through an HTML `<FORM>` or `<ISINDEX>` element.

Most often, CGI scripts live in the server’s special `cgi-bin` directory. The HTTP server places all sorts of information about the request (such as the client’s hostname, the requested URL, the query string, and lots of other goodies) in the script’s shell environment, executes the script, and sends the script’s output back to the client.

The script’s input is connected to the client too, and sometimes the form data is read this way; at other times the form data is passed via the “query string” part of the URL. This module is intended to take care of the different cases and provide a simpler interface to the Python script. It also provides a number of utilities that help in debugging scripts, and the latest addition is support for file uploads from a form (if your browser supports it).

The output of a CGI script should consist of two sections, separated by a blank line. The first section contains a number of headers, telling the client what kind of data is following. Python code to generate a minimal header section looks like this:

```python
print("Content-Type: text/html")  # HTML is follow
print()  # blank line, end of headers
```

The second section is usually HTML, which allows the client software to display nicely formatted text with header, in-line images, etc. Here’s Python code that prints a simple piece of HTML:

```python
print("<TITLE>CGI script output</TITLE>")
```
print("<H1>This is my first CGI script</H1>")
print("Hello, world!")
21.2.2. Using the cgi module

Begin by writing `import cgi`.

When you write a new script, consider adding these lines:

```python
import cgitb
cgitb.enable()
```

This activates a special exception handler that will display detailed reports in the Web browser if any errors occur. If you’d rather not show the guts of your program to users of your script, you can have the reports saved to files instead, with code like this:

```python
import cgitb
cgitb.enable(display=0, logdir="/path/to/logdir")
```

It’s very helpful to use this feature during script development. The reports produced by `cgitb` provide information that can save you a lot of time in tracking down bugs. You can always remove the `cgitb` line later when you have tested your script and are confident that it works correctly.

To get at submitted form data, use the FieldStorage class. If the form contains non-ASCII characters, use the `encoding` keyword parameter set to the value of the encoding defined for the document. It is usually contained in the META tag in the HEAD section of the HTML document or by the `Content-Type` header). This reads the form contents from the standard input or the environment (depending on the value of various environment variables set according to the CGI standard). Since it may consume standard input, it should be instantiated only once.
The FieldStorage instance can be indexed like a Python dictionary. It allows membership testing with the `in` operator, and also supports the standard dictionary method `keys()` and the built-in function `len()`. Form fields containing empty strings are ignored and do not appear in the dictionary; to keep such values, provide a true value for the optional `keep_blank_values` keyword parameter when creating the FieldStorage instance.

For instance, the following code (which assumes that the `Content-Type` header and blank line have already been printed) checks that the fields `name` and `addr` are both set to a non-empty string:

```python
form = cgi.FieldStorage()
if "name" not in form or "addr" not in form:
    print("<H1>Error</H1>")
    print("Please fill in the name and addr fields."
    return
print("<p>name:", form["name"].value)
print("<p>addr:", form["addr"].value)
...further form processing here...
```

Here the fields, accessed through `form[key]`, are themselves instances of FieldStorage (or MiniFieldStorage, depending on the form encoding). The value attribute of the instance yields the string value of the field. The `getvalue()` method returns this string value directly; it also accepts an optional second argument as a default to return if the requested key is not present.

If the submitted form data contains more than one field with the same name, the object retrieved by `form[key]` is not a FieldStorage or MiniFieldStorage instance but a list of such instances. Similarly, in this situation, `form.getvalue(key)` would return a list of strings. If
you expect this possibility (when your HTML form contains multiple fields with the same name), use the `getlist()` method, which always returns a list of values (so that you do not need to special-case the single item case). For example, this code concatenates any number of username fields, separated by commas:

```python
value = form.getlist("username")
usernames = ",".join(value)
```

If a field represents an uploaded file, accessing the value via the value attribute or the `getvalue()` method reads the entire file in memory as bytes. This may not be what you want. You can test for an uploaded file by testing either the filename attribute or the file attribute. You can then read the data from the file attribute before it is automatically closed as part of the garbage collection of the FieldStorage instance (the `read()` and `readline()` methods will return bytes):

```python
fileitem = form["userfile"]
if fileitem.file:
    # It's an uploaded file; count lines
    linecount = 0
    while True:
        line = fileitem.file.readline()
        if not line: break
    linecount = linecount + 1
```

FieldStorage objects also support being used in a `with` statement, which will automatically close them when done.

If an error is encountered when obtaining the contents of an uploaded file (for example, when the user interrupts the form submission by clicking on a Back or Cancel button) the done attribute of the object
for the field will be set to the value -1.

The file upload draft standard entertains the possibility of uploading multiple files from one field (using a recursive multipart/* encoding). When this occurs, the item will be a dictionary-like FieldStorage item. This can be determined by testing its type attribute, which should be multipart/form-data (or perhaps another MIME type matching multipart/*). In this case, it can be iterated over recursively just like the top-level form object.

When a form is submitted in the “old” format (as the query string or as a single data part of type application/x-www-form-urlencoded), the items will actually be instances of the class MiniFieldStorage. In this case, the list, file, and filename attributes are always None.

A form submitted via POST that also has a query string will contain both FieldStorage and MiniFieldStorage items.

*Changed in version 3.4:* The file attribute is automatically closed upon the garbage collection of the creating FieldStorage instance.

*Changed in version 3.5:* Added support for the context management protocol to the FieldStorage class.
21.2.3. Higher Level Interface

The previous section explains how to read CGI form data using the FieldStorage class. This section describes a higher level interface which was added to this class to allow one to do it in a more readable and intuitive way. The interface doesn't make the techniques described in previous sections obsolete — they are still useful to process file uploads efficiently, for example.

The interface consists of two simple methods. Using the methods you can process form data in a generic way, without the need to worry whether only one or more values were posted under one name.

In the previous section, you learned to write following code anytime you expected a user to post more than one value under one name:

```python
item = form.getvalue("item")
if isinstance(item, list):
    # The user is requesting more than one item.
else:
    # The user is requesting only one item.
```

This situation is common for example when a form contains a group of multiple checkboxes with the same name:

```html
<input type="checkbox" name="item" value="1" />
<input type="checkbox" name="item" value="2" />
```

In most situations, however, there’s only one form control with a particular name in a form and then you expect and need only one value associated with this name. So you write a script containing for example this code:
The problem with the code is that you should never expect that a client will provide valid input to your scripts. For example, if a curious user appends another `user=foo` pair to the query string, then the script would crash, because in this situation the `getvalue("user")` method call returns a list instead of a string. Calling the `upper()` method on a list is not valid (since lists do not have a method of this name) and results in an `AttributeError` exception.

Therefore, the appropriate way to read form data values was to always use the code which checks whether the obtained value is a single value or a list of values. That's annoying and leads to less readable scripts.

A more convenient approach is to use the methods `getfirst()` and `getlist()` provided by this higher level interface.

**FieldStorage.getfirst(name, default=None)**

This method always returns only one value associated with form field `name`. The method returns only the first value in case that more values were posted under such name. Please note that the order in which the values are received may vary from browser to browser and should not be counted on. [1] If no such form field or value exists then the method returns the value specified by the optional parameter `default`. This parameter defaults to `None` if not specified.

**FieldStorage.getlist(name)**

This method always returns a list of values associated with form field `name`. The method returns an empty list if no such form field or value exists for `name`. It returns a list consisting of one item if
only one such value exists.

Using these methods you can write nice compact code:

```python
import cgi
form = cgi.FieldStorage()
user = form.getfirst("user", "").upper()  # This way it's safe.
for item in form.getlist("item"):
    do_something(item)
```
21.2.4. Functions

These are useful if you want more control, or if you want to employ some of the algorithms implemented in this module in other circumstances.

cgi.\texttt{parse}(fp=None, environ=os.environ, keep_blank_values=False, strict_parsing=False)

Parse a query in the environment or from a file (the file defaults to \texttt{sys.stdin}). The \texttt{keep_blank_values} and \texttt{strict_parsing} parameters are passed to \texttt{urllib.parse.parse_qs()} unchanged.

cgi.\texttt{parse_qs}(qs, keep_blank_values=False, strict_parsing=False)

This function is deprecated in this module. Use \texttt{urllib.parse.parse_qs()} instead. It is maintained here only for backward compatibility.

cgi.\texttt{parse_qsl}(qs, keep_blank_values=False, strict_parsing=False)

This function is deprecated in this module. Use \texttt{urllib.parse.parse_qsl()} instead. It is maintained here only for backward compatibility.

cgi.\texttt{parse_multipart}(fp, pdict, encoding="utf-8")

Parse input of type \texttt{multipart/form-data} (for file uploads). Arguments are \texttt{fp} for the input file, \texttt{pdict} for a dictionary containing other parameters in the \texttt{Content-Type} header, and \texttt{encoding}, the request encoding.
Returns a dictionary just like `urllib.parse.parse_qs()`: keys are the field names, each value is a list of values for that field. For non-file fields, the value is a list of strings.

This is easy to use but not much good if you are expecting megabytes to be uploaded — in that case, use the `FieldStorage` class instead which is much more flexible.

cgi.**parse_header**(string)

Parse a MIME header (such as `Content-Type`) into a main value and a dictionary of parameters.

cgi.**test**()

Robust test CGI script, usable as main program. Writes minimal HTTP headers and formats all information provided to the script in HTML form.

cgi.**print_environ**()

Format the shell environment in HTML.

cgi.**print_form**(form)

Format a form in HTML.

cgi.**print_directory**()

Format the current directory in HTML.

cgi.**print_environ_usage**()

Print a list of useful (used by CGI) environment variables in HTML.

cgi.**escape**(s, quote=False)

Convert the characters '&', '<' and '>' in string s to HTML-safe sequences. Use this if you need to display text that might contain such characters in HTML. If the optional flag `quote` is true, the
quotation mark character (") is also translated; this helps for inclusion in an HTML attribute value delimited by double quotes, as in `<a href="...">`. Note that single quotes are never translated.

*Deprecation:* This function is unsafe because `quote` is false by default, and therefore deprecated. Use `html.escape()` instead.
21.2.5. Caring about security

There’s one important rule: if you invoke an external program (via the \texttt{os.system()} or \texttt{os.popen()} functions, or others with similar functionality), make very sure you don’t pass arbitrary strings received from the client to the shell. This is a well-known security hole whereby clever hackers anywhere on the Web can exploit a gullible CGI script to invoke arbitrary shell commands. Even parts of the URL or field names cannot be trusted, since the request doesn’t have to come from your form!

To be on the safe side, if you must pass a string gotten from a form to a shell command, you should make sure the string contains only alphanumeric characters, dashes, underscores, and periods.
21.2.6. Installing your CGI script on a Unix system

Read the documentation for your HTTP server and check with your local system administrator to find the directory where CGI scripts should be installed; usually this is in a directory `cgi-bin` in the server tree.

Make sure that your script is readable and executable by “others”; the Unix file mode should be `0o755` octal (use `chmod 0755 filename`). Make sure that the first line of the script contains `#!` starting in column 1 followed by the pathname of the Python interpreter, for instance:

```
#!/usr/local/bin/python
```

Make sure the Python interpreter exists and is executable by “others”.

Make sure that any files your script needs to read or write are readable or writable, respectively, by “others” — their mode should be `0o644` for readable and `0o666` for writable. This is because, for security reasons, the HTTP server executes your script as user “nobody”, without any special privileges. It can only read (write, execute) files that everybody can read (write, execute). The current directory at execution time is also different (it is usually the server’s cgi-bin directory) and the set of environment variables is also different from what you get when you log in. In particular, don’t count on the shell’s search path for executables (PATH) or the Python module search path (`PYTHONPATH`) to be set to anything interesting.

If you need to load modules from a directory which is not on Python's
default module search path, you can change the path in your script, before importing other modules. For example:

```python
import sys
sys.path.insert(0, "/usr/home/joe/lib/python")
sys.path.insert(0, "/usr/local/lib/python")
```

(This way, the directory inserted last will be searched first!)

Instructions for non-Unix systems will vary; check your HTTP server’s documentation (it will usually have a section on CGI scripts).
21.2.7. Testing your CGI script

Unfortunately, a CGI script will generally not run when you try it from the command line, and a script that works perfectly from the command line may fail mysteriously when run from the server. There's one reason why you should still test your script from the command line: if it contains a syntax error, the Python interpreter won't execute it at all, and the HTTP server will most likely send a cryptic error to the client.

Assuming your script has no syntax errors, yet it does not work, you have no choice but to read the next section.
21.2.8. Debugging CGI scripts

First of all, check for trivial installation errors — reading the section above on installing your CGI script carefully can save you a lot of time. If you wonder whether you have understood the installation procedure correctly, try installing a copy of this module file (cgi.py) as a CGI script. When invoked as a script, the file will dump its environment and the contents of the form in HTML form. Give it the right mode etc, and send it a request. If it's installed in the standardcgi-bin directory, it should be possible to send it a request by entering a URL into your browser of the form:

```
http://yourhostname/cgi-bin/cgi.py?name=Joe+Blow&addr=At+Home
```

If this gives an error of type 404, the server cannot find the script — perhaps you need to install it in a different directory. If it gives another error, there's an installation problem that you should fix before trying to go any further. If you get a nicely formatted listing of the environment and form content (in this example, the fields should be listed as “addr” with value “At Home” and “name” with value “Joe Blow”), the cgi.py script has been installed correctly. If you follow the same procedure for your own script, you should now be able to debug it.

The next step could be to call the cgi module's test() function from your script: replace its main code with the single statement

```
cgi.test()
```

This should produce the same results as those gotten from installing the cgi.py file itself.
When an ordinary Python script raises an unhandled exception (for whatever reason: of a typo in a module name, a file that can’t be opened, etc.), the Python interpreter prints a nice traceback and exits. While the Python interpreter will still do this when your CGI script raises an exception, most likely the traceback will end up in one of the HTTP server’s log files, or be discarded altogether.

Fortunately, once you have managed to get your script to execute some code, you can easily send tracesbacks to the Web browser using the cgitb module. If you haven’t done so already, just add the lines:

```python
import cgitb
cgitb.enable()
```

to the top of your script. Then try running it again; when a problem occurs, you should see a detailed report that will likely make apparent the cause of the crash.

If you suspect that there may be a problem in importing the cgitb module, you can use an even more robust approach (which only uses built-in modules):

```python
import sys
sys.stderr = sys.stdout
print("Content-Type: text/plain")
print()
...your code here...
```

This relies on the Python interpreter to print the traceback. The content type of the output is set to plain text, which disables all HTML processing. If your script works, the raw HTML will be displayed by your client. If it raises an exception, most likely after the first two lines have been printed, a traceback will be displayed. Because no HTML
interpretation is going on, the traceback will be readable.
21.2.9. Common problems and solutions

- Most HTTP servers buffer the output from CGI scripts until the script is completed. This means that it is not possible to display a progress report on the client's display while the script is running.
- Check the installation instructions above.
- Check the HTTP server's log files. (tail -f logfile in a separate window may be useful!)
- Always check a script for syntax errors first, by doing something like `python script.py`.
- If your script does not have any syntax errors, try adding `import cgitb; cgitb.enable()` to the top of the script.
- When invoking external programs, make sure they can be found. Usually, this means using absolute path names — PATH is usually not set to a very useful value in a CGI script.
- When reading or writing external files, make sure they can be read or written by the userid under which your CGI script will be running: this is typically the userid under which the web server is running, or some explicitly specified userid for a web server’s suexec feature.
- Don’t try to give a CGI script a set-uid mode. This doesn’t work on most systems, and is a security liability as well.

Footnotes

[1] Note that some recent versions of the HTML specification do state what order the field values should be supplied in, but knowing whether a request was received from a conforming browser, or even from a browser at all, is tedious and error-prone.
21.3. `cgitb` — Traceback manager for CGI scripts

Source code: Lib/cgitb.py

The `cgitb` module provides a special exception handler for Python scripts. (Its name is a bit misleading. It was originally designed to display extensive traceback information in HTML for CGI scripts. It was later generalized to also display this information in plain text.) After this module is activated, if an uncaught exception occurs, a detailed, formatted report will be displayed. The report includes a traceback showing excerpts of the source code for each level, as well as the values of the arguments and local variables to currently running functions, to help you debug the problem. Optionally, you can save this information to a file instead of sending it to the browser.

To enable this feature, simply add this to the top of your CGI script:

```python
import cgitb

cgitb.enable()
```

The options to the `enable()` function control whether the report is displayed in the browser and whether the report is logged to a file for later analysis.

```python

cgitb.enable(display=1, logdir=None, context=5, format="html")
```

This function causes the `cgitb` module to take over the interpreter’s default handling for exceptions by setting the value of `sys.excepthook`.
The optional argument *display* defaults to 1 and can be set to 0 to suppress sending the traceback to the browser. If the argument *logdir* is present, the traceback reports are written to files. The value of *logdir* should be a directory where these files will be placed. The optional argument *context* is the number of lines of context to display around the current line of source code in the traceback; this defaults to 5. If the optional argument *format* is "html", the output is formatted as HTML. Any other value forces plain text output. The default value is "html".

**cgitb.text(info, context=5)**

This function handles the exception described by *info* (a 3-tuple containing the result of `sys.exc_info()`), formatting its traceback as text and returning the result as a string. The optional argument *context* is the number of lines of context to display around the current line of source code in the traceback; this defaults to 5.

**cgitb.html(info, context=5)**

This function handles the exception described by *info* (a 3-tuple containing the result of `sys.exc_info()`), formatting its traceback as HTML and returning the result as a string. The optional argument *context* is the number of lines of context to display around the current line of source code in the traceback; this defaults to 5.

**cgitb.handler(info=None)**

This function handles an exception using the default settings (that is, show a report in the browser, but don’t log to a file). This can be used when you’ve caught an exception and want to report it using *cgitb*. The optional *info* argument should be a 3-tuple containing
an exception type, exception value, and traceback object, exactly like the tuple returned by `sys.exc_info()`. If the `info` argument is not supplied, the current exception is obtained from `sys.exc_info()`.
The Web Server Gateway Interface (WSGI) is a standard interface between web server software and web applications written in Python. Having a standard interface makes it easy to use an application that supports WSGI with a number of different web servers.

Only authors of web servers and programming frameworks need to know every detail and corner case of the WSGI design. You don’t need to understand every detail of WSGI just to install a WSGI application or to write a web application using an existing framework.

wsgiref is a reference implementation of the WSGI specification that can be used to add WSGI support to a web server or framework. It provides utilities for manipulating WSGI environment variables and response headers, base classes for implementing WSGI servers, a demo HTTP server that serves WSGI applications, and a validation tool that checks WSGI servers and applications for conformance to the WSGI specification (PEP 3333).

See wsgi.readthedocs.io for more information about WSGI, and links to tutorials and other resources.
21.4.1. **wsgiref.util** – WSGI environment utilities

This module provides a variety of utility functions for working with WSGI environments. A WSGI environment is a dictionary containing HTTP request variables as described in **PEP 3333**. All of the functions taking an `environ` parameter expect a WSGI-compliant dictionary to be supplied; please see **PEP 3333** for a detailed specification.

**wsgiref.util.guess_scheme(environ)**

Return a guess for whether `wsgi.url_scheme` should be “http” or “https”, by checking for a HTTPS environment variable in the `environ` dictionary. The return value is a string.

This function is useful when creating a gateway that wraps CGI or a CGI-like protocol such as FastCGI. Typically, servers providing such protocols will include a HTTPS variable with a value of “1” “yes”, or “on” when a request is received via SSL. So, this function returns “https” if such a value is found, and “http” otherwise.

**wsgiref.util.request_uri(environ, include_query=True)**

Return the full request URI, optionally including the query string, using the algorithm found in the “URL Reconstruction” section of **PEP 3333**. If `include_query` is false, the query string is not included in the resulting URI.

**wsgiref.util.application_uri(environ)**

Similar to `request_uri()`, except that the PATH_INFO and QUERY_STRING variables are ignored. The result is the base URI of the application object addressed by the request.
wsgiref.util.shift_path_info(environ)
Shift a single name from PATH_INFO to SCRIPT_NAME and return the name. The environ dictionary is modified in-place; use a copy if you need to keep the original PATH_INFO or SCRIPT_NAME intact.

If there are no remaining path segments in PATH_INFO, None is returned.

Typically, this routine is used to process each portion of a request URI path, for example to treat the path as a series of dictionary keys. This routine modifies the passed-in environment to make it suitable for invoking another WSGI application that is located at the target URI. For example, if there is a WSGI application at /foo, and the request URI path is /foo/bar/baz, and the WSGI application at /foo calls shift_path_info(), it will receive the string “bar”, and the environment will be updated to be suitable for passing to a WSGI application at /foo/bar. That is, SCRIPT_NAME will change from /foo to /foo/bar, and PATH_INFO will change from /bar/baz to /baz.

When PATH_INFO is just a “/”, this routine returns an empty string and appends a trailing slash to SCRIPT_NAME, even though empty path segments are normally ignored, and SCRIPT_NAME doesn’t normally end in a slash. This is intentional behavior, to ensure that an application can tell the difference between URIs ending in /x from ones ending in /x/ when using this routine to do object traversal.

wsgiref.util.setup_testing_defaults(environ)
Update environ with trivial defaults for testing purposes.

This routine adds various parameters required for WSGI, including
HTTP_HOST, SERVER_NAME, SERVER_PORT, REQUEST_METHOD, SCRIPT_NAME, PATH_INFO, and all of the PEP 3333-defined wsgi.* variables. It only supplies default values, and does not replace any existing settings for these variables.

This routine is intended to make it easier for unit tests of WSGI servers and applications to set up dummy environments. It should NOT be used by actual WSGI servers or applications, since the data is fake!

Example usage:

```python
from wsgiref.util import setup_testing_defaults
from wsgiref.simple_server import make_server

# A relatively simple WSGI application. It's going to print out the environment dictionary after being updated by setup_testing_defaults

def simple_app(environ, start_response):
    setup_testing_defaults(environ)

    status = '200 OK'
    headers = [('Content-type', 'text/plain; charset=utf-8')]

    start_response(status, headers)

    ret = ['%s: %s
' % (key, value) for key, value in environ.items()]
    return ret

with make_server('', 8000, simple_app) as httpd:
    print("Serving on port 8000...")
    httpd.serve_forever()
```

In addition to the environment functions above, the wsgiref.util
module also provides these miscellaneous utilities:

`wsgiref.util.is_hop_by_hop(header_name)`

Return true if ‘header_name’ is an HTTP/1.1 “Hop-by-Hop” header, as defined by RFC 2616.

class wsgiref.util.FileWrapper(filelike, blksize=8192)

A wrapper to convert a file-like object to an iterator. The resulting objects support both `__getitem__()` and `__iter__()` iteration styles, for compatibility with Python 2.1 and Jython. As the object is iterated over, the optional `blksize` parameter will be repeatedly passed to the `filelike` object’s `read()` method to obtain bytestrings to yield. When `read()` returns an empty bytestring, iteration is ended and is not resumable.

If `filelike` has a `close()` method, the returned object will also have a `close()` method, and it will invoke the `filelike` object’s `close()` method when called.

Example usage:

```python
from io import StringIO
from wsgiref.util import FileWrapper

# We're using a StringIO-buffer for as the file-like object
filelike = StringIO("This is an example file-like object")
wrapper = FileWrapper(filelike, blksize=5)

for chunk in wrapper:
    print(chunk)
```
21.4.2. `wsgiref.headers` – WSGI response header tools

This module provides a single class, `Headers`, for convenient manipulation of WSGI response headers using a mapping-like interface.

```python
class wsgiref.headers.Headers([headers])
```

Create a mapping-like object wrapping `headers`, which must be a list of header name/value tuples as described in PEP 3333. The default value of `headers` is an empty list.

`Headers` objects support typical mapping operations including `__getitem__()``, `get()`, `__setitem__()``, `setdefault()`, `__delitem__()` and `__contains__()`. For each of these methods, the key is the header name (treated case-insensitively), and the value is the first value associated with that header name. Setting a header deletes any existing values for that header, then adds a new value at the end of the wrapped header list. Headers’ existing order is generally maintained, with new headers added to the end of the wrapped list.

Unlike a dictionary, `Headers` objects do not raise an error when you try to get or delete a key that isn’t in the wrapped header list. Getting a nonexistent header just returns `None`, and deleting a nonexistent header does nothing.

`Headers` objects also support `keys()`, `values()`, and `items()` methods. The lists returned by `keys()` and `items()` can include the same key more than once if there is a multi-valued header. The `len()` of a `Headers` object is the same as the length of its
items(), which is the same as the length of the wrapped header list. In fact, the items() method just returns a copy of the wrapped header list.

Calling bytes() on a Headers object returns a formatted bytestring suitable for transmission as HTTP response headers. Each header is placed on a line with its value, separated by a colon and a space. Each line is terminated by a carriage return and line feed, and the bytestring is terminated with a blank line.

In addition to their mapping interface and formatting features, Headers objects also have the following methods for querying and adding multi-valued headers, and for adding headers with MIME parameters:

get_all(name)

Return a list of all the values for the named header.

The returned list will be sorted in the order they appeared in the original header list or were added to this instance, and may contain duplicates. Any fields deleted and re-inserted are always appended to the header list. If no fields exist with the given name, returns an empty list.

add_header(name, value, **_params)

Add a (possibly multi-valued) header, with optional MIME parameters specified via keyword arguments.

name is the header field to add. Keyword arguments can be used to set MIME parameters for the header field. Each parameter must be a string or None. Underscores in parameter names are converted to dashes, since dashes are illegal in Python identifiers, but many MIME parameter names include
dashes. If the parameter value is a string, it is added to the header value parameters in the form `name="value"`. If it is `None`, only the parameter name is added. (This is used for MIME parameters without a value.) Example usage:

```python
h.add_header('content-disposition', 'attachment')
```

The above will add a header that looks like this:

```
Content-Disposition: attachment; filename="bud.gif"
```

*Changed in version 3.5: headers parameter is optional.*
21.4.3. `wsgiref.simple_server` – a simple WSGI HTTP server

This module implements a simple HTTP server (based on `http.server`) that serves WSGI applications. Each server instance serves a single WSGI application on a given host and port. If you want to serve multiple applications on a single host and port, you should create a WSGI application that parses `PATH_INFO` to select which application to invoke for each request. (E.g., using the `shift_path_info()` function from `wsgiref.util`.)

`wsgiref.simple_server.make_server(host, port, app, server_class=WSGIServer, handler_class=WSGIRequestHandler)`

Create a new WSGI server listening on `host` and `port`, accepting connections for `app`. The return value is an instance of the supplied `server_class`, and will process requests using the specified `handler_class`. `app` must be a WSGI application object, as defined by PEP 3333.

Example usage:

```python
from wsgiref.simple_server import make_server, demo_app

with make_server('', 8000, demo_app) as httpd:
    print("Serving HTTP on port 8000...")

    # Respond to requests until process is killed
    httpd.serve_forever()

    # Alternative: serve one request, then exit
    httpd.handle_request()
```
wsgiref.simple_server.demo_app(environ, start_response)

This function is a small but complete WSGI application that returns a text page containing the message “Hello world!” and a list of the key/value pairs provided in the environ parameter. It's useful for verifying that a WSGI server (such as wsgiref.simple_server) is able to run a simple WSGI application correctly.

class wsgiref.simple_server.WSGIServer(server_address, RequestHandlerClass)

Create a WSGIServer instance. server_address should be a (host, port) tuple, and RequestHandlerClass should be the subclass of http.server.BaseHTTPRequestHandler that will be used to process requests.

You do not normally need to call this constructor, as the make_server() function can handle all the details for you.

WSGIServer is a subclass of http.server.HTTPServer, so all of its methods (such as serve_forever() and handle_request()) are available. WSGIServer also provides these WSGI-specific methods:

set_app(application)

Sets the callable application as the WSGI application that will receive requests.

get_app()

Returns the currently-set application callable.

Normally, however, you do not need to use these additional methods, as set_app() is normally called by make_server(),
and the `get_app()` exists mainly for the benefit of request handler instances.

```python
class wsgiref.simple_server.WSGIRequestHandler(request, client_address, server)
    Create an HTTP handler for the given `request` (i.e. a socket), `client_address` (a `(host, port)` tuple), and `server` (`WSGIServer` instance).

    You do not need to create instances of this class directly; they are automatically created as needed by `WSGIServer` objects. You can, however, subclass this class and supply it as a `handler_class` to the `make_server()` function. Some possibly relevant methods for overriding in subclasses:

    **get_environ()**
    Returns a dictionary containing the WSGI environment for a request. The default implementation copies the contents of the `WSGIServer` object's `base_environ` dictionary attribute and then adds various headers derived from the HTTP request. Each call to this method should return a new dictionary containing all of the relevant CGI environment variables as specified in PEP 3333.

    **get_stderr()**
    Return the object that should be used as the `wsgi.errors` stream. The default implementation just returns `sys.stderr`.

    **handle()**
    Process the HTTP request. The default implementation creates a handler instance using a `wsgiref.handlers` class to
implement the actual WSGI application interface.
21.4.4. **wsgiref.validate** — WSGI conformance checker

When creating new WSGI application objects, frameworks, servers, or middleware, it can be useful to validate the new code's conformance using **wsgiref.validate**. This module provides a function that creates WSGI application objects that validate communications between a WSGI server or gateway and a WSGI application object, to check both sides for protocol conformance.

Note that this utility does not guarantee complete PEP 3333 compliance; an absence of errors from this module does not necessarily mean that errors do not exist. However, if this module does produce an error, then it is virtually certain that either the server or application is not 100% compliant.

This module is based on the paste.lint module from Ian Bicking’s “Python Paste” library.

**wsgiref.validate.validator**(application)

Wrap *application* and return a new WSGI application object. The returned application will forward all requests to the original *application*, and will check that both the *application* and the server invoking it are conforming to the WSGI specification and to RFC 2616.

Any detected nonconformance results in an **AssertionError** being raised; note, however, that how these errors are handled is server-dependent. For example, **wsgiref.simple_server** and other servers based on **wsgiref.handlers** (that don't override the error handling methods to do something else) will simply output
a message that an error has occurred, and dump the traceback to sys.stderr or some other error stream.

This wrapper may also generate output using the warnings module to indicate behaviors that are questionable but which may not actually be prohibited by PEP 3333. Unless they are suppressed using Python command-line options or the warnings API, any such warnings will be written to sys.stderr (not wsgi.errors, unless they happen to be the same object).

Example usage:

```python
from wsgiref.validate import validator
from wsgiref.simple_server import make_server

# Our callable object which is intentionally not standard, so the validator is going to break
def simple_app(environ, start_response):
    status = '200 OK'  # HTTP Status
    headers = [('Content-type', 'text/plain')]  # HTTP Headers
    start_response(status, headers)

    # This is going to break because we need to return a list, and
    # the validator is going to inform us
    return b"Hello World"

# This is the application wrapped in a validator
validator_app = validator(simple_app)

with make_server('', 8000, validator_app) as httpd:
    print("Listening on port 8000....")
    httpd.serve_forever()
```
21.4.5. wsgiref.handlers – server/gateway base classes

This module provides base handler classes for implementing WSGI servers and gateways. These base classes handle most of the work of communicating with a WSGI application, as long as they are given a CGI-like environment, along with input, output, and error streams.

class wsgiref.handlers.CGIHandler

CGI-based invocation via sys.stdin, sys.stdout, sys.stderr and os.environ. This is useful when you have a WSGI application and want to run it as a CGI script. Simply invoke CGIHandler().run(app), where app is the WSGI application object you wish to invoke.

This class is a subclass of BaseCGIHandler that sets wsgi.run_once to true, wsgi.multithread to false, and wsgi.multiprocess to true, and always uses sys and os to obtain the necessary CGI streams and environment.

class wsgiref.handlers.IISCGIHandler

A specialized alternative to CGIHandler, for use when deploying on Microsoft’s IIS web server, without having set the config allowPathInfo option (IIS>=7) or metabase allowPathInfoForScriptMappings (IIS<7).

By default, IIS gives a PATH_INFO that duplicates the SCRIPT_NAME at the front, causing problems for WSGI applications that wish to implement routing. This handler strips any such duplicated path.
IIS can be configured to pass the correct PATH_INFO, but this causes another bug where PATH_TRANSLATED is wrong. Luckily this variable is rarely used and is not guaranteed by WSGI. On IIS<7, though, the setting can only be made on a vhost level, affecting all other script mappings, many of which break when exposed to the PATH_TRANSLATED bug. For this reason IIS<7 is almost never deployed with the fix. (Even IIS7 rarely uses it because there is still no UI for it.)

There is no way for CGI code to tell whether the option was set, so a separate handler class is provided. It is used in the same way as CGIHandler, i.e., by calling IISCGIHandler().run(app), where app is the WSGI application object you wish to invoke.

*New in version 3.2.*

class wsgiref.handlers.BaseCGIHandler(stdin, stdout, stderr, environ, multithread=True, multiprocess=False)

Similar to CGIHandler, but instead of using the sys and os modules, the CGI environment and I/O streams are specified explicitly. The multithread and multiprocess values are used to set the wsgi.multithread and wsgi.multiprocess flags for any applications run by the handler instance.

This class is a subclass of SimpleHandler intended for use with software other than HTTP “origin servers”. If you are writing a gateway protocol implementation (such as CGI, FastCGI, SCGI, etc.) that uses a Status: header to send an HTTP status, you probably want to subclass this instead of SimpleHandler.

class wsgiref.handlers.SimpleHandler(stdin, stdout, stderr, environ, multithread=True, multiprocess=False)
Similar to `BaseCGIHandler`, but designed for use with HTTP origin servers. If you are writing an HTTP server implementation, you will probably want to subclass this instead of `BaseCGIHandler`.

This class is a subclass of `BaseHandler`. It overrides the `__init__()`, `get_stdin()`, `get_stderr()`, `add_cgi_vars()`, `_write()`, and `_flush()` methods to support explicitly setting the environment and streams via the constructor. The supplied environment and streams are stored in the `stdin`, `stdout`, `stderr`, and `environ` attributes.

The `write()` method of `stdout` should write each chunk in full, like `io.BufferedIOBase`.

```python
class wsgiref.handlers.BaseHandler
```

This is an abstract base class for running WSGI applications. Each instance will handle a single HTTP request, although in principle you could create a subclass that was reusable for multiple requests.

`BaseHandler` instances have only one method intended for external use:

```python
run(app)
```

Run the specified WSGI application, `app`.

All of the other `BaseHandler` methods are invoked by this method in the process of running the application, and thus exist primarily to allow customizing the process.

The following methods MUST be overridden in a subclass:
_write(data)
Buffer the bytes data for transmission to the client. It's okay if this method actually transmits the data; BaseHandler just separates write and flush operations for greater efficiency when the underlying system actually has such a distinction.

_flush()
Force buffered data to be transmitted to the client. It’s okay if this method is a no-op (i.e., if _write() actually sends the data).

get_stdin()
Return an input stream object suitable for use as the wsgi.input of the request currently being processed.

get_stderr()
Return an output stream object suitable for use as the wsgi.errors of the request currently being processed.

add_cgi_vars()
Insert CGI variables for the current request into the environ attribute.

Here are some other methods and attributes you may wish to override. This list is only a summary, however, and does not include every method that can be overridden. You should consult the docstrings and source code for additional information before attempting to create a customized BaseHandler subclass.

Attributes and methods for customizing the WSGI environment:

wsgi_multithread
The value to be used for the `wsgi.multithread` environment variable. It defaults to true in `BaseHandler`, but may have a different default (or be set by the constructor) in the other subclasses.

**wsgi_multiprocess**

The value to be used for the `wsgi.multiprocess` environment variable. It defaults to true in `BaseHandler`, but may have a different default (or be set by the constructor) in the other subclasses.

**wsgi_run_once**

The value to be used for the `wsgi.run_once` environment variable. It defaults to false in `BaseHandler`, but `CGIHandler` sets it to true by default.

**os_environ**

The default environment variables to be included in every request's WSGI environment. By default, this is a copy of `os.environ` at the time that `wsgiref.handlers` was imported, but subclasses can either create their own at the class or instance level. Note that the dictionary should be considered read-only, since the default value is shared between multiple classes and instances.

**server_software**

If the `origin_server` attribute is set, this attribute's value is used to set the default `SERVER_SOFTWARE` WSGI environment variable, and also to set a default `Server:` header in HTTP responses. It is ignored for handlers (such as `BaseCGIHandler` and `CGIHandler`) that are not HTTP origin servers.
Changed in version 3.3: The term “Python” is replaced with implementation specific term like “CPython”, “Jython” etc.

get_scheme()

Return the URL scheme being used for the current request. The default implementation uses the guess_scheme() function from wsgiref.util to guess whether the scheme should be “http” or “https”, based on the current request's environ variables.

setup_environ()

Set the environ attribute to a fully-populated WSGI environment. The default implementation uses all of the above methods and attributes, plus the get_stdin(), get_stderr(), and add_cgi_vars() methods and the wsgi_file_wrapper attribute. It also inserts a SERVER_SOFTWARE key if not present, as long as the origin_server attribute is a true value and the server_software attribute is set.

Methods and attributes for customizing exception handling:

log_exception(exc_info)

Log the exc_info tuple in the server log. exc_info is a (type, value, traceback) tuple. The default implementation simply writes the traceback to the request's wsgi.errors stream and flushes it. Subclasses can override this method to change the format or retarget the output, mail the traceback to an administrator, or whatever other action may be deemed suitable.

traceback_limit
The maximum number of frames to include in tracebacks output by the default `log_exception()` method. If `None`, all frames are included.

**error_output** *(environ, start_response)*

This method is a WSGI application to generate an error page for the user. It is only invoked if an error occurs before headers are sent to the client.

This method can access the current error information using `sys.exc_info()`, and should pass that information to `start_response` when calling it (as described in the “Error Handling” section of PEP 3333).

The default implementation just uses the `error_status`, `error_headers`, and `error_body` attributes to generate an output page. Subclasses can override this to produce more dynamic error output.

Note, however, that it's not recommended from a security perspective to spit out diagnostics to any old user; ideally, you should have to do something special to enable diagnostic output, which is why the default implementation doesn't include any.

**error_status**

The HTTP status used for error responses. This should be a status string as defined in PEP 3333; it defaults to a 500 code and message.

**error_headers**

The HTTP headers used for error responses. This should be a list of WSGI response headers `((name, value) tuples)`, as
described in PEP 3333. The default list just sets the content type to `text/plain`.

**error_body**

The error response body. This should be an HTTP response body bytestring. It defaults to the plain text, “A server error occurred. Please contact the administrator.”

Methods and attributes for PEP 3333’s “Optional Platform-Specific File Handling” feature:

**wsgi_file_wrapper**

A `wsgi.file_wrapper` factory, or None. The default value of this attribute is the `wsgiref.util.FileWrapper` class.

**sendfile()**

Override to implement platform-specific file transmission. This method is called only if the application’s return value is an instance of the class specified by the `wsgi_file_wrapper` attribute. It should return a true value if it was able to successfully transmit the file, so that the default transmission code will not be executed. The default implementation of this method just returns a false value.

Miscellaneous methods and attributes:

**origin_server**

This attribute should be set to a true value if the handler’s `_write()` and `_flush()` are being used to communicate directly to the client, rather than via a CGI-like gateway protocol that wants the HTTP status in a special `Status:` header.

This attribute’s default value is true in `BaseHandler`, but false
in `BaseCGIHandler` and `CGIHandler`.

**http_version**

If `origin_server` is true, this string attribute is used to set the HTTP version of the response set to the client. It defaults to "1.0".

`wsgiref.handlers.read_environ()`

Transcode CGI variables from `os.environ` to PEP 3333 “bytes in unicode” strings, returning a new dictionary. This function is used by `CGIHandler` and `IISCGIHandler` in place of directly using `os.environ`, which is not necessarily WSGI-compliant on all platforms and web servers using Python 3 – specifically, ones where the OS's actual environment is Unicode (i.e. Windows), or ones where the environment is bytes, but the system encoding used by Python to decode it is anything other than ISO-8859-1 (e.g. Unix systems using UTF-8).

If you are implementing a CGI-based handler of your own, you probably want to use this routine instead of just copying values out of `os.environ` directly.

*New in version 3.2.*
21.4.6. Examples

This is a working “Hello World” WSGI application:

```python
from wsgiref.simple_server import make_server

# Every WSGI application must have an application object that accepts two arguments. For that purpose use a function (note that you're not limited to a class for example). The first argument passed is a dictionary containing CGI-style environment variables and the second variable is the callable object (see PEP 333).

def hello_world_app(environ, start_response):
    status = '200 OK'  # HTTP Status
    headers = [('Content-type', 'text/plain; charset=utf-8')]
    start_response(status, headers)

    # The returned object is going to be printed
    return [b"Hello World"]

with make_server('', 8000, hello_world_app) as httpd:
    print("Serving on port 8000...")

    # Serve until process is killed
    httpd.serve_forever()
```

Last updated on Jan 31, 2018. Found a bug?
Created using Sphinx 1.6.6.
21.5. urllib — URL handling modules

Source code: Lib/urllib/

urllib is a package that collects several modules for working with URLs:

- `urllib.request` for opening and reading URLs
- `urllib.error` containing the exceptions raised by `urllib.request`
- `urllib.parse` for parsing URLs
- `urllib.robotparser` for parsing robots.txt files
21.6. urllib.request — Extensible library for opening URLs

Source code: Lib/urllib/request.py

The urllib.request module defines functions and classes which help in opening URLs (mostly HTTP) in a complex world — basic and digest authentication, redirections, cookies and more.

See also: The Requests package is recommended for a higher-level HTTP client interface.

The urllib.request module defines the following functions:

urllib.request.urlopen(url, data=None, [timeout],
cafile=None, capath=None, cadefault=False, context=None)

Open the URL url, which can be either a string or a Request object.

- data must be an object specifying additional data to be sent to the server, or None if no such data is needed. See Request for details.

urllib.request module uses HTTP/1.1 and includes Connection:close header in its HTTP requests.

The optional timeout parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the
global default timeout setting will be used). This actually only works for HTTP, HTTPS and FTP connections.

If `context` is specified, it must be a `ssl.SSLContext` instance describing the various SSL options. See `HTTPSConnection` for more details.

The optional `cafile` and `capath` parameters specify a set of trusted CA certificates for HTTPS requests. `cafile` should point to a single file containing a bundle of CA certificates, whereas `capath` should point to a directory of hashed certificate files. More information can be found in `ssl.SSLContext.load_verify_locations()`.

The `cadefault` parameter is ignored.

This function always returns an object which can work as a context manager and has methods such as

- `geturl()` — return the URL of the resource retrieved, commonly used to determine if a redirect was followed
- `info()` — return the meta-information of the page, such as headers, in the form of an `email.message_from_string()` instance (see Quick Reference to HTTP Headers)
- `getcode()` — return the HTTP status code of the response.

For HTTP and HTTPS URLs, this function returns a `http.client.HTTPResponse` object slightly modified. In addition to the three new methods above, the `msg` attribute contains the same information as the `reason` attribute — the reason phrase returned by server — instead of the response headers as it is specified in the documentation for `HTTPResponse`.

For FTP, file, and data URLs and requests explicitly handled by
legacy `URLopener` and `FancyURLopener` classes, this function returns a `urllib.response.addinfourl` object.

Raises `URLError` on protocol errors.

Note that `None` may be returned if no handler handles the request (though the default installed global `OpenerDirector` uses `UnknownHandler` to ensure this never happens).

In addition, if proxy settings are detected (for example, when a `*_proxy` environment variable like `http_proxy` is set), `ProxyHandler` is default installed and makes sure the requests are handled through the proxy.

The legacy `urllib.urlopen` function from Python 2.6 and earlier has been discontinued; `urllib.request.urlopen()` corresponds to the old `urllib2.urlopen`. Proxy handling, which was done by passing a dictionary parameter to `urllib.urlopen`, can be obtained by using `ProxyHandler` objects.

*Changed in version 3.2:* `cafile` and `capath` were added.

*Changed in version 3.2:* HTTPS virtual hosts are now supported if possible (that is, if `ssl.HAS_SNI` is true).

*New in version 3.2:* `data` can be an iterable object.

*Changed in version 3.3:* `cadefault` was added.

*Changed in version 3.4.3:* `context` was added.

*Deprecated since version 3.6:* `cafile`, `capath` and `cadefault` are deprecated in favor of `context`. Please use
ssl.SSLContext.load_cert_chain() instead, or let
ssl.create_default_context() select the system’s trusted
CA certificates for you.

urllib.request.install_opener(opener)
Install an OpenerDirector instance as the default global opener. Installing an opener is only necessary if you want urlopen to use
that opener; otherwise, simply call OpenerDirector.open() instead of urlopen(). The code does not check for a real
OpenerDirector, and any class with the appropriate interface
will work.

urllib.request.build_opener([handler, ...])
Return an OpenerDirector instance, which chains the handlers
in the order given. handlers can be either instances of
BaseHandler, or subclasses of BaseHandler (in which case it
must be possible to call the constructor without any parameters).
Instances of the following classes will be in front of the handlers,
unless the handlers contain them, instances of them or subclasses
of them: ProxyHandler (if proxy settings are detected),
UnknownHandler, HTTPHandler, HTTPDefaultErrorHandler, HTTPRedirectHandler,
FTPHandler, FileHandler, HTTPErrorProcessor.

If the Python installation has SSL support (i.e., if the ssl module
can be imported), HTTPSHandler will also be added.

A BaseHandler subclass may also change its handler_order
attribute to modify its position in the handlers list.

urllib.request.pathname2url(path)
Convert the pathname *path* from the local syntax for a path to the form used in the path component of a URL. This does not produce a complete URL. The return value will already be quoted using the `quote()` function.

```
urllib.request.url2pathname(path)
```

Convert the path component *path* from a percent-encoded URL to the local syntax for a path. This does not accept a complete URL. This function uses `unquote()` to decode *path*.

```
urllib.request.getproxies()
```

This helper function returns a dictionary of scheme to proxy server URL mappings. It scans the environment for variables named `<scheme>_proxy`, in a case insensitive approach, for all operating systems first, and when it cannot find it, looks for proxy information from Mac OS X System Configuration for Mac OS X and Windows Systems Registry for Windows. If both lowercase and uppercase environment variables exist (and disagree), lowercase is preferred.

**Note:** If the environment variable REQUEST_METHOD is set, which usually indicates your script is running in a CGI environment, the environment variable HTTP_PROXY (uppercase _PROXY) will be ignored. This is because that variable can be injected by a client using the “Proxy:” HTTP header. If you need to use an HTTP proxy in a CGI environment, either use ProxyHandler explicitly, or make sure the variable name is in lowercase (or at least the _proxy suffix).

The following classes are provided:

```
class urllib.request.Request(url, data=None, headers={},
```
This class is an abstraction of a URL request.

`url` should be a string containing a valid URL.

`data` must be an object specifying additional data to send to the server, or `None` if no such data is needed. Currently HTTP requests are the only ones that use `data`. The supported object types include bytes, file-like objects, and iterables. If no Content-Length nor Transfer-Encoding header field has been provided, `HTTPHandler` will set these headers according to the type of `data`. Content-Length will be used to send bytes objects, while Transfer-Encoding: chunked as specified in **RFC 7230**, Section 3.3.1 will be used to send files and other iterables.

For an HTTP POST request method, `data` should be a buffer in the standard `application/x-www-form-urlencoded` format. The `urllib.parse.urlencode()` function takes a mapping or sequence of 2-tuples and returns an ASCII string in this format. It should be encoded to bytes before being used as the `data` parameter.

`headers` should be a dictionary, and will be treated as if `add_header()` was called with each key and value as arguments. This is often used to “spoof” the User-Agent header value, which is used by a browser to identify itself – some HTTP servers only allow requests coming from common browsers as opposed to scripts. For example, Mozilla Firefox may identify itself as "Mozilla/5.0 (X11; U; Linux i686) Gecko/20071127 Firefox/2.0.0.11", while `urllib`'s default user agent string is "Python-urllib/2.6" (on Python 2.6).
An appropriate `Content-Type` header should be included if the `data` argument is present. If this header has not been provided and `data` is not `None`, `Content-Type: application/x-www-form-urlencoded` will be added as a default.

The final two arguments are only of interest for correct handling of third-party HTTP cookies:

`origin_req_host` should be the request-host of the origin transaction, as defined by RFC 2965. It defaults to `http.cookiejar.request_host(self)`. This is the host name or IP address of the original request that was initiated by the user. For example, if the request is for an image in an HTML document, this should be the request-host of the request for the page containing the image.

`unverifiable` should indicate whether the request is unverifiable, as defined by RFC 2965. It defaults to `False`. An unverifiable request is one whose URL the user did not have the option to approve. For example, if the request is for an image in an HTML document, and the user had no option to approve the automatic fetching of the image, this should be true.

`method` should be a string that indicates the HTTP request method that will be used (e.g. `'HEAD'`). If provided, its value is stored in the `method` attribute and is used by `get_method()`. The default is `'GET'` if `data` is `None` or `POST` otherwise. Subclasses may indicate a different default method by setting the `method` attribute in the class itself.

**Note:** The request will not work as expected if the data object is unable to deliver its content more than once (e.g. a file or an
iterable that can produce the content only once) and the request is retried for HTTP redirects or authentication. The *data* is sent to the HTTP server right away after the headers. There is no support for a 100-continue expectation in the library.

*Changed in version 3.3:* Request.method argument is added to the Request class.

*Changed in version 3.4:* Default Request.method may be indicated at the class level.

*Changed in version 3.6:* Do not raise an error if the Content-Length has not been provided and *data* is neither None nor a bytes object. Fall back to use chunked transfer encoding instead.

class urllib.request.OpenerDirector
   The OpenerDirector class opens URLs via BaseHandlers chained together. It manages the chaining of handlers, and recovery from errors.

class urllib.request.BaseHandler
   This is the base class for all registered handlers — and handles only the simple mechanics of registration.

class urllib.request.HTTPDefaultErrorHandler
   A class which defines a default handler for HTTP error responses; all responses are turned into HTTPError exceptions.

class urllib.request.HTTPRedirectHandler
   A class to handle redirections.

class urllib.request.HTTPCookieProcessor(cookiejar=None)
A class to handle HTTP Cookies.

```python
class urllib.request.ProxyHandler(proxies=None)
```

Cause requests to go through a proxy. If `proxies` is given, it must be a dictionary mapping protocol names to URLs of proxies. The default is to read the list of proxies from the environment variables `<protocol>_proxy`. If no proxy environment variables are set, then in a Windows environment proxy settings are obtained from the registry's Internet Settings section, and in a Mac OS X environment proxy information is retrieved from the OS X System Configuration Framework.

To disable autodetected proxy pass an empty dictionary.

The `no_proxy` environment variable can be used to specify hosts which shouldn't be reached via proxy; if set, it should be a comma-separated list of hostname suffixes, optionally with `:port` appended, for example `cern.ch,ncsa.uiuc.edu,some.host:8080`.

**Note:** `HTTP_PROXY` will be ignored if a variable `REQUEST_METHOD` is set; see the documentation on `getproxies()`.

```python
class urllib.request.HTTPPasswordMgr
```

Keep a database of `(realm, uri) -> (user, password)` mappings.

```python
class urllib.request.HTTPPasswordMgrWithDefaultRealm
```

Keep a database of `(realm, uri) -> (user, password)` mappings. A realm of `None` is considered a catch-all realm, which
is searched if no other realm fits.

**class urllib.request.HTTPPasswordMgrWithPriorAuth**

A variant of `HTTPPasswordMgrWithDefaultRealm` that also has a database of `uri -> is_authenticated` mappings. Can be used by a BasicAuth handler to determine when to send authentication credentials immediately instead of waiting for a 401 response first.

*New in version 3.5.*

**class urllib.request.AbstractBasicAuthHandler**

This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. `password_mgr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported. If `passwd_mgr` also provides `is_authenticated` and `update_authenticated` methods (see `HTTPPasswordMgrWithPriorAuth Objects`), then the handler will use the `is_authenticated` result for a given URI to determine whether or not to send authentication credentials with the request. If `is_authenticated` returns `True` for the URI, credentials are sent. If `is_authenticated` is `False`, credentials are not sent, and then if a 401 response is received the request is re-sent with the authentication credentials. If authentication succeeds, `update_authenticated` is called to set `is_authenticated` `True` for the URI, so that subsequent requests to the URI or any of its super-URIs will automatically include the authentication credentials.

*New in version 3.5: Added `is_authenticated` support.*
class urllib.request.HTTPBasicAuthHandler(password_mgr=None)
    Handle authentication with the remote host. `password_mgr`, if given, should be something that is compatible with HTTPPasswordMgr; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported. HTTPBasicAuthHandler will raise a ValueError when presented with a wrong Authentication scheme.

class urllib.request.ProxyBasicAuthHandler(password_mgr=None)
    Handle authentication with the proxy. `password_mgr`, if given, should be something that is compatible with HTTPPasswordMgr; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported.

class urllib.request.AbstractDigestAuthHandler(password_mgr=None)
    This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. `password_mgr`, if given, should be something that is compatible with HTTPPasswordMgr; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported.

class urllib.request.HTTPDigestAuthHandler(password_mgr=None)
    Handle authentication with the remote host. `password_mgr`, if given, should be something that is compatible with HTTPPasswordMgr; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported. When both Digest Authentication Handler and Basic Authentication Handler are both added, Digest Authentication is always tried first. If the
Digest Authentication returns a 40x response again, it is sent to Basic Authentication handler to Handle. This Handler method will raise a ValueError when presented with an authentication scheme other than Digest or Basic.

*Changed in version 3.3:* Raise ValueError on unsupported Authentication Scheme.

class urllib.request.ProxyDigestAuthHandler(password_mgr
Handle authentication with the proxy. password_mgr, if given, should be something that is compatible with HTTPPasswordMgr; refer to section HTTPPasswordMgr Objects for information on the interface that must be supported.

class urllib.request.HTTPHandler
A class to handle opening of HTTP URLs.

class urllib.request.HTTPSHandler(debuglevel=0,
context=None, check_hostname=None)
A class to handle opening of HTTPS URLs. context and check_hostname have the same meaning as in http.client.HTTPSConnection.

*Changed in version 3.2:* context and check_hostname were added.

class urllib.request.FileHandler
Open local files.

class urllib.request.DataHandler
Open data URLs.

*New in version 3.4.*
class urllib.request.FTPHandler
    Open FTP URLs.

class urllib.request.CacheFTPHandler
    Open FTP URLs, keeping a cache of open FTP connections to minimize delays.

class urllib.request.UnknownHandler
    A catch-all class to handle unknown URLs.

class urllib.request.HTTPErrorProcessor
    Process HTTP error responses.
21.6.1. Request Objects

The following methods describe Request’s public interface, and so all may be overridden in subclasses. It also defines several public attributes that can be used by clients to inspect the parsed request.

Request. full_url
   The original URL passed to the constructor.

   Changed in version 3.4.

   Request.full_url is a property with setter, getter and a deleter. Getting full_url returns the original request URL with the fragment, if it was present.

Request. type
   The URI scheme.

Request. host
   The URI authority, typically a host, but may also contain a port separated by a colon.

Request. origin_req_host
   The original host for the request, without port.

Request. selector
   The URI path. If the Request uses a proxy, then selector will be the full URL that is passed to the proxy.

Request. data
   The entity body for the request, or None if not specified.

   Changed in version 3.4: Changing value of Request.data now
deletes “Content-Length” header if it was previously set or calculated.

Request.unverifiable
boolean, indicates whether the request is unverifiable as defined by RFC 2965.

Request.method
The HTTP request method to use. By default its value is None, which means that get_method() will do its normal computation of the method to be used. Its value can be set (thus overriding the default computation in get_method()) either by providing a default value by setting it at the class level in a Request subclass, or by passing a value in to the Request constructor via the method argument.

New in version 3.3.

Changed in version 3.4: A default value can now be set in subclasses; previously it could only be set via the constructor argument.

Request.get_method()
Return a string indicating the HTTP request method. If Request.method is not None, return its value, otherwise return 'GET' if Request.data is None, or 'POST' if it's not. This is only meaningful for HTTP requests.

Changed in version 3.3: get_method now looks at the value of Request.method.

Request.add_header(key, val)
Add another header to the request. Headers are currently ignored
by all handlers except HTTP handlers, where they are added to the list of headers sent to the server. Note that there cannot be more than one header with the same name, and later calls will overwrite previous calls in case the key collides. Currently, this is no loss of HTTP functionality, since all headers which have meaning when used more than once have a (header-specific) way of gaining the same functionality using only one header.

Request.\texttt{add_unredirected_header}(key, header)
Add a header that will not be added to a redirected request.

Request.\texttt{has_header}(header)
Return whether the instance has the named header (checks both regular and unredirected).

Request.\texttt{remove_header}(header)
Remove named header from the request instance (both from regular and unredirected headers).

\textit{New in version 3.4.}

Request.\texttt{get_full_url}()
Return the URL given in the constructor.

\textit{Changed in version 3.4.}

Returns \texttt{Request.full_url}

Request.\texttt{set_proxy}(host, type)
Prepare the request by connecting to a proxy server. The \texttt{host} and \texttt{type} will replace those of the instance, and the instance's selector will be the original URL given in the constructor.
Request. **get_header**(header_name,*default=None*)

Return the value of the given header. If the header is not present, return the default value.

Request. **header_items**( )

Return a list of tuples (header_name, header_value) of the Request headers.

* Changed in version 3.4: The request methods add_data, has_data, get_data, get_type, get_host, get_selector, get_origin_req_host and is_unverifiable that were deprecated since 3.3 have been removed. *
21.6.2. OpenerDirector Objects

OpenerDirector instances have the following methods:

OpenerDirector.\texttt{add\_handler}(\texttt{handler})

\texttt{handler} should be an instance of BaseHandler. The following methods are searched, and added to the possible chains (note that HTTP errors are a special case).

- protocol\_open() — signal that the handler knows how to open protocol URLs.
- http\_error\_type() — signal that the handler knows how to handle HTTP errors with HTTP error code type.
- protocol\_error() — signal that the handler knows how to handle errors from (non-http) protocol.
- protocol\_request() — signal that the handler knows how to pre-process protocol requests.
- protocol\_response() — signal that the handler knows how to post-process protocol responses.

OpenerDirector.\texttt{open}(\texttt{url, data=None[, timeout]})

Open the given \texttt{url} (which can be a request object or a string), optionally passing the given \texttt{data}. Arguments, return values and exceptions raised are the same as those of \texttt{urlopen()} (which simply calls the \texttt{open()} method on the currently installed global OpenerDirector). The optional \texttt{timeout} parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). The timeout feature actually works only for HTTP, HTTPS and FTP connections).
OpenerDirector.error(proto, *args)
Handle an error of the given protocol. This will call the registered error handlers for the given protocol with the given arguments (which are protocol specific). The HTTP protocol is a special case which uses the HTTP response code to determine the specific error handler; refer to the http_error_*() methods of the handler classes.

Return values and exceptions raised are the same as those of urlopen().

OpenerDirector objects open URLs in three stages:

The order in which these methods are called within each stage is determined by sorting the handler instances.

1. Every handler with a method named like protocol_request() has that method called to pre-process the request.

2. Handlers with a method named like protocol_open() are called to handle the request. This stage ends when a handler either returns a non-None value (ie. a response), or raises an exception (usually URLError). Exceptions are allowed to propagate.

In fact, the above algorithm is first tried for methods named default_open(). If all such methods return None, the algorithm is repeated for methods named like protocol_open(). If all such methods return None, the algorithm is repeated for methods named unknown_open().

Note that the implementation of these methods may involve calls of the parent OpenerDirector instance’s open() and
error() methods.

3. Every handler with a method named like protocol_response() has that method called to post-process the response.
21.6.3. BaseHandler Objects

**BaseHandler** objects provide a couple of methods that are directly useful, and others that are meant to be used by derived classes. These are intended for direct use:

**BaseHandler**. `add_parent(director)`

Add a director as parent.

**BaseHandler**. `close()`

Remove any parents.

The following attribute and methods should only be used by classes derived from **BaseHandler**.

**Note:** The convention has been adopted that subclasses defining `protocol_request()` or `protocol_response()` methods are named *Processor; all others are named *Handler.

**BaseHandler**. `parent`

A valid **OpenerDirector**, which can be used to open using a different protocol, or handle errors.

**BaseHandler**. `default_open(req)`

This method is *not* defined in **BaseHandler**, but subclasses should define it if they want to catch all URLs.

This method, if implemented, will be called by the parent **OpenerDirector**. It should return a file-like object as described in the return value of the `open()` of **OpenerDirector**, or `None`. It should raise **URLError**, unless a truly exceptional thing happens
(for example, `MemoryError` should not be mapped to `URLError`).

This method will be called before any protocol-specific open method.

**BaseHandler.** `protocol_open`(req)

This method is *not* defined in `BaseHandler`, but subclasses should define it if they want to handle URLs with the given protocol.

This method, if defined, will be called by the parent `OpenerDirector`. Return values should be the same as for `default_open()`.

**BaseHandler.** `unknown_open`(req)

This method is *not* defined in `BaseHandler`, but subclasses should define it if they want to catch all URLs with no specific registered handler to open it.

This method, if implemented, will be called by the parent `OpenerDirector`. Return values should be the same as for `default_open()`.

**BaseHandler.** `http_error_default`(req, fp, code, msg, hdrs)

This method is *not* defined in `BaseHandler`, but subclasses should override it if they intend to provide a catch-all for otherwise unhandled HTTP errors. It will be called automatically by the `OpenerDirector` getting the error, and should not normally be called in other circumstances.

`req` will be a `Request` object, `fp` will be a file-like object with the HTTP error body, `code` will be the three-digit code of the error, `msg`
will be the user-visible explanation of the code and hdrs will be a mapping object with the headers of the error.

Return values and exceptions raised should be the same as those of urlopen().

BaseHandler.http_error_nnn(req, fp, code, msg, hdrs)
nnn should be a three-digit HTTP error code. This method is also not defined in BaseHandler, but will be called, if it exists, on an instance of a subclass, when an HTTP error with code nnn occurs.

Subclasses should override this method to handle specific HTTP errors.

Arguments, return values and exceptions raised should be the same as for http_error_default().

BaseHandler.protocol_request(req)
This method is not defined in BaseHandler, but subclasses should define it if they want to pre-process requests of the given protocol.

This method, if defined, will be called by the parent OpenerDirector. req will be a Request object. The return value should be a Request object.

BaseHandler.protocol_response(req, response)
This method is not defined in BaseHandler, but subclasses should define it if they want to post-process responses of the given protocol.

This method, if defined, will be called by the parent OpenerDirector. req will be a Request object. response will be
an object implementing the same interface as the return value of `urlopen()`. The return value should implement the same interface as the return value of `urlopen()`.
21.6.4. HTTPRedirectHandler Objects

**Note:** Some HTTP redirections require action from this module's client code. If this is the case, HTTPError is raised. See RFC 2616 for details of the precise meanings of the various redirection codes.

An HTTPError exception raised as a security consideration if the HTTPRedirectHandler is presented with a redirected URL which is not an HTTP, HTTPS or FTP URL.

HTTPRedirectHandler. **redirect_request**(req, fp, code, msg, hdrs, newurl)

Return a Request or None in response to a redirect. This is called by the default implementations of the http_error_30*() methods when a redirection is received from the server. If a redirection should take place, return a new Request to allow http_error_30*() to perform the redirect to newurl. Otherwise, raise HTTPError if no other handler should try to handle this URL, or return None if you can’t but another handler might.

**Note:** The default implementation of this method does not strictly follow RFC 2616, which says that 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and the default implementation reproduces this behavior.

HTTPRedirectHandler. **http_error_301**(req, fp, code, msg, hdrs)

Redirect to the Location: or URI: URL. This method is called by
the parent `OpenerDirector` when getting an HTTP ‘moved permanently’ response.

HTTPRedirectHandler. `http_error_302(req, fp, code, msg, hdrs)`
   The same as `http_error_301()`, but called for the ‘found’ response.

HTTPRedirectHandler. `http_error_303(req, fp, code, msg, hdrs)`
   The same as `http_error_301()`, but called for the ‘see other’ response.

HTTPRedirectHandler. `http_error_307(req, fp, code, msg, hdrs)`
   The same as `http_error_301()`, but called for the ‘temporary redirect’ response.
21.6.5. `HTTPCookieProcessor` Objects

`HTTPCookieProcessor` instances have one attribute:

`HTTPCookieProcessor.cookiejar`

The `http.cookiejar.CookieJar` in which cookies are stored.
21.6.6. ProxyHandler Objects

ProxyHandler.\texttt{protocol\_open}(\textit{request})

The \texttt{ProxyHandler} will have a method \texttt{protocol\_open()} for every protocol which has a proxy in the \texttt{proxies} dictionary given in the constructor. The method will modify requests to go through the proxy, by calling \texttt{request.set\_proxy()}, and call the next handler in the chain to actually execute the protocol.
21.6.7. HTTPPasswordMgr Objects

These methods are available on HTTPPasswordMgr and HTTPPasswordMgrWithDefaultRealm objects.

HTTPPasswordMgr.\texttt{add\_password}(realm, uri, user, passwd)

\texttt{uri} can be either a single URI, or a sequence of URIs. \texttt{realm}, \texttt{user} and \texttt{passwd} must be strings. This causes \texttt{(user, passwd)} to be used as authentication tokens when authentication for \texttt{realm} and a super-URI of any of the given URIs is given.

HTTPPasswordMgr.\texttt{find\_user\_password}(realm, authuri)

Get user/password for given realm and URI, if any. This method will return \texttt{(None, None)} if there is no matching user/password.

For HTTPPasswordMgrWithDefaultRealm objects, the realm \texttt{None} will be searched if the given \texttt{realm} has no matching user/password.
21.6.8. HTTPPasswordMgrWithPriorAuth Objects

This password manager extends HTTPPasswordMgrWithDefaultRealm to support tracking URIs for which authentication credentials should always be sent.

HTTPPasswordMgrWithPriorAuth.add_password(realm, uri, user, passwd, is_authenticated=False)

realm, uri, user, passwd are as for HTTPPasswordMgr.add_password(). is_authenticated sets the initial value of the is_authenticated flag for the given URI or list of URIs. If is_authenticated is specified as True, realm is ignored.

HTTPPasswordMgr.find_user_password(realm, authuri)
Same as for HTTPPasswordMgrWithDefaultRealm objects

HTTPPasswordMgrWithPriorAuth.update_authenticated(uri, is_authenticated=False)
Update the is_authenticated flag for the given uri or list of URIs.

HTTPPasswordMgrWithPriorAuth.is_authenticated(self, authuri)
Returns the current state of the is_authenticated flag for the given URI.
21.6.9. AbstractBasicAuthHandler Objects

AbstractBasicAuthHandler. `http_error_auth_reqed(authreq, host, req, headers)`

Handle an authentication request by getting a user/password pair, and re-trying the request. `authreq` should be the name of the header where the information about the realm is included in the request, `host` specifies the URL and path to authenticate for, `req` should be the (failed) `Request` object, and `headers` should be the error headers.

`host` is either an authority (e.g. "python.org") or a URL containing an authority component (e.g. "http://python.org/"). In either case, the authority must not contain a userinfo component (so, "python.org" and "python.org:80" are fine, "joe:password@python.org" is not).
21.6.10. HTTPBasicAuthHandler Objects

HTTPBasicAuthHandler.http_error_401(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.
21.6.11. ProxyBasicAuthHandler Objects

ProxyBasicAuthHandler.\texttt{http\_error\_407}(\textit{req, fp, code, msg, hdrs})

Retry the request with authentication information, if available.
21.6.12. AbstractDigestAuthHandler

Objects

AbstractDigestAuthHandler.\texttt{http\_error\_auth\_reqed}(authreq, host, req, headers)

\texttt{authreq} should be the name of the header where the information about the realm is included in the request, \texttt{host} should be the host to authenticate to, \texttt{req} should be the (failed) \texttt{Request} object, and \texttt{headers} should be the error headers.
21.6.13. HTTPDigestAuthHandler Objects

HTTPDigestAuthHandler. **http_error_401**(*req, fp, code, msg,hdrs*)

Retry the request with authentication information, if available.

ProxyDigestAuthHandler.\texttt{http\_error\_407}(\texttt{req, fp, code, msg, hdrs})

Retry the request with authentication information, if available.
21.6.15. HTTPHandler Objects

HTTPHandler.\texttt{http\_open}(\texttt{req})

Send an HTTP request, which can be either GET or POST, depending on \texttt{req.has\_data}().
21.6.16. HTTPSHandler Objects

HTTPSHandler.\texttt{https\_open}(\texttt{req})

Send an HTTPS request, which can be either GET or POST, depending on \texttt{req.has\_data()}. 

21.6.17. FileHandler Objects

FileHandler.\texttt{file\_open}(\texttt{req})

Open the file locally, if there is no host name, or the host name is 'localhost'.

\textit{Changed in version 3.2:} This method is applicable only for local hostnames. When a remote hostname is given, an \texttt{URLError} is raised.
21.6.18. DataHandler Objects

DataHandler.\texttt{data\_open}(\texttt{req})

Read a data URL. This kind of URL contains the content encoded in the URL itself. The data URL syntax is specified in RFC 2397. This implementation ignores white spaces in base64 encoded data URLs so the URL may be wrapped in whatever source file it comes from. But even though some browsers don’t mind about a missing padding at the end of a base64 encoded data URL, this implementation will raise an \texttt{ValueError} in that case.
21.6.19. FTPHandler Objects

FTPHandler. **ftp_open**(req)

Open the FTP file indicated by *req*. The login is always done with empty username and password.
21.6.20. CacheFTPHandler Objects

CacheFTPHandler objects are FTPHandler objects with the following additional methods:

CacheFTPHandler. **setTimeout**(*t*)
   Set timeout of connections to *t* seconds.

CacheFTPHandler. **setMaxConns**(*m*)
   Set maximum number of cached connections to *m*. 
21.6.21. UnknownHandler Objects

UnknownHandler. **unknown_open()**

Raise a **URLError** exception.
21.6.22. HTTPErrorProcessor Objects

HTTPErrorProcessor. http_response()
Process HTTP error responses.

For 200 error codes, the response object is returned immediately.

For non-200 error codes, this simply passes the job on to the protocol_error_code() method via OpenerDirector.error(). Eventually, HTTPDefaultErrorHandler will raise an HTTPError if no other handler handles the error.

HTTPErrorProcessor. https_response()
Process HTTPS error responses.

The behavior is same as http_response().
21.6.23. Examples

In addition to the examples below, more examples are given in HOWTO Fetch Internet Resources Using The urllib Package.

This example gets the python.org main page and displays the first 300 bytes of it.

```python
>>> import urllib.request
>>> with urllib.request.urlopen('http://www.python.org/ ...
   print(f.read(300))
...
... b'<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Trans
... http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd"
... "http://www.w3.org/1999/xhtml" xml:lang="en"
... <title>Python Programming'
```

Note that urlopen returns a bytes object. This is because there is no way for urlopen to automatically determine the encoding of the byte stream it receives from the HTTP server. In general, a program will decode the returned bytes object to string once it determines or guesses the appropriate encoding.

The following W3C document, https://www.w3.org/International/O-charset, lists the various ways in which an (X)HTML or an XML document could have specified its encoding information.

As the python.org website uses utf-8 encoding as specified in its meta tag, we will use the same for decoding the bytes object.

```python
>>> with urllib.request.urlopen('http://www.python.org/ ...
   print(f.read(100).decode('utf-8'))
```
It is also possible to achieve the same result without using the context manager approach.

```python
>>> import urllib.request
>>> f = urllib.request.urlopen('http://www.python.org/100').decode('utf-8'))
>>> print(f.read(100).decode('utf-8'))
```

In the following example, we are sending a data-stream to the stdin of a CGI and reading the data it returns to us. Note that this example will only work when the Python installation supports SSL.

```python
>>> import urllib.request
>>> req = urllib.request.Request(url='https://localhost/cgi-bin/test.cgi',
>>> data=b'This data is passed to stdin of the CGI')
>>> with urllib.request.urlopen(req) as f:
...    print(f.read().decode('utf-8'))
```

The code for the sample CGI used in the above example is:

```python
#!/usr/bin/env python
import sys
data = sys.stdin.read()
print('Content-type: text/plain\n\nGot Data: "%s"' % data)
```

Here is an example of doing a PUT request using Request:
import urllib.request
DATA = b'some data'
req = urllib.request.Request(url='http://localhost:8080')
with urllib.request.urlopen(req) as f:
    pass
print(f.status)
print(f.reason)

Use of Basic HTTP Authentication:

import urllib.request
# Create an OpenerDirector with support for Basic HTTP Authentication...
auth_handler = urllib.request.HTTPBasicAuthHandler()
auth_handler.add_password(realm='PDQ Application',
                            uri='https://mahler:8092/site-updates.py',
                            user='klem',
                            passwd='kadidd!ehopper')
opener = urllib.request.build_opener(auth_handler)
# ...and install it globally so it can be used with urllib.request.install_opener(opener)
urllib.request.urlopen('http://www.example.com/login.html')

build_opener() provides many handlers by default, including a ProxyHandler. By default, ProxyHandler uses the environment variables named <scheme>_proxy, where <scheme> is the URL scheme involved. For example, the http_proxy environment variable is read to obtain the HTTP proxy's URL.

This example replaces the default ProxyHandler with one that uses programmatically-supplied proxy URLs, and adds proxy authorization support with ProxyBasicAuthHandler.
proxy_handler = urllib.request.ProxyHandler({'http':
})
proxy_auth_handler = urllib.request.ProxyBasicAuthHandler()
proxy_auth_handler.add_password('realm', 'host', 'username')
opener = urllib.request.build_opener(proxy_handler,
# This time, rather than install the OpenerDirector,
) open('http://www.example.com/login.html')

Adding HTTP headers:

Use the `headers` argument to the `Request` constructor, or:

```python
import urllib.request
req = urllib.request.Request('http://www.example.com/
req.add_header('Referer', 'http://www.python.org/')
# Customize the default User-Agent header value:
req.add_header('User-Agent', 'urllib-example/0.1 (Contact:	.	.	.)'
```

```
.elements
```

OpenerDirector automatically adds a `User-Agent` header to every `Request`. To change this:

```python
import urllib.request
opener = urllib.request.build_opener()
opener.addheaders = [(User-agent', 'Mozilla/5.0')]
opener.open('http://www.example.com/
```

Also, remember that a few standard headers (Content-Length, Content-Type and Host) are added when the `Request` is passed to `urlopen()` (or `OpenerDirector.open()`).

Here is an example session that uses the GET method to retrieve a URL containing parameters:
The following example uses the **POST** method instead. Note that params output from urlencode is encoded to bytes before it is sent to urlopen as data:

```python
>>> import urllib.request
>>> import urllib.parse
>>> data = urllib.parse.urlencode({'spam': 1, 'eggs'
>>> data = data.encode('ascii')
>>> with urllib.request.urlopen("http://requestb.in/
...   print(f.read().decode('utf-8'))
...}
```

The following example uses an explicitly specified HTTP proxy, overriding environment settings:

```python
>>> import urllib.request
>>> proxies = {'http': 'http://proxy.example.com:8080/'}
>>> opener = urllib.request.FancyURLopener(proxies)
>>> with opener.open("http://www.python.org") as f:
...   f.read().decode('utf-8')
...}
```

The following example uses no proxies at all, overriding environment settings:
>>> import urllib.request
>>> opener = urllib.request.FancyURLopener({})
>>> with opener.open("http://www.python.org/") as f:
...    f.read().decode('utf-8')
...
21.6.24. Legacy interface

The following functions and classes are ported from the Python 2 module `urllib` (as opposed to `urllib2`). They might become deprecated at some point in the future.

`urllib.request.urlretrieve(url, filename=None, reporthook=None, data=None)`

Copy a network object denoted by a URL to a local file. If the URL points to a local file, the object will not be copied unless filename is supplied. Return a tuple `(filename, headers)` where `filename` is the local file name under which the object can be found, and `headers` is whatever the `info()` method of the object returned by `urlopen()` returned (for a remote object). Exceptions are the same as for `urlopen()`.

The second argument, if present, specifies the file location to copy to (if absent, the location will be a tempfile with a generated name). The third argument, if present, is a hook function that will be called once on establishment of the network connection and once after each block read thereafter. The hook will be passed three arguments; a count of blocks transferred so far, a block size in bytes, and the total size of the file. The third argument may be `-1` on older FTP servers which do not return a file size in response to a retrieval request.

The following example illustrates the most common usage scenario:

```python
>>> import urllib.request
>>> local_filename, headers = urllib.request.urlretrieve
>>> html = open(local_filename)
```
If the *url* uses the http: scheme identifier, the optional *data* argument may be given to specify a POST request (normally the request type is GET). The *data* argument must be a bytes object in standard application/x-www-form-urlencoded format; see the urllib.parse.urlencode() function.

urlretrieve() will raise ContentTooShortError when it detects that the amount of data available was less than the expected amount (which is the size reported by a Content-Length header). This can occur, for example, when the download is interrupted.

The Content-Length is treated as a lower bound: if there’s more data to read, urlretrieve reads more data, but if less data is available, it raises the exception.

You can still retrieve the downloaded data in this case, it is stored in the content attribute of the exception instance.

If no Content-Length header was supplied, urlretrieve can not check the size of the data it has downloaded, and just returns it. In this case you just have to assume that the download was successful.

urllib.request.urlcleanup()
Clean up temporary files that may have been left behind by previous calls to urlretrieve().

class urllib.request.URLopener(proxies=None, **x509)
Deprecation since version 3.3.
Base class for opening and reading URLs. Unless you need to support opening objects using schemes other than http:, ftp:, or file:, you probably want to use FancyURLopener.

By default, the URLopener class sends a User-Agent header of urllib/VVV, where VVV is the urllib version number. Applications can define their own User-Agent header by subclassing URLopener or FancyURLopener and setting the class attribute version to an appropriate string value in the subclass definition.

The optional proxies parameter should be a dictionary mapping scheme names to proxy URLs, where an empty dictionary turns proxies off completely. Its default value is None, in which case environmental proxy settings will be used if present, as discussed in the definition of urlopen(), above.

Additional keyword parameters, collected in x509, may be used for authentication of the client when using the https: scheme. The keywords key_file and cert_file are supported to provide an SSL key and certificate; both are needed to support client authentication.

URLopener objects will raise an OSError exception if the server returns an error code.

open(fullurl, data=None)
  Open fullurl using the appropriate protocol. This method sets up cache and proxy information, then calls the appropriate open method with its input arguments. If the scheme is not recognized, open_unknown() is called. The data argument has the same meaning as the data argument of urlopen().
**open Unknown** *(fullurl, data=None)*

Overridable interface to open unknown URL types.

**retrieve**(url, filename=None, reporthook=None, data=None)

Retrieves the contents of url and places it in filename. The return value is a tuple consisting of a local filename and either an `email.message.Message` object containing the response headers (for remote URLs) or None (for local URLs). The caller must then open and read the contents of filename. If filename is not given and the URL refers to a local file, the input filename is returned. If the URL is non-local and filename is not given, the filename is the output of `tempfile.mktemp()` with a suffix that matches the suffix of the last path component of the input URL. If reporthook is given, it must be a function accepting three numeric parameters: A chunk number, the maximum size chunks are read in and the total size of the download (-1 if unknown). It will be called once at the start and after each chunk of data is read from the network. reporthook is ignored for local URLs.

If the url uses the `http:` scheme identifier, the optional data argument may be given to specify a POST request (normally the request type is GET). The data argument must in standard `application/x-www-form-urlencoded` format; see the `urllib.parse.urlencode()` function.

**version**

Variable that specifies the user agent of the opener object. To get `urllib` to tell servers that it is a particular user agent, set this in a subclass as a class variable or in the constructor before calling the base constructor.
class urllib.request.FancyURLopener(...)

Deprecated since version 3.3.

FancyURLopener subclasses URLopener providing default handling for the following HTTP response codes: 301, 302, 303, 307 and 401. For the 30x response codes listed above, the Location header is used to fetch the actual URL. For 401 response codes (authentication required), basic HTTP authentication is performed. For the 30x response codes, recursion is bounded by the value of the maxtries attribute, which defaults to 10.

For all other response codes, the method http_error_default() is called which you can override in subclasses to handle the error appropriately.

Note: According to the letter of RFC 2616, 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and urllib reproduces this behaviour.

The parameters to the constructor are the same as those for URLopener.

Note: When performing basic authentication, a FancyURLopener instance calls its prompt_user_passwd() method. The default implementation asks the users for the required information on the controlling terminal. A subclass may override this method to support more appropriate behavior if needed.

The FancyURLopener class offers one additional method that
should be overloaded to provide the appropriate behavior:

**prompt_user_passwd**(host, realm)

Return information needed to authenticate the user at the given host in the specified security realm. The return value should be a tuple, (user, password), which can be used for basic authentication.

The implementation prompts for this information on the terminal; an application should override this method to use an appropriate interaction model in the local environment.
21.6.25. **urllib.request** Restrictions

- Currently, only the following protocols are supported: HTTP (versions 0.9 and 1.0), FTP, local files, and data URLs.

  *Changed in version 3.4:* Added support for data URLs.

- The caching feature of `urlretrieve()` has been disabled until someone finds the time to hack proper processing of Expiration time headers.

- There should be a function to query whether a particular URL is in the cache.

- For backward compatibility, if a URL appears to point to a local file but the file can’t be opened, the URL is re-interpreted using the FTP protocol. This can sometimes cause confusing error messages.

- The `urlopen()` and `urlretrieve()` functions can cause arbitrarily long delays while waiting for a network connection to be set up. This means that it is difficult to build an interactive Web client using these functions without using threads.

- The data returned by `urlopen()` or `urlretrieve()` is the raw data returned by the server. This may be binary data (such as an image), plain text or (for example) HTML. The HTTP protocol provides type information in the reply header, which can be inspected by looking at the `Content-Type` header. If the returned data is HTML, you can use the module `html.parser` to parse it.

- The code handling the FTP protocol cannot differentiate between
a file and a directory. This can lead to unexpected behavior when attempting to read a URL that points to a file that is not accessible. If the URL ends in a `/`, it is assumed to refer to a directory and will be handled accordingly. But if an attempt to read a file leads to a 550 error (meaning the URL cannot be found or is not accessible, often for permission reasons), then the path is treated as a directory in order to handle the case when a directory is specified by a URL but the trailing `/` has been left off. This can cause misleading results when you try to fetch a file whose read permissions make it inaccessible; the FTP code will try to read it, fail with a 550 error, and then perform a directory listing for the unreadable file. If fine-grained control is needed, consider using the `ftplib` module, subclassing `FancyURLopener`, or changing `_urloper` to meet your needs.
21.7. urllib.response — Response classes used by urllib

The urllib.response module defines functions and classes which define a minimal file like interface, including `read()` and `readline()`. The typical response object is an addinfourl instance, which defines an `info()` method and that returns headers and a `geturl()` method that returns the url. Functions defined by this module are used internally by the urllib.request module.
This module defines a standard interface to break Uniform Resource Locator (URL) strings up in components (addressing scheme, network location, path etc.), to combine the components back into a URL string, and to convert a “relative URL” to an absolute URL given a “base URL.”

The module has been designed to match the Internet RFC on Relative Uniform Resource Locators. It supports the following URL schemes: `file`, `ftp`, `gopher`, `hdl`, `http`, `https`, `imap`, `mailto`, `mms`, `news`, `nntp`, `prospero`, `rsync`, `rtsp`, `rtspu`, `sftp`, `shttp`, `sip`, `sips`, `snews`, `svn`, `svn+ssh`, `telnet`, `wais`, `ws`, `wss`.

The `urllib.parse` module defines functions that fall into two broad categories: URL parsing and URL quoting. These are covered in detail in the following sections.
21.8.1. URL Parsing

The URL parsing functions focus on splitting a URL string into its components, or on combining URL components into a URL string.

`urllib.parse.urlparse(urlstring, scheme='', allow_fragments=True)`

Parse a URL into six components, returning a 6-tuple. This corresponds to the general structure of a URL: `scheme://netloc/path;parameters?query#fragment`. Each tuple item is a string, possibly empty. The components are not broken up in smaller parts (for example, the network location is a single string), and % escapes are not expanded. The delimiters as shown above are not part of the result, except for a leading slash in the `path` component, which is retained if present. For example:

```python
>>> from urllib.parse import urlparse
>>> o = urlparse('http://www.cwi.nl:80/%7Eguido/Python.html')
>>> o
ParseResult(scheme='http', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html', params='', query='', fragment='')
>>> o.scheme
'http'
>>> o.port
80
>>> o.geturl()
'http://www.cwi.nl:80/%7Eguido/Python.html'
```

Following the syntax specifications in RFC 1808, `urlparse` recognizes a netloc only if it is properly introduced by ‘///’. Otherwise the input is presumed to be a relative URL and thus to start with a
path component.

```python
>>> from urllib.parse import urlparse

>>> urlparse('//www.cwi.nl:80/%7Eguido/Python.html')
ParseResult(scheme='', netloc='www.cwi.nl:80', params='', query='', fragment='')

>>> urlparse('www.cwi.nl/%7Eguido/Python.html')
ParseResult(scheme='', netloc='', path='www.cwi.nl', params='', query='', fragment='')

>>> urlparse('help/Python.html')
ParseResult(scheme='', netloc='', path='help/Python.html', query='', fragment='')
```

The `scheme` argument gives the default addressing scheme, to be used only if the URL does not specify one. It should be the same type (text or bytes) as `urlstring`, except that the default value `'.' is always allowed, and is automatically converted to `b''` if appropriate.

If the `allow_fragments` argument is false, fragment identifiers are not recognized. Instead, they are parsed as part of the path, parameters or query component, and fragment is set to the empty string in the return value.

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheme</td>
<td>0</td>
<td>URL scheme specifier</td>
<td><code>scheme parameter</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Network location</td>
<td></td>
</tr>
<tr>
<td>netloc</td>
<td>1</td>
<td>part</td>
<td>empty string</td>
</tr>
<tr>
<td>---------</td>
<td>---</td>
<td>------------</td>
<td>--------------</td>
</tr>
<tr>
<td>path</td>
<td>2</td>
<td>Hierarchical path</td>
<td>empty string</td>
</tr>
<tr>
<td>params</td>
<td>3</td>
<td>Parameters for last path element</td>
<td>empty string</td>
</tr>
<tr>
<td>query</td>
<td>4</td>
<td>Query component</td>
<td>empty string</td>
</tr>
<tr>
<td>fragment</td>
<td>5</td>
<td>Fragment identifier</td>
<td>empty string</td>
</tr>
<tr>
<td>username</td>
<td></td>
<td>User name</td>
<td>None</td>
</tr>
<tr>
<td>password</td>
<td></td>
<td>Password</td>
<td>None</td>
</tr>
<tr>
<td>hostname</td>
<td></td>
<td>Host name (lower case)</td>
<td>None</td>
</tr>
<tr>
<td>port</td>
<td></td>
<td>Port number as integer, if present</td>
<td>None</td>
</tr>
</tbody>
</table>

Reading the port attribute will raise a `ValueError` if an invalid port is specified in the URL. See section Structured Parse Results for more information on the result object.

Unmatched square brackets in the netloc attribute will raise a `ValueError`.

*Changed in version 3.2:* Added IPv6 URL parsing capabilities.

*Changed in version 3.3:* The fragment is now parsed for all URL schemes (unless `allow_fragment` is false), in accordance with RFC 3986. Previously, a whitelist of schemes that support fragments existed.

*Changed in version 3.6:* Out-of-range port numbers now raise `ValueError`, instead of returning `None`.

```python
urllib.parse.parse_qs(qs, keep_blank_values=False),
```
Parse a query string given as a string argument (data of type `application/x-www-form-urlencoded`). Data are returned as a dictionary. The dictionary keys are the unique query variable names and the values are lists of values for each name.

The optional argument `keep_blank_values` is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument `strict_parsing` is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a `ValueError` exception.

The optional `encoding` and `errors` parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the `bytes.decode()` method.

Use the `urllib.parse.urlencode()` function (with the `doseq` parameter set to `True`) to convert such dictionaries into query strings.

*Changed in version 3.2*: Add `encoding` and `errors` parameters.

```
urllib.parse.parse_qsl(qs, keep_blank_values=False, strict_parsing=False, encoding='utf-8', errors='replace')
```

Parse a query string given as a string argument (data of type `application/x-www-form-urlencoded`). Data are returned as a list of name, value pairs.
The optional argument \textit{keep\_blank\_values} is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument \textit{strict\_parsing} is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a \texttt{ValueError} exception.

The optional \texttt{encoding} and \texttt{errors} parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the \texttt{bytes.decode()} method.

Use the \texttt{urllib.parse.urlencode()} function to convert such lists of pairs into query strings.

\textit{Changed in version 3.2: Add \textit{encoding} and \textit{errors} parameters.}

\texttt{urllib.parse.urlunparse}(\texttt{parts})

Construct a URL from a tuple as returned by \texttt{urlparse()}. The \texttt{parts} argument can be any six-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a \texttt{?} with an empty query; the RFC states that these are equivalent).

\texttt{urllib.parse.urlsplit}(\texttt{urlstring}, \texttt{scheme=\\textquoteleft\\textquoteleft}, \texttt{allow\_fragments=True})

This is similar to \texttt{urlparse()}, but does not split the params from the URL. This should generally be used instead of \texttt{urlparse()} if the more recent URL syntax allowing parameters to be applied to each segment of the \textit{path} portion of the URL (see \texttt{RFC 2396} is
wanted. A separate function is needed to separate the path segments and parameters. This function returns a 5-tuple: (addressing scheme, network location, path, query, fragment identifier).

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheme</td>
<td>0</td>
<td>URL scheme specifier</td>
<td><code>scheme</code> parameter</td>
</tr>
<tr>
<td>netloc</td>
<td>1</td>
<td>Network location part</td>
<td>empty string</td>
</tr>
<tr>
<td>path</td>
<td>2</td>
<td>Hierarchical path</td>
<td>empty string</td>
</tr>
<tr>
<td>query</td>
<td>3</td>
<td>Query component</td>
<td>empty string</td>
</tr>
<tr>
<td>fragment</td>
<td>4</td>
<td>Fragment identifier</td>
<td>empty string</td>
</tr>
<tr>
<td>username</td>
<td></td>
<td>User name</td>
<td><code>None</code></td>
</tr>
<tr>
<td>password</td>
<td></td>
<td>Password</td>
<td><code>None</code></td>
</tr>
<tr>
<td>hostname</td>
<td></td>
<td>Host name (lower case)</td>
<td><code>None</code></td>
</tr>
<tr>
<td>port</td>
<td></td>
<td>Port number as integer, if present</td>
<td><code>None</code></td>
</tr>
</tbody>
</table>

Reading the `port` attribute will raise a `ValueError` if an invalid port is specified in the URL. See section `Structured Parse Results` for more information on the result object.

Unmatched square brackets in the `netloc` attribute will raise a `ValueError`. 
Changed in version 3.6: Out-of-range port numbers now raise `ValueError`, instead of returning `None`.

```
urllib.parse.urlunsplit(parts)
```

Combine the elements of a tuple as returned by `urlsplit()` into a complete URL as a string. The `parts` argument can be any five-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a ? with an empty query; the RFC states that these are equivalent).

```
urllib.parse.urljoin(base, url, allow_fragments=True)
```

Construct a full (“absolute”) URL by combining a “base URL” (`base`) with another URL (`url`). Informally, this uses components of the base URL, in particular the addressing scheme, the network location and (part of) the path, to provide missing components in the relative URL. For example:

```
>>> from urllib.parse import urljoin
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html', 'http://www.cwi.nl/%7Eguido/FAQ.html')
'http://www.cwi.nl/%7Eguido/FAQ.html'
```

The `allow_fragments` argument has the same meaning and default as for `urlparse()`.

**Note:** If `url` is an absolute URL (that is, starting with // or scheme://), the `url`’s host name and/or scheme will be present in the result. For example:

```
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html', 'http://www.python.org/%7Eguido')
'http://www.python.org/%7Eguido'
```
If you do not want that behavior, preprocess the `url` with `urlsplit()` and `urlunsplit()`, removing possible `scheme` and `netloc` parts.

*Changed in version 3.5:* Behaviour updated to match the semantics defined in RFC 3986.

`urllib.parse.urldefrag(url)`

If `url` contains a fragment identifier, return a modified version of `url` with no fragment identifier, and the fragment identifier as a separate string. If there is no fragment identifier in `url`, return `url` unmodified and an empty string.

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>0</td>
<td>URL with no fragment</td>
<td>empty string</td>
</tr>
<tr>
<td>fragment</td>
<td>1</td>
<td>Fragment identifier</td>
<td>empty string</td>
</tr>
</tbody>
</table>

See section Structured Parse Results for more information on the result object.

*Changed in version 3.2:* Result is a structured object rather than a simple 2-tuple.
21.8.2. Parsing ASCII Encoded Bytes

The URL parsing functions were originally designed to operate on character strings only. In practice, it is useful to be able to manipulate properly quoted and encoded URLs as sequences of ASCII bytes. Accordingly, the URL parsing functions in this module all operate on bytes and bytearray objects in addition to str objects.

If str data is passed in, the result will also contain only str data. If bytes or bytearray data is passed in, the result will contain only bytes data.

Attempting to mix str data with bytes or bytearray in a single function call will result in a TypeError being raised, while attempting to pass in non-ASCII byte values will trigger UnicodeDecodeError.

To support easier conversion of result objects between str and bytes, all return values from URL parsing functions provide either an encode() method (when the result contains str data) or a decode() method (when the result contains bytes data). The signatures of these methods match those of the corresponding str and bytes methods (except that the default encoding is 'ascii' rather than 'utf-8'). Each produces a value of a corresponding type that contains either bytes data (for encode() methods) or str data (for decode() methods).

Applications that need to operate on potentially improperly quoted URLs that may contain non-ASCII data will need to do their own decoding from bytes to characters before invoking the URL parsing methods.
The behaviour described in this section applies only to the URL parsing functions. The URL quoting functions use their own rules when producing or consuming byte sequences as detailed in the documentation of the individual URL quoting functions.

*Changed in version 3.2:* URL parsing functions now accept ASCII encoded byte sequences
21.8.3. Structured Parse Results

The result objects from the `urlparse()`, `urlsplit()` and `urldefrag()` functions are subclasses of the `tuple` type. These subclasses add the attributes listed in the documentation for those functions, the encoding and decoding support described in the previous section, as well as an additional method:

```
urllib.parse.SplitResult.geturl()
```

Return the re-combined version of the original URL as a string. This may differ from the original URL in that the scheme may be normalized to lower case and empty components may be dropped. Specifically, empty parameters, queries, and fragment identifiers will be removed.

For `urldefrag()` results, only empty fragment identifiers will be removed. For `urlsplit()` and `urlparse()` results, all noted changes will be made to the URL returned by this method.

The result of this method remains unchanged if passed back through the original parsing function:

```python
>>> from urllib.parse import urlsplit
>>> url = 'HTTP://www.Python.org/doc/#'
>>> r1 = urlsplit(url)
>>> r1.geturl()
'http://www.Python.org/doc/'
>>> r2 = urlsplit(r1.geturl())
>>> r2.geturl()
'http://www.Python.org/doc/'
```

The following classes provide the implementations of the structured
parse results when operating on \texttt{str} objects:

class urllib.parse.\textbf{DefragResult}(url, fragment)
Concrete class for \texttt{urldefrag()} results containing \texttt{str} data. The encode() method returns a \texttt{DefragResultBytes} instance.

\textit{New in version 3.2.}

class urllib.parse.\textbf{ParseResult}(scheme, netloc, path, params, query, fragment)
Concrete class for \texttt{urlparse()} results containing \texttt{str} data. The encode() method returns a \texttt{ParseResultBytes} instance.

class urllib.parse.\textbf{SplitResult}(scheme, netloc, path, query, fragment)
Concrete class for \texttt{urlsplit()} results containing \texttt{str} data. The encode() method returns a \texttt{SplitResultBytes} instance.

The following classes provide the implementations of the parse results when operating on \texttt{bytes} or \texttt{bytearray} objects:

class urllib.parse.\textbf{DefragResultBytes}(url, fragment)
Concrete class for \texttt{urldefrag()} results containing \texttt{bytes} data.
The decode() method returns a \texttt{DefragResult} instance.

\textit{New in version 3.2.}

class urllib.parse.\textbf{ParseResultBytes}(scheme, netloc, path, params, query, fragment)
Concrete class for \texttt{urlparse()} results containing \texttt{bytes} data.
The decode() method returns a \texttt{ParseResult} instance.

\textit{New in version 3.2.}
class urllib.parse.SplitResultBytes(scheme, netloc, path, query, fragment)

Concrete class for urlsplit() results containing bytes data. The decode() method returns a SplitResult instance.

New in version 3.2.
21.8.4. URL Quoting

The URL quoting functions focus on taking program data and making it safe for use as URL components by quoting special characters and appropriately encoding non-ASCII text. They also support reversing these operations to recreate the original data from the contents of a URL component if that task isn't already covered by the URL parsing functions above.

`urllib.parse.quote(string, safe='/', encoding=None, errors=None)`

Replace special characters in `string` using the %xx escape. Letters, digits, and the characters '_.-~' are never quoted. By default, this function is intended for quoting the path section of URL. The optional `safe` parameter specifies additional ASCII characters that should not be quoted — its default value is '/'.

`string` may be either a `str` or a `bytes`.

*Changed in version 3.7:* Moved from RFC 2396 to RFC 3986 for quoting URL strings. “~” is now included in the set of reserved characters.

The optional `encoding` and `errors` parameters specify how to deal with non-ASCII characters, as accepted by the `str.encode()` method. `encoding` defaults to 'utf-8'. `errors` defaults to 'strict', meaning unsupported characters raise a `UnicodeEncodeError`. `encoding` and `errors` must not be supplied if `string` is a `bytes`, or a `TypeError` is raised.

Note that `quote(string, safe, encoding, errors)` is
equivalent to
quote_from_bytes(string.encode(encoding, errors), safe).

Example: quote('/El Niño/') yields '/El%20Ni%C3%B1o/'.

urllib.parse.quote_plus(string, safe='', encoding=None, errors=None)

Like quote(), but also replace spaces by plus signs, as required for quoting HTML form values when building up a query string to go into a URL. Plus signs in the original string are escaped unless they are included in safe. It also does not have safe default to '/'.

Example: quote_plus('/El Niño/') yields '%2FEl+Ni%C3%B1o%2F'.

urllib.parse.quote_from_bytes(bytes, safe='/')

Like quote(), but accepts a bytes object rather than a str, and does not perform string-to-bytes encoding.

Example: quote_from_bytes(b'a&\xef') yields 'a%26%EF'.

urllib.parse.unquote(string, encoding='utf-8', errors='replace')

Replace %xx escapes by their single-character equivalent. The optional encoding and errors parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the bytes.decode() method.

string must be a str.

encoding defaults to 'utf-8'. errors defaults to 'replace', meaning invalid sequences are replaced by a placeholder character.
Example: `unquote('/El%20Ni%C3%B1o/')` yields `/El Niño/`.

`urllib.parse.unquote_plus(string, encoding='utf-8', errors='replace')`

Like `unquote()` but also replace plus signs by spaces, as required for unquoting HTML form values.

`string` must be a `str`.

Example: `unquote_plus('/El+Ni%C3%B1o/')` yields `/El Niño/`.

`urllib.parse.unquote_to_bytes(string)`

Replace `%xx` escapes by their single-octet equivalent, and return a `bytes` object.

`string` may be either a `str` or a `bytes`.

If it is a `str`, unescaped non-ASCII characters in `string` are encoded into UTF-8 bytes.

Example: `unquote_to_bytes('a%26%EF')` yields b'a&\xef'.

`urllib.parseurlencode(query, doseq=False, safe='', encoding=None, errors=None, quote_via=quote_plus)`

Convert a mapping object or a sequence of two-element tuples, which may contain `str` or `bytes` objects, to a percent-encoded ASCII text string. If the resultant string is to be used as a `data` for POST operation with the `urlopen()` function, then it should be encoded to bytes, otherwise it would result in a `TypeError`.

The resulting string is a series of `key=value` pairs separated by
'&' characters, where both key and value are quoted using the
quote_via function. By default, quote_plus() is used to quote
the values, which means spaces are quoted as a '+' character
and '/' characters are encoded as %2F, which follows the standard
for GET requests (application/x-www-form-urlencoded).
An alternate function that can be passed as quote_via is quote(),
which will encode spaces as %20 and not encode '/' characters.
For maximum control of what is quoted, use quote and specify a
value for safe.

When a sequence of two-element tuples is used as the query
argument, the first element of each tuple is a key and the second is
a value. The value element in itself can be a sequence and in that
case, if the optional parameter doseq is evaluates to True,
individual key=value pairs separated by '&' are generated for
each element of the value sequence for the key. The order of
parameters in the encoded string will match the order of parameter
tuples in the sequence.

The safe, encoding, and errors parameters are passed down to
quote_via (the encoding and errors parameters are only passed
when a query element is a str).

To reverse this encoding process, parse_qs() and
parse_qsl() are provided in this module to parse query strings
into Python data structures.

Refer to urllib examples to find out how urlenquote method can be
used for generating query string for a URL or data for POST.

Changed in version 3.2: Query parameter supports bytes and
string objects.
New in version 3.5: *quote_via* parameter.

**RFC 3986 - Uniform Resource Identifiers**
This is the current standard (STD66). Any changes to urllib.parse module should conform to this. Certain deviations could be observed, which are mostly for backward compatibility purposes and for certain de-facto parsing requirements as commonly observed in major browsers.

**RFC 2732 - Format for Literal IPv6 Addresses in URL’s.**
This specifies the parsing requirements of IPv6 URLs.

**RFC 2396 - Uniform Resource Identifiers (URI): Generic Syntax**
Document describing the generic syntactic requirements for both Uniform Resource Names (URNs) and Uniform Resource Locators (URLs).

**RFC 2368 - The mailto URL scheme.**
Parsing requirements for mailto URL schemes.

**RFC 1808 - Relative Uniform Resource Locators**
This Request For Comments includes the rules for joining an absolute and a relative URL, including a fair number of “Abnormal Examples” which govern the treatment of border cases.

**RFC 1738 - Uniform Resource Locators (URL)**
This specifies the formal syntax and semantics of absolute URLs.
21.9. `urllib.error` — Exception classes raised by `urllib.request`

**Source code:** Lib/urllib/error.py

The `urllib.error` module defines the exception classes for exceptions raised by `urllib.request`. The base exception class is `URLError`.

The following exceptions are raised by `urllib.error` as appropriate:

**exception `urllib.error.URLError`**

The handlers raise this exception (or derived exceptions) when they run into a problem. It is a subclass of `OSError`.

**reason**

The reason for this error. It can be a message string or another exception instance.

*Changed in version 3.3:* `URLError` has been made a subclass of `OSError` instead of `IOError`.

**exception `urllib.error.HTTPError`**

Though being an exception (a subclass of `URLError`), an `HTTPError` can also function as a non-exceptional file-like return value (the same thing that `urlopen()` returns). This is useful when handling exotic HTTP errors, such as requests for
authentication.

**code**

An HTTP status code as defined in RFC 2616. This numeric value corresponds to a value found in the dictionary of codes as found in `http.server.BaseHTTPRequestHandler.responses`.

**reason**

This is usually a string explaining the reason for this error.

**headers**

The HTTP response headers for the HTTP request that caused the HTTPError.

*New in version 3.4.*

**exception urllib.error.ContentTooShortError**(msg, content)

This exception is raised when the `urlretrieve()` function detects that the amount of the downloaded data is less than the expected amount (given by the `Content-Length` header). The `content` attribute stores the downloaded (and supposedly truncated) data.
This module provides a single class, `RobotFileParser`, which answers questions about whether or not a particular user agent can fetch a URL on the Web site that published the `robots.txt` file. For more details on the structure of `robots.txt` files, see [http://www.robotstxt.org/orig.html](http://www.robotstxt.org/orig.html).

```python
class urllib.robotparser.RobotFileParser(url='')
    This class provides methods to read, parse and answer questions about the robots.txt file at url.

    set_url(url)
        Sets the URL referring to a robots.txt file.

    read()
        Reads the robots.txt URL and feeds it to the parser.

    parse(lines)
        Parses the lines argument.

    can_fetch(useragent, url)
        Returns True if the useragent is allowed to fetch the url according to the rules contained in the parsed robots.txt file.
```
mtime()  
Returns the time the robots.txt file was last fetched. This is useful for long-running web spiders that need to check for new robots.txt files periodically.

modified()  
Sets the time the robots.txt file was last fetched to the current time.

crawl_delay(useragent)  
Returns the value of the Crawl-delay parameter from robots.txt for the useragent in question. If there is no such parameter or it doesn't apply to the useragent specified or the robots.txt entry for this parameter has invalid syntax, return None.

    New in version 3.6.

request_rate(useragent)  
Returns the contents of the Request-rate parameter from robots.txt as a named tuple RequestRate(requests, seconds). If there is no such parameter or it doesn't apply to the useragent specified or the robots.txt entry for this parameter has invalid syntax, return None.

    New in version 3.6.

The following example demonstrates basic use of the RobotFileParser class:

```python
>>> import urllib.robotparser
>>> rp = urllib.robotparser.RobotFileParser()
```
```python
>>> rp.set_url("http://www.musi-cal.com/robots.txt")
>>> rp.read()
>>> rrate = rp.request_rate("*")
>>> rrate.requests
3
>>> rrate.seconds
20
>>> rp.crawl_delay("*")
6
>>> rp.can_fetch("*", "http://www.musi-cal.com/cgi-bin/search?city=San+Francisco")
False
>>> rp.can_fetch("*", "http://www.musi-cal.com/")
True
```
21.11. http — HTTP modules

Source code: Lib/http/__init__.py

http is a package that collects several modules for working with the HyperText Transfer Protocol:

- http.client is a low-level HTTP protocol client; for high-level URL opening use urllib.request
- http.server contains basic HTTP server classes based on socketserver
- http.cookies has utilities for implementing state management with cookies
- http.cookiejar provides persistence of cookies

http is also a module that defines a number of HTTP status codes and associated messages through the http.HTTPStatus enum:

class http.HTTPStatus

    New in version 3.5.

    A subclass of enum.IntEnum that defines a set of HTTP status codes, reason phrases and long descriptions written in English.

Usage:

```python
>>> from http import HTTPStatus
>>> HTTPStatus.OK
<HTTPStatus.OK: 200>
>>> HTTPStatus.OK == 200
True
>>> http.HTTPStatus.OK.value
```
200

>>> HTTPStatus.OK.phrase
'OK'

>>> HTTPStatus.OK.description
'Request fulfilled, document follows'

>>> list(HTTPStatus)
[<HTTPStatus.CONTINUE: 100>, <HTTPStatus.SWITCHING_PROTOCOLS: 101>, ...]
21.11.1. HTTP status codes

Supported, IANA-registered status codes available in http.HTTPStatus are:

<table>

In order to preserve backwards compatibility, enum values are also present in the `http.client` module in the form of constants. The enum name is equal to the constant name (i.e. `http.HTTPStatus.OK` is also available as `http.client.OK`).

*Changed in version 3.7:* Added 421 `MISDIRECTED_REQUEST` status code.
21.12. **http.client** — HTTP protocol client

**Source code:** [Lib/http/client.py](http://example.com)

This module defines classes which implement the client side of the HTTP and HTTPS protocols. It is normally not used directly — the module `urllib.request` uses it to handle URLs that use HTTP and HTTPS.

**See also:** The [Requests package](http://example.com) is recommended for a higher-level HTTP client interface.

**Note:** HTTPS support is only available if Python was compiled with SSL support (through the `ssl` module).

The module provides the following classes:

```python
class http.client.HTTPConnection(host, port=None,
[timeout, ]source_address=None, blocksize=8192)
```

An `HTTPConnection` instance represents one transaction with an HTTP server. It should be instantiated passing it a host and optional port number. If no port number is passed, the port is extracted from the host string if it has the form `host:port`, else the default HTTP port (80) is used. If the optional `timeout` parameter is given, blocking operations (like connection attempts) will timeout after that many seconds (if it is not given, the global default timeout setting is used). The optional `source_address` parameter may be a tuple of a (host, port) to use as the source.
address the HTTP connection is made from. The optional blocksize parameter sets the buffer size in bytes for sending a file-like message body.

For example, the following calls all create instances that connect to the server at the same host and port:

```python
>>> h1 = http.client.HTTPConnection('www.python.org')
>>> h2 = http.client.HTTPConnection('www.python.org:80')
>>> h3 = http.client.HTTPConnection('www.python.org')
>>> h4 = http.client.HTTPConnection('www.python.org')
```

Changed in version 3.2: `source_address` was added.

Changed in version 3.4: The `strict` parameter was removed. HTTP 0.9-style “Simple Responses” are not longer supported.

Changed in version 3.7: `blocksize` parameter was added.

class http.client.HTTPSConnection(host, port=None, key_file=None, cert_file=None, [timeout, ]source_address=None, *, context=None, check_hostname=None, blocksize=8192)

A subclass of HTTPConnection that uses SSL for communication with secure servers. Default port is 443. If `context` is specified, it must be a ssl.SSLContext instance describing the various SSL options.

Please read Security considerations for more information on best practices.

Changed in version 3.2: `source_address`, `context` and `check_hostname` were added.
Changed in version 3.2: This class now supports HTTPS virtual hosts if possible (that is, if `ssl.HAS_SNI` is true).

Changed in version 3.4: The `strict` parameter was removed. HTTP 0.9-style “Simple Responses” are no longer supported.

Changed in version 3.4.3: This class now performs all the necessary certificate and hostname checks by default. To revert to the previous, unverified, behavior `ssl._create_unverified_context()` can be passed to the `context` parameter.

Deprecated since version 3.6: `key_file` and `cert_file` are deprecated in favor of `context`. Please use `ssl.SSLContext.load_cert_chain()` instead, or let `ssl.create_default_context()` select the system’s trusted CA certificates for you.

The `check_hostname` parameter is also deprecated; the `ssl.SSLContext.check_hostname` attribute of `context` should be used instead.

class http.client.HTTPResponse(sock, debuglevel=0, method=None, url=None)

Class whose instances are returned upon successful connection. Not instantiated directly by user.

Changed in version 3.4: The `strict` parameter was removed. HTTP 0.9 style “Simple Responses” are no longer supported.

The following exceptions are raised as appropriate:

exception http.client.HTTPException
The base class of the other exceptions in this module. It is a subclass of Exception.

exception http.client.NotConnected
A subclass of HTTPException.

exception http.client.InvalidURL
A subclass of HTTPException, raised if a port is given and is either non-numeric or empty.

exception http.client.UnknownProtocol
A subclass of HTTPException.

exception http.client.UnknownTransferEncoding
A subclass of HTTPException.

exception http.client.UnimplementedFileMode
A subclass of HTTPException.

exception http.client.IncompleteRead
A subclass of HTTPException.

exception http.client.ImproperConnectionState
A subclass of HTTPException.

exception http.client.CannotSendRequest
A subclass of ImproperConnectionState.

exception http.client.CannotSendHeader
A subclass of ImproperConnectionState.

exception http.client.ResponseNotReady
A subclass of ImproperConnectionState.
exception http.client.BadStatusLine
   A subclass of HTTPException. Raised if a server responds with a HTTP status code that we don’t understand.

exception http.client.LineTooLong
   A subclass of HTTPException. Raised if an excessively long line is received in the HTTP protocol from the server.

exception http.client.RemoteDisconnected
   A subclass of ConnectionResetError and BadStatusLine. Raised by HTTPConnection.getresponse() when the attempt to read the response results in no data read from the connection, indicating that the remote end has closed the connection.

   *New in version 3.5:* Previously, BadStatusLine('') was raised.

The constants defined in this module are:

http.client.HTTP_PORT
   The default port for the HTTP protocol (always 80).

http.client.HTTPS_PORT
   The default port for the HTTPS protocol (always 443).

http.client.responses
   This dictionary maps the HTTP 1.1 status codes to the W3C names.

   Example:
   http.client.responses[http.client.NOT_FOUND] is 'Not Found'.

See HTTP status codes for a list of HTTP status codes that are
available in this module as constants.
21.12.1. HTTPConnection Objects

HTTPConnection instances have the following methods:

```
HTTPConnection.request(method, url, body=None, headers={}, *, encode_chunked=False)
```

This will send a request to the server using the HTTP request method `method` and the selector `url`.

If `body` is specified, the specified data is sent after the headers are finished. It may be a `str`, a `bytes-like object`, an open `file object`, or an iterable of `bytes`. If `body` is a string, it is encoded as ISO-8859-1, the default for HTTP. If it is a bytes-like object, the bytes are sent as is. If it is a `file object`, the contents of the file is sent; this file object should support at least the `read()` method. If the file object is an instance of `io.TextIOBase`, the data returned by the `read()` method will be encoded as ISO-8859-1, otherwise the data returned by `read()` is sent as is. If `body` is an iterable, the elements of the iterable are sent as is until the iterable is exhausted.

The `headers` argument should be a mapping of extra HTTP headers to send with the request.

If `headers` contains neither Content-Length nor Transfer-Encoding, but there is a request body, one of those header fields will be added automatically. If `body` is `None`, the Content-Length header is set to 0 for methods that expect a body (PUT, POST, and PATCH). If `body` is a string or a bytes-like object that is not also a `file`, the Content-Length header is set to its length. Any other type of `body` (files and iterables in general) will be chunk-encoded, and the
Transfer-Encoding header will automatically be set instead of Content-Length.

The `encode_chunked` argument is only relevant if Transfer-Encoding is specified in headers. If `encode_chunked` is `False`, the HTTPConnection object assumes that all encoding is handled by the calling code. If it is `True`, the body will be chunk-encoded.

**Note:** Chunked transfer encoding has been added to the HTTP protocol version 1.1. Unless the HTTP server is known to handle HTTP 1.1, the caller must either specify the Content-Length, or must pass a `str` or bytes-like object that is not also a file as the body representation.

*New in version 3.2:* `body` can now be an iterable.

*Changed in version 3.6:* If neither Content-Length nor Transfer-Encoding are set in headers, file and iterable `body` objects are now chunk-encoded. The `encode_chunked` argument was added. No attempt is made to determine the Content-Length for file objects.

**HTTPConnection.getresponse()**

Should be called after a request is sent to get the response from the server. Returns an `HTTPResponse` instance.

**Note:** Note that you must have read the whole response before you can send a new request to the server.

*Changed in version 3.5:* If a `ConnectionError` or subclass is raised, the `HTTPConnection` object will be ready to reconnect when a new request is sent.

**HTTPConnection.set_debuglevel(level)**
Set the debugging level. The default debug level is 0, meaning no debugging output is printed. Any value greater than 0 will cause all currently defined debug output to be printed to stdout. The debuglevel is passed to any new HTTPResponse objects that are created.

*New in version 3.1.*

HTTPConnection.set_tunnel(host, port=None, headers=None)

Set the host and the port for HTTP Connect Tunnelling. This allows running the connection through a proxy server.

The host and port arguments specify the endpoint of the tunneled connection (i.e. the address included in the CONNECT request, *not* the address of the proxy server).

The headers argument should be a mapping of extra HTTP headers to send with the CONNECT request.

For example, to tunnel through a HTTPS proxy server running locally on port 8080, we would pass the address of the proxy to the HTTPSConnection constructor, and the address of the host that we eventually want to reach to the set_tunnel() method:

```python
>>> import http.client
>>> conn = http.client.HTTPSConnection("localhost
>>> conn.set_tunnel("www.python.org")
>>> conn.request("HEAD","/index.html")
```

*New in version 3.2.*

HTTPConnection.connect()

Connect to the server specified when the object was created. By
default, this is called automatically when making a request if the client does not already have a connection.

HTTPConnection.close()
Close the connection to the server.

HTTPConnection.blocksize
Buffer size in bytes for sending a file-like message body.

New in version 3.7.

As an alternative to using the request() method described above, you can also send your request step by step, by using the four functions below.

HTTPConnection.putrequest(method, url, skip_host=False, skip_accept_encoding=False)
This should be the first call after the connection to the server has been made. It sends a line to the server consisting of the method string, the url string, and the HTTP version (HTTP/1.1). To disable automatic sending of Host: or Accept-Encoding: headers (for example to accept additional content encodings), specify skip_host or skip_accept_encoding with non-False values.

HTTPConnection.putheader(header, argument[, ...])
Send an RFC 822-style header to the server. It sends a line to the server consisting of the header, a colon and a space, and the first argument. If more arguments are given, continuation lines are sent, each consisting of a tab and an argument.

HTTPConnection.endheaders(message_body=None, *, encode_chunked=False)
Send a blank line to the server, signalling the end of the headers.
The optional *message_body* argument can be used to pass a message body associated with the request.

If *encode_chunked* is **True**, the result of each iteration of *message_body* will be chunk-encoded as specified in [RFC 7230](https://tools.ietf.org/html/rfc7230), Section 3.3.1. How the data is encoded is dependent on the type of *message_body*. If *message_body* implements the buffer interface the encoding will result in a single chunk. If *message_body* is a `collections.abc.Iterable`, each iteration of *message_body* will result in a chunk. If *message_body* is a file object, each call to `.read()` will result in a chunk. The method automatically signals the end of the chunk-encoded data immediately after *message_body*.

**Note:** Due to the chunked encoding specification, empty chunks yielded by an iterator body will be ignored by the chunk-encoder. This is to avoid premature termination of the read of the request by the target server due to malformed encoding.

*New in version 3.6:* Chunked encoding support. The *encode_chunked* parameter was added.

**HTTPConnection**. **send**(*data*)

Send data to the server. This should be used directly only after the `endheaders()` method has been called and before `getresponse()` is called.
21.12.2. HTTPResponse Objects

An `HTTPResponse` instance wraps the HTTP response from the server. It provides access to the request headers and the entity body. The response is an iterable object and can be used in a `with` statement.

*Changed in version 3.5:* The `io.BufferedIOBase` interface is now implemented and all of its reader operations are supported.

`HTTPResponse.read([amt])`  
Reads and returns the response body, or up to the next `amt` bytes.

`HTTPResponse.readinto(b)`  
Reads up to the next `len(b)` bytes of the response body into the buffer `b`. Returns the number of bytes read.

*New in version 3.3.*

`HTTPResponse.getheader(name, default=None)`  
Return the value of the header `name`, or `default` if there is no header matching `name`. If there is more than one header with the name `name`, return all of the values joined by ‘,’. If ‘default’ is any iterable other than a single string, its elements are similarly returned joined by commas.

`HTTPResponse.getheaders()`  
Return a list of (header, value) tuples.

`HTTPResponse.fileno()`  
Return the `fileno` of the underlying socket.
HTTPResponse. **msg**

HTTPResponse. **version**
HTTP protocol version used by server. 10 for HTTP/1.0, 11 for HTTP/1.1.

HTTPResponse. **status**
Status code returned by server.

HTTPResponse. **reason**
Reason phrase returned by server.

HTTPResponse. **debuglevel**
A debugging hook. If `debuglevel` is greater than zero, messages will be printed to stdout as the response is read and parsed.

HTTPResponse. **closed**
Is `True` if the stream is closed.
21.12.3. Examples

Here is an example session that uses the GET method:

```python
>>> import http.client
>>> conn = http.client.HTTPSConnection("www.python.org")
>>> conn.request("GET", "/")
>>> r1 = conn.getresponse()
>>> print(r1.status, r1.reason)
200 OK
>>> data1 = r1.read()  # This will return entire content.
>>> # The following example demonstrates reading data in chunks.
>>> conn.request("GET", "/")
>>> r1 = conn.getresponse()
>>> while not r1.closed:
...     print(r1.read(200))  # 200 bytes
...b'<!doctype html>\n<!--[if"
...>>> # Example of an invalid request
>>> conn.request("GET", "/parrot.spam")
>>> r2 = conn.getresponse()
>>> print(r2.status, r2.reason)
404 Not Found
>>> data2 = r2.read()
>>> conn.close()
```

Here is an example session that uses the HEAD method. Note that the HEAD method never returns any data.

```python
>>> import http.client
>>> conn = http.client.HTTPSConnection("www.python.org")
>>> conn.request("HEAD", "/")
>>> res = conn.getresponse()
>>> print(res.status, res.reason)
```
Here is an example session that shows how to POST requests:

```python
>>> import http.client, urllib.parse
>>> params = urllib.parse.urlencode({'@number': 12524})
>>> headers = {'Content-type': 'application/x-www-form-urlencoded',
...            'Accept': 'text/plain'}
>>> conn = http.client.HTTPConnection("bugs.python.org")
>>> conn.request("POST", ", params, headers)
>>> response = conn.getresponse()
>>> print(response.status, response.reason)
302 Found
>>> data = response.read()
>>> data
b'Redirecting to <a href="http://bugs.python.org/issue12524">
>>> conn.close()
```

Client side HTTP PUT requests are very similar to POST requests. The difference lies only on the server side where HTTP server will allow resources to be created via PUT request. It should be noted that custom HTTP methods are also handled in `urllib.request.Request` by sending the appropriate `+method` attribute. Here is an example session that shows how to do PUT request using http.client:

```python
>>> # This creates an HTTP message
>>> # with the content of BODY as the enclosed representation
>>> # for the resource http://localhost:8080/file
```
>>> import http.client
>>> BODY = "***filecontents***"
>>> conn = http.client.HTTPConnection("localhost", 8080)
>>> conn.request("PUT", "/file", BODY)
>>> response = conn.getresponse()
>>> print(response.status, response.reason)
200, OK
21.12.4. HTTPMessage Objects

An `http.client.HTTPMessage` instance holds the headers from an HTTP response. It is implemented using the `email.message.Message` class.
21.13. `ftplib` — FTP protocol client

Source code: Lib/ftplib.py

This module defines the class `FTP` and a few related items. The `FTP` class implements the client side of the FTP protocol. You can use this to write Python programs that perform a variety of automated FTP jobs, such as mirroring other FTP servers. It is also used by the module `urllib.request` to handle URLs that use FTP. For more information on FTP (File Transfer Protocol), see Internet RFC 959.

Here's a sample session using the `ftplib` module:

```python
>>> from ftplib import FTP
>>> ftp = FTP('ftp.debian.org')  # connect to host
>>> ftp.login()  # user anonymous
'230 Login successful.'
>>> ftp.cwd('debian')  # change into "debian" directory
>>> ftp.retrlines('LIST')  # list directory contents
-rw-rw-r--  1 1176  1176  1063 Jun 15 10:18 README
...  
-drwxr-sr-x  5 1176  1176  4096 Dec 19  2000 pool
-drwxr-sr-x  4 1176  1176  4096 Nov 17  2008 project
-drwxr-xr-x  3 1176  1176  4096 Oct 10  2012 tools
'226 Directory send OK.'
>>> ftp.retrbinary('RETR README', open('README', 'wb'))  # transfer README
'226 Transfer complete.'
>>> ftp.quit()
```

The module defines the following items:
class ftplib.FTP(host='', user='', passwd='', acct='', timeout=None, source_address=None)

Return a new instance of the FTP class. When host is given, the method call connect(host) is made. When user is given, additionally the method call login(user, passwd, acct) is made (where passwd and acct default to the empty string when not given). The optional timeout parameter specifies a timeout in seconds for blocking operations like the connection attempt (if is not specified, the global default timeout setting will be used). source_address is a 2-tuple (host, port) for the socket to bind to as its source address before connecting.

The FTP class supports the with statement, e.g.:

```python
>>> from ftplib import FTP
>>> with FTP("ftp1.at.proftpd.org") as ftp:
...     ftp.login()
...     ftp.dir()
...
'230 Anonymous login ok, restrictions apply.'
dr-xr-xr-x  9 ftp      ftp    154 May  6
dr-xr-xr-x  9 ftp      ftp    154 May  6
dr-xr-xr-x  5 ftp      ftp    4096 May  6
dr-xr-xr-x  3 ftp      ftp    18 Jul 10

>>>```

Changed in version 3.2: Support for the with statement was added.

Changed in version 3.3: source_address parameter was added.

class ftplib.FTP_TLS(host='', user='', passwd='', acct='',
keyfile=None, certfile=None, context=None, timeout=None,
source_address=None)

A FTP subclass which adds TLS support to FTP as described in RFC 4217. Connect as usual to port 21 implicitly securing the FTP control connection before authenticating. Securing the data connection requires the user to explicitly ask for it by calling the \texttt{prot_p()} method. \texttt{context} is a \texttt{ssl.SSLContext} object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security considerations for best practices.

\texttt{keyfile} and \texttt{certfile} are a legacy alternative to \texttt{context} – they can point to PEM-formatted private key and certificate chain files (respectively) for the SSL connection.

\textit{New in version 3.2.}

\textit{Changed in version 3.3: source_address parameter was added.}

\textit{Changed in version 3.4:} The class now supports hostname check with \texttt{ssl.SSLContext.check_hostname} and Server Name Indication (see \texttt{ssl.HAS_SNI}).

\textit{Deprecated since version 3.6:} \texttt{keyfile} and \texttt{certfile} are deprecated in favor of \texttt{context}. Please use \texttt{ssl.SSLContext.load_cert_chain()} instead, or let \texttt{ssl.create_default_context()} select the system’s trusted CA certificates for you.

Here's a sample session using the \texttt{FTP_TLS} class:

```python
>>> ftps = FTP_TLS('ftp.pureftpd.org')
>>> ftps.login()
'230 Anonymous user logged in'
```
exception `ftplib.error_reply`
Exception raised when an unexpected reply is received from the server.

exception `ftplib.error_temp`
Exception raised when an error code signifying a temporary error (response codes in the range 400–499) is received.

exception `ftplib.error_perm`
Exception raised when an error code signifying a permanent error (response codes in the range 500–599) is received.

exception `ftplib.error_proto`
Exception raised when a reply is received from the server that does not fit the response specifications of the File Transfer Protocol, i.e. begin with a digit in the range 1–5.

`ftplib.all_errors`
The set of all exceptions (as a tuple) that methods of FTP instances may raise as a result of problems with the FTP connection (as opposed to programming errors made by the caller). This set includes the four exceptions listed above as well as `OSError`.

See also:

Module `netrc`
Parser for the `.netrc` file format. The file `.netrc` is typically
used by FTP clients to load user authentication information before prompting the user.
21.13.1. FTP Objects

Several methods are available in two flavors: one for handling text files and another for binary files. These are named for the command which is used followed by lines for the text version or binary for the binary version.

FTP instances have the following methods:

FTP.set_debuglevel(level)
Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

FTP.connect(host='', port=0, timeout=None, source_address=None)
Connect to the given host and port. The default port number is 21, as specified by the FTP protocol specification. It is rarely needed to specify a different port number. This function should be called only once for each instance; it should not be called at all if a host was given when the instance was created. All other methods can only be used after a connection has been made. The optional timeout parameter specifies a timeout in seconds for the connection attempt. If no timeout is passed, the global default timeout setting will be used. source_address is a 2-tuple (host, port) for the socket to bind to as its source address before connecting.

Changed in version 3.3: source_address parameter was added.
FTP. **getwelcome()**

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

FTP. **login**(user='anonymous', passwd='', acct='')

Log in as the given user. The passwd and acct parameters are optional and default to the empty string. If no user is specified, it defaults to 'anonymous'. If user is 'anonymous', the default passwd is 'anonymous@'. This function should be called only once for each instance, after a connection has been established; it should not be called at all if a host and user were given when the instance was created. Most FTP commands are only allowed after the client has logged in. The acct parameter supplies "accounting information"; few systems implement this.

FTP. **abort()**

Abort a file transfer that is in progress. Using this does not always work, but it's worth a try.

FTP. **sendcmd**(cmd)

Send a simple command string to the server and return the response string.

FTP. **voidcmd**(cmd)

Send a simple command string to the server and handle the response. Return nothing if a response code corresponding to success (codes in the range 200–299) is received. Raise error_reply otherwise.

FTP. **retrbinary**(cmd, callback, blocksize=8192, rest=None)

Retrieve a file in binary transfer mode. cmd should be an
appropriate RETR command: 'RETR filename'. The callback function is called for each block of data received, with a single bytes argument giving the data block. The optional blocksize argument specifies the maximum chunk size to read on the low-level socket object created to do the actual transfer (which will also be the largest size of the data blocks passed to callback). A reasonable default is chosen. rest means the same thing as in the transferrcmd() method.

**FTP. retrlines(cmd, callback=None)**
Retrieve a file or directory listing in ASCII transfer mode. cmd should be an appropriate RETR command (see retrbinary()) or a command such as LIST or NLST (usually just the string 'LIST'). LIST retrieves a list of files and information about those files. NLST retrieves a list of file names. The callback function is called for each line with a string argument containing the line with the trailing CRLF stripped. The default callback prints the line to sys.stdout.

**FTP. set_pasv(val)**
Enable “passive” mode if val is true, otherwise disable passive mode. Passive mode is on by default.

**FTP. storbinary(cmd, fp, blocksize=8192, callback=None, rest=None)**
Store a file in binary transfer mode. cmd should be an appropriate STOR command: "STOR filename". fp is a file object (opened in binary mode) which is read until EOF using its read() method in blocks of size blocksize to provide the data to be stored. The blocksize argument defaults to 8192. callback is an optional single parameter callable that is called on each block of data after it is
sent. rest means the same thing as in the \texttt{transfercmd()} method.

\textit{Changed in version 3.2: rest parameter added.}

\textbf{FTP. \texttt{storlines}(cmd, \textit{fp}, \textit{callback=\texttt{None}})}

Store a file in ASCII transfer mode. \textit{cmd} should be an appropriate \texttt{STOR} command (see \texttt{storbinary()}). Lines are read until EOF from the \textit{file object} \textit{fp} (opened in binary mode) using its \texttt{readline()} method to provide the data to be stored. \textit{callback} is an optional single parameter callable that is called on each line after it is sent.

\textbf{FTP. \texttt{transfercmd}(cmd, rest=\texttt{None})}

Initiate a transfer over the data connection. If the transfer is active, send an \texttt{EPRT} or \texttt{PORT} command and the transfer command specified by \textit{cmd}, and accept the connection. If the server is passive, send an \texttt{EPSV} or \texttt{PASV} command, connect to it, and start the transfer command. Either way, return the socket for the connection.

If optional \textit{rest} is given, a \texttt{REST} command is sent to the server, passing \textit{rest} as an argument. \textit{rest} is usually a byte offset into the requested file, telling the server to restart sending the file’s bytes at the requested offset, skipping over the initial bytes. Note however that RFC 959 requires only that \textit{rest} be a string containing characters in the printable range from ASCII code 33 to ASCII code 126. The \texttt{transfercmd()} method, therefore, converts \textit{rest} to a string, but no check is performed on the string’s contents. If the server does not recognize the \texttt{REST} command, an \texttt{error_reply} exception will be raised. If this happens, simply call \texttt{transfercmd()} without a \textit{rest} argument.
FTP. ntransfercmd(cmd, rest=None)

Like transfercmd(), but returns a tuple of the data connection and the expected size of the data. If the expected size could not be computed, None will be returned as the expected size. cmd and rest means the same thing as in transfercmd().

FTP. mlsd(path='', facts=[])

List a directory in a standardized format by using MLSD command (RFC 3659). If path is omitted the current directory is assumed. facts is a list of strings representing the type of information desired (e.g. ['type', 'size', 'perm']). Return a generator object yielding a tuple of two elements for every file found in path. First element is the file name, the second one is a dictionary containing facts about the file name. Content of this dictionary might be limited by the facts argument but server is not guaranteed to return all requested facts.

New in version 3.3.

FTP. nlist(argument[, ...])

Return a list of file names as returned by the NLST command. The optional argument is a directory to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the NLST command.

**Note:** If your server supports the command, mlsd() offers a better API.

FTP. dir(argument[, ...])

Produce a directory listing as returned by the LIST command, printing it to standard output. The optional argument is a directory
to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the LIST command. If the last argument is a function, it is used as a callback function as for retrlines(); the default prints to sys.stdout. This method returns None.

**Note:** If your server supports the command, mlsd() offers a better API.

**FTP. rename** *(fromname, toname)*

Rename file *fromname* on the server to *toname*.

**FTP. delete** *(filename)*

Remove the file named *filename* from the server. If successful, returns the text of the response, otherwise raises error_perm on permission errors or error_reply on other errors.

**FTP. cwd** *(pathname)*

Set the current directory on the server.

**FTP. mkd** *(pathname)*

Create a new directory on the server.

**FTP. pwd()**

Return the pathname of the current directory on the server.

**FTP. rmd** *(dirname)*

Remove the directory named *dirname* on the server.

**FTP. size** *(filename)*

Request the size of the file named *filename* on the server. On success, the size of the file is returned as an integer, otherwise
None is returned. Note that the SIZE command is not standardized, but is supported by many common server implementations.

**FTP.quit()**

Send a QUIT command to the server and close the connection. This is the “polite” way to close a connection, but it may raise an exception if the server responds with an error to the QUIT command. This implies a call to the close() method which renders the FTP instance useless for subsequent calls (see below).

**FTP.close()**

Close the connection unilaterally. This should not be applied to an already closed connection such as after a successful call to quit(). After this call the FTP instance should not be used any more (after a call to close() or quit() you cannot reopen the connection by issuing another login() method).
21.13.2. FTP_TLS Objects

**FTP_TLS** class inherits from **FTP**, defining these additional objects:

**FTP_TLS.** *ssl_version*

The SSL version to use (defaults to *ssl.PROTOCOL_SSLv23*).

**FTP_TLS.** *auth()*

Set up a secure control connection by using TLS or SSL, depending on what is specified in the *ssl_version* attribute.

*Changed in version 3.4:* The method now supports hostname check with *ssl.SSLContext.check_hostname* and *Server Name Indication* (see *ssl.HAS_SNI*).

**FTP_TLS.** *ccc()*

Revert control channel back to plaintext. This can be useful to take advantage of firewalls that know how to handle NAT with non-secure FTP without opening fixed ports.

*New in version 3.3.*

**FTP_TLS.** *prot_p()*

Set up secure data connection.

**FTP_TLS.** *prot_c()*

Set up clear text data connection.
21.14. **poplib — POP3 protocol client**

**Source code:** Lib/poplib.py

This module defines a class, **POP3**, which encapsulates a connection to a POP3 server and implements the protocol as defined in [RFC 1939](https://tools.ietf.org/html/rfc1939). The **POP3** class supports both the minimal and optional command sets from [RFC 1939](https://tools.ietf.org/html/rfc1939). The **POP3** class also supports the **STLS** command introduced in [RFC 2595](https://tools.ietf.org/html/rfc2595) to enable encrypted communication on an already established connection.

Additionally, this module provides a class **POP3_SSL**, which provides support for connecting to POP3 servers that use SSL as an underlying protocol layer.

Note that POP3, though widely supported, is obsolescent. The implementation quality of POP3 servers varies widely, and too many are quite poor. If your mailserver supports IMAP, you would be better off using the `imaplib.IMAP4` class, as IMAP servers tend to be better implemented.

The **poplib** module provides two classes:

```python
class poplib.POP3(host, port=POP3_PORT[, timeout])
```

This class implements the actual POP3 protocol. The connection is created when the instance is initialized. If `port` is omitted, the standard POP3 port (110) is used. The optional `timeout` parameter specifies a timeout in seconds for the connection attempt (if not
specified, the global default timeout setting will be used).

```python
class poplib.POP3_SSL(host, port=POP3_SSL_PORT, keyfile=None, certfile=None, timeout=None, context=None)
```

This is a subclass of `POP3` that connects to the server over an SSL encrypted socket. If `port` is not specified, 995, the standard POP3-over-SSL port is used. `timeout` works as in the `POP3` constructor. `context` is an optional `ssl.SSLContext` object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security considerations for best practices.

`keyfile` and `certfile` are a legacy alternative to `context` - they can point to PEM-formatted private key and certificate chain files, respectively, for the SSL connection.

*Changed in version 3.2:* `context` parameter added.

*Changed in version 3.4:* The class now supports hostname check with `ssl.SSLContext.check_hostname` and `Server Name Indication` (see `ssl.HAS_SNI`).

*Deprecated since version 3.6:* `keyfile` and `certfile` are deprecated in favor of `context`. Please use `ssl.SSLContext.load_cert_chain()` instead, or let `ssl.create_default_context()` select the system’s trusted CA certificates for you.

One exception is defined as an attribute of the `poplib` module:

```python
exception poplib.error_proto
```

Exception raised on any errors from this module (errors from `socket` module are not caught). The reason for the exception is
passed to the constructor as a string.

See also:

**Module imaplib**
The standard Python IMAP module.

**Frequently Asked Questions About Fetchmail**
The FAQ for the *fetchmail* POP/IMAP client collects information on POP3 server variations and RFC noncompliance that may be useful if you need to write an application based on the POP protocol.
21.14.1. POP3 Objects

All POP3 commands are represented by methods of the same name, in lower-case; most return the response text sent by the server.

An POP3 instance has the following methods:

**POP3.set_debuglevel**(level)
Set the instance's debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

**POP3.getwelcome()**
Returns the greeting string sent by the POP3 server.

**POP3.capa()**
Query the server's capabilities as specified in RFC 2449. Returns a dictionary in the form {'name': ['param'...]}. 

*New in version 3.4.*

**POP3.user**(username)
Send user command, response should indicate that a password is required.

**POP3.pass**(password)
Send password, response includes message count and mailbox size. Note: the mailbox on the server is locked until quit() is called.
POP3. **apop**(user, secret)
   Use the more secure APOP authentication to log into the POP3 server.

POP3. **rpop**(user)
   Use RPOP authentication (similar to UNIX r-commands) to log into POP3 server.

POP3. **stat**()
   Get mailbox status. The result is a tuple of 2 integers: (message count, mailbox size).

POP3. **list**([which])
   Request message list, result is in the form (response, ['mesg_num octets', ...], octets). If which is set, it is the message to list.

POP3. **retr**(which)
   Retrieve whole message number which, and set its seen flag. Result is in form (response, ['line', ...], octets).

POP3. **dele**(which)
   Flag message number which for deletion. On most servers deletions are not actually performed until QUIT (the major exception is Eudora QPOP, which deliberately violates the RFCs by doing pending deletes on any disconnect).

POP3. **rset**( )
   Remove any deletion marks for the mailbox.

POP3. **noop**( )
   Do nothing. Might be used as a keep-alive.
POP3. **quit()**

Signoff: commit changes, unlock mailbox, drop connection.

POP3. **top(which, howmuch)**

Retrieves the message header plus *howmuch* lines of the message after the header of message number *which*. Result is in form (response, ['line', ...], octets).

The POP3 TOP command this method uses, unlike the RETR command, doesn’t set the message’s seen flag; unfortunately, TOP is poorly specified in the RFCs and is frequently broken in off-brand servers. Test this method by hand against the POP3 servers you will use before trusting it.

POP3. **uidl(which=None)**

Return message digest (unique id) list. If *which* is specified, result contains the unique id for that message in the form 'response mesgnum uid', otherwise result is list (response, ['mesgnum uid', ...], octets).

POP3. **utf8()**

Try to switch to UTF-8 mode. Returns the server response if successful, raises error_proto if not. Specified in RFC 6856.

*New in version 3.5.*

POP3. **stls(context=None)**

Start a TLS session on the active connection as specified in RFC 2595. This is only allowed before user authentication.

*context* parameter is a *ssl.SSLContext* object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security
considerations for best practices.

This method supports hostname checking via \texttt{ssl\_SSLContext.check\_hostname} and \textit{Server Name Indication} (see \texttt{ssl.HAS\_SNI}).

\textit{New in version 3.4.}

Instances of \texttt{POP3\_SSL} have no additional methods. The interface of this subclass is identical to its parent.
21.14.2. POP3 Example

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```python
import getpass, poplib

M = poplib.POP3('localhost')
M.user(getpass.getuser())
M.pass_(getpass.getpass())
numMessages = len(M.list())[1]
for i in range(numMessages):
    for j in M.retr(i+1)[1]:
        print(j)
```

At the end of the module, there is a test section that contains a more extensive example of usage.
21.15. **imaplib** — IMAP4 protocol client

**Source code:** Lib/imaplib.py

This module defines three classes, **IMAP4**, **IMAP4_SSL** and **IMAP4_stream**, which encapsulate a connection to an IMAP4 server and implement a large subset of the IMAP4rev1 client protocol as defined in **RFC 2060**. It is backward compatible with IMAP4 (**RFC 1730**) servers, but note that the STATUS command is not supported in IMAP4.

Three classes are provided by the **imaplib** module, **IMAP4** is the base class:

```python
class imaplib.IMAP4(host='', port=IMAP4_PORT)
```

This class implements the actual IMAP4 protocol. The connection is created and protocol version (IMAP4 or IMAP4rev1) is determined when the instance is initialized. If *host* is not specified, "" (the local host) is used. If *port* is omitted, the standard IMAP4 port (143) is used.

The **IMAP4** class supports the **with** statement. When used like this, the IMAP4 **LOGOUT** command is issued automatically when the **with** statement exits. E.g.:

```
>>> from imaplib import IMAP4
>>> with IMAP4("domain.org") as M:
...     M.noop()
... ```
Changed in version 3.5: Support for the `with` statement was added.

Three exceptions are defined as attributes of the `IMAP4` class:

**exception IMAP4.error**

Exception raised on any errors. The reason for the exception is passed to the constructor as a string.

**exception IMAP4.abort**

IMAP4 server errors cause this exception to be raised. This is a sub-class of `IMAP4.error`. Note that closing the instance and instantiating a new one will usually allow recovery from this exception.

**exception IMAP4.readonly**

This exception is raised when a writable mailbox has its status changed by the server. This is a sub-class of `IMAP4.error`. Some other client now has write permission, and the mailbox will need to be re-opened to re-obtain write permission.

There’s also a subclass for secure connections:

```python
class imaplib.IMAP4_SSL(host='', port=IMAP4_SSL_PORT, keyfile=None, certfile=None, ssl_context=None)
```

This is a subclass derived from `IMAP4` that connects over an SSL encrypted socket (to use this class you need a socket module that was compiled with SSL support). If `host` is not specified, `'.'` (the local host) is used. If `port` is omitted, the standard IMAP4-over-SSL port (993) is used. `ssl_context` is a `ssl.SSLContext` object which
allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read Security considerations for best practices.

`keyfile` and `certfile` are a legacy alternative to `ssl_context` - they can point to PEM-formatted private key and certificate chain files for the SSL connection. Note that the `keyfile/certfile` parameters are mutually exclusive with `ssl_context`, a `ValueError` is raised if `keyfile/certfile` is provided along with `ssl_context`.

*Changed in version 3.3*: `ssl_context` parameter added.

*Changed in version 3.4*: The class now supports hostname check with `ssl.SSLContext.check_hostname` and Server Name Indication (see `ssl.HAS_SNI`).

*Deprecated since version 3.6*: `keyfile` and `certfile` are deprecated in favor of `ssl_context`. Please use `ssl.SSLContext.load_cert_chain()` instead, or let `ssl.create_default_context()` select the system’s trusted CA certificates for you.

The second subclass allows for connections created by a child process:

```python
class imaplib.IMAP4_stream(command)
```

This is a subclass derived from `IMAP4` that connects to the `stdin/stdout` file descriptors created by passing `command` to `subprocess.Popen()`.

The following utility functions are defined:

```python
imaplib.Internaldate2tuple(datestr)
```
Parse an IMAP4 INTERNALDATE string and return corresponding local time. The return value is a `time.struct_time` tuple or None if the string has wrong format.

`imaplib.Int2AP(num)`

Converts an integer into a string representation using characters from the set [A .. P].

`imaplib.ParseFlags(flagstr)`

Converts an IMAP4 FLAGS response to a tuple of individual flags.

`imaplib.Time2Internaldate(date_time)`

Convert `date_time` to an IMAP4 INTERNALDATE representation. The return value is a string in the form: "DD-Mmm-YYYY HH:MM:SS +HHMM" (including double-quotes). The `date_time` argument can be a number (int or float) representing seconds since epoch (as returned by `time.time()`), a 9-tuple representing local time an instance of `time.struct_time` (as returned by `time.localtime()`), an aware instance of `datetime.datetime`, or a double-quoted string. In the last case, it is assumed to already be in the correct format.

Note that IMAP4 message numbers change as the mailbox changes; in particular, after an EXPUNGE command performs deletions the remaining messages are renumbered. So it is highly advisable to use UIDs instead, with the UID command.

At the end of the module, there is a test section that contains a more extensive example of usage.

See also: Documents describing the protocol, and sources and binaries for servers implementing it, can all be found at the
University of Washington’s *IMAP Information Center* (https://www.washington.edu/imap/).
21.15.1. IMAP4 Objects

All IMAP4rev1 commands are represented by methods of the same name, either upper-case or lower-case.

All arguments to commands are converted to strings, except for AUTHENTICATE, and the last argument to APPEND which is passed as an IMAP4 literal. If necessary (the string contains IMAP4 protocol-sensitive characters and isn’t enclosed with either parentheses or double quotes) each string is quoted. However, the password argument to the LOGIN command is always quoted. If you want to avoid having an argument string quoted (eg: the flags argument to STORE) then enclose the string in parentheses (eg: r'("Deleted)').

Each command returns a tuple: (type, [data, ...]) where type is usually 'OK' or 'NO', and data is either the text from the command response, or mandated results from the command. Each data is either a string, or a tuple. If a tuple, then the first part is the header of the response, and the second part contains the data (ie: ‘literal’ value).

The message_set options to commands below is a string specifying one or more messages to be acted upon. It may be a simple message number ('1'), a range of message numbers ('2:4'), or a group of non-contiguous ranges separated by commas ('1:3, 6:9'). A range can contain an asterisk to indicate an infinite upper bound ('3:*').

An IMAP4 instance has the following methods:

IMAP4. **append**(mailbox, flags, date_time, message)

Append message to named mailbox.
**IMAP4. authenticate**(mechanism, authobject)

Authenticate command — requires response processing.

*mechanism* specifies which authentication mechanism is to be used - it should appear in the instance variable capabilities in the form AUTH=mechanism.

*authobject* must be a callable object:

```python
data = authobject(response)
```

It will be called to process server continuation responses; the *response* argument it is passed will be bytes. It should return bytes *data* that will be base64 encoded and sent to the server. It should return *None* if the client abort response * should be sent instead.

*Changed in version 3.5:* string usernames and passwords are now encoded to *utf-8* instead of being limited to ASCII.

**IMAP4. check()**

Checkpoint mailbox on server.

**IMAP4. close()**

Close currently selected mailbox. Deleted messages are removed from writable mailbox. This is the recommended command before LOGOUT.

**IMAP4. copy**(message_set, new_mailbox)

Copy *message_set* messages onto end of *new_mailbox*.

**IMAP4. create**(mailbox)

Create new mailbox named *mailbox*. 
**IMAP4.** `delete(mailbox)`  
Delete old mailbox named `mailbox`.

**IMAP4.** `deleteacl(mailbox, who)`  
Delete the ACLs (remove any rights) set for who on mailbox.

**IMAP4.** `enable(capability)`  
Enable `capability` (see RFC 5161). Most capabilities do not need to be enabled. Currently only the `UTF8=ACCEPT` capability is supported (see RFC 6855).

*New in version 3.5:* The `enable()` method itself, and RFC 6855 support.

**IMAP4.** `expunge()`  
Permanently remove deleted items from selected mailbox. Generates an EXPUNGE response for each deleted message. Returned data contains a list of EXPUNGE message numbers in order received.

**IMAP4.** `fetch(message_set, message_parts)`  
Fetch (parts of) messages. `message_parts` should be a string of message part names enclosed within parentheses, eg: "(UID BODY[TEXT])". Returned data are tuples of message part envelope and data.

**IMAP4.** `getacl(mailbox)`  
Get the ACLs for `mailbox`. The method is non-standard, but is supported by the Cyrus server.

**IMAP4.** `getannotation(mailbox, entry, attribute)`  
Retrieve the specified ANNOTATIONs for `mailbox`. The method is
non-standard, but is supported by the Cyrus server.

**IMAP4. getquota(root)**

Get the quota root’s resource usage and limits. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

**IMAP4. getquotaroot(mailbox)**

Get the list of quota roots for the named mailbox. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

**IMAP4. list([directory[, pattern]])**

List mailbox names in directory matching pattern. directory defaults to the top-level mail folder, and pattern defaults to match anything. Returned data contains a list of LIST responses.

**IMAP4. login(user, password)**

Identify the client using a plaintext password. The password will be quoted.

**IMAP4. login_cram_md5(user, password)**

Force use of CRAM-MD5 authentication when identifying the client to protect the password. Will only work if the server CAPABILITY response includes the phrase AUTH=CRAM-MD5.

**IMAP4. logout()**

Shutdown connection to server. Returns server BYE response.

**IMAP4. lsub(directory=",", pattern=*)**

List subscribed mailbox names in directory matching pattern. directory defaults to the top level directory and pattern defaults to match any mailbox. Returned data are tuples of message part envelope and data.
IMAP4. **myrights**(mailbox)
   Show my ACLs for a mailbox (i.e. the rights that I have on mailbox).

IMAP4. **namespace()**
   Returns IMAP namespaces as defined in RFC2342.

IMAP4. **noop()**
   Send N00P to server.

IMAP4. **open**(host, port)
   Opens socket to port at host. This method is implicitly called by the IMAP4 constructor. The connection objects established by this method will be used in the IMAP4.read(), IMAP4.readline(), IMAP4.send(), and IMAP4.shutdown() methods. You may override this method.

IMAP4. **partial**(message_num, message_part, start, length)
   Fetch truncated part of a message. Returned data is a tuple of message part envelope and data.

IMAP4. **proxyauth**(user)
   Assume authentication as user. Allows an authorised administrator to proxy into any user’s mailbox.

IMAP4. **read**(size)
   Reads size bytes from the remote server. You may override this method.

IMAP4. **readline()**
   Reads one line from the remote server. You may override this method.
**IMAP4.** **recent()**

Prompt server for an update. Returned data is None if no new messages, else value of RECENT response.

**IMAP4.** **rename(oldmailbox, newmailbox)**

Rename mailbox named oldmailbox to newmailbox.

**IMAP4.** **response(code)**

Return data for response code if received, or None. Returns the given code, instead of the usual type.

**IMAP4.** **search(charset, criterion[,...])**

Search mailbox for matching messages. charset may be None, in which case no CHARSET will be specified in the request to the server. The IMAP protocol requires that at least one criterion be specified; an exception will be raised when the server returns an error. charset must be None if the UTF8=ACCEPT capability was enabled using the *enable()* command.

Example:

```python
# M is a connected IMAP4 instance...
typ, msgnums = M.search(None, 'FROM', '"LDJ"')
# or:
typ, msgnums = M.search(None, '(FROM "LDJ")')
```

**IMAP4.** **select(mailbox='INBOX', readonly=False)**

Select a mailbox. Returned data is the count of messages in mailbox (EXISTS response). The default mailbox is 'INBOX'. If the readonly flag is set, modifications to the mailbox are not allowed.
**IMAP4. send**(*data*)

Sends data to the remote server. You may override this method.

**IMAP4. setacl**(*mailbox, who, what*)

Set an ACL for *mailbox*. The method is non-standard, but is supported by the *Cyrus* server.

**IMAP4. setannotation**(*mailbox, entry, attribute[,...]*)

Set ANNOTATIONs for *mailbox*. The method is non-standard, but is supported by the *Cyrus* server.

**IMAP4. setquota**(*root, limits*)

Set the quota *root’s* resource *limits*. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

**IMAP4. shutdown**()

Close connection established in open. This method is implicitly called by **IMAP4. logout()**. You may override this method.

**IMAP4. socket**()

Returns socket instance used to connect to server.

**IMAP4. sort**(*sort_criteria, charset, search_criterion[,...]*)

The *sort* command is a variant of *search* with sorting semantics for the results. Returned data contains a space separated list of matching message numbers.

Sort has two arguments before the *search_criterion* argument(s); a parenthesized list of *sort_criteria*, and the searching *charset*. Note that unlike *search*, the searching *charset* argument is mandatory. There is also a *uid sort* command which corresponds to *sort*
the way that `uid search` corresponds to `search`. The `sort` command first searches the mailbox for messages that match the given searching criteria using the charset argument for the interpretation of strings in the searching criteria. It then returns the numbers of matching messages.

This is an **IMAP4rev1** extension command.

**IMAP4. `starttls`** *(ssl_context=None)*

Send a `STARTTLS` command. The `ssl_context` argument is optional and should be a `ssl.SSLContext` object. This will enable encryption on the IMAP connection. Please read *Security considerations* for best practices.

*New in version 3.2.*

*Changed in version 3.4:* The method now supports hostname check with `ssl.SSLContext.check_hostname` and *Server Name Indication* (see `ssl.HAS_SNI`).

**IMAP4. `status`** *(mailbox, names)*

Request named status conditions for `mailbox`.

**IMAP4. `store`** *(message_set, command, flag_list)*

Alters flag dispositions for messages in mailbox. `command` is specified by section 6.4.6 of *RFC 2060* as being one of “FLAGS”, “+FLAGS”, or “-FLAGS”, optionally with a suffix of “.SILENT”.

For example, to set the delete flag on all messages:

```python
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    M.store(num, '+FLAGS', '\\Deleted')
```
Note: Creating flags containing ']' (for example: "[test]") violates RFC 3501 (the IMAP protocol). However, imaplib has historically allowed creation of such tags, and popular IMAP servers, such as Gmail, accept and produce such flags. There are non-Python programs which also create such tags. Although it is an RFC violation and IMAP clients and servers are supposed to be strict, imaplib nonetheless continues to allow such tags to be created for backward compatibility reasons, and as of python 3.6, handles them if they are sent from the server, since this improves real-world compatibility.

IMAP4. `subscribe(mailbox)`

Subscribe to new mailbox.

IMAP4. `thread(threading_algorithm, charset, search_criterion[, ...])`

The `thread` command is a variant of `search` with threading semantics for the results. Returned data contains a space separated list of thread members.

Thread members consist of zero or more messages numbers, delimited by spaces, indicating successive parent and child.

Thread has two arguments before the `search_criterion` argument(s); a `threading_algorithm`, and the searching `charset`. Note that unlike `search`, the searching `charset` argument is mandatory. There is also a `uid thread` command which corresponds to `thread` the way that `uid search` corresponds to `search`. The `thread` command first searches the mailbox for messages that match the given searching criteria using the charset argument for the interpretation of strings in the searching criteria. It
then returns the matching messages threaded according to the specified threading algorithm.

This is an IMAP4rev1 extension command.

**IMAP4.** *uid*(command, arg[, ...])

Execute command args with messages identified by UID, rather than message number. Returns response appropriate to command. At least one argument must be supplied; if none are provided, the server will return an error and an exception will be raised.

**IMAP4.** *unsubscribe*(mailbox)

Unsubscribe from old mailbox.

**IMAP4.** *xatom*(name[, ...])

Allow simple extension commands notified by server in **CAPABILITY** response.

The following attributes are defined on instances of **IMAP4**:

**IMAP4.** *PROTOCOL_VERSION*

The most recent supported protocol in the **CAPABILITY** response from the server.

**IMAP4.** *debug*

Integer value to control debugging output. The initialize value is taken from the module variable **Debug**. Values greater than three trace each command.

**IMAP4.** *utf8_enabled*

Boolean value that is normally False, but is set to True if an **enable()** command is successfully issued for the UTF8=ACCEPT
capability.

New in version 3.5.
21.15.2. IMAP4 Example

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```python
import getpass, imaplib

M = imaplib.IMAP4()
M.login(getpass.getuser(), getpass.getpass())
M.select()

typ, data = M.search(None, 'ALL')
for num in data[0].split():
    typ, data = M.fetch(num, '(RFC822)'
    print('Message %s
%s
' % (num, data[0][1]))
M.close()
M.logout()
```
21.16. **nntplib** — NNTP protocol client

**Source code:** Lib/nntplib.py

This module defines the class `NNTP` which implements the client side of the Network News Transfer Protocol. It can be used to implement a news reader or poster, or automated news processors. It is compatible with [RFC 3977](https://tools.ietf.org/html/rfc3977) as well as the older [RFC 977](https://tools.ietf.org/html/rfc977) and [RFC 2980](https://tools.ietf.org/html/rfc2980).

Here are two small examples of how it can be used. To list some statistics about a newsgroup and print the subjects of the last 10 articles:

```python
>>> s = nntplib.NNTP('news.gmane.org')
>>> resp, count, first, last, name = s.group('gmane.comp.python.committers')
>>> print('Group', name, 'has', count, 'articles, range', first, '-', last)
Group gmane.comp.python.committers has 1096 articles, range 1 to 1096
>>> resp, overviews = s.over((last - 9, last))
>>> for id, over in overviews:
...     print(id, nntplib.decode_header(over['subject']))
1087 Re: Commit privileges for Łukasz Langa
1088 Re: 3.2 alpha 2 freeze
1089 Re: 3.2 alpha 2 freeze
1090 Re: Commit privileges for Łukasz Langa
1091 Re: Commit privileges for Łukasz Langa
1092 Updated ssh key
1093 Re: Updated ssh key
1094 Re: Updated ssh key
1095 Hello fellow committers!
1096 Re: Hello fellow committers!
```
To post an article from a binary file (this assumes that the article has valid headers, and that you have right to post on the particular newsgroup):

```python
>>> s = nntplib.NNTP('news.gmane.org')
>>> f = open('article.txt', 'rb')
>>> s.post(f)
'240 Article posted successfully.'
>>> s.quit()
'205 Bye!'
```

The module itself defines the following classes:

```python
class nntplib.NNTP(host, port=119, user=None, password=None, readermode=None, usenetrc=False[, timeout])
```

Return a new **NNTP** object, representing a connection to the NNTP server running on host `host`, listening at port `port`. An optional `timeout` can be specified for the socket connection. If the optional `user` and `password` are provided, or if suitable credentials are present in `/netrc` and the optional flag `usenetrc` is true, the **AUTHINFO USER** and **AUTHINFO PASS** commands are used to identify and authenticate the user to the server. If the optional flag `readermode` is true, then a **mode reader** command is sent before authentication is performed. Reader mode is sometimes necessary if you are connecting to an NNTP server on the local machine and intend to call reader-specific commands, such as **group**. If you get unexpected **NNTPPermanentErrors**, you might need to set `readermode`. The **NNTP** class supports the **with** statement to unconditionally consume **OSError** exceptions and to close the
NNTP connection when done, e.g.:

```python
>>> from nntplib import NNTP
>>> with NNTP('news.gmane.org') as n:
...    n.group('gmane.comp.python.committers')
...
('211 1755 1 1755 gmane.comp.python.committers',
```

*Changed in version 3.2:* `usenetrc` is now `False` by default.

*Changed in version 3.3:* Support for the `with` statement was added.

```python
class nntplib.NNTP_SSL(host, port=563, user=None, password=None, ssl_context=None, readermode=None, usenetrc=False[, timeout])
```

Return a new `NNTP_SSL` object, representing an encrypted connection to the NNTP server running on host `host`, listening at port `port`. `NNTP_SSL` objects have the same methods as `NNTP` objects. If `port` is omitted, port 563 (NNTPS) is used. `ssl_context` is also optional, and is a `SSLContext` object. Please read Security considerations for best practices. All other parameters behave the same as for `NNTP`.

Note that SSL-on-563 is discouraged per RFC 4642, in favor of STARTTLS as described below. However, some servers only support the former.

*New in version 3.2.*

*Changed in version 3.4:* The class now supports hostname check with `ssl.SSLContext.check_hostname` and `Server Name...`
Indication (see ssl.HAS_SNI).

exception nntplib.NNTPError
Derived from the standard exception Exception, this is the base class for all exceptions raised by the nntplib module. Instances of this class have the following attribute:

**response**
The response of the server if available, as a str object.

exception nntplib.NNTPReplyError
Exception raised when an unexpected reply is received from the server.

exception nntplib.NNTPTemporaryError
Exception raised when a response code in the range 400–499 is received.

exception nntplib.NNTPPermanentError
Exception raised when a response code in the range 500–599 is received.

exception nntplib.NNTPProtocolError
Exception raised when a reply is received from the server that does not begin with a digit in the range 1–5.

exception nntplib.NNTPDataError
Exception raised when there is some error in the response data.
21.16.1. NNTP Objects

When connected, `NNTP` and `NNTP_SSL` objects support the following methods and attributes.

21.16.1.1. Attributes

**NNTP.** `nntp_version`

An integer representing the version of the NNTP protocol supported by the server. In practice, this should be 2 for servers advertising **RFC 3977** compliance and 1 for others.

*New in version 3.2.*

**NNTP.** `nntp_implementation`

A string describing the software name and version of the NNTP server, or **None** if not advertised by the server.

*New in version 3.2.*

21.16.1.2. Methods

The *response* that is returned as the first item in the return tuple of almost all methods is the server’s response: a string beginning with a three-digit code. If the server’s response indicates an error, the method raises one of the above exceptions.

Many of the following methods take an optional keyword-only argument `file`. When the `file` argument is supplied, it must be either a `file object` opened for binary writing, or the name of an on-disk file to be written to. The method will then write any data returned by the
server (except for the response line and the terminating dot) to the file; any list of lines, tuples or objects that the method normally returns will be empty.

*Changed in version 3.2:* Many of the following methods have been reworked and fixed, which makes them incompatible with their 3.1 counterparts.

**NNTP.** `quit()`

Send a QUIT command and close the connection. Once this method has been called, no other methods of the NNTP object should be called.

**NNTP.** `getwelcome()`

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

**NNTP.** `getcapabilities()`

Return the RFC 3977 capabilities advertised by the server, as a `dict` instance mapping capability names to (possibly empty) lists of values. On legacy servers which don’t understand the CAPABILITIES command, an empty dictionary is returned instead.

```python
>>> s = NNTP('news.gmane.org')
>>> 'POST' in s.getcapabilities()
True
```

*New in version 3.2.*

**NNTP.** `login(user=None, password=None, usenetrc=True)`

Send AUTHINFO commands with the user name and password. If
user and password are None and usenetrc is true, credentials from ~/.netrc will be used if possible.

Unless intentionally delayed, login is normally performed during the NNTP object initialization and separately calling this function is unnecessary. To force authentication to be delayed, you must not set user or password when creating the object, and must set usenetrc to False.

New in version 3.2.

NNTP.starttls(ssl_context=None)

Send a STARTTLS command. This will enable encryption on the NNTP connection. The ssl_context argument is optional and should be a ssl.SSLContext object. Please read Security considerations for best practices.

Note that this may not be done after authentication information has been transmitted, and authentication occurs by default if possible during a NNTP object initialization. See NNTP.login() for information on suppressing this behavior.

New in version 3.2.

Changed in version 3.4: The method now supports hostname check with ssl.SSLContext.check_hostname and Server Name Indication (see ssl.HAS_SNI).

NNTP.newgroups(date, *, file=None)

Send a NEWGROUPS command. The date argument should be a datetime.date or datetime.datetime object. Return a pair (response, groups) where groups is a list representing the groups that are new since the given date. If file is supplied, though,
then groups will be empty.

```python
>>> from datetime import date, timedelta
>>> resp, groups = s.newgroups(date.today() - timedelta(days=4))
>>> len(groups)
85
>>> groups[0]
GroupInfo(group='gmane.network.tor.devel', last='4', first='1', flag='m')
```

NNTP. `newnews(group, date, *, file=None)`

Send a NEWNEWS command. Here, `group` is a group name or `'*'`, and `date` has the same meaning as for `newgroups()`. Return a pair `(response, articles)` where `articles` is a list of message ids.

This command is frequently disabled by NNTP server administrators.

NNTP. `list(group_pattern=None, *, file=None)`

Send a LIST or LIST ACTIVE command. Return a pair `(response, list)` where `list` is a list of tuples representing all the groups available from this NNTP server, optionally matching the pattern string `group_pattern`. Each tuple has the form `(group, last, first, flag)`, where `group` is a group name, `last` and `first` are the last and first article numbers, and `flag` usually takes one of these values:

- `y`: Local postings and articles from peers are allowed.
- `m`: The group is moderated and all postings must be approved.
- `n`: No local postings are allowed, only articles from peers.
- `j`: Articles from peers are filed in the junk group instead.
- `x`: No local postings, and articles from peers are ignored.
- `=foo.bar`: Articles are filed in the `foo.bar` group instead.

If `flag` has another value, then the status of the newsgroup should be considered unknown.

This command can return very large results, especially if `group_pattern` is not specified. It is best to cache the results offline unless you really need to refresh them.

*Changed in version 3.2: `group_pattern` was added.*

**NNTP. descriptions(grouppattern)**

Send a `LIST NEWSGROUPS` command, where `grouppattern` is a wildmat string as specified in [RFC 3977](https://tools.ietf.org/html/rfc3977) (it's essentially the same as DOS or UNIX shell wildcard strings). Return a pair `(response, descriptions)`, where `descriptions` is a dictionary mapping group names to textual descriptions.

```python
>>> resp, descs = s.descriptions('gmane.comp.python.*
>>> len(descs)
295
>>> descs.popitem()
('gmane.comp.python.bio.general', 'BioPython discussion list (Moderated)')
```

**NNTP. description(group)**

Get a description for a single group `group`. If more than one group matches (if `group` is a real wildmat string), return the first match. If no group matches, return an empty string.

This elides the response code from the server. If the response code is needed, use `descriptions()`.

**NNTP. group(name)**
Send a **GROUP** command, where *name* is the group name. The group is selected as the current group, if it exists. Return a tuple `(response, count, first, last, name)` where *count* is the (estimated) number of articles in the group, *first* is the first article number in the group, *last* is the last article number in the group, and *name* is the group name.

**NNTP. over**(message_spec, *, file=None)

Send an **OVER** command, or an **XOVER** command on legacy servers. *message_spec* can be either a string representing a message id, or a *(first, last)* tuple of numbers indicating a range of articles in the current group, or a *(first, None)* tuple indicating a range of articles starting from *first* to the last article in the current group, or **None** to select the current article in the current group.

Return a pair `(response, overviews)`. *overviews* is a list of *(article_number, overview)* tuples, one for each article selected by *message_spec*. Each *overview* is a dictionary with the same number of items, but this number depends on the server. These items are either message headers (the key is then the lower-cased header name) or metadata items (the key is then the metadata name prepended with ":"). The following items are guaranteed to be present by the NNTP specification:

- the *subject*, *from*, *date*, *message-id* and *references* headers
- the *:bytes* metadata: the number of bytes in the entire raw article (including headers and body)
- the *:lines* metadata: the number of lines in the article body

The value of each item is either a string, or **None** if not present.
It is advisable to use the `decode_header()` function on header values when they may contain non-ASCII characters:

```python
>>> _, _, first, last, _ = s.group('gmane.comp.python.devel')
>>> resp, overviews = s.over((last, last))
>>> art_num, over = overviews[0]
>>> art_num
117216
>>> list(over.keys())
['xref', 'from', ':lines', ':bytes', 'references'
>>> over['from']
'=?UTF-8?B?Ik1hcnRpbjB2LiBm7Z3aXMi=?= <martin@v.loewis.de>
>>> nntplib.decode_header(over['from'])
'Martin v. Löwis' <martin@v.loewis.de>'
```

New in version 3.2.

**NNTP**. `help(*, file=None)`

Send a HELP command. Return a pair `(response, list)` where `list` is a list of help strings.

**NNTP**. `stat(message_spec=None)`

Send a STAT command, where `message_spec` is either a message id (enclosed in `'<' and '>'+') or an article number in the current group. If `message_spec` is omitted or `None`, the current article in the current group is considered. Return a triple `(response, number, id)` where `number` is the article number and `id` is the message id.

```python
>>> _, _, first, last, _ = s.group('gmane.comp.python.devel')
>>> resp, number, message_id = s.stat(first)
>>> number, message_id
(9099, '<20030112190404.GE29873@epoch.metaslash.com>')
```
NNTP. `next()`

Send a NEXT command. Return as for `stat()`.

NNTP. `last()`

Send a LAST command. Return as for `stat()`.

NNTP. `article(message_spec=None, *, file=None)`

Send an ARTICLE command, where `message_spec` has the same meaning as for `stat()`. Return a tuple `(response, info)` where `info` is a namedtuple with three attributes `number`, `message_id` and `lines` (in that order). `number` is the article number in the group (or 0 if the information is not available), `message_id` the message id as a string, and `lines` a list of lines (without terminating newlines) comprising the raw message including headers and body.

```python
>>> resp, info = s.article('<20030112190404.GE29873@epoch.metaslash.com>
>>> info.number
0
>>> info.message_id
'<20030112190404.GE29873@epoch.metaslash.com>'
>>> len(info.lines)
65
>>> info.lines[0]
b'Path: main.gmane.org!not-for-mail'
>>> info.lines[1]
b'From: Neal Norwitz <neal@metaslash.com>'
>>> info.lines[3]:
[b'There is a patch for 2.3 as well as 2.2.', b'
```

NNTP. `head(message_spec=None, *, file=None)`

Same as `article()`, but sends a HEAD command. The `lines`
returned (or written to file) will only contain the message headers, not the body.

**NNTP. body**(*message_spec=*, *, *file=*)

Same as `article()`, but sends a BODY command. The lines returned (or written to file) will only contain the message body, not the headers.

**NNTP. post**(*data*)

Post an article using the POST command. The `data` argument is either a file object opened for binary reading, or any iterable of bytes objects (representing raw lines of the article to be posted). It should represent a well-formed news article, including the required headers. The `post()` method automatically escapes lines beginning with `.` and appends the termination line.

If the method succeeds, the server’s response is returned. If the server refuses posting, a `NNTPReplyError` is raised.

**NNTP. ihave**(*message_id, data*)

Send an IHAVE command. `message_id` is the id of the message to send to the server (enclosed in `<` and `>`). The `data` parameter and the return value are the same as for `post()`.

**NNTP. date()**

Return a pair `(response, date)`. `date` is a `datetime` object containing the current date and time of the server.

**NNTP. slave()**

Send a SLAVE command. Return the server’s `response`.

**NNTP. set_debuglevel**(*level*)
Set the instance’s debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request or response. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the connection (including message text).

The following are optional NNTP extensions defined in RFC 2980. Some of them have been superseded by newer commands in RFC 3977.

**NNTP. xhdr (hdr, str, *, file=None)**

Send an XHDR command. The hdr argument is a header keyword, e.g. 'subject'. The str argument should have the form 'first-last' where first and last are the first and last article numbers to search. Return a pair (response, list), where list is a list of pairs (id, text), where id is an article number (as a string) and text is the text of the requested header for that article. If the file parameter is supplied, then the output of the XHDR command is stored in a file. If file is a string, then the method will open a file with that name, write to it then close it. If file is a file object, then it will start calling write() on it to store the lines of the command output. If file is supplied, then the returned list is an empty list.

**NNTP. xover (start, end, *, file=None)**

Send an XOVER command. start and end are article numbers delimiting the range of articles to select. The return value is the same of for over(). It is recommended to use over() instead, since it will automatically use the newer OVER command if available.
NNTP. \texttt{xpath(id)}

Return a pair \((\text{resp, path})\), where \textit{path} is the directory path to the article with message ID \textit{id}. Most of the time, this extension is not enabled by NNTP server administrators.

\textit{Deprecated since version 3.3}: The XPATH extension is not actively used.
21.16.2. Utility functions

The module also defines the following utility function:

\texttt{nntplib.decode\_header(header\_str)}

Decode a header value, un-escaping any escaped non-ASCII characters. \texttt{header\_str} must be a \texttt{str} object. The unescaped value is returned. Using this function is recommended to display some headers in a human readable form:

\begin{verbatim}
>>> decode_header("Some subject")
'Some subject'
'Débuter en Python'
>>> decode_header("Re: =?UTF-8?B?cHJvYmzDqG1lIGRlIG1hdHJpY2U=?=
'Re: problème de matrice'
\end{verbatim}
21.17. `smtplib` — SMTP protocol client

**Source code:** `Lib/smtplib.py`

The `smtplib` module defines an SMTP client session object that can be used to send mail to any Internet machine with an SMTP or ESMTP listener daemon. For details of SMTP and ESMTP operation, consult RFC 821 (Simple Mail Transfer Protocol) and RFC 1869 (SMTP Service Extensions).

```python
class smtplib.SMTP(host='', port=0, local_hostname=None,
                    [timeout, ]source_address=None)
```

An `SMTP` instance encapsulates an SMTP connection. It has methods that support a full repertoire of SMTP and ESMTP operations. If the optional host and port parameters are given, the SMTP `connect()` method is called with those parameters during initialization. If specified, `local_hostname` is used as the FQDN of the local host in the HELO/EHLO command. Otherwise, the local hostname is found using `socket.getfqdn()`. If the `connect()` call returns anything other than a success code, an `SMTPConnectError` is raised. The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). If the timeout expires, `socket.timeout` is raised. The optional `source_address` parameter allows binding to some specific source address in a machine with multiple network interfaces, and/or to some specific source TCP port. It takes a 2-tuple (host, port), for the socket to bind to as its source address.
before connecting. If omitted (or if host or port are '' and/or 0 respectively) the OS default behavior will be used.

For normal use, you should only require the initialization/connect, sendmail(), and quit() methods. An example is included below.

The SMTP class supports the with statement. When used like this, the SMTP QUIT command is issued automatically when the with statement exits. E.g.:

```python
>>> from smtplib import SMTP
>>> with SMTP("domain.org") as smtp:
...   smtp noop()
... (250, b'Ok')
>>> 
```

*Changed in version 3.3:* Support for the with statement was added.

*Changed in version 3.3:* source_address argument was added.

*New in version 3.5:* The SMTPUTF8 extension ([RFC 6531](https://tools.ietf.org/rfc/rfc6531.txt)) is now supported.

class smtplib.SMTP_SSL(host='', port=0, localHostname=None, keyfile=None, certfile=None, [timeout, ]context=None, source_address=None)

An SMTP_SSL instance behaves exactly the same as instances of SMTP. SMTP_SSL should be used for situations where SSL is required from the beginning of the connection and using starttls() is not appropriate. If host is not specified, the local
host is used. If *port* is zero, the standard SMTP-over-SSL port (465) is used. The optional arguments *local_hostname*, *timeout* and *source_address* have the same meaning as they do in the *SMTP* class. *context*, also optional, can contain a *SSLContext* and allows configuring various aspects of the secure connection. Please read *Security considerations* for best practices.

*keyfile* and *certfile* are a legacy alternative to *context*, and can point to a PEM formatted private key and certificate chain file for the SSL connection.

*Changed in version 3.3*: *context* was added.

*Changed in version 3.3*: *source_address* argument was added.

*Changed in version 3.4*: The class now supports hostname check with *ssl.SSLContext.check_hostname* and *Server Name Indication* (see *ssl.HAS_SNI*).

*Deprecated since version 3.6*: *keyfile* and *certfile* are deprecated in favor of *context*. Please use *ssl.SSLContext.load_cert_chain()* instead, or let *ssl.create_default_context()* select the system's trusted CA certificates for you.

```python
class smtplib.LMTP(host='', port=LMTP_PORT,
local_hostname=None, source_address=None)
```

The LMTP protocol, which is very similar to ESMTP, is heavily based on the standard SMTP client. It’s common to use Unix sockets for LMTP, so our `connect()` method must support that as well as a regular host:port server. The optional arguments *local_hostname* and *source_address* have the same meaning as they do in the *SMTP* class. To specify a Unix socket, you must use
an absolute path for `host`, starting with a ‘/’.

Authentication is supported, using the regular SMTP mechanism. When using a Unix socket, LMTP generally don’t support or require any authentication, but your mileage might vary.

A nice selection of exceptions is defined as well:

`exception smtplib.SMTPException`

Subclass of `OSError` that is the base exception class for all the other exceptions provided by this module.

*Changed in version 3.4:* `SMTPException` became subclass of `OSError`

`exception smtplib.SMTPServerDisconnected`

This exception is raised when the server unexpectedly disconnects, or when an attempt is made to use the `SMTP` instance before connecting it to a server.

`exception smtplib.SMTPResponseException`

Base class for all exceptions that include an SMTP error code. These exceptions are generated in some instances when the SMTP server returns an error code. The error code is stored in the `smtp_code` attribute of the error, and the `smtp_error` attribute is set to the error message.

`exception smtplib.SMTPSenderRefused`

Sender address refused. In addition to the attributes set by on all `SMTPResponseException` exceptions, this sets ‘sender’ to the string that the SMTP server refused.

`exception smtplib.SMTPRecipientsRefused`
All recipient addresses refused. The errors for each recipient are accessible through the attribute `recipients`, which is a dictionary of exactly the same sort as `SMTP.sendmail()` returns.

**exception `smtplib.SMTPDataError`**

The SMTP server refused to accept the message data.

**exception `smtplib.SMTPConnectError`**

Error occurred during establishment of a connection with the server.

**exception `smtplib.SMTPHeloError`**

The server refused our `HELO` message.

**exception `smtplib.SMTPNotSupportedError`**

The command or option attempted is not supported by the server.

*New in version 3.5.*

**exception `smtplib.SMTPAuthenticationError`**

SMTP authentication went wrong. Most probably the server didn’t accept the username/password combination provided.

**See also:**

**RFC 821 - Simple Mail Transfer Protocol**

Protocol definition for SMTP. This document covers the model, operating procedure, and protocol details for SMTP.

**RFC 1869 - SMTP Service Extensions**

Definition of the ESMTP extensions for SMTP. This describes a framework for extending SMTP with new commands, supporting dynamic discovery of the commands provided by the server, and defines a few additional commands.
21.17.1. SMTP Objects

An SMTP instance has the following methods:

**SMTP. set_debuglevel**(level)

Set the debug output level. A value of 1 or True for level results in debug messages for connection and for all messages sent to and received from the server. A value of 2 for level results in these messages being timestamped.

*Changed in version 3.5: Added debuglevel 2.*

**SMTP. docmd**(cmd, args=“”)

Send a command cmd to the server. The optional argument args is simply concatenated to the command, separated by a space.

This returns a 2-tuple composed of a numeric response code and the actual response line (multiline responses are joined into one long line.)

In normal operation it should not be necessary to call this method explicitly. It is used to implement other methods and may be useful for testing private extensions.

If the connection to the server is lost while waiting for the reply, **SMTPServerDisconnected** will be raised.

**SMTP. connect**(host='localhost', port=0)

Connect to a host on a given port. The defaults are to connect to the local host at the standard SMTP port (25). If the hostname ends with a colon (':') followed by a number, that suffix will be stripped off and the number interpreted as the port number to use. This
method is automatically invoked by the constructor if a host is specified during instantiation. Returns a 2-tuple of the response code and message sent by the server in its connection response.

**SMTP. helo(name="")**

Identify yourself to the SMTP server using HEL0. The hostname argument defaults to the fully qualified domain name of the local host. The message returned by the server is stored as the helo_resp attribute of the object.

In normal operation it should not be necessary to call this method explicitly. It will be implicitly called by the `sendmail()` when necessary.

**SMTP. ehlo(name="")**

Identify yourself to an ESMTP server using EHLO. The hostname argument defaults to the fully qualified domain name of the local host. Examine the response for ESMTP option and store them for use by `has_extn()`. Also sets several informational attributes: the message returned by the server is stored as the ehlo_resp attribute, does_esmtp is set to true or false depending on whether the server supports ESMTP, and esmtp_features will be a dictionary containing the names of the SMTP service extensions this server supports, and their parameters (if any).

Unless you wish to use `has_extn()` before sending mail, it should not be necessary to call this method explicitly. It will be implicitly called by `sendmail()` when necessary.

**SMTP. ehlo_or_helo_if_needed()**

This method call `ehlo()` and or `helo()` if there has been no previous EHLO or HELO command this session. It tries ESMTP
EHLO first.

**SMTPHeloError**

The server didn’t reply properly to the HELO greeting.

**SMTP.** has_extn(name)

Return True if name is in the set of SMTP service extensions returned by the server, False otherwise. Case is ignored.

**SMTP.** verify(address)

Check the validity of an address on this server using SMTP VRFY. Returns a tuple consisting of code 250 and a full RFC 822 address (including human name) if the user address is valid. Otherwise returns an SMTP error code of 400 or greater and an error string.

**Note:** Many sites disable SMTP VRFY in order to foil spammers.

**SMTP.** login(user, password, *, initial_response_ok=True)

Log in on an SMTP server that requires authentication. The arguments are the username and the password to authenticate with. If there has been no previous EHLO or HELO command this session, this method tries ESMTP EHLO first. This method will return normally if the authentication was successful, or may raise the following exceptions:

**SMTPHeloError**

The server didn’t reply properly to the HELO greeting.

**SMTPAuthenticationError**

The server didn’t accept the username/password combination.

**SMTPNotSupportedError**

The AUTH command is not supported by the server.
**SMTPException**

No suitable authentication method was found.

Each of the authentication methods supported by `smtplib` are tried in turn if they are advertised as supported by the server. See `auth()` for a list of supported authentication methods. `initial_response_ok` is passed through to `auth()`.

Optional keyword argument `initial_response_ok` specifies whether, for authentication methods that support it, an “initial response” as specified in RFC 4954 can be sent along with the AUTH command, rather than requiring a challenge/response.

*Changed in version 3.5:* `SMTPNotSupportedError` may be raised, and the `initial_response_ok` parameter was added.

```python
SMTP.auth(mechanism, authobject, *, initial_response_ok=True)
```

Issue an SMTP AUTH command for the specified authentication `mechanism`, and handle the challenge response via `authobject`.

`mechanism` specifies which authentication mechanism is to be used as argument to the AUTH command; the valid values are those listed in the `auth` element of `esmtplib_features`.

`authobject` must be a callable object taking an optional single argument:

```
data = authobject(challenge=None)
```

If optional keyword argument `initial_response_ok` is true, `authobject()` will be called first with no argument. It can return the RFC 4954 “initial response” bytes which will be encoded and sent with the AUTH command as below. If the `authobject()`
does not support an initial response (e.g. because it requires a challenge), it should return None when called with challenge=None. If initial_response_ok is false, then authobject() will not be called first with None.

If the initial response check returns None, or if initial_response_ok is false, authobject() will be called to process the server's challenge response; the challenge argument it is passed will be a bytes. It should return bytes data that will be base64 encoded and sent to the server.

The SMTP class provides authobjects for the CRAM-MD5, PLAIN, and LOGIN mechanisms; they are named SMTP.auth_cram_md5, SMTP.auth_plain, and SMTP.auth_login respectively. They all require that the user and password properties of the SMTP instance are set to appropriate values.

User code does not normally need to call auth directly, but can instead call the login() method, which will try each of the above mechanisms in turn, in the order listed. auth is exposed to facilitate the implementation of authentication methods not (or not yet) supported directly by smtplib.

New in version 3.5.

SMTP.starttls(keyfile=None, certfile=None, context=None)
Put the SMTP connection in TLS (Transport Layer Security) mode. All SMTP commands that follow will be encrypted. You should then call ehlo() again.

If keyfile and certfile are provided, these are passed to the socket
module's `ssl()` function.

Optional `context` parameter is a `ssl.SSLContext` object; This is an alternative to using a keyfile and a certfile and if specified both `keyfile` and `certfile` should be None.

If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first.

**SMTPHeloError**

The server didn’t reply properly to the `HELO` greeting.

**SMTPNotSupportedError**

The server does not support the STARTTLS extension.

**RuntimeError**

SSL/TLS support is not available to your Python interpreter.

*Changed in version 3.3:* `context` was added.

*Changed in version 3.4:* The method now supports hostname check with `SSLContext.check_hostname` and `Server Name Indicator` (see `HAS_SNI`).

*Changed in version 3.5:* The error raised for lack of STARTTLS support is now the `SMTPNotSupportedError` subclass instead of the base `SMTPException`.

```python
SMTP.sendmail(from_addr, to_addrs, msg, mail_options=[], rcpt_options=[])  # Send mail. The required arguments are an `RFC 822` from-address string, a list of `RFC 822` to-address strings (a bare string will be treated as a list with 1 address), and a message string. The caller may pass a list of ESMTP options (such as `8bitmime`) to be used
```
in MAIL FROM commands as mail_options. ESMTP options (such as DSN commands) that should be used with all RCPT commands can be passed as rcpt_options. (If you need to use different ESMTP options to different recipients you have to use the low-level methods such as mail(), rcpt() and data() to send the message.)

**Note:** The from_addr and to_addrs parameters are used to construct the message envelope used by the transport agents. sendmail does not modify the message headers in any way.

msg may be a string containing characters in the ASCII range, or a byte string. A string is encoded to bytes using the ascii codec, and lone \r and \n characters are converted to \r\n characters. A byte string is not modified.

If there has been no previous EHLO or HELO command this session, this method tries ESMTP EHLO first. If the server does ESMTP, message size and each of the specified options will be passed to it (if the option is in the feature set the server advertises). If EHLO fails, HELO will be tried and ESMTP options suppressed.

This method will return normally if the mail is accepted for at least one recipient. Otherwise it will raise an exception. That is, if this method does not raise an exception, then someone should get your mail. If this method does not raise an exception, it returns a dictionary, with one entry for each recipient that was refused. Each entry contains a tuple of the SMTP error code and the accompanying error message sent by the server.

If SMTPUTF8 is included in mail_options, and the server supports it, from_addr and to_addrs may contain non-ASCII characters.
This method may raise the following exceptions:

**SMTPRecipientsRefused**

All recipients were refused. Nobody got the mail. The recipients attribute of the exception object is a dictionary with information about the refused recipients (like the one returned when at least one recipient was accepted).

**SMTPHeloError**

The server didn’t reply properly to the HELO greeting.

**SMTPSenderRefused**

The server didn’t accept the from_addr.

**SMTPDataError**

The server replied with an unexpected error code (other than a refusal of a recipient).

**SMTPNotSupportedError**

SMTPUTF8 was given in the mail_options but is not supported by the server.

Unless otherwise noted, the connection will be open even after an exception is raised.

*Changed in version 3.2:* msg may be a byte string.

*Changed in version 3.5:* SMTPUTF8 support added, and SMTPNotSupportedError may be raised if SMTPUTF8 is specified but the server does not support it.

**SMTP.send_message**

```
smtp.send_message(msg, from_addr=None, to_addrs=None, mail_options=[], rcpt_options=[])
```

This is a convenience method for calling sendmail() with the message represented by an email.message.Message object. The arguments have the same meaning as for sendmail(),
except that 

except that *msg* is a *Message* object.

If *from_addr* is None or *to_addrs* is None, *send_message* fills those arguments with addresses extracted from the headers of *msg* as specified in RFC 5322: *from_addr* is set to the *Sender* field if it is present, and otherwise to the *From* field. *to_addrs* combines the values (if any) of the *To*, *Cc*, and *Bcc* fields from *msg*. If exactly one set of *Resent-* headers appear in the message, the regular headers are ignored and the *Resent-* headers are used instead. If the message contains more than one set of *Resent-* headers, a *ValueError* is raised, since there is no way to unambiguously detect the most recent set of *Resent-* headers.

*send_message* serializes *msg* using *BytesGenerator* with \r\n as the *linesep*, and calls *sendmail()* to transmit the resulting message. Regardless of the values of *from_addr* and *to_addrs*, *send_message* does not transmit any *Bcc* or *Resent-Bcc* headers that may appear in *msg*. If any of the addresses in *from_addr* and *to_addrs* contain non-ASCII characters and the server does not advertise SMTPUTF8 support, an *SMTPNotSupported* error is raised. Otherwise the *Message* is serialized with a clone of its *policy* with the *utf8* attribute set to *True*, and *SMTPUTF8* and *BODY=8BITMIME* are added to *mail_options*.

*New in version 3.2.*

*New in version 3.5:* Support for internationalized addresses (SMTPUTF8).

**SMTP.quit()**

Terminate the SMTP session and close the connection. Return the
result of the SMTP QUIT command.

Low-level methods corresponding to the standard SMTP/ESMTP commands HELP, RSET, NOOP, MAIL, RCPT, and DATA are also supported. Normally these do not need to be called directly, so they are not documented here. For details, consult the module code.
21.17.2. SMTP Example

This example prompts the user for addresses needed in the message envelope ('To' and 'From' addresses), and the message to be delivered. Note that the headers to be included with the message must be included in the message as entered; this example doesn’t do any processing of the RFC 822 headers. In particular, the ‘To’ and ‘From’ addresses must be included in the message headers explicitly.

```python
import smtplib

def prompt(prompt):
    return input(prompt).strip()

fromaddr = prompt("From: ")
toaddrs = prompt("To: ").split()
print("Enter message, end with ^D (Unix) or ^Z (Windows)

# Add the From: and To: headers at the start!
msg = ("From: %s\n\nTo: %s\n\r\n\r\n" % (fromaddr, ", ", join(toaddrs)))
while True:
    try:
        line = input()
    except EOFError:
        break
    if not line:
        break
    msg = msg + line

print("Message length is", len(msg))

server = smtplib.SMTP('localhost')
server.set_debuglevel(1)
server.sendmail(fromaddr, toaddrs, msg)
```
Note: In general, you will want to use the `email` package's features to construct an email message, which you can then send via `send_message()`; see `email: Examples`.
21.18. smtpd — SMTP Server

Source code: Lib/smtpd.py

This module offers several classes to implement SMTP (email) servers.

See also: The aiosmtpd package is a recommended replacement for this module. It is based on asyncio and provides a more straightforward API. smtpd should be considered deprecated.

Several server implementations are present; one is a generic do-nothing implementation, which can be overridden, while the other two offer specific mail-sending strategies.

Additionally the SMTPChannel may be extended to implement very specific interaction behaviour with SMTP clients.

The code supports RFC 5321, plus the RFC 1870 SIZE and RFC 6531 SMTPUTF8 extensions.
21.18.1. SMTPServer Objects

class smtpd.SMTPServer(localaddr, remoteaddr,
data_size_limit=33554432, map=None, enable_SMTPUTF8=False,
decode_data=False)

Create a new SMTPServer object, which binds to local address
localaddr. It will treat remoteaddr as an upstream SMTP relayer. Both
localaddr and remoteaddr should be a (host, port) tuple. The
object inherits from asyncore.dispatcher, and so will insert
itself into asyncore’s event loop on instantiation.

data_size_limit specifies the maximum number of bytes that will be
accepted in a DATA command. A value of None or 0 means no
limit.

map is the socket map to use for connections (an initially empty
dictionary is a suitable value). If not specified the asyncore global
socket map is used.

enable_SMTPUTF8 determines whether the SMTPUTF8 extension
(as defined in RFC 6531) should be enabled. The default is
False. When True, SMTPUTF8 is accepted as a parameter to the
MAIL command and when present is passed to
process_message() in the kwars['mail_options'] list.
decode_data and enable_SMTPUTF8 cannot be set to True at the
same time.

decode_data specifies whether the data portion of the SMTP
transaction should be decoded using UTF-8. When decode_data is
False (the default), the server advertises the 8BITMIME
extension (RFC 6152), accepts the BODY=8BITMIME parameter to
the MAIL command, and when present passes it to `process_message()` in the `kwargs['mail_options']` list. `decode_data` and `enable_SMTPUTF8` cannot be set to `True` at the same time.

**process_message**(*peer, mailfrom, rcpttos, data, **kwargs*)

Raise a `NotImplementedError` exception. Override this in subclasses to do something useful with this message. Whatever was passed in the constructor as `remoteaddr` will be available as the `_remoteaddr` attribute. `peer` is the remote host's address, `mailfrom` is the envelope originator, `rcpttos` are the envelope recipients and `data` is a string containing the contents of the e-mail (which should be in RFC 5321 format).

If the `decode_data` constructor keyword is set to `True`, the `data` argument will be a unicode string. If it is set to `False`, it will be a bytes object.

`kwargs` is a dictionary containing additional information. It is empty if `decode_data=True` was given as an init argument, otherwise it contains the following keys:

- **mail_options**: a list of all received parameters to the MAIL command (the elements are uppercase strings; example: `['BODY=8BITMIME', 'SMTPUTF8']`).

- **rcpt_options**: same as `mail_options` but for the RCPT command. Currently no RCPT TO options are supported, so for now this will always be an empty list.

Implementations of `process_message` should use the
**kwargs signature to accept arbitrary keyword arguments, since future feature enhancements may add keys to the kwargs dictionary.

Return None to request a normal 250 0k response; otherwise return the desired response string in RFC 5321 format.

channel_class

Override this in subclasses to use a custom SMTPChannel for managing SMTP clients.

New in version 3.4: The map constructor argument.

Changed in version 3.5: localaddr and remoteaddr may now contain IPv6 addresses.

New in version 3.5: The decode_data and enable_SMTPUTF8 constructor parameters, and the kwargs parameter to process_message() when decode_data is False.

Changed in version 3.6: decode_data is now False by default.
21.18.2. DebuggingServer Objects

class smtpd. **DebuggingServer**(*localaddr*, *remoteaddr*)

Create a new debugging server. Arguments are as per **SMTPServer**. Messages will be discarded, and printed on stdout.
21.18.3. PureProxy Objects

class smtdp. **PureProxy**(*localaddr, remoteaddr*)

Create a new pure proxy server. Arguments are as per **SMTPServer**. Everything will be relayed to *remoteaddr*. Note that running this has a good chance to make you into an open relay, so please be careful.
21.18.4. MailmanProxy Objects

class smtptd.MailmanProxy(localaddr, remoteaddr)
    Create a new pure proxy server. Arguments are as per SMTPServer. Everything will be relayed to remoteaddr, unless local mailman configurations knows about an address, in which case it will be handled via mailman. Note that running this has a good chance to make you into an open relay, so please be careful.
21.18.5. SMTPChannel Objects

class smtplib.SMTPChannel(server, conn, addr, data_size_limit=33554432, map=None, enable_SMTPUTF8=False, decode_data=False)

Create a new SMTPChannel object which manages the communication between the server and a single SMTP client.

(conn and addr) are as per the instance variables described below.

data_size_limit specifies the maximum number of bytes that will be accepted in a DATA command. A value of None or 0 means no limit.

enable_SMTPUTF8 determines whether the SMTPUTF8 extension (as defined in RFC 6531) should be enabled. The default is False. decode_data and enable_SMTPUTF8 cannot be set to True at the same time.

A dictionary can be specified in map to avoid using a global socket map.

decode_data specifies whether the data portion of the SMTP transaction should be decoded using UTF-8. The default is False. decode_data and enable_SMTPUTF8 cannot be set to True at the same time.

To use a custom SMTPChannel implementation you need to override the SMTPServer.channel_class of your SMTPServer.

Changed in version 3.5: The decode_data and enable_SMTPUTF8
parameters were added.

*Changed in version 3.6: decode_data is now False by default.*

The **SMTPChannel** has the following instance variables:

**smtp_server**

Holds the **SMTPServer** that spawned this channel.

**conn**

Holds the socket object connecting to the client.

**addr**

Holds the address of the client, the second value returned by `socket.accept`

**received_lines**

Holds a list of the line strings (decoded using UTF-8) received from the client. The lines have their `\r\n` line ending translated to `\n`.

**smtp_state**

Holds the current state of the channel. This will be either `COMMAND` initially and then `DATA` after the client sends a “DATA” line.

**seen_greeting**

Holds a string containing the greeting sent by the client in its “HELO”.

**mailfrom**

Holds a string containing the address identified in the “MAIL FROM:” line from the client.
**rcpttos**

Holds a list of strings containing the addresses identified in the “RCPT TO:” lines from the client.

**received_data**

Holds a string containing all of the data sent by the client during the DATA state, up to but not including the terminating "\r\n\r\n".

**fqdn**

Holds the fully-qualified domain name of the server as returned by socket.getfqdn().

**peer**

Holds the name of the client peer as returned by conn.getpeername() where conn is conn.

The **SMTPChannel** operates by invoking methods named smtp_<command> upon reception of a command line from the client. Built into the base **SMTPChannel** class are methods for handling the following commands (and responding to them appropriately):

<table>
<thead>
<tr>
<th>Command</th>
<th>Action taken</th>
</tr>
</thead>
<tbody>
<tr>
<td>HELO</td>
<td>Accepts the greeting from the client and stores it in seen_greeting. Sets server to base command mode.</td>
</tr>
<tr>
<td>EHLO</td>
<td>Accepts the greeting from the client and stores it in seen_greeting. Sets server to extended command mode.</td>
</tr>
<tr>
<td>NOOP</td>
<td>Takes no action.</td>
</tr>
<tr>
<td>QUIT</td>
<td>Closes the connection cleanly.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>MAIL</td>
<td>Accepts the “MAIL FROM:” syntax and stores the supplied address as <code>mailfrom</code>. In extended command mode, accepts the RFC 1870 SIZE attribute and responds appropriately based on the value of <code>data_size_limit</code>.</td>
</tr>
<tr>
<td>RCPT</td>
<td>Accepts the “RCPT TO:” syntax and stores the supplied addresses in the <code>rcpttos</code> list.</td>
</tr>
<tr>
<td>RSET</td>
<td>Resets the <code>mailfrom</code>, <code>rcpttos</code>, and <code>received_data</code>, but not the greeting.</td>
</tr>
<tr>
<td>DATA</td>
<td>Sets the internal state to DATA and stores remaining lines from the client in <code>received_data</code> until the terminator <code>\r\n.\r\n</code> is received.</td>
</tr>
<tr>
<td>HELP</td>
<td>Returns minimal information on command syntax</td>
</tr>
<tr>
<td>VRFY</td>
<td>Returns code 252 (the server doesn’t know if the address is valid)</td>
</tr>
<tr>
<td>EXPN</td>
<td>Reports that the command is not implemented.</td>
</tr>
</tbody>
</table>
The `telnetlib` module provides a `Telnet` class that implements the Telnet protocol. See RFC 854 for details about the protocol. In addition, it provides symbolic constants for the protocol characters (see below), and for the telnet options. The symbolic names of the telnet options follow the definitions in `arpa/telnet.h`, with the leading `TELOPT_` removed. For symbolic names of options which are traditionally not included in `arpa/telnet.h`, see the module source itself.

The symbolic constants for the telnet commands are: IAC, DONT, DO, WONT, WILL, SE (Subnegotiation End), NOP (No Operation), DM (Data Mark), BRK (Break), IP (Interrupt process), AO (Abort output), AYT (Are You There), EC (Erase Character), EL (Erase Line), GA (Go Ahead), SB (Subnegotiation Begin).

```python
class telnetlib.Telnet(host=None, port=0[, timeout])
```

`Telnet` represents a connection to a Telnet server. The instance is initially not connected by default; the `open()` method must be used to establish a connection. Alternatively, the host name and optional port number can be passed to the constructor too, in which case the connection to the server will be established before the constructor returns. The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).
Do not reopen an already connected instance.

This class has many read_*() methods. Note that some of them raise E0FError when the end of the connection is read, because they can return an empty string for other reasons. See the individual descriptions below.

A Telnet object is a context manager and can be used in a with statement. When the with block ends, the close() method is called:

```python
>>> from telnetlib import Telnet
>>> with Telnet('localhost', 23) as tn:
    ...
    tn.interact()
...
```

*Changed in version 3.6*: Context manager support added

**See also:**

- [RFC 854 - Telnet Protocol Specification](#)
  - Definition of the Telnet protocol.
21.19.1. Telnet Objects

Telnet instances have the following methods:

Telnet.\texttt{read\_until}(\textit{expected}, \textit{timeout}=\texttt{None})

Read until a given byte string, \textit{expected}, is encountered or until \textit{timeout} seconds have passed.

When no match is found, return whatever is available instead, possibly empty bytes. Raise \texttt{EOFError} if the connection is closed and no cooked data is available.

Telnet.\texttt{read\_all}()

Read all data until EOF as bytes; block until connection closed.

Telnet.\texttt{read\_some}()

Read at least one byte of cooked data unless EOF is hit. Return \texttt{b''} if EOF is hit. Block if no data is immediately available.

Telnet.\texttt{read\_very\_eager}()

Read everything that can be without blocking in I/O (eager).

Raise \texttt{EOFError} if connection closed and no cooked data available. Return \texttt{b''} if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

Telnet.\texttt{read\_eager}()

Read readily available data.

Raise \texttt{EOFError} if connection closed and no cooked data available. Return \texttt{b''} if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.
Telnet.read_lazy()
Process and return data already in the queues (lazy).

Raise EOFError if connection closed and no data available. Return b'' if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

Telnet.read_very_lazy()
Return any data available in the cooked queue (very lazy).

Raise EOFError if connection closed and no data available. Return b'' if no cooked data available otherwise. This method never blocks.

Telnet.read_sb_data()
Return the data collected between a SB/SE pair (suboption begin/end). The callback should access these data when it was invoked with a SE command. This method never blocks.

Telnet.open(host, port=0[, timeout])
Connect to a host. The optional second argument is the port number, which defaults to the standard Telnet port (23). The optional timeout parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

Do not try to reopen an already connected instance.

Telnet.msg(msg, *args)
Print a debug message when the debug level is > 0. If extra arguments are present, they are substituted in the message using the standard string formatting operator.
Telnet.set_debuglevel(debuglevel)
    Set the debug level. The higher the value of debuglevel, the more debug output you get (on sys.stdout).

Telnet.close()
    Close the connection.

Telnet.get_socket()
    Return the socket object used internally.

Telnet.fileno()
    Return the file descriptor of the socket object used internally.

Telnet.write(buffer)
    Write a byte string to the socket, doubling any IAC characters. This can block if the connection is blocked. May raise OSError if the connection is closed.

    Changed in version 3.3: This method used to raise socket.error, which is now an alias of OSError.

Telnet.interact()
    Interaction function, emulates a very dumb Telnet client.

Telnet.mt_interact()
    Multithreaded version of interact().

Telnet.expect(list, timeout=None)
    Read until one from a list of a regular expressions matches.

    The first argument is a list of regular expressions, either compiled (regex objects) or uncompiled (byte strings). The optional second argument is a timeout, in seconds; the default is to block
indefinitely.

Return a tuple of three items: the index in the list of the first regular expression that matches; the match object returned; and the bytes read up till and including the match.

If end of file is found and no bytes were read, raise `EOFError`. Otherwise, when nothing matches, return `(-1, None, data)` where `data` is the bytes received so far (may be empty bytes if a timeout happened).

If a regular expression ends with a greedy match (such as `.*`) or if more than one expression can match the same input, the results are non-deterministic, and may depend on the I/O timing.

**Telnet**. `set_option_negotiation_callback(callback)`

Each time a telnet option is read on the input flow, this `callback` (if set) is called with the following parameters: `callback(telnet socket, command (DO/DONT/WILL/WONT), option)`. No other action is done afterwards by telnetlib.
21.19.2. Telnet Example

A simple example illustrating typical use:

```python
import getpass
import telnetlib

HOST = "localhost"
user = input("Enter your remote account: ")
password = getpass.getpass()

tn = telnetlib.Telnet(HOST)
	nn.read_until(b"login: ")
	nn.write(user.encode('ascii') + b"\n")

if password:
    tn.read_until(b"Password: ")
    tn.write(password.encode('ascii') + b"\n")
	nn.write(b"ls\n")
	nn.write(b"exit\n")

print(tn.read_all().decode('ascii'))
```
21.20. **uuid** — UUID objects according to RFC 4122

**Source code:** Lib/uuid.py

This module provides immutable **UUID** objects (the **UUID** class) and the functions **uuid1()**, **uuid3()**, **uuid4()**, **uuid5()** for generating version 1, 3, 4, and 5 UUIDs as specified in **RFC 4122**.

If all you want is a unique ID, you should probably call **uuid1()** or **uuid4()**. Note that **uuid1()** may compromise privacy since it creates a UUID containing the computer’s network address. **uuid4()** creates a random UUID.

Depending on support from the underlying platform, **uuid1()** may or may not return a “safe” UUID. A safe UUID is one which is generated using synchronization methods that ensure no two processes can obtain the same UUID. All instances of **UUID** have an **is_safe** attribute which relays any information about the UUID’s safety, using this enumeration:

```python
class uuid.SafeUUID
    New in version 3.7.

    safe
        The UUID was generated by the platform in a multiprocessing-safe way.

    unsafe
        The UUID was not generated in a multiprocessing-safe way.
```
The platform does not provide information on whether the UUID was generated safely or not.

```
class uuid.UUID(hex=None, bytes=None, bytes_le=None, fields=None, int=None, version=None, *, is_safe=SafeUUID.unknown)
```

Create a UUID from either a string of 32 hexadecimal digits, a string of 16 bytes as the `bytes` argument, a string of 16 bytes in little-endian order as the `bytes_le` argument, a tuple of six integers (32-bit `time_low`, 16-bit `time_mid`, 16-bit `time_hi_version`, 8-bit `clock_seq_hi_variant`, 8-bit `clock_seq_low`, 48-bit `node`) as the `fields` argument, or a single 128-bit integer as the `int` argument. When a string of hex digits is given, curly braces, hyphens, and a URN prefix are all optional. For example, these expressions all yield the same UUID:

```
UUID('{12345678-1234-5678-1234-567812345678}')
UUID('12345678-1234-5678-1234-567812345678')
UUID('urn:uuid:12345678-1234-5678-1234-567812345678')
UUID(bytes=b'\x12\x34\x56\x78'*4)
UUID(bytes_le=b'\x78\x56\x34\x12\x34\x12\x78\x56'
            'b'\x12\x34\x56\x78\x12\x34\x56\x78')
UUID(fields=(0x12345678, 0x1234, 0x5678, 0x12, 0x1234567812345678123456781234567812345678))
```

Exactly one of `hex`, `bytes`, `bytes_le`, `fields`, or `int` must be given. The `version` argument is optional; if given, the resulting UUID will have its variant and version number set according to RFC 4122, overriding bits in the given `hex`, `bytes`, `bytes_le`, `fields`, or `int`.

Comparison of UUID objects are made by way of comparing their `UUID.int` attributes. Comparison with a non-UUID object raises a `TypeError`.
str(uuid) returns a string in the form 12345678-1234-5678-1234-567812345678 where the 32 hexadecimal digits represent the UUID.

UUID instances have these read-only attributes:

**UUID.** `bytes`

The UUID as a 16-byte string (containing the six integer fields in big-endian byte order).

**UUID.** `bytes_le`

The UUID as a 16-byte string (with `time_low`, `time_mid`, and `time_hi_version` in little-endian byte order).

**UUID.** `fields`

A tuple of the six integer fields of the UUID, which are also available as six individual attributes and two derived attributes:

<table>
<thead>
<tr>
<th>Field</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>time_low</code></td>
<td>the first 32 bits of the UUID</td>
</tr>
<tr>
<td><code>time_mid</code></td>
<td>the next 16 bits of the UUID</td>
</tr>
<tr>
<td><code>time_hi_version</code></td>
<td>the next 16 bits of the UUID</td>
</tr>
<tr>
<td><code>clock_seq_hi_variant</code></td>
<td>the next 8 bits of the UUID</td>
</tr>
<tr>
<td><code>clock_seq_low</code></td>
<td>the next 8 bits of the UUID</td>
</tr>
<tr>
<td><code>node</code></td>
<td>the last 48 bits of the UUID</td>
</tr>
<tr>
<td><code>time</code></td>
<td>the 60-bit timestamp</td>
</tr>
<tr>
<td><code>clock_seq</code></td>
<td>the 14-bit sequence number</td>
</tr>
</tbody>
</table>

**UUID.** `hex`

The UUID as a 32-character hexadecimal string.
**UUID.int**
The UUID as a 128-bit integer.

**UUID.urn**
The UUID as aURN as specified in RFC 4122.

**UUID.variant**
The UUID variant, which determines the internal layout of the UUID. This will be one of the constants RESERVED_NCS, RFC_4122, RESERVED_MICROSOFT, or RESERVED_FUTURE.

**UUID.version**
The UUID version number (1 through 5, meaningful only when the variant is RFC_4122).

**UUID.is_safe**
An enumeration of SafeUUID which indicates whether the platform generated the UUID in a multiprocessing-safe way.

New in version 3.7.

The *uuid* module defines the following functions:

**uuid.getnode()**
Get the hardware address as a 48-bit positive integer. The first time this runs, it may launch a separate program, which could be quite slow. If all attempts to obtain the hardware address fail, we choose a random 48-bit number with the multicast bit (least significant bit of the first octet) set to 1 as recommended in RFC 4122. “Hardware address” means the MAC address of a network interface. On a machine with multiple network interfaces, universally administered MAC addresses (i.e. where the second least significant bit of the first octet is unset) will be preferred over...
locally administered MAC addresses, but with no other ordering guarantees.

*Changed in version 3.7:* Universally administered MAC addresses are preferred over locally administered MAC addresses, since the former are guaranteed to be globally unique, while the latter are not.

**uuid.** **uuid1**(node=None, clock_seq=None)

Generate a UUID from a host ID, sequence number, and the current time. If `node` is not given, `getnode()` is used to obtain the hardware address. If `clock_seq` is given, it is used as the sequence number; otherwise a random 14-bit sequence number is chosen.

**uuid.** **uuid3**(namespace, name)

Generate a UUID based on the MD5 hash of a namespace identifier (which is a UUID) and a name (which is a string).

**uuid.** **uuid4**()

Generate a random UUID.

**uuid.** **uuid5**(namespace, name)

Generate a UUID based on the SHA-1 hash of a namespace identifier (which is a UUID) and a name (which is a string).

The **uuid** module defines the following namespace identifiers for use with `uuid3()` or `uuid5()`.

**uuid.** **NAMESPACE_DNS**

When this namespace is specified, the `name` string is a fully-qualified domain name.

**uuid.** **NAMESPACE_URL**
When this namespace is specified, the *name* string is a URL.

**uuid.NAMESPACE_OID**

When this namespace is specified, the *name* string is an ISO OID.

**uuid.NAMESPACE_X500**

When this namespace is specified, the *name* string is an X.500 DN in DER or a text output format.

The `uuid` module defines the following constants for the possible values of the variant attribute:

**uuid.RESERVED_NCS**

Reserved for NCS compatibility.

**uuid.RFC_4122**

**uuid.RESERVED_MICROSOFT**

Reserved for Microsoft compatibility.

**uuid.RESERVED_FUTURE**

Reserved for future definition.

---

**See also:**

[RFC 4122](https://tools.ietf.org/html/rfc4122) - A Universally Unique IDentifier (UUID) URN Namespace

This specification defines a Uniform Resource Name namespace for UUIDs, the internal format of UUIDs, and methods of generating UUIDs.
21.20.1. Example

Here are some examples of typical usage of the `uuid` module:

```python
>>> import uuid

>>> # make a UUID based on the host ID and current time
>>> uuid.uuid1()
UUID('a8098c1a-f86e-11da-bd1a-00112444be1e')

>>> # make a UUID using an MD5 hash of a namespace UUID and a name
>>> uuid.uuid3(uuid.NAMESPACE_DNS, 'python.org')
UUID('6fa459ea-ee8a-3ca4-894e-db77e160355e')

>>> # make a random UUID
>>> uuid.uuid4()
UUID('16fd2706-8baf-433b-82eb-8c7fada847da')

>>> # make a UUID using a SHA-1 hash of a namespace UUID and a name
>>> uuid.uuid5(uuid.NAMESPACE_DNS, 'python.org')
UUID('886313e1-3b8a-5372-9b90-0c9aee199e5d')

>>> # make a UUID from a string of hex digits (braces and hyphens ignored)
>>> x = uuid.UUID('{00010203-0405-0607-0809-0a0b0c0d0e0f}')

>>> # convert a UUID to a string of hex digits in standard form
>>> str(x)
'00010203-0405-0607-0809-0a0b0c0d0e0f'

>>> # get the raw 16 bytes of the UUID
>>> x.bytes
b'\x00\x01\x02\x03\x04\x05\x06\x07\x08\t\n\x0b\x0c\r\n\x15\x16\x17\x18\x19\x1a' 

>>> # make a UUID from a 16-byte string
>>> uuid.UUID(bytes=x.bytes)
```

**Source code:** Lib/socketserver.py

The `socketserver` module simplifies the task of writing network servers.

There are four basic concrete server classes:

```python
class socketserver.TCPServer(server_address, RequestHandlerClass, bind_and_activate=True)
```

This uses the Internet TCP protocol, which provides for continuous streams of data between the client and server. If `bind_and_activate` is true, the constructor automatically attempts to invoke `server_bind()` and `server_activate()`. The other parameters are passed to the `BaseServer` base class.

```python
class socketserver.UDPServer(server_address, RequestHandlerClass, bind_and_activate=True)
```

This uses datagrams, which are discrete packets of information that may arrive out of order or be lost while in transit. The parameters are the same as for `TCPServer`.

```python
class socketserver.UnixStreamServer(server_address, RequestHandlerClass, bind_and_activate=True)
class socketserver.UnixDatagramServer(server_address, RequestHandlerClass, bind_and_activate=True)
```

These more infrequently used classes are similar to the TCP and UDP classes, but use Unix domain sockets; they're not available...
on non-Unix platforms. The parameters are the same as for `TCPServer`.

These four classes process requests *synchronously*; each request must be completed before the next request can be started. This isn’t suitable if each request takes a long time to complete, because it requires a lot of computation, or because it returns a lot of data which the client is slow to process. The solution is to create a separate process or thread to handle each request; the `ForkingMixIn` and `ThreadingMixIn` mix-in classes can be used to support asynchronous behaviour.

Creating a server requires several steps. First, you must create a request handler class by subclassing the `BaseRequestHandler` class and overriding its `handle()` method; this method will process incoming requests. Second, you must instantiate one of the server classes, passing it the server’s address and the request handler class. It is recommended to use the server in a `with` statement. Then call the `handle_request()` or `serve_forever()` method of the server object to process one or many requests. Finally, call `server_close()` to close the socket (unless you used a `with` statement).

When inheriting from `ThreadingMixIn` for threaded connection behavior, you should explicitly declare how you want your threads to behave on an abrupt shutdown. The `ThreadingMixIn` class defines an attribute `daemon_threads`, which indicates whether or not the server should wait for thread termination. You should set the flag explicitly if you would like threads to behave autonomously; the default is `False`, meaning that Python will not exit until all threads created by `ThreadingMixIn` have exited.
Server classes have the same external methods and attributes, no matter what network protocol they use.
21.21.1. Server Creation Notes

There are five classes in an inheritance diagram, four of which represent synchronous servers of four types:

```
+------------+
| BaseServer |
+------------+
    |   \
    v
+------------+ +------------------+
| TCPStream  |------->| UnixStreamServer |
+------------+ +------------------+
    |   \
    v
+------------+ +------------------+
| UDPServer  |------->| UnixDatagramServer |
+------------+ +------------------+
```

Note that `UnixDatagramServer` derives from `UDPServer`, not from `UnixStreamServer` — the only difference between an IP and a Unix stream server is the address family, which is simply repeated in both Unix server classes.

class socketserver.**ForkingMixIn**
class socketserver.**ThreadingMixIn**

Forking and threading versions of each type of server can be created using these mix-in classes. For instance, `ThreadingUDPServer` is created as follows:

```
class ThreadingUDPServer(ThreadingMixIn, UDPServer)
```
The mix-in class comes first, since it overrides a method defined in `UDPServer`. Setting the various attributes also changes the behavior of the underlying server mechanism.

`ForkingMixIn` and the Forking classes mentioned below are only available on POSIX platforms that support `fork()`.

socketserver.ForkingMixIn.server_close() waits until all child processes complete.

socketserver.ThreadingMixIn.server_close() waits until all non-daemon threads complete. Use daemonic threads by setting ThreadingMixIn.daemon_threads to `True` to not wait until threads complete.

*Changed in version 3.7:* socketserver.ForkingMixIn.server_close() and socketserver.ThreadingMixIn.server_close() now waits until all child processes and non-daemonic threads complete.

```python
class socketserver.ForkingTCPServer
class socketserver.ForkingUDPServer
class socketserver.ThreadingTCPServer
class socketserver.ThreadingUDPServer
```

These classes are pre-defined using the mix-in classes.

To implement a service, you must derive a class from `BaseRequestHandler` and redefine its `handle()` method. You can then run various versions of the service by combining one of the server classes with your request handler class. The request handler class must be different for datagram or stream services. This can be hidden by using the handler subclasses `StreamRequestHandler` or `DatagramRequestHandler`. 
Of course, you still have to use your head! For instance, it makes no sense to use a forking server if the service contains state in memory that can be modified by different requests, since the modifications in the child process would never reach the initial state kept in the parent process and passed to each child. In this case, you can use a threading server, but you will probably have to use locks to protect the integrity of the shared data.

On the other hand, if you are building an HTTP server where all data is stored externally (for instance, in the file system), a synchronous class will essentially render the service “deaf” while one request is being handled – which may be for a very long time if a client is slow to receive all the data it has requested. Here a threading or forking server is appropriate.

In some cases, it may be appropriate to process part of a request synchronously, but to finish processing in a forked child depending on the request data. This can be implemented by using a synchronous server and doing an explicit fork in the request handler class handle() method.

Another approach to handling multiple simultaneous requests in an environment that supports neither threads nor fork() (or where these are too expensive or inappropriate for the service) is to maintain an explicit table of partially finished requests and to use selectors to decide which request to work on next (or whether to handle a new incoming request). This is particularly important for stream services where each client can potentially be connected for a long time (if threads or subprocesses cannot be used). See asyncore for another way to manage this.
21.21.2. Server Objects

class socketserver.**BaseServer**(server_address, RequestHandlerClass)

This is the superclass of all Server objects in the module. It defines the interface, given below, but does not implement most of the methods, which is done in subclasses. The two parameters are stored in the respective server_address and RequestHandlerClass attributes.

**fileno()**

Return an integer file descriptor for the socket on which the server is listening. This function is most commonly passed to selectors, to allow monitoring multiple servers in the same process.

**handle_request()**

Process a single request. This function calls the following methods in order: get_request(), verify_request(), and process_request(). If the user-provided handle() method of the handler class raises an exception, the server's handle_error() method will be called. If no request is received within timeout seconds, handle_timeout() will be called and handle_request() will return.

**serve_forever**(poll_interval=0.5)

Handle requests until an explicit shutdown() request. Poll for shutdown every poll_interval seconds. Ignores the timeout attribute. It also calls service_actions(), which may be used by a subclass or mixin to provide actions specific to a
given service. For example, the `ForkingMixIn` class uses `service_actions()` to clean up zombie child processes.

*Changed in version 3.3:* Added `service_actions` call to the `serve_forever` method.

**service_actions()**
This is called in the `serve_forever()` loop. This method can be overridden by subclasses or mixin classes to perform actions specific to a given service, such as cleanup actions.

*New in version 3.3.*

**shutdown()**
Tell the `serve_forever()` loop to stop and wait until it does.

**server_close()**
Clean up the server. May be overridden.

**address_family**
The family of protocols to which the server’s socket belongs. Common examples are `socket.AF_INET` and `socket.AF_UNIX`.

**RequestHandlerClass**
The user-provided request handler class; an instance of this class is created for each request.

**server_address**
The address on which the server is listening. The format of addresses varies depending on the protocol family; see the documentation for the `socket` module for details. For Internet protocols, this is a tuple containing a string giving the address,
and an integer port number: ('127.0.0.1', 80), for example.

**socket**

The socket object on which the server will listen for incoming requests.

The server classes support the following class variables:

**allow_reuse_address**

Whether the server will allow the reuse of an address. This defaults to `False`, and can be set in subclasses to change the policy.

**request_queue_size**

The size of the request queue. If it takes a long time to process a single request, any requests that arrive while the server is busy are placed into a queue, up to `request_queue_size` requests. Once the queue is full, further requests from clients will get a “Connection denied” error. The default value is usually 5, but this can be overridden by subclasses.

**socket_type**

The type of socket used by the server; `socket.SOCK_STREAM` and `socket.SOCK_DGRAM` are two common values.

**timeout**

Timeout duration, measured in seconds, or `None` if no timeout is desired. If `handle_request()` receives no incoming requests within the timeout period, the `handle_timeout()` method is called.

There are various server methods that can be overridden by
subclasses of base server classes like TCPServer; these methods aren't useful to external users of the server object.

**finish_request**(request, client_address)
Actually processes the request by instantiating RequestHandlerClass and calling its handle() method.

**get_request()**
Must accept a request from the socket, and return a 2-tuple containing the new socket object to be used to communicate with the client, and the client’s address.

**handle_error**(request, client_address)
This function is called if the handle() method of a RequestHandlerClass instance raises an exception. The default action is to print the traceback to standard error and continue handling further requests.

*Changed in version 3.6:* Now only called for exceptions derived from the Exception class.

**handle_timeout()**
This function is called when the timeout attribute has been set to a value other than None and the timeout period has passed with no requests being received. The default action for forking servers is to collect the status of any child processes that have exited, while in threading servers this method does nothing.

**process_request**(request, client_address)
Calls finish_request() to create an instance of the RequestHandlerClass. If desired, this function can create a
new process or thread to handle the request; the ForkingMixIn and ThreadingMixIn classes do this.

**server_activate()**

Called by the server’s constructor to activate the server. The default behavior for a TCP server just invokes `listen()` on the server’s socket. May be overridden.

**server_bind()**

Called by the server’s constructor to bind the socket to the desired address. May be overridden.

**verify_request(request, client_address)**

Must return a Boolean value; if the value is `True`, the request will be processed, and if it’s `False`, the request will be denied. This function can be overridden to implement access controls for a server. The default implementation always returns `True`.

*Changed in version 3.6:* Support for the context manager protocol was added. Exiting the context manager is equivalent to calling `server_close()`.
21.21.3. Request Handler Objects

class socketserver.BaseRequestHandler

This is the superclass of all request handler objects. It defines the interface, given below. A concrete request handler subclass must define a new handle() method, and can override any of the other methods. A new instance of the subclass is created for each request.

setup()

Called before the handle() method to perform any initialization actions required. The default implementation does nothing.

handle()

This function must do all the work required to service a request. The default implementation does nothing. Several instance attributes are available to it; the request is available as self.request; the client address as self.client_address; and the server instance as self.server, in case it needs access to per-server information.

The type of self.request is different for datagram or stream services. For stream services, self.request is a socket object; for datagram services, self.request is a pair of string and socket.

finish()

Called after the handle() method to perform any clean-up actions required. The default implementation does nothing. If
setup() raises an exception, this function will not be called.

```python
class socketserver.StreamRequestHandler
class socketserver.DatagramRequestHandler
```

These BaseRequestHandler subclasses override the setup() and finish() methods, and provide self.rfile and self.wfile attributes. The self.rfile and self.wfile attributes can be read or written, respectively, to get the request data or return data to the client.

The rfile attributes of both classes support the io.BufferedIOBase readable interface, and DatagramRequestHandler.wfile supports the io.BufferedIOBase writable interface.

*Changed in version 3.6:* StreamRequestHandler.wfile also supports the io.BufferedIOBase writable interface.
21.21.4. Examples

21.21.4.1. socketserver.TCPServer Example

This is the server side:

```python
import socketserver

class MyTCPHandler(socketserver.BaseRequestHandler):
    """
    The request handler class for our server.

    It is instantiated once per connection to the server, and must
    override the handle() method to implement communication with
    the client.
    """
    def handle(self):
        # self.request is the TCP socket connected to
        self.data = self.request.recv(1024).strip()
        print("{} wrote:").format(self.client_address)
        print(self.data)
        # just send back the same data, but upper-cased
        self.request.sendall(self.data.upper())

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999

    # Create the server, binding to localhost on port 9999
    with socketserver.TCPServer((HOST, PORT), MyTCPHandler):
        # Activate the server; this will keep running
        # interrupt the program with Ctrl-C
        server.serve_forever()
```
An alternative request handler class that makes use of streams (file-like objects that simplify communication by providing the standard file interface):

```python
class MyTCPHandler(socketserver.StreamRequestHandler):
    def handle(self):
        # self.rfile is a file-like object created by the handler;
        # we can now use e.g. readline() instead of raw recv() calls
        self.data = self.rfile.readline().strip()
        print("{} wrote:").format(self.client_address)
        print(self.data)
        # Likewise, self.wfile is a file-like object to the client
        self.wfile.write(self.data.upper())
```

The difference is that the `readline()` call in the second handler will call `recv()` multiple times until it encounters a newline character, while the single `recv()` call in the first handler will just return what has been sent from the client in one `sendall()` call.

This is the client side:

```python
import socket
import sys

HOST, PORT = "localhost", 9999
data = " " .join(sys.argv[1:])

# Create a socket (SOCK_STREAM means a TCP socket)
with socket.socket(socket.AF_INET, socket.SOCK_STREAM) as sock:
    # Connect to server and send data
    sock.connect((HOST, PORT))
    sock.sendall(bytes(data + "\n", "utf-8"))
```
# Receive data from the server and shut down
received = str(sock.recv(1024), "utf-8")
print("Sent: {}".format(data))
print("Received: {}".format(received))

The output of the example should look something like this:

Server:

```
$ python TCPServer.py
127.0.0.1 wrote:
b'hello world with TCP'
127.0.0.1 wrote:
b'python is nice'
```

Client:

```
$ python TCPClient.py hello world with TCP
Sent: hello world with TCP
Received: HELLO WORLD WITH TCP
$ python TCPClient.py python is nice
Sent: python is nice
Received: PYTHON IS NICE
```

21.21.4.2. `socketserver.UDPServer` Example

This is the server side:

```python
import socketserver

class MyUDPHandler(socketserver.BaseRequestHandler):
    
    """
    This class works similar to the TCP handler clas
```
self.request consists of a pair of data and client socket, and since there is no connection the client address must be given explicitly when sending data back via sendto().

```python

def handle(self):
    data = self.request[0].strip()
    socket = self.request[1]
    print("{} wrote:").format(self.client_address)
    print(data)
    socket.sendto(data.upper(), self.client_address)

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999
    with socketserver.UDPServer((HOST, PORT), MyUDPHandler):
        server.serve_forever()

This is the client side:

```python

```
The output of the example should look exactly like for the TCP server example.

21.21.4.3. Asynchronous Mixins

To build asynchronous handlers, use the `ThreadingMixIn` and `ForkingMixIn` classes.

An example for the `ThreadingMixIn` class:

```python
import socket
import threading
import socketserver

class ThreadedTCPRequestHandler(socketserver.BaseRequestHandler):
    
def handle(self):
        data = str(self.request.recv(1024), 'ascii')
        cur_thread = threading.current_thread()
        response = bytes('{}: {}'.format(cur_thread.name, self.request.sendall(response))

class ThreadedTCPServer(socketserver.ThreadingMixIn, socketserver.TCPServer):
    pass

def client(ip, port, message):
    with socket.socket(socket.AF_INET, socket.SOCK_STREAM)
    sock.connect((ip, port))
    sock.sendall(bytes(message, 'ascii'))
    response = str(sock.recv(1024), 'ascii')
    print("Received: {}".format(response))

if __name__ == "__main__":
    HOST, PORT = "localhost", 0
```
server = ThreadedTCPServer((HOST, PORT), ThreadedTCPRequestHandler)

with server:
    ip, port = server.server_address

    # Start a thread with the server -- that thread will then start one
    # more thread for each request
    server_thread = threading.Thread(target=server.serve_forever)
    server_thread.daemon = True
    server_thread.start()

    print("Server loop running in thread: ", server_thread.name)

    client(ip, port, "Hello World 1")
    client(ip, port, "Hello World 2")
    client(ip, port, "Hello World 3")

    server.shutdown()

The output of the example should look something like this:

$ python ThreadedTCPServer.py
Server loop running in thread: Thread-1
Received: Thread-2: Hello World 1
Received: Thread-3: Hello World 2
Received: Thread-4: Hello World 3

The ForkingMixIn class is used in the same way, except that the server will spawn a new process for each request. Available only on POSIX platforms that support fork().
The Python Software Foundation is a non-profit corporation. Please donate.
Last updated on Jan 31, 2018. Found a bug?
Created using Sphinx 1.6.6.
21.22. `http.server` — HTTP servers

Source code: `Lib/http/server.py`

This module defines classes for implementing HTTP servers (Web servers).

One class, `HTTPServer`, is a `socketserver.TCPServer` subclass. It creates and listens at the HTTP socket, dispatching the requests to a handler. Code to create and run the server looks like this:

```python
def run(server_class=HTTPServer, handler_class=BaseHTTPRequestHandler, server_address = ('', 8000)):
    httpd = server_class(server_address, handler_class)
    httpd.serve_forever()
```

```python
class http.server.HTTPServer(server_address, RequestHandlerClass):
    This class builds on the `TCPServer` class by storing the server address as instance variables named `server_name` and `server_port`. The server is accessible by the handler, typically through the handler's server instance variable.

The `HTTPServer` must be given a `RequestHandlerClass` on instantiation, of which this module provides three different variants:

class http.server.BaseHTTPRequestHandler(request, client_address, server)```
This class is used to handle the HTTP requests that arrive at the server. By itself, it cannot respond to any actual HTTP requests; it must be subclassed to handle each request method (e.g. GET or POST). `BaseHTTPRequestHandler` provides a number of class and instance variables, and methods for use by subclasses.

The handler will parse the request and the headers, then call a method specific to the request type. The method name is constructed from the request. For example, for the request method SPAM, the `do_SPAM()` method will be called with no arguments. All of the relevant information is stored in instance variables of the handler. Subclasses should not need to override or extend the `__init__()` method.

`BaseHTTPRequestHandler` has the following instance variables:

**client_address**
Contains a tuple of the form `(host, port)` referring to the client's address.

**server**
Contains the server instance.

**close_connection**
Boolean that should be set before `handle_one_request()` returns, indicating if another request may be expected, or if the connection should be shut down.

**requestline**
Contains the string representation of the HTTP request line. The terminating CRLF is stripped. This attribute should be set by `handle_one_request()`. If no valid request line was processed, it should be set to the empty string.
**command**
Contains the command (request type). For example, 'GET'.

**path**
Contains the request path.

**request_version**
Contains the version string from the request. For example, 'HTTP/1.0'.

**headers**
Holds an instance of the class specified by the `MessageClass` class variable. This instance parses and manages the headers in the HTTP request. The `parse_headers()` function from `http.client` is used to parse the headers and it requires that the HTTP request provide a valid RFC 2822 style header.

**rfile**
An `io.BufferedIOBase` input stream, ready to read from the start of the optional input data.

**wfile**
Contains the output stream for writing a response back to the client. Proper adherence to the HTTP protocol must be used when writing to this stream in order to achieve successful interoperation with HTTP clients.

*Changed in version 3.6:* This is an `io.BufferedIOBase` stream.

`BaseHTTPRequestHandler` has the following attributes:

**server_version**
Specifies the server software version. You may want to override this. The format is multiple whitespace-separated strings, where each string is of the form name[/version]. For example, 'BaseHTTP/0.2'.

**sys_version**
Contains the Python system version, in a form usable by the *version_string* method and the *server_version* class variable. For example, 'Python/1.4'.

**error_message_format**
Specifies a format string that should be used by *send_error()* method for building an error response to the client. The string is filled by default with variables from *responses* based on the status code that passed to *send_error()*.

**error_content_type**
Specifies the Content-Type HTTP header of error responses sent to the client. The default value is 'text/html'.

**protocol_version**
This specifies the HTTP protocol version used in responses. If set to 'HTTP/1.1', the server will permit HTTP persistent connections; however, your server *must* then include an accurate Content-Length header (using *send_header()*)) in all of its responses to clients. For backwards compatibility, the setting defaults to 'HTTP/1.0'.

**MessageClass**
Specifies an *email.message.Message*-like class to parse HTTP headers. Typically, this is not overridden, and it defaults
to http.client.HTTPMessage.

responses
This attribute contains a mapping of error code integers to two-
element tuples containing a short and long message. For example, `{code: (shortmessage, longmessage)}`. The shortmessage is usually used as the message key in an error response, and longmessage as the explain key. It is used by send_response_only() and send_error() methods.

A BaseHTTPRequestHandler instance has the following methods:

handle()
Calls handle_one_request() once (or, if persistent connections are enabled, multiple times) to handle incoming HTTP requests. You should never need to override it; instead, implement appropriate do_*() methods.

handle_one_request()
This method will parse and dispatch the request to the appropriate do_*() method. You should never need to override it.

handle_expect_100()
When a HTTP/1.1 compliant server receives an Expect: 100-continue request header it responds back with a 100 Continue followed by 200  OK headers. This method can be overridden to raise an error if the server does not want the client to continue. For e.g. server can chose to send 417 Expectation Failed as a response header and return False.
New in version 3.2.

**send_error**(code, message=None, explain=None)
Sends and logs a complete error reply to the client. The numeric code specifies the HTTP error code, with message as an optional, short, human readable description of the error. The explain argument can be used to provide more detailed information about the error; it will be formatted using the error_message_format attribute and emitted, after a complete set of headers, as the response body. The responses attribute holds the default values for message and explain that will be used if no value is provided; for unknown codes the default value for both is the string ???.

The body will be empty if the method is HEAD or the response code is one of the following: 1xx, 204 No Content, 205 Reset Content, 304 Not Modified.

*Changed in version 3.4:* The error response includes a Content-Length header. Added the explain argument.

**send_response**(code, message=None)
Adds a response header to the headers buffer and logs the accepted request. The HTTP response line is written to the internal buffer, followed by Server and Date headers. The values for these two headers are picked up from the version_string() and date_time_string() methods, respectively. If the server does not intend to send any other headers using the send_header() method, then send_response() should be followed by an end_headers() call.

*Changed in version 3.3:* Headers are stored to an internal buffer.
and `end_headers()` needs to be called explicitly.

**send_header**(*keyword, value*)

Adds the HTTP header to an internal buffer which will be written to the output stream when either `end_headers()` or `flush_headers()` is invoked. *keyword* should specify the header keyword, with *value* specifying its value. Note that, after the send_header calls are done, `end_headers()` MUST BE called in order to complete the operation.

*Changed in version 3.2:* Headers are stored in an internal buffer.

**send_response_only**(*code, message=None*)

Sends the response header only, used for the purposes when 100 **Continue** response is sent by the server to the client. The headers not buffered and sent directly the output stream. If the *message* is not specified, the HTTP message corresponding the response *code* is sent.

*New in version 3.2.*

**end_headers()**

Adds a blank line (indicating the end of the HTTP headers in the response) to the headers buffer and calls `flush_headers()`.

*Changed in version 3.2:* The buffered headers are written to the output stream.

**flush_headers()**

Finally send the headers to the output stream and flush the internal headers buffer.
New in version 3.3.

**log_request**(code='-', size='-')
Logs an accepted (successful) request. *code* should specify the numeric HTTP code associated with the response. If a size of the response is available, then it should be passed as the *size* parameter.

**log_error**( )
Logs an error when a request cannot be fulfilled. By default, it passes the message to **log_message()**, so it takes the same arguments (*format* and additional values).

**log_message**(format, ...)
Logs an arbitrary message to **sys.stderr**. This is typically overridden to create custom error logging mechanisms. The *format* argument is a standard printf-style format string, where the additional arguments to **log_message()** are applied as inputs to the formatting. The client ip address and current date and time are prefixed to every message logged.

**version_string**( )
Returns the server software’s version string. This is a combination of the *server_version* and *sys_version* attributes.

**date_time_string**(timestamp=None)
Returns the date and time given by *timestamp* (which must be *None* or in the format returned by **time.time()**), formatted for a message header. If *timestamp* is omitted, it uses the current date and time.
The result looks like 'Sun, 06 Nov 1994 08:49:37 GMT'.

**log_date_time_string()**
Returns the current date and time, formatted for logging.

**address_string()**
Returns the client address.

*Changed in version 3.3:* Previously, a name lookup was performed. To avoid name resolution delays, it now always returns the IP address.

```python
class http.server.SimpleHTTPRequestHandler(request, client_address, server, directory=None)
```
This class serves files from the current directory and below, directly mapping the directory structure to HTTP requests.

A lot of the work, such as parsing the request, is done by the base class `BaseHTTPRequestHandler`. This class implements the `do_GET()` and `do_HEAD()` functions.

The following are defined as class-level attributes of `SimpleHTTPRequestHandler`:

**server_version**
This will be "SimpleHTTP/" + `__version__`, where `__version__` is defined at the module level.

**extensions_map**
A dictionary mapping suffixes into MIME types. The default is signified by an empty string, and is considered to be `application/octet-stream`. The mapping is used case-insensitively, and so should contain only lower-cased keys.
directory

If not specified, the directory to serve is the current working directory.

The SimpleHTTPRequestHandler class defines the following methods:

**do_HEAD()**

This method serves the 'HEAD' request type: it sends the headers it would send for the equivalent GET request. See the do_GET() method for a more complete explanation of the possible headers.

**do_GET()**

The request is mapped to a local file by interpreting the request as a path relative to the current working directory.

If the request was mapped to a directory, the directory is checked for a file named `index.html` or `index.htm` (in that order). If found, the file's contents are returned; otherwise a directory listing is generated by calling the list_directory() method. This method uses `os.listdir()` to scan the directory, and returns a 404 error response if the listdir() fails.

If the request was mapped to a file, it is opened. Any OSError exception in opening the requested file is mapped to a 404, 'File not found' error. If there was a 'If-Modified-Since' header in the request, and the file was not modified after this time, a 304, 'Not Modified' response is sent. Otherwise, the content type is guessed by calling the guess_type() method, which in turn uses the
The `extensions_map` variable, and the file contents are returned.

A 'Content-type:' header with the guessed content type is output, followed by a 'Content-Length:' header with the file's size and a 'Last-Modified:' header with the file's modification time.

Then follows a blank line signifying the end of the headers, and then the contents of the file are output. If the file's MIME type starts with text/ the file is opened in text mode; otherwise binary mode is used.

For example usage, see the implementation of the `test()` function invocation in the `http.server` module.

*Changed in version 3.7:* Support of the 'If-Modified-Since' header.

The `SimpleHTTPRequestHandler` class can be used in the following manner in order to create a very basic webserver serving files relative to the current directory:

```python
import http.server
import socketserver

PORT = 8000

Handler = http.server.SimpleHTTPRequestHandler

with socketserver.TCPServer(('', PORT), Handler) as httpd:
    print("serving at port", PORT)
    httpd.serve_forever()
```
**http.server** can also be invoked directly using the `-m` switch of the interpreter with a `port number` argument. Similar to the previous example, this serves files relative to the current directory:

```python
python -m http.server 8000
```

By default, server binds itself to all interfaces. The option `-b/--bind` specifies a specific address to which it should bind. For example, the following command causes the server to bind to localhost only:

```python
python -m http.server 8000 --bind 127.0.0.1
```

*New in version 3.4:* `--bind` argument was introduced.

By default, server uses the current directory. The option `-d/--directory` specifies a directory to which it should serve the files. For example, the following command uses a specific directory:

```python
python -m http.server --directory /tmp/
```

*New in version 3.7:* `--directory` specify alternate directory

**class** http.server.[CGIHTTPRequestHandler](http.server.CGIHTTPRequestHandler)(`request`, `client_address`, `server`)

This class is used to serve either files or output of CGI scripts from the current directory and below. Note that mapping HTTP hierarchic structure to local directory structure is exactly as in [SimpleHTTPRequestHandler](http.server.SimpleHTTPRequestHandler).

**Note:** CGI scripts run by the [CGIHTTPRequestHandler](http.server.CGIHTTPRequestHandler) class cannot execute redirects (HTTP code 302), because code 200 (script output follows) is sent prior to execution of the CGI script.
This pre-empts the status code.

The class will however, run the CGI script, instead of serving it as a file, if it guesses it to be a CGI script. Only directory-based CGI are used — the other common server configuration is to treat special extensions as denoting CGI scripts.

The `do_GET()` and `do_HEAD()` functions are modified to run CGI scripts and serve the output, instead of serving files, if the request leads to somewhere below the `cgi_directories` path.

The `CGIHTTPRequestHandler` defines the following data member:

**cgi_directories**

This defaults to `['/cgi-bin', '/htbin']` and describes directories to treat as containing CGI scripts.

The `CGIHTTPRequestHandler` defines the following method:

**do_POST()**

This method serves the 'POST' request type, only allowed for CGI scripts. Error 501, “Can only POST to CGI scripts”, is output when trying to POST to a non-CGI url.

Note that CGI scripts will be run with UID of user nobody, for security reasons. Problems with the CGI script will be translated to error 403.

`CGIHTTPRequestHandler` can be enabled in the command line by passing the `--cgi` option:

```
python -m http.server --cgi 8000
```
21.23. **http.cookies — HTTP state management**

**Source code:** Lib/http/cookies.py

The `http.cookies` module defines classes for abstracting the concept of cookies, an HTTP state management mechanism. It supports both simple string-only cookies, and provides an abstraction for having any serializable data-type as cookie value.

The module formerly strictly applied the parsing rules described in the [RFC 2109](https://tools.ietf.org/html/rfc2109) and [RFC 2068](https://tools.ietf.org/html/rfc2068) specifications. It has since been discovered that MSIE 3.0x doesn’t follow the character rules outlined in those specs and also many current day browsers and servers have relaxed parsing rules when comes to Cookie handling. As a result, the parsing rules used are a bit less strict.

The character set, `string.ascii_letters`, `string.digits` and `!#$%&'*+-.^_`~: denote the set of valid characters allowed by this module in Cookie name (as key).

*Changed in version 3.3:* Allowed ‘:’ as a valid Cookie name character.

**Note:** On encountering an invalid cookie, `CookieError` is raised, so if your cookie data comes from a browser you should always prepare for invalid data and catch `CookieError` on parsing.

```python
exception http.cookies.CookieError
    Exception failing because of RFC 2109 invalidity: incorrect
```
attributes, incorrect *Set-Cookie* header, etc.

```python
class http.cookies.BaseCookie([input])
```
This class is a dictionary-like object whose keys are strings and whose values are `Morsel` instances. Note that upon setting a key to a value, the value is first converted to a `Morsel` containing the key and the value.

If `input` is given, it is passed to the `load()` method.

```python
class http.cookies.SimpleCookie([input])
```
This class derives from `BaseCookie` and overrides `value_decode()` and `value_encode()` to be the identity and `str()` respectively.

**See also:**

**Module** `http.cookiejar`  
HTTP cookie handling for web *clients*. The `http.cookiejar` and `http.cookies` modules do not depend on each other.

**RFC 2109 - HTTP State Management Mechanism**  
This is the state management specification implemented by this module.
21.23.1. Cookie Objects

BaseCookie.value_decode(val)
Return a decoded value from a string representation. Return value can be any type. This method does nothing in BaseCookie — it exists so it can be overridden.

BaseCookie.value_encode(val)
Return an encoded value. val can be any type, but return value must be a string. This method does nothing in BaseCookie — it exists so it can be overridden.

In general, it should be the case that value_encode() and value_decode() are inverses on the range of value_decode.

BaseCookie.output(attrs=None, header='Set-Cookie:', sep='
')
Return a string representation suitable to be sent as HTTP headers. attrs and header are sent to each Morsel’s output() method. sep is used to join the headers together, and is by default the combination '
' (CRLF).

BaseCookie.js_output(attrs=None)
Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP headers was sent.

The meaning for attrs is the same as in output().

BaseCookie.load(rawdata)
If rawdata is a string, parse it as an HTTP_COOKIE and add the values found there as Morsels. If it is a dictionary, it is equivalent
for k, v in rawdata.items():
    cookie[k] = v
21.23.2. Morsel Objects

class http.cookies.Morsel

Abstract a key/value pair, which has some RFC 2109 attributes.

Morsels are dictionary-like objects, whose set of keys is constant — the valid RFC 2109 attributes, which are

- `expires`
- `path`
- `comment`
- `domain`
- `max-age`
- `secure`
- `version`
- `httponly`

The attribute `httponly` specifies that the cookie is only transferred in HTTP requests, and is not accessible through JavaScript. This is intended to mitigate some forms of cross-site scripting.

The keys are case-insensitive and their default value is ''. 

*Changed in version 3.5:* `__eq__() now takes key and value into account.*

*Changed in version 3.7:* Attributes `key`, `value` and `coded_value` are read-only. Use `set()` for setting them.

Morsel.value

The value of the cookie.
Morsel.coded_value

The encoded value of the cookie — this is what should be sent.

Morsel.key

The name of the cookie.

Morsel.set(key, value, coded_value)

Set the key, value and coded_value attributes.

Morsel.isReservedKey(K)

Whether K is a member of the set of keys of a Morsel.

Morsel.output(attrs=None, header='Set-Cookie: ')

Return a string representation of the Morsel, suitable to be sent as an HTTP header. By default, all the attributes are included, unless attrs is given, in which case it should be a list of attributes to use. header is by default "Set-Cookie: ".

Morsel.js_output(attrs=None)

Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP header was sent.

The meaning for attrs is the same as in output().

Morsel.OutputString(attrs=None)

Return a string representing the Morsel, without any surrounding HTTP or JavaScript.

The meaning for attrs is the same as in output().

Morsel.update(values)

Update the values in the Morsel dictionary with the values in the
dictionary values. Raise an error if any of the keys in the values dict is not a valid RFC 2109 attribute.

Changed in version 3.5: an error is raised for invalid keys.

Morsel.copy(value)
Return a shallow copy of the Morsel object.

Changed in version 3.5: return a Morsel object instead of a dict.

Morsel.setdefault(key, value=None)
Raise an error if key is not a valid RFC 2109 attribute, otherwise behave the same as dict.setdefault().
21.23.3. Example

The following example demonstrates how to use the `http.cookies` module.

```python
>>> from http import cookies
>>> C = cookies.SimpleCookie()
>>> C["fig"] = "newton"
>>> C["sugar"] = "wafer"
>>> print(C) # generate HTTP headers
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> print(C.output()) # same thing
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> C = cookies.SimpleCookie()
>>> C["rocky"] = "road"
>>> C["rocky"]["path"] = "/cookie"
>>> print(C.output(header="Cookie:"))
Cookie: rocky=road; Path=/cookie
>>> print(C.output(attrs=[], header="Cookie:"))
Cookie: rocky=road
>>> C = cookies.SimpleCookie()
>>> C.load("chips=ahoy; vienna=finger") # load from
>>> print(C)
Set-Cookie: chips=ahoy
Set-Cookie: vienna=finger
>>> C = cookies.SimpleCookie()
>>> C.load('keebler="E=everybody; L="Loves"; fudge')
>>> print(C)
Set-Cookie: keebler="E=everybody; L="Loves"; fudge
>>> C = cookies.SimpleCookie()
>>> C["oreo"] = "doublestuff"
>>> C["oreo"]["path"] = "/"
>>> print(C)
```
Set-Cookie: oreo=doublestuff; Path=/
>>> C = cookies.SimpleCookie()
>>> C["twix"] = "none for you"
>>> C["twix"]).value
'none for you'
>>> C = cookies.SimpleCookie()
>>> C["number"] = 7  # equivalent to C["number"] = str(7)
>>> C["string"] = "seven"
>>> C["number"]).value
'7'
>>> C["string"]).value
'seven'
>>> print(C)
Set-Cookie: number=7
Set-Cookie: string=seven
21.24. http.cookiejar — Cookie handling for HTTP clients

Source code: Lib/http/cookiejar.py

The http.cookiejar module defines classes for automatic handling of HTTP cookies. It is useful for accessing web sites that require small pieces of data – cookies – to be set on the client machine by an HTTP response from a web server, and then returned to the server in later HTTP requests.

Both the regular Netscape cookie protocol and the protocol defined by RFC 2965 are handled. RFC 2965 handling is switched off by default. RFC 2109 cookies are parsed as Netscape cookies and subsequently treated either as Netscape or RFC 2965 cookies according to the 'policy' in effect. Note that the great majority of cookies on the Internet are Netscape cookies. http.cookiejar attempts to follow the de-facto Netscape cookie protocol (which differs substantially from that set out in the original Netscape specification), including taking note of the max-age and port cookie-attributes introduced with RFC 2965.

**Note:** The various named parameters found in Set-Cookie and Set-Cookie2 headers (eg. domain and expires) are conventionally referred to as attributes. To distinguish them from Python attributes, the documentation for this module uses the term cookie-attribute instead.

The module defines the following exception:
exception http.cookiejar.LoadError

Instances of FileCookieJar raise this exception on failure to load cookies from a file. LoadError is a subclass of OSError.

Changed in version 3.3: LoadError was made a subclass of OSError instead of IOError.

The following classes are provided:

class http.cookiejar.CookieJar(policy=\n
    policy is an object implementing the CookiePolicy interface.

    The CookieJar class stores HTTP cookies. It extracts cookies from HTTP requests, and returns them in HTTP responses. CookieJar instances automatically expire contained cookies when necessary. Subclasses are also responsible for storing and retrieving cookies from a file or database.

class http.cookiejar.FileCookieJar(filename, delayload=None, policy=\n
    policy is an object implementing the CookiePolicy interface. For the other arguments, see the documentation for the corresponding attributes.

    A CookieJar which can load cookies from, and perhaps save cookies to, a file on disk. Cookies are NOT loaded from the named file until either the load() or revert() method is called. Subclasses of this class are documented in section FileCookieJar subclasses and co-operation with web browsers.

class http.cookiejar.CookiePolicy

    This class is responsible for deciding whether each cookie should be accepted from / returned to the server.
class http.cookiejar.DefaultCookiePolicy(blocked_domains=None, allowed_domains=None, netscape=True, rfc2965=False, rfc2109_as_netscape=None, hide_cookie2=False, strict_domain=False, strict_rfc2965_unverifiable=True, strict_ns_unverifiable=False, strict_ns_domain=http.cookiejar.DefaultCookiePolicy.DomainLiberal, strict_ns_set_initial_dollar=False, strict_ns_set_path=False)

Constructor arguments should be passed as keyword arguments only. `blocked_domains` is a sequence of domain names that we never accept cookies from, nor return cookies to. `allowed_domains` if not `None`, this is a sequence of the only domains for which we accept and return cookies. For all other arguments, see the documentation for `CookiePolicy` and `DefaultCookiePolicy` objects.

`DefaultCookiePolicy` implements the standard accept / reject rules for Netscape and RFC 2965 cookies. By default, RFC 2109 cookies (i.e., cookies received in a Set-Cookie header with a version cookie-attribute of 1) are treated according to the RFC 2965 rules. However, if RFC 2965 handling is turned off or `rfc2109_as_netscape` is `True`, RFC 2109 cookies are 'downgraded' by the `CookieJar` instance to Netscape cookies, by setting the version attribute of the `Cookie` instance to 0. `DefaultCookiePolicy` also provides some parameters to allow some fine-tuning of policy.

class http.cookiejar.Cookie

This class represents Netscape, RFC 2109 and RFC 2965 cookies. It is not expected that users of `http.cookiejar` construct their own `Cookie` instances. Instead, if necessary, call `make_cookies()` on a `CookieJar` instance.
See also:

**Module urllib.request**
URL opening with automatic cookie handling.

**Module http.cookies**
HTTP cookie classes, principally useful for server-side code. The `http.cookiejar` and `http.cookies` modules do not depend on each other.

https://curl.haxx.se/rfc/cookie_spec.html
The specification of the original Netscape cookie protocol. Though this is still the dominant protocol, the ‘Netscape cookie protocol’ implemented by all the major browsers (and `http.cookiejar`) only bears a passing resemblance to the one sketched out in `cookie_spec.html`.

**RFC 2109 - HTTP State Management Mechanism**
Obsoleted by RFC 2965. Uses `Set-Cookie` with version=1.

**RFC 2965 - HTTP State Management Mechanism**
The Netscape protocol with the bugs fixed. Uses `Set-Cookie2` in place of `Set-Cookie`. Not widely used.

http://kristol.org/cookie/errata.html
Unfinished errata to RFC 2965.

**RFC 2964 - Use of HTTP State Management**

CookieJar objects support the iterator protocol for iterating over contained Cookie objects.

CookieJar has the following methods:

CookieJar.add_cookie_header(request)

Add correct Cookie header to request.

If policy allows (ie. the rfc2965 and hide_cookie2 attributes of the CookieJar's CookiePolicy instance are true and false respectively), the Cookie2 header is also added when appropriate.

The request object (usually a urllib.request.Request instance) must support the methods get_full_url(), get_host(), get_type(), unverifiable(), has_header(), get_header(), header_items(), add_unredirected_header() and origin_req_host attribute as documented by urllib.request.

Changed in version 3.3: request object needs origin_req_host attribute. Dependency on a deprecated method get_origin_req_host() has been removed.

CookieJar.extract_cookies(response, request)

Extract cookies from HTTP response and store them in the CookieJar, where allowed by policy.

The CookieJar will look for allowable Set-Cookie and Set-
Cookie2 headers in the `response` argument, and store cookies as appropriate (subject to the `CookiePolicy.set_ok()` method's approval).

The `response` object (usually the result of a call to `urllib.request.urlopen()`, or similar) should support an `info()` method, which returns an `email.message.Message` instance.

The `request` object (usually a `urllib.request.Request` instance) must support the methods `get_full_url()`, `get_host()`, `unverifiable()`, and `origin_req_host` attribute, as documented by `urllib.request`. The request is used to set default values for cookie-attributes as well as for checking that the cookie is allowed to be set.

*Changed in version 3.3:* `request` object needs `origin_req_host` attribute. Dependency on a deprecated method `get_origin_req_host()` has been removed.

**CookieJar**. `set_policy(policy)`
Set the `CookiePolicy` instance to be used.

**CookieJar**. `make_cookies(response, request)`
Return sequence of `Cookie` objects extracted from `response` object.

See the documentation for `extract_cookies()` for the interfaces required of the `response` and `request` arguments.

**CookieJar**. `set_cookie_if_ok(cookie, request)`
Set a `Cookie` if policy says it's OK to do so.
CookieJar.\texttt{set\_cookie}(\texttt{cookie})

Set a \texttt{Cookie}, without checking with policy to see whether or not it should be set.

CookieJar.\texttt{clear}([\texttt{domain}[, \texttt{path}[[, \texttt{name}]])]

Clear some cookies.

If invoked without arguments, clear all cookies. If given a single argument, only cookies belonging to that \texttt{domain} will be removed. If given two arguments, cookies belonging to the specified \texttt{domain} and URL \texttt{path} are removed. If given three arguments, then the cookie with the specified \texttt{domain}, \texttt{path} and \texttt{name} is removed.

Raises \texttt{KeyError} if no matching cookie exists.

CookieJar.\texttt{clear\_session\_cookies}()

Discard all session cookies.

Discards all contained cookies that have a true discard attribute (usually because they had either no \texttt{max-age} or \texttt{expires} cookie-attribute, or an explicit \texttt{discard} cookie-attribute). For interactive browsers, the end of a session usually corresponds to closing the browser window.

Note that the \texttt{save()} method won’t save session cookies anyway, unless you ask otherwise by passing a true \texttt{ignore\_discard} argument.

\texttt{FileCookieJar} implements the following additional methods:

FileCookieJar.\texttt{save}(\texttt{filename=\texttt{None}}, \texttt{ignore\_discard=\texttt{False}}, \texttt{ignore\_expires=\texttt{False}})

Save cookies to a file.
This base class raises `NotImplementedError`. Subclasses may leave this method unimplemented.

`filename` is the name of file in which to save cookies. If `filename` is not specified, `self.filename` is used (whose default is the value passed to the constructor, if any); if `self.filename` is `None`, `ValueError` is raised.

`ignore_discard`: save even cookies set to be discarded.
`ignore_expires`: save even cookies that have expired

The file is overwritten if it already exists, thus wiping all the cookies it contains. Saved cookies can be restored later using the `load()` or `revert()` methods.

```
FileCookieJar.load(filename=None, ignore_discard=False, ignore_expires=False)
```

Load cookies from a file.

Old cookies are kept unless overwritten by newly loaded ones.

Arguments are as for `save()`.

The named file must be in the format understood by the class, or `LoadError` will be raised. Also, `OSError` may be raised, for example if the file does not exist.

*Changed in version 3.3*: `I0Error` used to be raised, it is now an alias of `OSError`.

```
FileCookieJar.revert(filename=None, ignore_discard=False, ignore_expires=False)
```

Clear all cookies and reload cookies from a saved file.
revert() can raise the same exceptions as load(). If there is a failure, the object's state will not be altered.

FileCookieJar instances have the following public attributes:

FileCookieJar.filename
Filename of default file in which to keep cookies. This attribute may be assigned to.

FileCookieJar.delayload
If true, load cookies lazily from disk. This attribute should not be assigned to. This is only a hint, since this only affects performance, not behaviour (unless the cookies on disk are changing). A CookieJar object may ignore it. None of the FileCookieJar classes included in the standard library lazily loads cookies.
21.24.2. FileCookieJar subclasses and cooperation with web browsers

The following CookieJar subclasses are provided for reading and writing.

```
class http.cookiejar.MozillaCookieJar(filename, delayload=None, policy=None)
```

A FileCookieJar that can load from and save cookies to disk in the Mozilla cookies.txt file format (which is also used by the Lynx and Netscape browsers).

**Note:** This loses information about RFC 2965 cookies, and also about newer or non-standard cookie-attributes such as port.

**Warning:** Back up your cookies before saving if you have cookies whose loss / corruption would be inconvenient (there are some subtleties which may lead to slight changes in the file over a load / save round-trip).

Also note that cookies saved while Mozilla is running will get clobbered by Mozilla.

```
class http.cookiejar.LWPCookieJar(filename, delayload=None, policy=None)
```

A FileCookieJar that can load from and save cookies to disk in format compatible with the libwww-perl library's Set-Cookie3 file format. This is convenient if you want to store cookies in a human-readable file.
21.24.3. CookiePolicy Objects

Objects implementing the CookiePolicy interface have the following methods:

**CookiePolicy.set_ok**(cookie, request)
Return boolean value indicating whether cookie should be accepted from server.

*cookie* is a Cookie instance. *request* is an object implementing the interface defined by the documentation for CookieJar.extract_cookies().

**CookiePolicy.return_ok**(cookie, request)
Return boolean value indicating whether cookie should be returned to server.

*cookie* is a Cookie instance. *request* is an object implementing the interface defined by the documentation for CookieJar.add_cookie_header().

**CookiePolicy.domain_return_ok**(domain, request)
Return false if cookies should not be returned, given cookie domain.

This method is an optimization. It removes the need for checking every cookie with a particular domain (which might involve reading many files). Returning true from domain_return_ok() and path_return_ok() leaves all the work to return_ok().

If domain_return_ok() returns true for the cookie domain, path_return_ok() is called for the cookie path. Otherwise,
path_return_ok() and return_ok() are never called for that cookie domain. If path_return_ok() returns true, return_ok() is called with the Cookie object itself for a full check. Otherwise, return_ok() is never called for that cookie path.

Note that domain_return_ok() is called for every cookie domain, not just for the request domain. For example, the function might be called with both "example.com" and "www.example.com" if the request domain is "www.example.com". The same goes for path_return_ok().

The request argument is as documented for return_ok().

CookiePolicy.path_return_ok(path, request)
Return false if cookies should not be returned, given cookie path.

See the documentation for domain_return_ok().

In addition to implementing the methods above, implementations of the CookiePolicy interface must also supply the following attributes, indicating which protocols should be used, and how. All of these attributes may be assigned to.

CookiePolicy.netscape
Implement Netscape protocol.

CookiePolicy.rfc2965
Implement RFC 2965 protocol.

CookiePolicy.hide_cookie2
Don’t add Cookie2 header to requests (the presence of this header indicates to the server that we understand RFC 2965 cookies).
The most useful way to define a `CookiePolicy` class is by subclassing from `DefaultCookiePolicy` and overriding some or all of the methods above. `CookiePolicy` itself may be used as a ‘null policy’ to allow setting and receiving any and all cookies (this is unlikely to be useful).
21.24.4. DefaultCookiePolicy Objects

Implements the standard rules for accepting and returning cookies.

Both RFC 2965 and Netscape cookies are covered. RFC 2965 handling is switched off by default.

The easiest way to provide your own policy is to override this class and call its methods in your overridden implementations before adding your own additional checks:

```python
import http.cookiejar

class MyCookiePolicy(http.cookiejar.DefaultCookiePolicy):
    def set_ok(self, cookie, request):
        if not http.cookiejar.DefaultCookiePolicy.set_ok(self, cookie, request):
            return False
        if i_dont_want_to_store_this_cookie(cookie):
            return False
        return True
```

In addition to the features required to implement the CookiePolicy interface, this class allows you to block and allow domains from setting and receiving cookies. There are also some strictness switches that allow you to tighten up the rather loose Netscape protocol rules a little bit (at the cost of blocking some benign cookies).

A domain blacklist and whitelist is provided (both off by default). Only domains not in the blacklist and present in the whitelist (if the whitelist is active) participate in cookie setting and returning. Use the blocked_domains constructor argument, and blocked_domains() and set_blocked_domains() methods (and the corresponding argument and methods for allowed_domains). If you set a whitelist,
you can turn it off again by setting it to None.

Domains in block or allow lists that do not start with a dot must equal the cookie domain to be matched. For example, "example.com" matches a blacklist entry of "example.com", but "www.example.com" does not. Domains that do start with a dot are matched by more specific domains too. For example, both "www.example.com" and "www.coyote.example.com" match ".example.com" (but "example.com" itself does not). IP addresses are an exception, and must match exactly. For example, if blocked_domains contains "192.168.1.2" and ".168.1.2", 192.168.1.2 is blocked, but 193.168.1.2 is not.

DefaultCookiePolicy implements the following additional methods:

DefaultCookiePolicy.**blocked_domains**()

    Return the sequence of blocked domains (as a tuple).

DefaultCookiePolicy.**set_blocked_domains**(blocked_domains)

    Set the sequence of blocked domains.

DefaultCookiePolicy.**is_blocked**(domain)

    Return whether domain is on the blacklist for setting or receiving cookies.

DefaultCookiePolicy.**allowed_domains**()

    Return None, or the sequence of allowed domains (as a tuple).

DefaultCookiePolicy.**set_allowed_domains**(allowed_domains)

    Set the sequence of allowed domains, or None.
DefaultCookiePolicy\texttt{.is\_not\_allowed}(\texttt{domain})

Return whether \texttt{domain} is not on the whitelist for setting or receiving cookies.

\texttt{DefaultCookiePolicy} instances have the following attributes, which are all initialised from the constructor arguments of the same name, and which may all be assigned to.

\texttt{DefaultCookiePolicy.\texttt{rfc2109\_as\_netscape}}

If true, request that the \texttt{CookieJar} instance downgrade RFC 2109 cookies (ie. cookies received in a \texttt{Set-Cookie} header with a version cookie-attribute of 1) to Netscape cookies by setting the version attribute of the \texttt{Cookie} instance to 0. The default value is \texttt{None}, in which case RFC 2109 cookies are downgraded if and only if RFC 2965 handling is turned off. Therefore, RFC 2109 cookies are downgraded by default.

General strictness switches:

\texttt{DefaultCookiePolicy.\texttt{strict\_domain}}

Don’t allow sites to set two-component domains with country-code top-level domains like \texttt{.co.uk}, \texttt{.gov.uk}, \texttt{.co.nz} etc. This is far from perfect and isn’t guaranteed to work!

RFC 2965 protocol strictness switches:

\texttt{DefaultCookiePolicy.\texttt{strict\_rfc2965\_unverifiable}}

Follow RFC 2965 rules on unverifiable transactions (usually, an unverifiable transaction is one resulting from a redirect or a request for an image hosted on another site). If this is false, cookies are \textit{never} blocked on the basis of verifiability

Netscape protocol strictness switches:
DefaultCookiePolicy.\texttt{strict\_ns\_unverifiable}

Apply RFC 2965 rules on unverifiable transactions even to Netscape cookies.

DefaultCookiePolicy.\texttt{strict\_ns\_domain}

Flags indicating how strict to be with domain-matching rules for Netscape cookies. See below for acceptable values.

DefaultCookiePolicy.\texttt{strict\_ns\_set\_initial\_dollar}

Ignore cookies in Set-Cookie: headers that have names starting with '$$'.

DefaultCookiePolicy.\texttt{strict\_ns\_set\_path}

Don’t allow setting cookies whose path doesn’t path-match request URI.

\texttt{strict\_ns\_domain} is a collection of flags. Its value is constructed by or-ing together (for example, \texttt{DomainStrictNoDots|DomainStrictNonDomain} means both flags are set).

DefaultCookiePolicy.\texttt{DomainStrictNoDots}

When setting cookies, the ‘host prefix’ must not contain a dot (eg. \texttt{www.foo.bar.com} can’t set a cookie for \texttt{.bar.com}, because \texttt{www.foo} contains a dot).

DefaultCookiePolicy.\texttt{DomainStrictNonDomain}

Cookies that did not explicitly specify a domain cookie-attribute can only be returned to a domain equal to the domain that set the cookie (eg. spam.example.com won’t be returned cookies from example.com that had no domain cookie-attribute).

DefaultCookiePolicy.\texttt{DomainRFC2965Match}
When setting cookies, require a full RFC 2965 domain-match.

The following attributes are provided for convenience, and are the most useful combinations of the above flags:

DefaultCookiePolicy. **DomainLiberal**

Equivalent to 0 (ie. all of the above Netscape domain strictness flags switched off).

DefaultCookiePolicy. **DomainStrict**

Equivalent to **DomainStrictNoDots**|**DomainStrictNonDomain**.
21.24.5. Cookie Objects

Cookie instances have Python attributes roughly corresponding to the standard cookie-attributes specified in the various cookie standards. The correspondence is not one-to-one, because there are complicated rules for assigning default values, because the max-age and expires cookie-attributes contain equivalent information, and because RFC 2109 cookies may be ‘downgraded’ by http.cookiejar from version 1 to version 0 (Netscape) cookies.

Assignment to these attributes should not be necessary other than in rare circumstances in a CookiePolicy method. The class does not enforce internal consistency, so you should know what you’re doing if you do that.

Cookie. version

Integer or None. Netscape cookies have version 0. RFC 2965 and RFC 2109 cookies have a version cookie-attribute of 1. However, note that http.cookiejar may 'downgrade' RFC 2109 cookies to Netscape cookies, in which case version is 0.

Cookie. name

Cookie name (a string).

Cookie. value

Cookie value (a string), or None.

Cookie. port

String representing a port or a set of ports (eg. ‘80’, or ‘80,8080’), or None.

Cookie. path
Cookie path (a string, eg. '/acme/rocket_launchers').

Cookie. **secure**
True if cookie should only be returned over a secure connection.

Cookie. **expires**
Integer expiry date in seconds since epoch, or None. See also the **is_expired()** method.

Cookie. **discard**
True if this is a session cookie.

Cookie. **comment**
String comment from the server explaining the function of this cookie, or None.

Cookie. **comment_url**
URL linking to a comment from the server explaining the function of this cookie, or None.

Cookie. **rfc2109**
True if this cookie was received as an RFC 2109 cookie (ie. the cookie arrived in a Set-Cookie header, and the value of the Version cookie-attribute in that header was 1). This attribute is provided because http.cookiejar may ‘downgrade’ RFC 2109 cookies to Netscape cookies, in which case version is 0.

Cookie. **port_specified**
True if a port or set of ports was explicitly specified by the server (in the Set-Cookie / Set-Cookie2 header).

Cookie. **domain_specified**
True if a domain was explicitly specified by the server.

Cookie. **domain_initial_dot**

True if the domain explicitly specified by the server began with a dot ('.').

Cookies may have additional non-standard cookie-attributes. These may be accessed using the following methods:

Cookie. **has_nonstandard_attr**(name)

Return true if cookie has the named cookie-attribute.

Cookie. **get_nonstandard_attr**(name, default=None)

If cookie has the named cookie-attribute, return its value. Otherwise, return default.

Cookie. **set_nonstandard_attr**(name, value)

Set the value of the named cookie-attribute.

The **Cookie** class also defines the following method:

Cookie. **is_expired**(now=None)

True if cookie has passed the time at which the server requested it should expire. If now is given (in seconds since the epoch), return whether the cookie has expired at the specified time.
21.24.6. Examples

The first example shows the most common usage of `http.cookiejar`:

```python
import http.cookiejar, urllib.request
cj = http.cookiejar.CookieJar()
opener = urllib.request.build_opener(urllib.request.
r = opener.open("http://example.com/")
```

This example illustrates how to open a URL using your Netscape, Mozilla, or Lynx cookies (assumes Unix/Netscape convention for location of the cookies file):

```python
import os, http.cookiejar, urllib.request
cj = http.cookiejar.MozillaCookieJar()
cj.load(os.path.join(os.path.expanduser("~"), ".nets
cj = http.cookiejar.MozillaCookieJar()
cj.load(os.path.join(os.path.expanduser("~"), ".nets
cj.load(os.path.join(os.path.expanduser("~"), ".nets

cj = http.cookiejar.MozillaCookieJar()
cj.load(os.path.join(os.path.expanduser("~"), ".nets

import urllib.request
from http.cookiejar import CookieJar, DefaultCookiePolicy
policy = DefaultCookiePolicy(
    rfc2965=True, strict_ns_domain=Policy.DomainStri
blocked_domains=["ads.net", ".ads.net"]
cj = CookieJar(policy)
opener = urllib.request.build_opener(urllib.request.
```

The next example illustrates the use of `DefaultCookiePolicy`. Turn on RFC 2965 cookies, be more strict about domains when setting and returning Netscape cookies, and block some domains from setting cookies or having them returned:
r = opener.open("http://example.com/")
XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get back structured data.

xmlrpc is a package that collects server and client modules implementing XML-RPC. The modules are:

- xmlrpc.client
- xmlrpc.server
XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP(S) as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get back structured data. This module supports writing XML-RPC client code; it handles all the details of translating between conformable Python objects and XML on the wire.

**Warning:** The `xmlrpc.client` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

*Changed in version 3.5:* For HTTPS URIs, `xmlrpc.client` now performs all the necessary certificate and hostname checks by default.

```python
class xmlrpc.client.ServerProxy(uri, transport=None, encoding=None, verbose=False, allow_none=False, use_datetime=False, use_builtin_types=False, *, context=None)
```

*Changed in version 3.3:* The `use_builtin_types` flag was added.

A `ServerProxy` instance is an object that manages communication with a remote XML-RPC server. The required first argument is a URI (Uniform Resource Indicator), and will normally be the URL of the server. The optional second argument is a transport factory instance; by default it is an internal
SafeTransport instance for https: URLs and an internal HTTP Transport instance otherwise. The optional third argument is an encoding, by default UTF-8. The optional fourth argument is a debugging flag.

The following parameters govern the use of the returned proxy instance. If allow_none is true, the Python constant None will be translated into XML; the default behaviour is for None to raise a TypeError. This is a commonly-used extension to the XML-RPC specification, but isn't supported by all clients and servers; see http://ontosys.com/xml-rpc/extensions.php for a description. The use_builtin_types flag can be used to cause date/time values to be presented as datetime.datetime objects and binary data to be presented as bytes objects; this flag is false by default. datetime.datetime, bytes and bytearray objects may be passed to calls. The obsolete use_datetime flag is similar to use_builtin_types but it applies only to date/time values.

Both the HTTP and HTTPS transports support the URL syntax extension for HTTP Basic Authentication: http://user:pass@host:port/path. The user:pass portion will be base64-encoded as an HTTP ‘Authorization’ header, and sent to the remote server as part of the connection process when invoking an XML-RPC method. You only need to use this if the remote server requires a Basic Authentication user and password. If an HTTPS URL is provided, context may be ssl.SSLContext and configures the SSL settings of the underlying HTTPS connection.

The returned instance is a proxy object with methods that can be used to invoke corresponding RPC calls on the remote server. If the remote server supports the introspection API, the proxy can
also be used to query the remote server for the methods it supports (service discovery) and fetch other server-associated metadata.

Types that are conformable (e.g. that can be marshalled through XML), include the following (and except where noted, they are unmarshalled as the same Python type):

<table>
<thead>
<tr>
<th>XML-RPC type</th>
<th>Python type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>bool</td>
</tr>
<tr>
<td>int, i1, i2, i4, i8 or integer</td>
<td>int in range from -2147483648 to 2147483647. Values get the <code>&lt;int&gt;</code> tag.</td>
</tr>
<tr>
<td>double or float</td>
<td>float. Values get the <code>&lt;double&gt;</code> tag.</td>
</tr>
<tr>
<td>string</td>
<td>str</td>
</tr>
<tr>
<td>array</td>
<td>list or tuple containing conformable elements. Arrays are returned as lists.</td>
</tr>
<tr>
<td>struct</td>
<td>dict. Keys must be strings, values may be any conformable type. Objects of user-defined classes can be passed in; only their <code>__dict__</code> attribute is transmitted.</td>
</tr>
<tr>
<td>dateTime.iso8601</td>
<td><code>DateTime</code> or <code>datetime.datetime</code>. Returned type depends on values of <code>use_builtin_types</code> and <code>use_datetime</code> flags.</td>
</tr>
<tr>
<td>base64</td>
<td><code>Binary</code>, <code>bytes</code> or <code>bytearray</code>. Returned type depends on the value of the <code>use_builtin_types</code> flag.</td>
</tr>
<tr>
<td>nil</td>
<td>The None constant. Passing is allowed only if <code>allow_none</code> is true.</td>
</tr>
<tr>
<td>bigdecimal</td>
<td><code>decimal.Decimal</code>. Returned type</td>
</tr>
</tbody>
</table>
This is the full set of data types supported by XML-RPC. Method calls may also raise a special `Fault` instance, used to signal XML-RPC server errors, or `ProtocolError` used to signal an error in the HTTP/HTTPS transport layer. Both `Fault` and `ProtocolError` derive from a base class called `Error`. Note that the xmlrpc client module currently does not marshal instances of subclasses of built-in types.

When passing strings, characters special to XML such as `<`, `>`, and `&` will be automatically escaped. However, it's the caller's responsibility to ensure that the string is free of characters that aren't allowed in XML, such as the control characters with ASCII values between 0 and 31 (except, of course, tab, newline and carriage return); failing to do this will result in an XML-RPC request that isn't well-formed XML. If you have to pass arbitrary bytes via XML-RPC, use `bytes` or `bytearray` classes or the `Binary` wrapper class described below.

Server is retained as an alias for `ServerProxy` for backwards compatibility. New code should use `ServerProxy`.

*Changed in version 3.5:* Added the `context` argument.

*Changed in version 3.6:* Added support of type tags with prefixes (e.g. `ex:nil`). Added support of unmarshalling additional types used by Apache XML-RPC implementation for numerics: `i1`, `i2`, `i8`, `biginteger`, `float` and `bigdecimal`. See [http://ws.apache.org/xmlrpc/types.html](http://ws.apache.org/xmlrpc/types.html) for a description.

See also:
XML-RPC HOWTO
A good description of XML-RPC operation and client software in several languages. Contains pretty much everything an XML-RPC client developer needs to know.

XML-RPC Introspection
Describes the XML-RPC protocol extension for introspection.

XML-RPC Specification
The official specification.

Unofficial XML-RPC Errata
Fredrik Lundh’s “unofficial errata, intended to clarify certain details in the XML-RPC specification, as well as hint at ‘best practices’ to use when designing your own XML-RPC implementations.”

A `ServerProxy` instance has a method corresponding to each remote procedure call accepted by the XML-RPC server. Calling the method performs an RPC, dispatched by both name and argument signature (e.g. the same method name can be overloaded with multiple argument signatures). The RPC finishes by returning a value, which may be either returned data in a conformant type or a `Fault` or `ProtocolError` object indicating an error.

Servers that support the XML introspection API support some common methods grouped under the reserved `system` attribute:

`ServerProxy.system.listMethods()`

This method returns a list of strings, one for each (non-system) method supported by the XML-RPC server.

`ServerProxy.system.methodSignature(name)`

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns an array of possible signatures for this method. A signature is an array of types. The first of these types is the return type of the method, the rest are parameters.

Because multiple signatures (i.e. overloading) is permitted, this method returns a list of signatures rather than a singleton.

Signatures themselves are restricted to the top level parameters expected by a method. For instance if a method expects one array of structs as a parameter, and it returns a string, its signature is simply “string, array”. If it expects three integers and returns a string, its signature is “string, int, int, int”.
If no signature is defined for the method, a non-array value is returned. In Python this means that the type of the returned value will be something other than list.

ServerProxy.system.methodHelp(name)
This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns a documentation string describing the use of that method. If no such string is available, an empty string is returned. The documentation string may contain HTML markup.

Changed in version 3.5: Instances of ServerProxy support the context manager protocol for closing the underlying transport.

A working example follows. The server code:

```python
from xmlrpc.server import SimpleXMLRPCServer
def is_even(n):
    return n % 2 == 0
server = SimpleXMLRPCServer(('localhost', 8000))
print('Listening on port 8000...')
server.register_function(is_even, 'is_even')
server.serve_forever()
```

The client code for the preceding server:

```python
import xmlrpc.client

with xmlrpc.client.ServerProxy('http://localhost:8000/') as proxy:
    print('3 is even: %s' % str(proxy.is_even(3)))
    print('100 is even: %s' % str(proxy.is_even(100)))
```
21.26.2. DateTime Objects

class xmlrpc.client.DateTime

This class may be initialized with seconds since the epoch, a time tuple, an ISO 8601 time/date string, or a datetime.datetime instance. It has the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

decode(string)
Accept a string as the instance’s new time value.

encode(out)
Write the XML-RPC encoding of this DateTime item to the out stream object.

It also supports certain of Python’s built-in operators through rich comparison and __repr__() methods.

A working example follows. The server code:

```python
import datetime
from xmlrpc.server import SimpleXMLRPCServer
import xmlrpc.client

def today():
    today = datetime.datetime.today()
    return xmlrpc.client.DateTime(today)

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(today, "today")
server.serve_forever()
```
The client code for the preceding server:

```python
import xmlrpc.client
import datetime

proxy = xmlrpc.client.ServerProxy("http://localhost:

today = proxy.today()
# convert the ISO8601 string to a datetime object
converted = datetime.datetime.strptime(today.value,
print("Today: %s\n
```
21.26.3. Binary Objects

class xmlrpc.client.Binary

This class may be initialized from bytes data (which may include NULs). The primary access to the content of a Binary object is provided by an attribute:

data

The binary data encapsulated by the Binary instance. The data is provided as a bytes object.

Binary objects have the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

decode(bytes)

Accept a base64 bytes object and decode it as the instance's new data.

encode(out)

Write the XML-RPC base 64 encoding of this binary item to the out stream object.

The encoded data will have newlines every 76 characters as per RFC 2045 section 6.8, which was the de facto standard base64 specification when the XML-RPC spec was written.

It also supports certain of Python’s built-in operators through __eq__() and __ne__() methods.

Example usage of the binary objects. We’re going to transfer an image over XMLRPC:
from xmlrpc.server import SimpleXMLRPCServer
import xmlrpc.client

def python_logo():
    with open("python_logo.jpg", "rb") as handle:
        return xmlrpc.client.Binary(handle.read())

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(python_logo, 'python_logo')

server.serve_forever()

The client gets the image and saves it to a file:

import xmlrpc.client

proxy = xmlrpc.client.ServerProxy("http://localhost:8000/"
with open("fetched_python_logo.jpg", "wb") as handle:
    handle.write(proxy.python_logo().data)
21.26.4. Fault Objects

```
class xmlrpc.client.Fault
    A Fault object encapsulates the content of an XML-RPC fault tag. Fault objects have the following attributes:

    faultCode
        A string indicating the fault type.

    faultString
        A string containing a diagnostic message associated with the fault.
```

In the following example we're going to intentionally cause a Fault by returning a complex type object. The server code:

```
from xmlrpc.server import SimpleXMLRPCServer

# A marshalling error is going to occur because we're returning a complex number
def add(x, y):
    return x+y+0j

server = SimpleXMLRPCServer(("localhost", 8000))
print("Listening on port 8000...")
server.register_function(add, 'add')
server.serve_forever()
```

The client code for the preceding server:

```
import xmlrpc.client
```

try:
    proxy.add(2, 5)
except xmlrpc.client.Fault as err:
    print("A fault occurred")
    print("Fault code: %d" % err.faultCode)
    print("Fault string: %s" % err.faultString)
21.26.5. ProtocolError Objects

```python
import xmlrpc.client

# create a ServerProxy with a URI that doesn't respond
proxy = xmlrpc.client.ServerProxy("http://google.com/")

try:
    proxy.some_method()
except xmlrpc.client.ProtocolError as err:
    print("A protocol error occurred")
```
print("URL: %s" % err.url)
print("HTTP/HTTPS headers: %s" % err.headers)
print("Error code: %d" % err.errcode)
print("Error message: %s" % err.errmsg)
21.26.6. MultiCall Objects

The **MultiCall** object provides a way to encapsulate multiple calls to a remote server into a single request [1].

```python
class xmlrpc.client.MultiCall(server)
    Create an object used to boxcar method calls. server is the eventual target of the call. Calls can be made to the result object, but they will immediately return None, and only store the call name and parameters in the MultiCall object. Calling the object itself causes all stored calls to be transmitted as a single system.multicall request. The result of this call is a generator; iterating over this generator yields the individual results.
```

A usage example of this class follows. The server code:

```python
from xmlrpc.server import SimpleXMLRPCServer

def add(x, y):
    return x + y

def subtract(x, y):
    return x - y

def multiply(x, y):
    return x * y

def divide(x, y):
    return x // y

# A simple server with simple arithmetic functions
server = SimpleXMLRPCServer(["localhost", 8000])
print("Listening on port 8000...")
server.register_multicall_functions()
```
server.register_function(add, 'add')
server.register_function(subtract, 'subtract')
server.register_function(multiply, 'multiply')
server.register_function(divide, 'divide')
server.serve_forever()

The client code for the preceding server:

```python
import xmlrpc.client

multicall = xmlrpc.client.MultiCall(proxy)
multicall.add(7, 3)
multicall.subtract(7, 3)
multicall.multiply(7, 3)
multicall.divide(7, 3)
result = multicall()

print("7+3=%d, 7-3=%d, 7*3=%d, 7//3=%d" % tuple(result))
```
21.26.7. Convenience Functions

```python
xmlrpc.client.dumps(params, methodname=None, methodresponse=None, encoding=None, allow_none=False)
```

Convert `params` into an XML-RPC request. or into a response if `methodresponse` is true. `params` can be either a tuple of arguments or an instance of the `Fault` exception class. If `methodresponse` is true, only a single value can be returned, meaning that `params` must be of length 1. `encoding`, if supplied, is the encoding to use in the generated XML; the default is UTF-8. Python's `None` value cannot be used in standard XML-RPC; to allow using it via an extension, provide a true value for `allow_none`.

```python
xmlrpc.client.loads(data, use_datetime=False, use_builtin_types=False)
```

Convert an XML-RPC request or response into Python objects, a `(params, methodname)`. `params` is a tuple of argument; `methodname` is a string, or `None` if no method name is present in the packet. If the XML-RPC packet represents a fault condition, this function will raise a `Fault` exception. The `use_builtin_types` flag can be used to cause date/time values to be presented as `datetime.datetime` objects and binary data to be presented as `bytes` objects; this flag is false by default.

The obsolete `use_datetime` flag is similar to `use_builtin_types` but it applies only to date/time values.

*Changed in version 3.3:* The `use_builtin_types` flag was added.

```python
from xmlrpc.client import ServerProxy, Error

# server = ServerProxy("http://localhost:8000")  # local server
with ServerProxy("http://betty.userland.com") as proxy:
    print(proxy)

    try:
        print(proxy.examples.getStateName(41))
    except Error as v:
        print("ERROR", v)
```

To access an XML-RPC server through an HTTP proxy, you need to define a custom transport. The following example shows how:

```python
import http.client
import xmlrpc.client

class ProxiedTransport(xmlrpc.client.Transport):
    def set_proxy(self, host, port=None, headers=None):
        self.proxy = host, port
        self.proxy_headers = headers

    def make_connection(self, host):
        connection = self.HTTPConnection(*self.proxy)
        connection.set_tunnel(host, headers=self.proxy_headers)
        self._connection = host, connection
        return connection

transport = ProxiedTransport()
```
transport.set_proxy('proxy-server', 8080)
server = xmlrpc.client.ServerProxy('http://betty.use
print(server.examples.getStateName(41))
21.26.9. Example of Client and Server Usage

See SimpleXMLRPCServer Example.

Footnotes

[1] This approach has been first presented in a discussion on xmlrpc.com.
21.27. xmlrpc.server — Basic XML-RPC servers

Source code: Lib/xmlrpc/server.py

The xmlrpc.server module provides a basic server framework for XML-RPC servers written in Python. Servers can either be free standing, using SimpleXMLRPCServer, or embedded in a CGI environment, using CGIXMLRPCRequestHandler.

Warning: The xmlrpc.server module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see XML vulnerabilities.

class xmlrpc.server.SimpleXMLRPCServer(addr, requestHandler=SimpleXMLRPCRequestHandler, logRequests=True, allow_none=False, encoding=None, bind_and_activate=True, use_builtin_types=False)

Create a new server instance. This class provides methods for registration of functions that can be called by the XML-RPC protocol. The requestHandler parameter should be a factory for request handler instances; it defaults to SimpleXMLRPCRequestHandler. The addr and requestHandler parameters are passed to the socketserver.TCPServer constructor. If logRequests is true (the default), requests will be logged; setting this parameter to false will turn off logging. The allow_none and encoding parameters are passed on to xmlrpc.client and control the XML-RPC responses that will be returned from the server. The bind_and_activate parameter
controls whether server_bind() and server_activate() are called immediately by the constructor; it defaults to true. Setting it to false allows code to manipulate the allow_reuse_address class variable before the address is bound. The use_builtin_types parameter is passed to the loads() function and controls which types are processed when date/times values or binary data are received; it defaults to false.

*Changed in version 3.3:* The use_builtin_types flag was added.

class xmlrpc.server.CGIXMLRPCRequestHandler(allow_none=False, encoding=None, use_builtin_types=False)

Create a new instance to handle XML-RPC requests in a CGI environment. The allow_none and encoding parameters are passed on to xmlrpc.client and control the XML-RPC responses that will be returned from the server. The use_builtin_types parameter is passed to the loads() function and controls which types are processed when date/times values or binary data are received; it defaults to false.

*Changed in version 3.3:* The use_builtin_types flag was added.

class xmlrpc.server.SimpleXMLRPCRequestHandler

Create a new request handler instance. This request handler supports POST requests and modifies logging so that the logRequests parameter to the SimpleXMLRPCServer constructor parameter is honored.
21.27.1. SimpleXMLRPCServer Objects

The `SimpleXMLRPCServer` class is based on `socketserver.TCPServer` and provides a means of creating simple, stand alone XML-RPC servers.

`SimpleXMLRPCServer.register_function(function=None, name=None)`

Register a function that can respond to XML-RPC requests. If `name` is given, it will be the method name associated with `function`, otherwise `function.__name__` will be used. `name` is a string, and may contain characters not legal in Python identifiers, including the period character.

This method can also be used as a decorator. When used as a decorator, `name` can only be given as a keyword argument to register `function` under `name`. If no `name` is given, `function.__name__` will be used.

*Changed in version 3.7:* `register_function()` can be used as a decorator.

`SimpleXMLRPCServer.register_instance(instance, allow_dotted_names=False)`

Register an object which is used to expose method names which have not been registered using `register_function()`. If `instance` contains a `_dispatch()` method, it is called with the requested method name and the parameters from the request. Its API is `def _dispatch(self, method, params)` (note that `params` does not represent a variable argument list). If it calls an underlying function to perform its task, that function is called as
func(*params), expanding the parameter list. The return value from _dispatch() is returned to the client as the result. If instance does not have a _dispatch() method, it is searched for an attribute matching the name of the requested method.

If the optional allow_dotted_names argument is true and the instance does not have a _dispatch() method, then if the requested method name contains periods, each component of the method name is searched for individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

**Warning:** Enabling the allow_dotted_names option allows intruders to access your module’s global variables and may allow intruders to execute arbitrary code on your machine. Only use this option on a secure, closed network.

SimpleXMLRPCServer.register_introspection_functions
Registers the XML-RPC introspection functions system.listMethods, system.methodHelp and system.methodSignature.

SimpleXMLRPCServer.register_multicall_functions()
 Registers the XML-RPC multicall function system.multicall.

SimpleXMLRPCRequestHandler.rpc_paths
An attribute value that must be a tuple listing valid path portions of the URL for receiving XML-RPC requests. Requests posted to other paths will result in a 404 “no such page” HTTP error. If this tuple is empty, all paths will be considered valid. The default value is (('/', '/RPC2')).
21.27.1.1. SimpleXMLRPCServer Example

Server code:

```python
from xmlrpc.server import SimpleXMLRPCServer
from xmlrpc.server import SimpleXMLRPCRequestHandler

# Restrict to a particular path.
class RequestHandler(SimpleXMLRPCRequestHandler):
    rpc_paths = ('/RPC2',)

# Create server
with SimpleXMLRPCServer(('localhost', 8000),
    requestHandler=RequestHandler)
    server.register_introspection_functions()

    # Register pow() function; this will use the value of
    # pow.__name__ as the name, which is just 'pow'.
    server.register_function(pow)

    # Register a function under a different name
    def adder_function(x, y):
        return x + y
    server.register_function(adder_function, 'add')

    # Register an instance; all the methods of the instance
    # published as XML-RPC methods (in this case, just
    class MyFuncs:
        def mul(self, x, y):
            return x * y
    server.register_instance(MyFuncs())

    # Run the server's main loop
    server.serve_forever()
```
The following client code will call the methods made available by the preceding server:

```python
import xmlrpc.client

s = xmlrpc.client.ServerProxy('http://localhost:8000')
print(s.pow(2, 3))  # Returns 2**3 = 8
print(s.add(2, 3))  # Returns 5
print(s.mul(5, 2))  # Returns 5*2 = 10

# Print list of available methods
print(s.system.listMethods())
```

`register_function()` can also be used as a decorator. The previous server example can register functions in a decorator way:

```python
from xmlrpc.server import SimpleXMLRPCServer
from xmlrpc.server import SimpleXMLRPCRequestHandler

class RequestHandler(SimpleXMLRPCRequestHandler):
    rpc_paths = ('/RPC2',)

with SimpleXMLRPCServer(('localhost', 8000),
                        requestHandler=RequestHandler)

    server.register_introspection_functions()

    # Register pow() function; this will use the value
    # pow.__name__ as the name, which is just 'pow'.
    server.register_function(pow)

    # Register a function under a different name, using
    # register_function as a decorator. *name* can only
    # as a keyword argument.
    @server.register_function(name='add')
    def adder_function(x, y):
```

```python
return x + y

# Register a function under function.__name__.
@server.register_function
def mul(x, y):
    return x * y

server.serve_forever()
```

The following example included in the `Lib/xmlrpc/server.py` module shows a server allowing dotted names and registering a multicall function.

**Warning:** Enabling the `allow_dotted_names` option allows intruders to access your module’s global variables and may allow intruders to execute arbitrary code on your machine. Only use this example only within a secure, closed network.

```python
import datetime
class ExampleService:
    def getData(self):
        return '42'

class currentTime:
    @staticmethod
def getCurrentTime():
        return datetime.datetime.now()

with SimpleXMLRPCServer(("localhost", 8000)) as server:
    server.register_function(pow)
    server.register_function(lambda x, y: x+y, 'add')
    server.register_instance(ExampleService(), allow_dotted_names=True)
    server.register_multicall_functions()
```
print('Serving XML-RPC on localhost port 8000')
try:
    server.serve_forever()
except KeyboardInterrupt:
    print("\nKeyboard interrupt received, exiting.")
sys.exit(0)

This ExampleService demo can be invoked from the command line:

```python
python -m xmlrpc.server
```

The client that interacts with the above server is included in `Lib/xmlrpc/client.py`:

```python
server = ServerProxy("http://localhost:8000")
try:
    print(server.currentTime.getCurrentTime())
except Error as v:
    print("ERROR", v)

multi = MultiCall(server)
multi.getData()  
multi.pow(2, 9)  
multi.add(1, 2)
try:
    for response in multi():
        print(response)
except Error as v:
    print("ERROR", v)
```

This client which interacts with the demo XMLRPC server can be invoked as:

```python
python -m xmlrpc.client
```
21.27.2. CGI XMLRPCRequestHandler

The CGI XMLRPCRequestHandler class can be used to handle XML-RPC requests sent to Python CGI scripts.

CGIXMLRPCRequestHandler.register_function(function=None, name=None)

Register a function that can respond to XML-RPC requests. If name is given, it will be the method name associated with function, otherwise function.__name__ will be used. name is a string, and may contain characters not legal in Python identifiers, including the period character.

This method can also be used as a decorator. When used as a decorator, name can only be given as a keyword argument to register function under name. If no name is given, function.__name__ will be used.

*Changed in version 3.7:* register_function() can be used as a decorator.

CGIXMLRPCRequestHandler.register_instance(instance)

Register an object which is used to expose method names which have not been registered using register_function(). If instance contains a _dispatch() method, it is called with the requested method name and the parameters from the request; the return value is returned to the client as the result. If instance does not have a _dispatch() method, it is searched for an attribute matching the name of the requested method; if the requested method name contains periods, each component of the method name is searched for individually, with the effect that a simple
hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

CGIXMLRPCRequestHandler.register_introspection_functions
Register the XML-RPC introspection functions system.listMethods, system.methodHelp and system.methodSignature.

CGIXMLRPCRequestHandler.register_multicall_functions
Register the XML-RPC multicall function system.multicall.

CGIXMLRPCRequestHandler.handle_request(request_text=None)
Handle an XML-RPC request. If request_text is given, it should be the POST data provided by the HTTP server, otherwise the contents of stdin will be used.

Example:

class MyFuncs:
    def mul(self, x, y):
        return x * y

handler = CGIXMLRPCRequestHandler()
handler.register_function(pow)
handler.register_function(lambda x,y: x+y, 'add')
handler.register_introspection_functions()
handler.register_instance(MyFuncs())
handler.handle_request()
21.27.3. Documenting XMLRPC server

These classes extend the above classes to serve HTML documentation in response to HTTP GET requests. Servers can either be free standing, using `DocXMLRPCServer`, or embedded in a CGI environment, using `DocCGIXMLRPCRequestHandler`.

```python
class xmlrpc.server.DocXMLRPCServer(addr, requestHandler=DocXMLRPCRequestHandler, logRequests=True, allow_none=False, encoding=None, bind_and_activate=True, use_builtin_types=True)
```

Create a new server instance. All parameters have the same meaning as for `SimpleXMLRPCServer`; `requestHandler` defaults to `DocXMLRPCRequestHandler`.

*Changed in version 3.3:* The `use_builtin_types` flag was added.

```python
class xmlrpc.server.DocCGIXMLRPCRequestHandler
```

Create a new instance to handle XML-RPC requests in a CGI environment.

```python
class xmlrpc.server.DocXMLRPCRequestHandler
```

Create a new request handler instance. This request handler supports XML-RPC POST requests, documentation GET requests, and modifies logging so that the `logRequests` parameter to the `DocXMLRPCServer` constructor parameter is honored.
21.27.4. DocXMLRPCServer Objects

The DocXMLRPCServer class is derived from SimpleXMLRPCServer and provides a means of creating self-documenting, stand alone XML-RPC servers. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

DocXMLRPCServer.set_server_title(server_title)

Set the title used in the generated HTML documentation. This title will be used inside the HTML “title” element.

DocXMLRPCServer.set_server_name(server_name)

Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a “h1” element.

DocXMLRPCServer.set_server_documentation(server_documentation)

Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.
21.27.5. DocCGIXMLRPCRequestHandler

The DocCGIXMLRPCRequestHandler class is derived from CGIXMLRPCRequestHandler and provides a means of creating self-documenting, XML-RPC CGI scripts. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

DocCGIXMLRPCRequestHandler.set_server_title(server_title)

Set the title used in the generated HTML documentation. This title will be used inside the HTML “title” element.

DocCGIXMLRPCRequestHandler.set_server_name(server_name)

Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a “h1” element.

DocCGIXMLRPCRequestHandler.set_server_documentation()

Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.
21.28. **ipaddress** — IPv4/IPv6 manipulation library

**Source code:** Lib/ipaddress.py

`ipaddress` provides the capabilities to create, manipulate and operate on IPv4 and IPv6 addresses and networks.

The functions and classes in this module make it straightforward to handle various tasks related to IP addresses, including checking whether or not two hosts are on the same subnet, iterating over all hosts in a particular subnet, checking whether or not a string represents a valid IP address or network definition, and so on.

This is the full module API reference—for an overview and introduction, see *An introduction to the ipaddress module*.

*New in version 3.3.*
21.28.1. Convenience factory functions

The `ipaddress` module provides factory functions to conveniently create IP addresses, networks and interfaces:

`ipaddress.ip_address(address)`

Return an `IPv4Address` or `IPv6Address` object depending on the IP address passed as argument. Either IPv4 or IPv6 addresses may be supplied; integers less than 2**32 will be considered to be IPv4 by default. A `ValueError` is raised if `address` does not represent a valid IPv4 or IPv6 address.

```python
>>> ipaddress.ip_address('192.168.0.1')
IPv4Address('192.168.0.1')
>>> ipaddress.ip_address('2001:db8::')
IPv6Address('2001:db8::')
```

`ipaddress.ip_network(address, strict=True)`

Return an `IPv4Network` or `IPv6Network` object depending on the IP address passed as argument. `address` is a string or integer representing the IP network. Either IPv4 or IPv6 networks may be supplied; integers less than 2**32 will be considered to be IPv4 by default. `strict` is passed to `IPv4Network` or `IPv6Network` constructor. A `ValueError` is raised if `address` does not represent a valid IPv4 or IPv6 address, or if the network has host bits set.

```python
>>> ipaddress.ip_network('192.168.0.0/28')
IPv4Network('192.168.0.0/28')
```

`ipaddress.ip_interface(address)`

Return an `IPv4Interface` or `IPv6Interface` object depending
on the IP address passed as argument. address is a string or integer representing the IP address. Either IPv4 or IPv6 addresses may be supplied; integers less than 2**32 will be considered to be IPv4 by default. A ValueError is raised if address does not represent a valid IPv4 or IPv6 address.

One downside of these convenience functions is that the need to handle both IPv4 and IPv6 formats means that error messages provide minimal information on the precise error, as the functions don't know whether the IPv4 or IPv6 format was intended. More detailed error reporting can be obtained by calling the appropriate version specific class constructors directly.
21.28.2. IP Addresses

21.28.2.1. Address objects

The IPv4Address and IPv6Address objects share a lot of common attributes. Some attributes that are only meaningful for IPv6 addresses are also implemented by IPv4Address objects, in order to make it easier to write code that handles both IP versions correctly.

class ipaddress.IPv4Address(address)

Construct an IPv4 address. An AddressValueError is raised if address is not a valid IPv4 address.

The following constitutes a valid IPv4 address:

1. A string in decimal-dot notation, consisting of four decimal integers in the inclusive range 0–255, separated by dots (e.g. 192.168.0.1). Each integer represents an octet (byte) in the address. Leading zeroes are tolerated only for values less than 8 (as there is no ambiguity between the decimal and octal interpretations of such strings).
2. An integer that fits into 32 bits.
3. An integer packed into a bytes object of length 4 (most significant octet first).

```python
>>> ipaddress.IPv4Address('192.168.0.1')
IPv4Address('192.168.0.1')
>>> ipaddress.IPv4Address(3232235521)
IPv4Address('192.168.0.1')
>>> ipaddress.IPv4Address(b'\x0C\xA8\x00\x01')
IPv4Address('192.168.0.1')
```
The appropriate version number: 4 for IPv4, 6 for IPv6.

**max_prefixlen**

The total number of bits in the address representation for this version: 32 for IPv4, 128 for IPv6.

The prefix defines the number of leading bits in an address that are compared to determine whether or not an address is part of a network.

**compressed**

**exploded**

The string representation in dotted decimal notation. Leading zeroes are never included in the representation.

As IPv4 does not define a shorthand notation for addresses with octets set to zero, these two attributes are always the same as `str(addr)` for IPv4 addresses. Exposing these attributes makes it easier to write display code that can handle both IPv4 and IPv6 addresses.

**packed**

The binary representation of this address - a `bytes` object of the appropriate length (most significant octet first). This is 4 bytes for IPv4 and 16 bytes for IPv6.

**reverse_pointer**

The name of the reverse DNS PTR record for the IP address, e.g.:

```python
>>> ipaddress.ip_address("127.0.0.1").reverse_pointer
'1.0.0.127.in-addr.arpa'
>>> ipaddress.ip_address("2001:db8::1").reverse_pointer
'::1.in-addr.arpa'
```
This is the name that could be used for performing a PTR lookup, not the resolved hostname itself.

*New in version 3.5.*

**is_multicast**

True if the address is reserved for multicast use. See [RFC 3171](https://tools.ietf.org/html/rfc3171) (for IPv4) or [RFC 2373](https://tools.ietf.org/html/rfc2373) (for IPv6).

**is_private**

True if the address is allocated for private networks. See [iana-ipv4-special-registry](https://www.iana.org/assignments/ipv4-address-space/ipv4-address-space.xhtml) (for IPv4) or [iana-ipv6-special-registry](https://www.iana.org/assignments/ipv6-address-space/ipv6-address-space.xhtml) (for IPv6).

**is_global**

True if the address is allocated for public networks. See [iana-ipv4-special-registry](https://www.iana.org/assignments/ipv4-address-space/ipv4-address-space.xhtml) (for IPv4) or [iana-ipv6-special-registry](https://www.iana.org/assignments/ipv6-address-space/ipv6-address-space.xhtml) (for IPv6).

*New in version 3.4.*

**is_unspecified**

**is Reserved**

True if the address is otherwise IETF reserved.

**is_loopback**

True if this is a loopback address. See [RFC 3330](https://tools.ietf.org/html/rfc3330) (for IPv4) or [RFC 2373](https://tools.ietf.org/html/rfc2373) (for IPv6).
**is_link_local**

True if the address is reserved for link-local usage. See RFC 3927.

**class ipaddress.IPv6Address(address)**

Construct an IPv6 address. An AddressValueError is raised if `address` is not a valid IPv6 address.

The following constitutes a valid IPv6 address:

1. A string consisting of eight groups of four hexadecimal digits, each group representing 16 bits. The groups are separated by colons. This describes an *exploded* (longhand) notation. The string can also be *compressed* (shorthand notation) by various means. See RFC 4291 for details. For example, "0000:0000:0000:0000:0000:0abc:0007:0def" can be compressed to "::abc:7:0def".
2. An integer that fits into 128 bits.
3. An integer packed into a bytes object of length 16, big-endian.

```python
>>> ipaddress.IPv6Address('2001:db8::1000')
IPv6Address('2001:db8::1000')
```

**compressed**

The short form of the address representation, with leading zeroes in groups omitted and the longest sequence of groups consisting entirely of zeroes collapsed to a single empty group.

This is also the value returned by `str(addr)` for IPv6 addresses.

**exploded**

The long form of the address representation, with all leading
zeroes and groups consisting entirely of zeroes included.

For the following attributes, see the corresponding documentation of the `IPv4Address` class:

- packed
- reverse_pointer
- version
- max_prefixlen
- is_multicast
- is_private
- is_global
- is_unspecified
- is_reserved
- is_loopback
- is_link_local
  
  *New in version 3.4:* is_global

- is_site_local
  
  *True* if the address is reserved for site-local usage. Note that the site-local address space has been deprecated by [RFC 3879](https://tools.ietf.org/html/rfc3879). Use `is_private` to test if this address is in the space of unique local addresses as defined by [RFC 4193](https://tools.ietf.org/html/rfc4193).

- ipv4_mapped
  
  For addresses that appear to be IPv4 mapped addresses (starting with `::FFFF/96`), this property will report the
embedded IPv4 address. For any other address, this property will be None.

sixtofour
For addresses that appear to be 6to4 addresses (starting with 2002::/16) as defined by RFC 3056, this property will report the embedded IPv4 address. For any other address, this property will be None.

teredo
For addresses that appear to be Teredo addresses (starting with 2001::/32) as defined by RFC 4380, this property will report the embedded (server, client) IP address pair. For any other address, this property will be None.

21.28.2.2. Conversion to Strings and Integers

To interoperate with networking interfaces such as the socket module, addresses must be converted to strings or integers. This is handled using the str() and int() builtin functions:

```python
>>> str(ipaddress.IPv4Address('192.168.0.1'))
'192.168.0.1'
>>> int(ipaddress.IPv4Address('192.168.0.1'))
3232235521
>>> str(ipaddress.IPv6Address('::1'))
'::1'
>>> int(ipaddress.IPv6Address('::1'))
1
```

21.28.2.3. Operators
Address objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

21.28.2.3.1. Comparison operators

Address objects can be compared with the usual set of comparison operators. Some examples:

```
>>> IPv4Address('127.0.0.2') > IPv4Address('127.0.0.1')
True
>>> IPv4Address('127.0.0.2') == IPv4Address('127.0.0.1')
False
>>> IPv4Address('127.0.0.2') != IPv4Address('127.0.0.1')
True
```

21.28.2.3.2. Arithmetic operators

Integers can be added to or subtracted from address objects. Some examples:

```
>>> IPv4Address('127.0.0.2') + 3
IPv4Address('127.0.0.5')
>>> IPv4Address('127.0.0.2') - 3
IPv4Address('126.255.255.255')
>>> IPv4Address('255.255.255.255') + 1
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ipaddress.AddressValueError: 4294967296 (>= 2**32)
```
21.28.3. IP Network definitions

The **IPv4Network** and **IPv6Network** objects provide a mechanism for defining and inspecting IP network definitions. A network definition consists of a *mask* and a *network address*, and as such defines a range of IP addresses that equal the network address when masked (binary AND) with the mask. For example, a network definition with the mask `255.255.255.0` and the network address `192.168.1.0` consists of IP addresses in the inclusive range `192.168.1.0` to `192.168.1.255`.

21.28.3.1. Prefix, net mask and host mask

There are several equivalent ways to specify IP network masks. A *prefix* `/<nbites>` is a notation that denotes how many high-order bits are set in the network mask. A *net mask* is an IP address with some number of high-order bits set. Thus the prefix `/24` is equivalent to the net mask `255.255.255.0` in IPv4, or `ffff:ff00::` in IPv6. In addition, a *host mask* is the logical inverse of a *net mask*, and is sometimes used (for example in Cisco access control lists) to denote a network mask. The host mask equivalent to `/24` in IPv4 is `0.0.0.255`.

21.28.3.2. Network objects

All attributes implemented by address objects are implemented by network objects as well. In addition, network objects implement additional attributes. All of these are common between **IPv4Network** and **IPv6Network**, so to avoid duplication they are only documented for **IPv4Network**.
class ipaddress.IPv4Network(address, strict=True)

Construct an IPv4 network definition. address can be one of the following:

1. A string consisting of an IP address and an optional mask, separated by a slash (/). The IP address is the network address, and the mask can be either a single number, which means it's a prefix, or a string representation of an IPv4 address. If it's the latter, the mask is interpreted as a net mask if it starts with a non-zero field, or as a host mask if it starts with a zero field. If no mask is provided, it's considered to be /32.

For example, the following address specifications are equivalent:

   192.168.1.0/24, 192.168.1.0/255.255.255.0 and 192.168.1.0/0.0.0.255.

2. An integer that fits into 32 bits. This is equivalent to a single-address network, with the network address being address and the mask being /32.

3. An integer packed into a bytes object of length 4, big-endian. The interpretation is similar to an integer address.

4. A two-tuple of an address description and a netmask, where the address description is either a string, a 32-bits integer, a 4-bytes packed integer, or an existing IPv4Address object; and the netmask is either an integer representing the prefix length (e.g. 24) or a string representing the prefix mask (e.g. 255.255.255.0).

An ValueError is raised if address is not a valid IPv4
A `NetmaskValueError` is raised if the mask is not valid for an IPv4 address.

If `strict` is `True` and host bits are set in the supplied address, then `ValueError` is raised. Otherwise, the host bits are masked out to determine the appropriate network address.

Unless stated otherwise, all network methods accepting other network/address objects will raise `TypeError` if the argument’s IP version is incompatible to `self`.

*Changed in version 3.5:* Added the two-tuple form for the `address` constructor parameter.

- `version`
- `max_prefixlen`
  - Refer to the corresponding attribute documentation in `IPv4Address`
- `is_multicast`
- `is_private`
- `is_unspecified`
- `is_reserved`
- `is_loopback`
- `is_link_local`
  - These attributes are true for the network as a whole if they are true for both the network address and the broadcast address

- `network_address`
  - The network address for the network. The network address and
the prefix length together uniquely define a network.

**broadcast_address**

The broadcast address for the network. Packets sent to the broadcast address should be received by every host on the network.

**hostmask**

The host mask, as a string.

**with_prefixlen**

**compressed**

**exploded**

A string representation of the network, with the mask in prefix notation.

with_prefixlen and compressed are always the same as str(network). exploded uses the exploded form the network address.

**with_netmask**

A string representation of the network, with the mask in net mask notation.

**with_hostmask**

A string representation of the network, with the mask in host mask notation.

**num_addresses**

The total number of addresses in the network.

**prefixlen**
Length of the network prefix, in bits.

**hosts()**

Returns an iterator over the usable hosts in the network. The usable hosts are all the IP addresses that belong to the network, except the network address itself and the network broadcast address.

```python
>>> list(ip_network('192.0.2.0/29').hosts())
[IPv4Address('192.0.2.1'), IPv4Address('192.0.2.2'), IPv4Address('192.0.2.3'), IPv4Address('192.0.2.4'), IPv4Address('192.0.2.5'), IPv4Address('192.0.2.6')]
```

**overlaps(other)**

`True` if this network is partly or wholly contained in `other` or `other` is wholly contained in this network.

**address_exclude(network)**

Computes the network definitions resulting from removing the given `network` from this one. Returns an iterator of network objects. Raises `ValueError` if `network` is not completely contained in this network.

```python
>>> n1 = ip_network('192.0.2.0/28')
>>> n2 = ip_network('192.0.2.1/32')
>>> list(n1.address_exclude(n2))
[IPv4Network('192.0.2.8/29'), IPv4Network('192.0.2.4/30'), IPv4Network('192.0.2.2/31'), IPv4Network('192.0.2.0/32')]
```

**subnets(prefixlen_diff=1, new_prefix=None)**

The subnets that join to make the current network definition, depending on the argument values. `prefixlen_diff` is the amount...
our prefix length should be increased by. \textit{new\_prefix} is the desired new prefix of the subnets; it must be larger than our prefix. One and only one of \textit{prefixlen\_diff} and \textit{new\_prefix} must be set. Returns an iterator of network objects.

code

>>> list(ip_network('192.0.2.0/24').subnets())
[IPv4Network('192.0.2.0/25'), IPv4Network('192.0.2.128/25')]
>>> list(ip_network('192.0.2.0/24').subnets(prefixlen_diff=1))
[IPv4Network('192.0.2.0/26'), IPv4Network('192.0.2.128/26'), IPv4Network('192.0.2.192/26')]
>>> list(ip_network('192.0.2.0/24').subnets(new_prefix=IPv4Network('192.0.2.0/26'), IPv4Network('192.0.2.64/26'), IPv4Network('192.0.2.128/26'), IPv4Network('192.0.2.192/26'))
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
    raise ValueError('new prefix must be longer than your prefix')

ValueError: new prefix must be longer

>>> list(ip_network('192.0.2.0/24').subnets(new_prefix=IPv4Network('192.0.2.0/25'), IPv4Network('192.0.2.128/25'))

\textbf{supernet}(\textit{prefixlen\_diff}=1, \textit{new\_prefix}=None)

The supernet containing this network definition, depending on the argument values. \textit{prefixlen\_diff} is the amount our prefix length should be decreased by. \textit{new\_prefix} is the desired new prefix of the supernet; it must be smaller than our prefix. One and only one of \textit{prefixlen\_diff} and \textit{new\_prefix} must be set. Returns a single network object.

code

>>> ip_network('192.0.2.0/24').supernet()
IPv4Network('192.0.2.0/23')
>>> ip_network('192.0.2.0/24').supernet(prefixlen_diff=1)
IPv4Network('192.0.0.0/22')
>>> ip_network('192.0.2.0/24').supernet(new_prefix=IPv4Network('192.0.0.0/22'))
IPv4Network('192.0.0.0/22')
IPv4Network('192.0.0.0/20')

subnet_of(other)
Returns True if this network is a subnet of other.

>>> a = ip_network('192.168.1.0/24')
>>> b = ip_network('192.168.1.128/30')
>>> b.subnet_of(a)
True

New in version 3.7.

supernet_of(other)
Returns True if this network is a supernet of other.

>>> a = ip_network('192.168.1.0/24')
>>> b = ip_network('192.168.1.128/30')
>>> a.supernet_of(b)
True

New in version 3.7.

compare_networks(other)
Compare this network to other. In this comparison only the network addresses are considered; host bits aren't. Returns either -1, 0 or 1.

>>> ip_network('192.0.2.1/32').compare_networks
-1
>>> ip_network('192.0.2.1/32').compare_networks
1
>>> ip_network('192.0.2.1/32').compare_networks
0
**Deprecated since version 3.7:** It uses the same ordering and comparison algorithm as “<”, “==”, and “>”

```python
class ipaddress.IPv6Network(address, strict=True)
```

Construct an IPv6 network definition. `address` can be one of the following:

1. A string consisting of an IP address and an optional mask, separated by a slash (/). The IP address is the network address, and the mask can be either a single number, which means it's a `prefix`, or a string representation of an IPv6 address. If it's the latter, the mask is interpreted as a `net mask`. If no mask is provided, it's considered to be `/128`.

   For example, the following `address` specifications are equivalent: `2001:db00::0/24` and `2001:db00::0/ffff:ff00::`.

2. An integer that fits into 128 bits. This is equivalent to a single-address network, with the network address being `address` and the mask being `/128`.

3. An integer packed into a `bytes` object of length 16, big-endian. The interpretation is similar to an integer `address`.

4. A two-tuple of an address description and a netmask, where the address description is either a string, a 128-bits integer, a 16-bytes packed integer, or an existing IPv6Address object; and the netmask is an integer representing the prefix length.

An `AddressValueError` is raised if `address` is not a valid IPv6 address. A `NetmaskValueError` is raised if the mask is not valid for an IPv6 address.
If `strict` is `True` and host bits are set in the supplied address, then `ValueError` is raised. Otherwise, the host bits are masked out to determine the appropriate network address.

*Changed in version 3.5:* Added the two-tuple form for the `address` constructor parameter.

```python
version
max_prefixlen
is_multicast
is_private
is_unspecified
is_reserved
is_loopback
is_link_local
network_address
broadcast_address
hostmask
with_prefixlen
compressed
exploded
with_netmask
with_hostmask
num_addresses
```
prefixlen
hosts()
overlaps(other)
address_exclude(network)
subnets(prefixlen_diff=1, new_prefix=None)
supernet(prefixlen_diff=1, new_prefix=None)
subnet_of(other)
supernet_of(other)
compare_networks(other)
    Refer to the corresponding attribute documentation in IPv4Network

is_site_local
    These attribute is true for the network as a whole if it is true for both the network address and the broadcast address

21.28.3.3. Operators

Network objects support some operators. Unless stated otherwise, operators can only be applied between compatible objects (i.e. IPv4 with IPv4, IPv6 with IPv6).

21.28.3.3.1. Logical operators

Network objects can be compared with the usual set of logical operators, similarly to address objects.
21.28.3.3.2. Iteration

Network objects can be iterated to list all the addresses belonging to the network. For iteration, all hosts are returned, including unusable hosts (for usable hosts, use the `hosts()` method). An example:

```python
>>> for addr in IPv4Network('192.0.2.0/28'):
...     addr
...
IPv4Address('192.0.2.0')
IPv4Address('192.0.2.1')
IPv4Address('192.0.2.2')
IPv4Address('192.0.2.3')
IPv4Address('192.0.2.4')
IPv4Address('192.0.2.5')
IPv4Address('192.0.2.6')
IPv4Address('192.0.2.7')
IPv4Address('192.0.2.8')
IPv4Address('192.0.2.9')
IPv4Address('192.0.2.10')
IPv4Address('192.0.2.11')
IPv4Address('192.0.2.12')
IPv4Address('192.0.2.13')
IPv4Address('192.0.2.14')
IPv4Address('192.0.2.15')
```

21.28.3.3.3. Networks as containers of addresses

Network objects can act as containers of addresses. Some examples:

```python
>>> IPv4Network('192.0.2.0/28')[0]
IPv4Address('192.0.2.0')
>>> IPv4Network('192.0.2.0/28')[15]
IPv4Address('192.0.2.15')
>>> IPv4Address('192.0.2.6') in IPv4Network('192.0.2.0/28')
True
```
True

>>> IPv4Address('192.0.3.6') in IPv4Network('192.0.2.0/28')
False
21.28.4. Interface objects

class ipaddress.IPv4Interface(address)

Construct an IPv4 interface. The meaning of address is as in the constructor of IPv4Network, except that arbitrary host addresses are always accepted.

IPv4Interface is a subclass of IPv4Address, so it inherits all the attributes from that class. In addition, the following attributes are available:

**ip**

The address (IPv4Address) without network information.

```python
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.ip
IPv4Address('192.0.2.5')
```

**network**

The network (IPv4Network) this interface belongs to.

```python
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.network
IPv4Network('192.0.2.0/24')
```

**with_prefixlen**

A string representation of the interface with the mask in prefix notation.

```python
>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_prefixlen
'192.0.2.5/24'
```
with_netmask
A string representation of the interface with the network as a net mask.

>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_netmask
'192.0.2.5/255.255.255.0'

with_hostmask
A string representation of the interface with the network as a host mask.

>>> interface = IPv4Interface('192.0.2.5/24')
>>> interface.with_hostmask
'192.0.2.5/0.0.0.255'

class ipaddress.IPv6Interface(address)
Construct an IPv6 interface. The meaning of address is as in the constructor of IPv6Network, except that arbitrary host addresses are always accepted.

IPv6Interface is a subclass of IPv6Address, so it inherits all the attributes from that class. In addition, the following attributes are available:

ip
network
with_prefixlen
with_netmask
with_hostmask
Refer to the corresponding attribute documentation in
IPv4Interface.
21.28.5. Other Module Level Functions

The module also provides the following module level functions:

`ipaddress.v4_int_to_packed(address)`

Represent an address as 4 packed bytes in network (big-endian) order. `address` is an integer representation of an IPv4 IP address. A `ValueError` is raised if the integer is negative or too large to be an IPv4 IP address.

```python
>>> ipaddress.ip_address(3221225985)
IPv4Address('192.0.2.1')
>>> ipaddress.v4_int_to_packed(3221225985)
b'\xc0\x00\x02\x01'
```

`ipaddress.v6_int_to_packed(address)`

Represent an address as 16 packed bytes in network (big-endian) order. `address` is an integer representation of an IPv6 IP address. A `ValueError` is raised if the integer is negative or too large to be an IPv6 IP address.

`ipaddress.summarize_address_range(first, last)`

Return an iterator of the summarized network range given the first and last IP addresses. `first` is the first `IPv4Address` or `IPv6Address` in the range and `last` is the last `IPv4Address` or `IPv6Address` in the range. A `TypeError` is raised if `first` or `last` are not IP addresses or are not of the same version. A `ValueError` is raised if `last` is not greater than `first` or if `first` address version is not 4 or 6.

```python
>>> [ipaddr for ipaddr in ipaddress.summarize_address_range(...)]
ipaddress.IPv4Address('192.0.2.0'),
```
... ipaddress.IPv4Address('192.0.2.130'))
[IPv4Network('192.0.2.0/25'), IPv4Network('192.0.

ipaddress.collapse_addresses(addresses)
Return an iterator of the collapsed IPv4Network or IPv6Network objects. addresses is an iterator of IPv4Network or IPv6Network objects. A TypeError is raised if addresses contains mixed version objects.

>>> [ipaddr for ipaddr in ...
... ipaddress.collapse_addresses([ipaddress.IPv4N ... ipaddress.IPv4Network('192.0.2.128/25')])]
[IPv4Network('192.0.2.0/24')]

ipaddress.get_mixed_type_key(obj)
Return a key suitable for sorting between networks and addresses. Address and Network objects are not sortable by default; they’re fundamentally different, so the expression:

IPv4Address('192.0.2.0') <= IPv4Network('192.0.2.

doesn’t make sense. There are some times however, where you may wish to have ipaddress sort these anyway. If you need to do this, you can use this function as the key argument to sorted().

obj is either a network or address object.
21.28.6. Custom Exceptions

To support more specific error reporting from class constructors, the module defines the following exceptions:

exception ipaddress.\texttt{AddressValueError}(\texttt{ValueError})

Any value error related to the address.

exception ipaddress.\texttt{NetmaskValueError}(\texttt{ValueError})

Any value error related to the netmask.
22. Multimedia Services

The modules described in this chapter implement various algorithms or interfaces that are mainly useful for multimedia applications. They are available at the discretion of the installation. Here’s an overview:

- **22.1. audioop** — Manipulate raw audio data
- **22.2. aifc** — Read and write AIFF and AIFC files
- **22.3. sunau** — Read and write Sun AU files
  - **22.3.1. AU_read Objects**
  - **22.3.2. AU_write Objects**
- **22.4. wave** — Read and write WAV files
  - **22.4.1. Wave_read Objects**
  - **22.4.2. Wave_write Objects**
- **22.5. chunk** — Read IFF chunked data
- **22.6. colorsys** — Conversions between color systems
- **22.7. imghdr** — Determine the type of an image
- **22.8. sndhdr** — Determine type of sound file
- **22.9. ossaudiodev** — Access to OSS-compatible audio devices
  - **22.9.1. Audio Device Objects**
  - **22.9.2. Mixer Device Objects**
22.1. audioop — Manipulate raw audio data

The audioop module contains some useful operations on sound fragments. It operates on sound fragments consisting of signed integer samples 8, 16, 24 or 32 bits wide, stored in bytes-like objects. All scalar items are integers, unless specified otherwise.

*Changed in version 3.4:* Support for 24-bit samples was added. All functions now accept any bytes-like object. String input now results in an immediate error.

This module provides support for a-LAW, u-LAW and Intel/DVI ADPCM encodings.

A few of the more complicated operations only take 16-bit samples, otherwise the sample size (in bytes) is always a parameter of the operation.

The module defines the following variables and functions:

- **exception audioop.error**
  This exception is raised on all errors, such as unknown number of bytes per sample, etc.

- **audioop.add(fragment1, fragment2, width)**
  Return a fragment which is the addition of the two samples passed as parameters. width is the sample width in bytes, either 1, 2, 3 or 4. Both fragments should have the same length. Samples are truncated in case of overflow.
audioop. **adpcm2lin**(adpcmfragment, width, state)

Decode an Intel/DVI ADPCM coded fragment to a linear fragment. See the description of **lin2adpcm()** for details on ADPCM coding. Return a tuple `(sample, newstate)` where the sample has the width specified in `width`.

audioop. **alaw2lin**(fragment, width)

Convert sound fragments in a-LAW encoding to linearly encoded sound fragments. a-LAW encoding always uses 8 bits samples, so `width` refers only to the sample width of the output fragment here.

audioop. **avg**(fragment, width)

Return the average over all samples in the fragment.

audioop. **avgpp**(fragment, width)

Return the average peak-peak value over all samples in the fragment. No filtering is done, so the usefulness of this routine is questionable.

audioop. **bias**(fragment, width, bias)

Return a fragment that is the original fragment with a bias added to each sample. Samples wrap around in case of overflow.

audioop. **byteswap**(fragment, width)

“Byteswap” all samples in a fragment and returns the modified fragment. Converts big-endian samples to little-endian and vice versa.

*New in version 3.4.*

audioop. **cross**(fragment, width)

Return the number of zero crossings in the fragment passed as an argument.
audioop.**findfactor**(fragment, reference)

Return a factor \( F \) such that \( \text{rms}(\text{add}(\text{fragment}, \text{mul}(\text{reference}, -F))) \) is minimal, i.e., return the factor with which you should multiply \( \text{reference} \) to make it match as well as possible to \( \text{fragment} \). The fragments should both contain 2-byte samples.

The time taken by this routine is proportional to \( \text{len}(\text{fragment}) \).

audioop.**findfit**(fragment, reference)

Try to match \( \text{reference} \) as well as possible to a portion of \( \text{fragment} \) (which should be the longer fragment). This is (conceptually) done by taking slices out of \( \text{fragment} \), using \( \text{findfactor()} \) to compute the best match, and minimizing the result. The fragments should both contain 2-byte samples. Return a tuple \( (\text{offset}, \text{factor}) \) where \( \text{offset} \) is the (integer) offset into \( \text{fragment} \) where the optimal match started and \( \text{factor} \) is the (floating-point) factor as per \( \text{findfactor()} \).

audioop.**findmax**(fragment, length)

Search \( \text{fragment} \) for a slice of length \( \text{length} \) samples (not bytes!) with maximum energy, i.e., return \( i \) for which \( \text{rms}(\text{fragment}[i*2:(i+\text{length})*2]) \) is maximal. The fragments should both contain 2-byte samples.

The routine takes time proportional to \( \text{len}(\text{fragment}) \).

audioop.**getsample**(fragment, width, index)

Return the value of sample \( \text{index} \) from the fragment.

audioop.**lin2adpcm**(fragment, width, state)
Convert samples to 4 bit Intel/DVI ADPCM encoding. ADPCM coding is an adaptive coding scheme, whereby each 4 bit number is the difference between one sample and the next, divided by a (varying) step. The Intel/DVI ADPCM algorithm has been selected for use by the IMA, so it may well become a standard.

state is a tuple containing the state of the coder. The coder returns a tuple (adpcmfrag, newstate), and the newstate should be passed to the next call of `lin2adpcm()`. In the initial call, None can be passed as the state. adpcmfrag is the ADPCM coded fragment packed 2 4-bit values per byte.

audioop. `lin2alaw(fragment, width)`
Convert samples in the audio fragment to a-LAW encoding and return this as a bytes object. a-LAW is an audio encoding format whereby you get a dynamic range of about 13 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

audioop. `lin2lin(fragment, width, newwidth)`
Convert samples between 1-, 2-, 3- and 4-byte formats.

**Note:** In some audio formats, such as .WAV files, 16, 24 and 32 bit samples are signed, but 8 bit samples are unsigned. So when converting to 8 bit wide samples for these formats, you need to also add 128 to the result:

```
new_frames = audioop.lin2lin(frames, old_width, new_width)
new_frames = audioop.bias(new_frames, 1, 128)
```

The same, in reverse, has to be applied when converting from 8 to 16, 24 or 32 bit width samples.
audioop.\texttt{lin2ulaw}(\textit{fragment, width})

Convert samples in the audio fragment to u-LAW encoding and return this as a bytes object. u-LAW is an audio encoding format whereby you get a dynamic range of about 14 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

audioop.\texttt{max}(\textit{fragment, width})

Return the maximum of the \textit{absolute value} of all samples in a fragment.

audioop.\texttt{maxpp}(\textit{fragment, width})

Return the maximum peak-peak value in the sound fragment.

audioop.\texttt{minmax}(\textit{fragment, width})

Return a tuple consisting of the minimum and maximum values of all samples in the sound fragment.

audioop.\texttt{mul}(\textit{fragment, width, factor})

Return a fragment that has all samples in the original fragment multiplied by the floating-point value \textit{factor}. Samples are truncated in case of overflow.

audioop.\texttt{ratecv}(\textit{fragment, width, nchannels, inrate, outrate, state[, weightA[, weightB]]})

Convert the frame rate of the input fragment.

\textit{state} is a tuple containing the state of the converter. The converter returns a tuple \texttt{(newfragment, newstate)}, and \textit{newstate} should be passed to the next call of \texttt{ratecv()}. The initial call should pass \texttt{None} as the state.

The \textit{weightA} and \textit{weightB} arguments are parameters for a simple
digital filter and default to 1 and 0 respectively.

audioop.reverse(fragment, width)

Reverse the samples in a fragment and returns the modified fragment.

audioop.rms(fragment, width)

Return the root-mean-square of the fragment, i.e. \( \sqrt{\frac{\sum S_i^2}{n}} \).

This is a measure of the power in an audio signal.

audioop.tomono(fragment, width, lfactor, rfactor)

Convert a stereo fragment to a mono fragment. The left channel is multiplied by \( \text{lfactor} \) and the right channel by \( \text{rfactor} \) before adding the two channels to give a mono signal.

audioop.tostereo(fragment, width, lfactor, rfactor)

Generate a stereo fragment from a mono fragment. Each pair of samples in the stereo fragment are computed from the mono sample, whereby left channel samples are multiplied by \( \text{lfactor} \) and right channel samples by \( \text{rfactor} \).

audioop.ulaw2lin(fragment, width)

Convert sound fragments in u-LAW encoding to linearly encoded sound fragments. u-LAW encoding always uses 8 bits samples, so \( \text{width} \) refers only to the sample width of the output fragment here.

Note that operations such as \( \text{mul()} \) or \( \text{max()} \) make no distinction between mono and stereo fragments, i.e. all samples are treated equal. If this is a problem the stereo fragment should be split into two mono fragments first and recombined later. Here is an example of how to do that:
def mul_stereo(sample, width, lfactor, rfactor):
    lsample = audioop.tomono(sample, width, 1, 0)
    rsample = audioop.tomono(sample, width, 0, 1)
    lsample = audioop.mul(lsample, width, lfactor)
    rsample = audioop.mul(rsample, width, rfactor)
    lsample = audioop.tostereo(lsample, width, 1, 0)
    rsample = audioop.tostereo(rsample, width, 0, 1)
    return audioop.add(lsample, rsample, width)

If you use the ADPCM coder to build network packets and you want your protocol to be stateless (i.e. to be able to tolerate packet loss) you should not only transmit the data but also the state. Note that you should send the initial state (the one you passed to lin2adpcm()) along to the decoder, not the final state (as returned by the coder). If you want to use struct.Struct to store the state in binary you can code the first element (the predicted value) in 16 bits and the second (the delta index) in 8.

The ADPCM coders have never been tried against other ADPCM coders, only against themselves. It could well be that I misinterpreted the standards in which case they will not be interoperable with the respective standards.

The find*() routines might look a bit funny at first sight. They are primarily meant to do echo cancellation. A reasonably fast way to do this is to pick the most energetic piece of the output sample, locate that in the input sample and subtract the whole output sample from the input sample:

def echocancel(outputdata, inputdata):
    pos = audioop.findmax(outputdata, 800)  # one
    out_test = outputdata[pos*2:]
    in_test = inputdata[pos*2:]
```python
ipos, factor = audioop.findfit(in_test, out_test, 2)
# Optional (for better cancellation):
# factor = audioop.findfactor(in_test[ipos*2:ipos*2+len(out_test)], out_test)
préfill = '\0'*(pos+ipos)*2
postfill = '\0'*(len(inputdata)-len(prefill)-len(outputdata))
outputdata = préfill + audioop.mul(outputdata, 2)
return audioop.add(inputdata, outputdata, 2)
```
22.2. aifc — Read and write AIFF and AIFC files

Source code: Lib/aifc.py

This module provides support for reading and writing AIFF and AIF-C files. AIFF is Audio Interchange File Format, a format for storing digital audio samples in a file. AIF-C is a newer version of the format that includes the ability to compress the audio data.

Audio files have a number of parameters that describe the audio data. The sampling rate or frame rate is the number of times per second the sound is sampled. The number of channels indicate if the audio is mono, stereo, or quadro. Each frame consists of one sample per channel. The sample size is the size in bytes of each sample. Thus a frame consists of \texttt{nchannels} * \texttt{samplesize} bytes, and a second's worth of audio consists of \texttt{nchannels} * \texttt{samplesize} * \texttt{framerate} bytes.

For example, CD quality audio has a sample size of two bytes (16 bits), uses two channels (stereo) and has a frame rate of 44,100 frames/second. This gives a frame size of 4 bytes (2*2), and a second's worth occupies 2*2*44100 bytes (176,400 bytes).

Module \texttt{aifc} defines the following function:

\texttt{aifc.open(file, mode=None)}

Open an AIFF or AIF-C file and return an object instance with methods that are described below. The argument \texttt{file} is either a string naming a file or a file object. \texttt{mode} must be \texttt{r} or \texttt{rb}.
when the file must be opened for reading, or 'w' or 'wb' when the file must be opened for writing. If omitted, file.mode is used if it exists, otherwise 'rb' is used. When used for writing, the file object should be seekable, unless you know ahead of time how many samples you are going to write in total and use writeframesraw() and setnframes(). The open() function may be used in a with statement. When the with block completes, the close() method is called.

*Changed in version 3.4:* Support for the with statement was added.

Objects returned by open() when a file is opened for reading have the following methods:

aifc.getnchannels()

Return the number of audio channels (1 for mono, 2 for stereo).

aifc.getsampwidth()

Return the size in bytes of individual samples.

aifc.getframerate()

Return the sampling rate (number of audio frames per second).

aifc.getnframes()

Return the number of audio frames in the file.

aifc.getcomptype()

Return a bytes array of length 4 describing the type of compression used in the audio file. For AIFF files, the returned value is b'NONE'.

aifc.getcompname()
Return a bytes array convertible to a human-readable description of the type of compression used in the audio file. For AIFF files, the returned value is `b'not compressed'`.

**aifc.getparams()**

Returns a `namedtuple()` `(nchannels, sampwidth, framerate, nframes, comptype, compname)`, equivalent to output of the `get*()` methods.

**aifc.getmarkers()**

Return a list of markers in the audio file. A marker consists of a tuple of three elements. The first is the mark ID (an integer), the second is the mark position in frames from the beginning of the data (an integer), the third is the name of the mark (a string).

**aifc.getmark(id)**

Return the tuple as described in `getmarkers()` for the mark with the given `id`.

**aifc.readframes(nframes)**

Read and return the next `nframes` frames from the audio file. The returned data is a string containing for each frame the uncompressed samples of all channels.

**aifc.rewind()**

Rewind the read pointer. The next `readframes()` will start from the beginning.

**aifc.setpos(pos)**

Seek to the specified frame number.

**aifc.tell()**
Return the current frame number.

`aifc.close()`
Close the AIFF file. After calling this method, the object can no longer be used.

Objects returned by `open()` when a file is opened for writing have all the above methods, except for `readframes()` and `setpos()`. In addition the following methods exist. The `get*()` methods can only be called after the corresponding `set*()` methods have been called. Before the first `writeframes()` or `writeframesraw()`, all parameters except for the number of frames must be filled in.

`aifc.aiff()`
Create an AIFF file. The default is that an AIFF-C file is created, unless the name of the file ends in `.aiff` in which case the default is an AIFF file.

`aifc.aifc()`
Create an AIFF-C file. The default is that an AIFF-C file is created, unless the name of the file ends in `.aiff` in which case the default is an AIFF file.

`aifc.setnchannels(nchannels)`
Specify the number of channels in the audio file.

`aifc.setsampwidth(width)`
Specify the size in bytes of audio samples.

`aifc.setframerate(rate)`
Specify the sampling frequency in frames per second.

`aifc.setnframes(nframes)`
Specify the number of frames that are to be written to the audio file. If this parameter is not set, or not set correctly, the file needs to support seeking.

**aifc.setcomptype**(type, name)

Specify the compression type. If not specified, the audio data will not be compressed. In AIFF files, compression is not possible. The name parameter should be a human-readable description of the compression type as a bytes array, the type parameter should be a bytes array of length 4. Currently the following compression types are supported: b'NONE', b'ULAW', b'ALAW', b'G722'.

**aifc.setparams**(nchannels, sampwidth, framerate, comptype, compname)

Set all the above parameters at once. The argument is a tuple consisting of the various parameters. This means that it is possible to use the result of a getparams() call as argument to setparams().

**aifc.setmark**(id, pos, name)

Add a mark with the given id (larger than 0), and the given name at the given position. This method can be called at any time before close().

**aifc.tell()**

Return the current write position in the output file. Useful in combination with setmark().

**aifc.writeframes**(data)

Write data to the output file. This method can only be called after the audio file parameters have been set.
*Changed in version 3.4:* Any bytes-like object is now accepted.

```python
aifc.writeframesraw(data)
```

Like `writeframes()` except that the header of the audio file is not updated.

*Changed in version 3.4:* Any bytes-like object is now accepted.

```python
aifc.close()
```

Close the AIFF file. The header of the file is updated to reflect the actual size of the audio data. After calling this method, the object can no longer be used.
22.3. sunau — Read and write Sun AU files

Source code: Lib/sunau.py

The sunau module provides a convenient interface to the Sun AU sound format. Note that this module is interface-compatible with the modules aifc and wave.

An audio file consists of a header followed by the data. The fields of the header are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>magic word</td>
<td>The four bytes .snd.</td>
</tr>
<tr>
<td>header size</td>
<td>Size of the header, including info, in bytes.</td>
</tr>
<tr>
<td>data size</td>
<td>Physical size of the data, in bytes.</td>
</tr>
<tr>
<td>encoding</td>
<td>Indicates how the audio samples are encoded.</td>
</tr>
<tr>
<td>sample rate</td>
<td>The sampling rate.</td>
</tr>
<tr>
<td># of channels</td>
<td>The number of channels in the samples.</td>
</tr>
<tr>
<td>info</td>
<td>ASCII string giving a description of the audio file (padded with null bytes).</td>
</tr>
</tbody>
</table>

Apart from the info field, all header fields are 4 bytes in size. They are all 32-bit unsigned integers encoded in big-endian byte order.

The sunau module defines the following functions:

sunau.open(file, mode)
If file is a string, open the file by that name, otherwise treat it as a seekable file-like object. mode can be any of

\texttt{'r'}

Read only mode.

\texttt{'w'}

Write only mode.

Note that it does not allow read/write files.

A \textit{mode} of \texttt{'r'} returns an AU\_read object, while a \textit{mode} of \texttt{'w'} or \texttt{'wb'} returns an AU\_write object.

\texttt{sunau.openfp(file, mode)}

A synonym for \texttt{open()}, maintained for backwards compatibility.

\textit{Deprecated since version 3.7, will be removed in version 3.9.}

The \texttt{sunau} module defines the following exception:

\texttt{exception sunau.Error}

An error raised when something is impossible because of Sun AU specs or implementation deficiency.

The \texttt{sunau} module defines the following data items:

\texttt{sunau.AUDIO\_FILE\_MAGIC}

An integer every valid Sun AU file begins with, stored in big-endian form. This is the string .\texttt{snd} interpreted as an integer.

\texttt{sunau.AUDIO\_FILE\_ENCODING\_MULAW\_8}
\texttt{sunau.AUDIO\_FILE\_ENCODING\_LINEAR\_8}
\texttt{sunau.AUDIO\_FILE\_ENCODING\_LINEAR\_16}
\texttt{sunau.AUDIO\_FILE\_ENCODING\_LINEAR\_24}
sunau. **AUDIO_FILE_ENCODING_LINEAR_32**

Values of the encoding field from the AU header which are supported by this module.

sunau. **AUDIO_FILE_ENCODING_ALAW_8**

sunau. **AUDIO_FILE_ENCODING_FLOAT**

sunau. **AUDIO_FILE_ENCODING_DOUBLE**

sunau. **AUDIO_FILE_ENCODING_ADPCM_G721**

sunau. **AUDIO_FILE_ENCODING_ADPCM_G722**

sunau. **AUDIO_FILE_ENCODING_ADPCM_G723_3**

sunau. **AUDIO_FILE_ENCODING_ADPCM_G723_5**

Additional known values of the encoding field from the AU header, but which are not supported by this module.
22.3.1. AU_read Objects

AU_read objects, as returned by `open()` above, have the following methods:

AU_read.close()
    Close the stream, and make the instance unusable. (This is called automatically on deletion.)

AU_read.getnchannels()
    Returns number of audio channels (1 for mono, 2 for stereo).

AU_read.getsampwidth()
    Returns sample width in bytes.

AU_read.getframerate()
    Returns sampling frequency.

AU_read.getnframes()
    Returns number of audio frames.

AU_read.getcomptype()
    Returns compression type. Supported compression types are 'ULAW', 'ALAW' and 'NONE'.

AU_read.getcompname()
    Human-readable version of getcomptype(). The supported types have the respective names 'CCITT G.711 u-law', 'CCITT G.711 A-law' and 'not compressed'.

AU_read.getparams()
    Returns a namedtuple(nchannels, sampwidth,
framerate, nframes, comptype, compname), equivalent to output of the get*() methods.

AU_read.readframes(n)
Reads and returns at most n frames of audio, as a bytes object. The data will be returned in linear format. If the original data is in u-LAW format, it will be converted.

AU_read.rewind()
Rewind the file pointer to the beginning of the audio stream.

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

AU_read.setpos(pos)
Set the file pointer to the specified position. Only values returned from tell() should be used for pos.

AU_read.tell()
Return current file pointer position. Note that the returned value has nothing to do with the actual position in the file.

The following two functions are defined for compatibility with the aifc, and don’t do anything interesting.

AU_read.getmarkers()
Returns None.

AU_read.getmark(id)
Raise an error.
22.3.2. AU_write Objects

AU_write objects, as returned by open() above, have the following methods:

AU_write.setnchannels(n)
Set the number of channels.

AU_write.setsampwidth(n)
Set the sample width (in bytes.)

*Changed in version 3.4:* Added support for 24-bit samples.

AU_write.setframerate(n)
Set the frame rate.

AU_write.setnframes(n)
Set the number of frames. This can be later changed, when and if more frames are written.

AU_write.setcomptype(type, name)
Set the compression type and description. Only 'NONE' and 'ULAW' are supported on output.

AU_write.setparams(tuple)
The tuple should be (nchannels, sampwidth, framerate, nframes, comptype, compname), with values valid for the set*() methods. Set all parameters.

AU_write.tell()
Return current position in the file, with the same disclaimer for the AU_read.tell() and AU_read.setpos() methods.
AU_write.writeframesraw(data)
Write audio frames, without correcting nframes.

*Changed in version 3.4:* Any bytes-like object is now accepted.

AU_write.writeframes(data)
Write audio frames and make sure nframes is correct.

*Changed in version 3.4:* Any bytes-like object is now accepted.

AU_write.close()
Make sure nframes is correct, and close the file.

This method is called upon deletion.

Note that it is invalid to set any parameters after calling writeframes() or writeframesraw().
22.4. wave — Read and write WAV files

Source code: Lib/wave.py

The wave module provides a convenient interface to the WAV sound format. It does not support compression/decompression, but it does support mono/stereo.

The wave module defines the following function and exception:

```
wave.open(file, mode=None)
```

If `file` is a string, open the file by that name, otherwise treat it as a file-like object. `mode` can be:

- `'rb'`
  - Read only mode.
- `'wb'`
  - Write only mode.

Note that it does not allow read/write WAV files.

A `mode` of `'rb'` returns a `Wave_read` object, while a `mode` of `'wb'` returns a `Wave_write` object. If `mode` is omitted and a file-like object is passed as `file`, `file.mode` is used as the default value for `mode`.

If you pass in a file-like object, the wave object will not close it when its `close()` method is called; it is the caller’s responsibility to close the file object.
The `open()` function may be used in a `with` statement. When the `with` block completes, the `Wave_read.close()` or `Wave_write.close()` method is called.

*Changed in version 3.4:* Added support for unseekable files.

```python
wave.openfp(file, mode)
```

A synonym for `open()`, maintained for backwards compatibility.

*Deprecated since version 3.7, will be removed in version 3.9.*

```python
exception wave.Error
```

An error raised when something is impossible because it violates the WAV specification or hits an implementation deficiency.
22.4.1. Wave_read Objects

Wave_read objects, as returned by open(), have the following methods:

Wave_read.close()

Close the stream if it was opened by wave, and make the instance unusable. This is called automatically on object collection.

Wave_read.getnchannels()

Returns number of audio channels (1 for mono, 2 for stereo).

Wave_read.getsampwidth()

Returns sample width in bytes.

Wave_read.getframerate()

Returns sampling frequency.

Wave_read.getnframes()

Returns number of audio frames.

Wave_read.getcomptype()

Returns compression type ('NONE' is the only supported type).

Wave_read.getcompname()

Human-readable version of getcomptype(). Usually 'not compressed' parallels 'NONE'.

Wave_read.getparams()

Returns a namedtuple(nchannels, sampwidth, framerate, nframes, comptype, compname), equivalent to
output of the get*() methods.

Wave_read.readframes(n)
Reads and returns at most n frames of audio, as a bytes object.

Wave_read.rewind()
Rewind the file pointer to the beginning of the audio stream.

The following two methods are defined for compatibility with the aiffc module, and don’t do anything interesting.

Wave_read.getmarkers()
Returns None.

Wave_read.getmark(id)
Raise an error.

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

Wave_read.setpos(pos)
Set the file pointer to the specified position.

Wave_read.tell()
Return current file pointer position.
22.4.2. Wave_write Objects

For seekable output streams, the wave header will automatically be updated to reflect the number of frames actually written. For unseekable streams, the nframes value must be accurate when the first frame data is written. An accurate nframes value can be achieved either by calling setnframes() or setparams() with the number of frames that will be written before close() is called and then using writeframesraw() to write the frame data, or by calling writeframes() with all of the frame data to be written. In the latter case writeframes() will calculate the number of frames in the data and set nframes accordingly before writing the frame data.

Wave_write objects, as returned by open(), have the following methods:

*Changed in version 3.4:* Added support for unseekable files.

Wave_write.close()

Make sure nframes is correct, and close the file if it was opened by wave. This method is called upon object collection. It will raise an exception if the output stream is not seekable and nframes does not match the number of frames actually written.

Wave_write.setnchannels(n)

Set the number of channels.

Wave_write.setsampwidth(n)

Set the sample width to n bytes.

Wave_write.setframerate(n)
Set the frame rate to $n$.

*Changed in version 3.2:* A non-integral input to this method is rounded to the nearest integer.

**Wave_write.setnframes**($n$)
Set the number of frames to $n$. This will be changed later if the number of frames actually written is different (this update attempt will raise an error if the output stream is not seekable).

**Wave_write.setcomptype**(*type*, *name*)
Set the compression type and description. At the moment, only compression type **NONE** is supported, meaning no compression.

**Wave_write.setparams**(*tuple*)
The *tuple* should be `(nchannels, sampwidth, framerate, nframes, comptype, compname)`, with values valid for the `set*()` methods. Sets all parameters.

**Wave_write.tell**()
Return current position in the file, with the same disclaimer for the `Wave_read.tell()` and `Wave_read.setpos()` methods.

**Wave_write.writeframesraw**(*data*)
Write audio frames, without correcting *nframes*.

*Changed in version 3.4:* Any bytes-like object is now accepted.

**Wave_write.writeframes**(*data*)
Write audio frames and make sure *nframes* is correct. It will raise an error if the output stream is not seekable and the total number of frames that have been written after *data* has been written does not match the previously set value for *nframes*. 
Changed in version 3.4: Any bytes-like object is now accepted.

Note that it is invalid to set any parameters after calling writeframes() or writeframesraw(), and any attempt to do so will raise wave.Error.
22.5. chunk — Read IFF chunked data

Source code: Lib/chunk.py

This module provides an interface for reading files that use EA IFF 85 chunks. [1] This format is used in at least the Audio Interchange File Format (AIFF/AIFF-C) and the Real Media File Format (RMFF). The WAVE audio file format is closely related and can also be read using this module.

A chunk has the following structure:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Length</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>Chunk ID</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Size of chunk in big-endian byte order, not including the header</td>
</tr>
<tr>
<td>8</td>
<td>$n$</td>
<td>Data bytes, where $n$ is the size given in the preceding field</td>
</tr>
<tr>
<td>$8 + n$</td>
<td>0 or 1</td>
<td>Pad byte needed if $n$ is odd and chunk alignment is used</td>
</tr>
</tbody>
</table>

The ID is a 4-byte string which identifies the type of chunk.

The size field (a 32-bit value, encoded using big-endian byte order) gives the size of the chunk data, not including the 8-byte header.

Usually an IFF-type file consists of one or more chunks. The proposed usage of the Chunk class defined here is to instantiate an instance at
the start of each chunk and read from the instance until it reaches the end, after which a new instance can be instantiated. At the end of the file, creating a new instance will fail with an `EOFError` exception.

class chunk. **Chunk** *(file, align=True, bigendian=True, inclheader=False)*

Class which represents a chunk. The *file* argument is expected to be a file-like object. An instance of this class is specifically allowed. The only method that is needed is `read()`. If the methods `seek()` and `tell()` are present and don’t raise an exception, they are also used. If these methods are present and raise an exception, they are expected to not have altered the object. If the optional argument *align* is true, chunks are assumed to be aligned on 2-byte boundaries. If *align* is false, no alignment is assumed. The default value is true. If the optional argument *bigendian* is false, the chunk size is assumed to be in little-endian order. This is needed for WAVE audio files. The default value is true. If the optional argument *inclheader* is true, the size given in the chunk header includes the size of the header. The default value is false.

A **Chunk** object supports the following methods:

**getname()**

Returns the name (ID) of the chunk. This is the first 4 bytes of the chunk.

**getsize()**

Returns the size of the chunk.

**close()**

Close and skip to the end of the chunk. This does not close the underlying file.
The remaining methods will raise OSError if called after the close() method has been called. Before Python 3.3, they used to raise IOError, now an alias of OSError.

**isatty()**
Returns False.

**seek(pos, whence=0)**
Set the chunk's current position. The whence argument is optional and defaults to 0 (absolute file positioning); other values are 1 (seek relative to the current position) and 2 (seek relative to the file's end). There is no return value. If the underlying file does not allow seek, only forward seeks are allowed.

**tell()**
Return the current position into the chunk.

**read(size=-1)**
Read at most size bytes from the chunk (less if the read hits the end of the chunk before obtaining size bytes). If the size argument is negative or omitted, read all data until the end of the chunk. An empty bytes object is returned when the end of the chunk is encountered immediately.

**skip()**
Skip to the end of the chunk. All further calls to read() for the chunk will return b''. If you are not interested in the contents of the chunk, this method should be called so that the file points to the start of the next chunk.

Footnotes
22.6. `colorsys` — Conversions between color systems

Source code: Lib/colorsys.py

The `colorsys` module defines bidirectional conversions of color values between colors expressed in the RGB (Red Green Blue) color space used in computer monitors and three other coordinate systems: YIQ, HLS (Hue Lightness Saturation) and HSV (Hue Saturation Value). Coordinates in all of these color spaces are floating point values. In the YIQ space, the Y coordinate is between 0 and 1, but the I and Q coordinates can be positive or negative. In all other spaces, the coordinates are all between 0 and 1.

The `colorsys` module defines the following functions:

- `colorsys.rgb_to_yiq(r, g, b)`
  Convert the color from RGB coordinates to YIQ coordinates.

- `colorsys.yiq_to_rgb(y, i, q)`
  Convert the color from YIQ coordinates to RGB coordinates.

- `colorsys.rgb_to_hls(r, g, b)`
  Convert the color from RGB coordinates to HLS coordinates.

- `colorsys.hls_to_rgb(h, l, s)`
Convert the color from HLS coordinates to RGB coordinates.

colorsys.\texttt{rgb\_to\_hsv}(r, g, b)

Convert the color from RGB coordinates to HSV coordinates.

colorsys.\texttt{hsv\_to\_rgb}(h, s, v)

Convert the color from HSV coordinates to RGB coordinates.

Example:

```python
>>> import colorsys
>>> colorsys.rgb_to_hsv(0.2, 0.4, 0.4)
(0.5, 0.5, 0.4)
>>> colorsys.hsv_to_rgb(0.5, 0.5, 0.4)
(0.2, 0.4, 0.4)
```
22.7. `imghdr` — Determine the type of an image

Source code: Lib/imghdr.py

The `imghdr` module determines the type of image contained in a file or byte stream.

The `imghdr` module defines the following function:

`imghdr.what(filename, h=None)`

Tests the image data contained in the file named by `filename`, and returns a string describing the image type. If optional `h` is provided, the `filename` is ignored and `h` is assumed to contain the byte stream to test.

*Changed in version 3.6:* Accepts a path-like object.

The following image types are recognized, as listed below with the return value from `what()`:

<table>
<thead>
<tr>
<th>Value</th>
<th>Image format</th>
</tr>
</thead>
<tbody>
<tr>
<td>'rgb'</td>
<td>SGI ImgLib Files</td>
</tr>
<tr>
<td>'gif'</td>
<td>GIF 87a and 89a Files</td>
</tr>
<tr>
<td>'pbm'</td>
<td>Portable Bitmap Files</td>
</tr>
<tr>
<td>'pgm'</td>
<td>Portable Graymap Files</td>
</tr>
<tr>
<td>'ppm'</td>
<td>Portable Pixmap Files</td>
</tr>
<tr>
<td>'tiff'</td>
<td>TIFF Files</td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>'rast'</td>
<td>Sun Raster Files</td>
</tr>
<tr>
<td>'xbm'</td>
<td>X Bitmap Files</td>
</tr>
<tr>
<td>'jpeg'</td>
<td>JPEG data in JFIF or Exif formats</td>
</tr>
<tr>
<td>'bmp'</td>
<td>BMP files</td>
</tr>
<tr>
<td>'png'</td>
<td>Portable Network Graphics</td>
</tr>
<tr>
<td>'webp'</td>
<td>WebP files</td>
</tr>
<tr>
<td>'exr'</td>
<td>OpenEXR Files</td>
</tr>
</tbody>
</table>

New in version 3.5: The exr and webp formats were added.

You can extend the list of file types `imghdr` can recognize by appending to this variable:

`imghdr.tests`

A list of functions performing the individual tests. Each function takes two arguments: the byte-stream and an open file-like object. When `what()` is called with a byte-stream, the file-like object will be `None`.

The test function should return a string describing the image type if the test succeeded, or `None` if it failed.

Example:

```python
>>> import imghdr
>>> imghdr.what('bass.gif')
'gif'
```
22.8. **sndhdr** — Determine type of sound file

**Source code:** Lib/sndhdr.py

The `sndhdr` provides utility functions which attempt to determine the type of sound data which is in a file. When these functions are able to determine what type of sound data is stored in a file, they return a `namedtuple()`, containing five attributes: (`filetype`, `framerate`, `nchannels`, `nframes`, `sampwidth`). The value for `type` indicates the data type and will be one of the strings `'aifc'`, `'aiff'`, `'au'`, `'hcom'`, `'sndr'`, `'sndt'`, `'voc'`, `'wav'`, `'8svx'`, `'sb'`, `'ub'`, or `'ul'`. The `sampling_rate` will be either the actual value or 0 if unknown or difficult to decode. Similarly, `channels` will be either the number of channels or 0 if it cannot be determined or if the value is difficult to decode. The value for `frames` will be either the number of frames or -1. The last item in the tuple, `bits_per_sample`, will either be the sample size in bits or `'A'` for A-LAW or `'U'` for u-LAW.

```python
sndhdr.what(filename)
```

Determines the type of sound data stored in the file `filename` using `whathdr()`. If it succeeds, returns a namedtuple as described above, otherwise None is returned.

*Changed in version 3.5:* Result changed from a tuple to a namedtuple.

```python
sndhdr.whathdr(filename)
```

Determines the type of sound data stored in a file based on the file
header. The name of the file is given by *filename*. This function returns a namedtuple as described above on success, or `None`.

*Changed in version 3.5:* Result changed from a tuple to a namedtuple.
22.9. **ossaudiodev** — Access to OSS-compatible audio devices

This module allows you to access the OSS (Open Sound System) audio interface. OSS is available for a wide range of open-source and commercial Unices, and is the standard audio interface for Linux and recent versions of FreeBSD.

*Changed in version 3.3:* Operations in this module now raise `OSError` where `IOError` was raised.

**See also:**

*Open Sound System Programmer’s Guide*

the official documentation for the OSS C API

The module defines a large number of constants supplied by the OSS device driver; see `<sys/soundcard.h>` on either Linux or FreeBSD for a listing.

**ossaudiodev** defines the following variables and functions:

*exception* `ossaudiodev.OSSAudioError`

This exception is raised on certain errors. The argument is a string describing what went wrong.

(If `ossaudiodev` receives an error from a system call such as `open()`, `write()`, or `ioctl()`, it raises `OSError`. Errors detected directly by `ossaudiodev` result in `OSSAudioError`.)
ossaudiodev.open

ossaudiodev.open(device, mode)

Open an audio device and return an OSS audio device object. This object supports many file-like methods, such as read(), write(), and fileno() (although there are subtle differences between conventional Unix read/write semantics and those of OSS audio devices). It also supports a number of audio-specific methods; see below for the complete list of methods.

device is the audio device filename to use. If it is not specified, this module first looks in the environment variable AUDIODEV for a device to use. If not found, it falls back to /dev/dsp.

mode is one of 'r' for read-only (record) access, 'w' for write-only (playback) access and 'rw' for both. Since many sound cards only allow one process to have the recorder or player open at a time, it is a good idea to open the device only for the activity needed. Further, some sound cards are half-duplex: they can be opened for reading or writing, but not both at once.

Note the unusual calling syntax: the first argument is optional, and the second is required. This is a historical artifact for compatibility with the older linuxaudiodev module which ossaudiodev supersedes.

ossaudiodev.openmixer([device])

Open a mixer device and return an OSS mixer device object. device is the mixer device filename to use. If it is not specified, this module first looks in the environment variable MIXERDEV for a
device to use. If not found, it falls back to /dev/mixer.
22.9.1. Audio Device Objects

Before you can write to or read from an audio device, you must call three methods in the correct order:

1. `setfmt()` to set the output format
2. `channels()` to set the number of channels
3. `speed()` to set the sample rate

Alternately, you can use the `setparameters()` method to set all three audio parameters at once. This is more convenient, but may not be as flexible in all cases.

The audio device objects returned by `open()` define the following methods and (read-only) attributes:

`oss_audio_device.close()`
Explicitly close the audio device. When you are done writing to or reading from an audio device, you should explicitly close it. A closed device cannot be used again.

`oss_audio_device.fileno()`
Return the file descriptor associated with the device.

`oss_audio_device.read(size)`
Read `size` bytes from the audio input and return them as a Python string. Unlike most Unix device drivers, OSS audio devices in blocking mode (the default) will block `read()` until the entire requested amount of data is available.

`oss_audio_device.write(data)`
Write a bytes-like object `data` to the audio device and return the
number of bytes written. If the audio device is in blocking mode (the default), the entire data is always written (again, this is different from usual Unix device semantics). If the device is in non-blocking mode, some data may not be written—see `writeall()`.

*Changed in version 3.5:* Writable bytes-like object is now accepted.

```python
oss_audio_device.writeall(data)
```

Write a bytes-like object `data` to the audio device: waits until the audio device is able to accept data, writes as much data as it will accept, and repeats until `data` has been completely written. If the device is in blocking mode (the default), this has the same effect as `write(); writeall()` is only useful in non-blocking mode. Has no return value, since the amount of data written is always equal to the amount of data supplied.

*Changed in version 3.5:* Writable bytes-like object is now accepted.

*Changed in version 3.2:* Audio device objects also support the context management protocol, i.e. they can be used in a `with` statement.

The following methods each map to exactly one `ioctl()` system call. The correspondence is obvious: for example, `setfmt()` corresponds to the `SNDCTL_DSP_SETFMT` `ioctl`, and `sync()` to `SNDCTL_DSP_SYNC` (this can be useful when consulting the OSS documentation). If the underlying `ioctl()` fails, they all raise `OSError`.

```python
oss_audio_device.nonblock()
```

Put the device into non-blocking mode. Once in non-blocking mode, there is no way to return it to blocking mode.

```python
oss_audio_device.getfmts()
```
Return a bitmask of the audio output formats supported by the soundcard. Some of the formats supported by OSS are:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFMT_MU_LAW</td>
<td>a logarithmic encoding (used by Sun .au files and /dev/audio)</td>
</tr>
<tr>
<td>AFMT_A_LAW</td>
<td>a logarithmic encoding</td>
</tr>
<tr>
<td>AFMT_IMA_ADPCM</td>
<td>a 4:1 compressed format defined by the Interactive Multimedia Association</td>
</tr>
<tr>
<td>AFMT_U8</td>
<td>Unsigned, 8-bit audio</td>
</tr>
<tr>
<td>AFMT_S16_LE</td>
<td>Signed, 16-bit audio, little-endian byte order (as used by Intel processors)</td>
</tr>
<tr>
<td>AFMT_S16_BE</td>
<td>Signed, 16-bit audio, big-endian byte order (as used by 68k, PowerPC, Sparc)</td>
</tr>
<tr>
<td>AFMT_S8</td>
<td>Signed, 8 bit audio</td>
</tr>
<tr>
<td>AFMT_U16_LE</td>
<td>Unsigned, 16-bit little-endian audio</td>
</tr>
<tr>
<td>AFMT_U16_BE</td>
<td>Unsigned, 16-bit big-endian audio</td>
</tr>
</tbody>
</table>

Consult the OSS documentation for a full list of audio formats, and note that most devices support only a subset of these formats. Some older devices only support AFMT_U8; the most common format used today is AFMT_S16_LE.

**oss_audio_device.setfmt(format)**

Try to set the current audio format to `format`—see `getfmts()` for a list. Returns the audio format that the device was set to, which may not be the requested format. May also be used to return the current audio format—do this by passing an “audio format” of AFMT_QUERY.
oss_audio_device.channels(nchannels)
Set the number of output channels to nchannels. A value of 1 indicates monophonic sound, 2 stereophonic. Some devices may have more than 2 channels, and some high-end devices may not support mono. Returns the number of channels the device was set to.

oss_audio_device.speed(samplerate)
Try to set the audio sampling rate to samplerate samples per second. Returns the rate actually set. Most sound devices don’t support arbitrary sampling rates. Common rates are:

<table>
<thead>
<tr>
<th>Rate</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8000</td>
<td>default rate for /dev/audio</td>
</tr>
<tr>
<td>11025</td>
<td>speech recording</td>
</tr>
<tr>
<td>22050</td>
<td></td>
</tr>
<tr>
<td>44100</td>
<td>CD quality audio (at 16 bits/sample and 2 channels)</td>
</tr>
<tr>
<td>96000</td>
<td>DVD quality audio (at 24 bits/sample)</td>
</tr>
</tbody>
</table>

oss_audio_device.sync()
Wait until the sound device has played every byte in its buffer. (This happens implicitly when the device is closed.) The OSS documentation recommends closing and re-opening the device rather than using sync().

oss_audio_device.reset()
Immediately stop playing or recording and return the device to a state where it can accept commands. The OSS documentation recommends closing and re-opening the device after calling
reset().

oss_audio_device.post()

Tell the driver that there is likely to be a pause in the output, making it possible for the device to handle the pause more intelligently. You might use this after playing a spot sound effect, before waiting for user input, or before doing disk I/O.

The following convenience methods combine several ioctl's, or one ioctl and some simple calculations.

oss_audio_device.setparameters(format, nchannels, samplerate[, strict=False])

Set the key audio sampling parameters—sample format, number of channels, and sampling rate—in one method call. format, nchannels, and samplerate should be as specified in the setfmt(), channels(), and speed() methods. If strict is true, setparameters() checks to see if each parameter was actually set to the requested value, and raises OSSAudioError if not. Returns a tuple (format, nchannels, samplerate) indicating the parameter values that were actually set by the device driver (i.e., the same as the return values of setfmt(), channels(), and speed()).

For example,

```
(fmt, channels, rate) = dsp.setparameters(fmt, channels, samplerate)
```

is equivalent to

```
fmt = dsp.setfmt(fmt)
channels = dsp.channels(channels)
```
rate = dsp.rate(rate)

oss_audio_device.bufsize()
Returns the size of the hardware buffer, in samples.

oss_audio_device.obufcount()
Returns the number of samples that are in the hardware buffer yet to be played.

oss_audio_device.obuffree()
Returns the number of samples that could be queued into the hardware buffer to be played without blocking.

Audio device objects also support several read-only attributes:

oss_audio_device.closed
Boolean indicating whether the device has been closed.

oss_audio_device.name
String containing the name of the device file.

oss_audio_device.mode
The I/O mode for the file, either "r", "rw", or "w".
22.9.2. Mixer Device Objects

The mixer object provides two file-like methods:

oss_mixer_device.close()

This method closes the open mixer device file. Any further attempts to use the mixer after this file is closed will raise an OSError.

oss_mixer_device.fileno()

Returns the file handle number of the open mixer device file.

Changed in version 3.2: Mixer objects also support the context management protocol.

The remaining methods are specific to audio mixing:

oss_mixer_device.controls()

This method returns a bitmask specifying the available mixer controls (“Control” being a specific mixable “channel”, such as SOUND_MIXER_PCM or SOUND_MIXER_SYNTH). This bitmask indicates a subset of all available mixer controls—the SOUND_MIXER_* constants defined at module level. To determine if, for example, the current mixer object supports a PCM mixer, use the following Python code:

```python
mixer=ossaudiodev.openmixer()
if mixer.controls() & (1 << ossaudiodev.SOUND_MIXER_PCM):
    # PCM is supported
    ... code ...
```

For most purposes, the SOUND_MIXER_VOLUME (master volume) and SOUND_MIXER_PCM controls should suffice—but code that
uses the mixer should be flexible when it comes to choosing mixer controls. On the Gravis Ultrasound, for example, SOUND_MIXER_VOLUME does not exist.

`oss_mixer_device.stereocontrols()`
Returns a bitmask indicating stereo mixer controls. If a bit is set, the corresponding control is stereo; if it is unset, the control is either monophonic or not supported by the mixer (use in combination with `controls()` to determine which).

See the code example for the `controls()` function for an example of getting data from a bitmask.

`oss_mixer_device.reccontrols()`
Returns a bitmask specifying the mixer controls that may be used to record. See the code example for `controls()` for an example of reading from a bitmask.

`oss_mixer_device.get(control)`
Returns the volume of a given mixer control. The returned volume is a 2-tuple `(left_volume, right_volume)`. Volumes are specified as numbers from 0 (silent) to 100 (full volume). If the control is monophonic, a 2-tuple is still returned, but both volumes are the same.

Raises `OSSAudioError` if an invalid control is specified, or `OSError` if an unsupported control is specified.

`oss_mixer_device.set(control, (left, right))`
Sets the volume for a given mixer control to `(left, right)`. `left` and `right` must be ints and between 0 (silent) and 100 (full volume). On success, the new volume is returned as a 2-tuple.
Note that this may not be exactly the same as the volume specified, because of the limited resolution of some soundcard’s mixers.

Raises **OSSAudioError** if an invalid mixer control was specified, or if the specified volumes were out-of-range.

**oss_mixer_device.get_recsrc()**

This method returns a bitmask indicating which control(s) are currently being used as a recording source.

**oss_mixer_device.set_recsrc(bitmask)**

Call this function to specify a recording source. Returns a bitmask indicating the new recording source (or sources) if successful; raises **OSError** if an invalid source was specified. To set the current recording source to the microphone input:

```python
mixer.set_recsrc (1 << ossaudiodev.SOUND_MIXER_MIC)
```
23. Internationalization

The modules described in this chapter help you write software that is independent of language and locale by providing mechanisms for selecting a language to be used in program messages or by tailoring output to match local conventions.

The list of modules described in this chapter is:

- **23.1. gettext — Multilingual internationalization services**
  - 23.1.1. GNU gettext API
  - 23.1.2. Class-based API
    - 23.1.2.1. The NullTranslations class
    - 23.1.2.2. The GNUTranslations class
    - 23.1.2.3. Solaris message catalog support
    - 23.1.2.4. The Catalog constructor
  - 23.1.3. Internationalizing your programs and modules
    - 23.1.3.1. Localizing your module
    - 23.1.3.2. Localizing your application
    - 23.1.3.3. Changing languages on the fly
    - 23.1.3.4. Deferred translations
  - 23.1.4. Acknowledgements

- **23.2. locale — Internationalization services**
  - 23.2.1. Background, details, hints, tips and caveats
  - 23.2.2. For extension writers and programs that embed Python
  - 23.2.3. Access to message catalogs
Last updated on Jan 31, 2018. Found a bug?
Created using Sphinx 1.6.6.
23.1. gettext — Multilingual internationalization services

Source code: Lib/gettext.py

The gettext module provides internationalization (I18N) and localization (L10N) services for your Python modules and applications. It supports both the GNU gettext message catalog API and a higher level, class-based API that may be more appropriate for Python files. The interface described below allows you to write your module and application messages in one natural language, and provide a catalog of translated messages for running under different natural languages.

Some hints on localizing your Python modules and applications are also given.
23.1.1. GNU gettext API

The gettext module defines the following API, which is very similar to the GNU gettext API. If you use this API you will affect the translation of your entire application globally. Often this is what you want if your application is monolingual, with the choice of language dependent on the locale of your user. If you are localizing a Python module, or if your application needs to switch languages on the fly, you probably want to use the class-based API instead.

`gettext.bindtextdomain(domain, localedir=None)`

Bind the `domain` to the locale directory `localedir`. More concretely, gettext will look for binary `.mo` files for the given domain using the path (on Unix):

```
localedir/language/LC_MESSAGES/domain.mo
```

where `languages` is searched for in the environment variables `LANGUAGE`, `LC_ALL`, `LC_MESSAGES`, and `LANG` respectively.

If `localedir` is omitted or `None`, then the current binding for `domain` is returned. [1]

`gettext.bind_textdomain_codeset(domain, codeset=None)`

Bind the `domain` to `codeset`, changing the encoding of byte strings returned by the `gettext()`, `ldgettext()`, `lngettext()` and `ldngettext()` functions. If `codeset` is omitted, then the current binding is returned.

`gettext.textdomain(domain=None)`

Change or query the current global domain. If `domain` is `None`, then the current global domain is returned, otherwise the global
domain is set to *domain*, which is returned.

**gettext**(*message*)

Return the localized translation of *message*, based on the current global domain, language, and locale directory. This function is usually aliased as `_()` in the local namespace (see examples below).

**gettext**. **dgettext**(*domain, message*)

Like **gettext()**, but look the message up in the specified *domain*.

**gettext**. **ngettext**(*singular, plural, n*)

Like **gettext()**, but consider plural forms. If a translation is found, apply the plural formula to *n*, and return the resulting message (some languages have more than two plural forms). If no translation is found, return *singular* if *n* is 1; return *plural* otherwise.

The Plural formula is taken from the catalog header. It is a C or Python expression that has a free variable *n*; the expression evaluates to the index of the plural in the catalog. See the GNU gettext documentation for the precise syntax to be used in .po files and the formulas for a variety of languages.

**gettext**. **dngettext**(*domain, singular, plural, n*)

Like **ngettext()**, but look the message up in the specified *domain*.

**gettext**. **lgettext**(*message*)

**gettext**. **ldgettext**(*domain, message*)

**gettext**. **lngettext**(*singular, plural, n*)
gettext.**ldgettext**(domain, singular, plural, n)

Equivalent to the corresponding functions without the l prefix (gettext(), dgettext(), ngettext() and dngettext()), but the translation is returned as a byte string encoded in the preferred system encoding if no other encoding was explicitly set with `bind_textdomain_codeset()`.

**Warning:** These functions should be avoided in Python 3, because they return encoded bytes. It’s much better to use alternatives which return Unicode strings instead, since most Python applications will want to manipulate human readable text as strings instead of bytes. Further, it’s possible that you may get unexpected Unicode-related exceptions if there are encoding problems with the translated strings. It is possible that the l*() functions will be deprecated in future Python versions due to their inherent problems and limitations.

Note that GNU gettext also defines a dcgettext() method, but this was deemed not useful and so it is currently unimplemented.

Here’s an example of typical usage for this API:

```python
import gettext
gettext.bindtextdomain('myapplication', '/path/to/my
gettext.textdomain('myapplication')
_ = gettext.gettext
# ...
print(_('This is a translatable string.'))
```
23.1.2. Class-based API

The class-based API of the gettext module gives you more flexibility and greater convenience than the GNU gettext API. It is the recommended way of localizing your Python applications and modules. gettext defines a “translations” class which implements the parsing of GNU .mo format files, and has methods for returning strings. Instances of this “translations” class can also install themselves in the built-in namespace as the function _().

```
gettext.find(domain, localedir=None, languages=None, all=False)
```

This function implements the standard .mo file search algorithm. It takes a domain, identical to what textdomain() takes. Optional localedir is as in bindtextdomain() Optional languages is a list of strings, where each string is a language code.

If localedir is not given, then the default system locale directory is used. [2] If languages is not given, then the following environment variables are searched: LANGUAGE, LC_ALL, LC_MESSAGES, and LANG. The first one returning a non-empty value is used for the languages variable. The environment variables should contain a colon separated list of languages, which will be split on the colon to produce the expected list of language code strings.

find() then expands and normalizes the languages, and then iterates through them, searching for an existing file built of these components:

```
localedir/language/LC_MESSAGES/domain.mo
```
The first such file name that exists is returned by `find()`. If no such file is found, then `None` is returned. If all is given, it returns a list of all file names, in the order in which they appear in the languages list or the environment variables.

```
gettext.translation(domain, localedir=None, languages=None, class_=None, fallback=False, codeset=None)
```

Return a Translations instance based on the `domain`, `localedir`, and `languages`, which are first passed to `find()` to get a list of the associated `.mo` file paths. Instances with identical `.mo` file names are cached. The actual class instantiated is either `class_` if provided, otherwise `GNUTranslations`. The class's constructor must take a single `file object` argument. If provided, `codeset` will change the charset used to encode translated strings in the `lgettext()` and `lngettext()` methods.

If multiple files are found, later files are used as fallbacks for earlier ones. To allow setting the fallback, `copy.copy()` is used to clone each translation object from the cache; the actual instance data is still shared with the cache.

If no `.mo` file is found, this function raises `OSError` if `fallback` is false (which is the default), and returns a `NullTranslations` instance if `fallback` is true.

*Changed in version 3.3*: `IOError` used to be raised instead of `OSError`.

```
gettext.install(domain, localedir=None, codeset=None, names=None)
```

This installs the function `_( )` in Python's builtins namespace, based on `domain`, `localedir`, and `codeset` which are passed to the
function **translation**().

For the *names* parameter, please see the description of the translation object's *install()* method.

As seen below, you usually mark the strings in your application that are candidates for translation, by wrapping them in a call to the *() function, like this:

```python
print(_('This string will be translated.'))
```

For convenience, you want the *() function to be installed in Python's builtins namespace, so it is easily accessible in all modules of your application.

### 23.1.2.1. The **NullTranslations** class

Translation classes are what actually implement the translation of original source file message strings to translated message strings. The base class used by all translation classes is **NullTranslations**; this provides the basic interface you can use to write your own specialized translation classes. Here are the methods of **NullTranslations**:

```python
class gettext.**NullTranslations**(fp=None)
```

Takes an optional file object *fp*, which is ignored by the base class. Initializes “protected” instance variables *info* and *charset* which are set by derived classes, as well as *fallback*, which is set through *add_fallback()* . It then calls *self._parse(fp)* if *fp* is not None.

```python
_parse(fp)
```
No-op’d in the base class, this method takes file object \( fp \), and reads the data from the file, initializing its message catalog. If you have an unsupported message catalog file format, you should override this method to parse your format.

**add_fallback\(^*\)(fallback)**

Add fallback as the fallback object for the current translation object. A translation object should consult the fallback if it cannot provide a translation for a given message.

**gettext\(^*\)(message)**

If a fallback has been set, forward gettext() to the fallback. Otherwise, return message. Overridden in derived classes.

**ngettext\(^*\)(singular, plural, n)**

If a fallback has been set, forward ngettext() to the fallback. Otherwise, return singular if \( n \) is 1; return plural otherwise. Overridden in derived classes.

**lgettext\(^*\)(message)**

**lngettext\(^*\)(singular, plural, n)**

Equivalent to gettext() and ngettext(), but the translation is returned as a byte string encoded in the preferred system encoding if no encoding was explicitly set with set_output_charset(). Overridden in derived classes.

**Warning:** These methods should be avoided in Python 3. See the warning for the lgettext() function.

**info\(^*\)**

Return the “protected” \_info variable.
charset()
Return the encoding of the message catalog file.

output_charset()
Return the encoding used to return translated messages in lgettext() and lngettext().

set_output_charset(charset)
Change the encoding used to return translated messages.

install(names=None)
This method installs gettext() into the built-in namespace, binding it to _.

If the names parameter is given, it must be a sequence containing the names of functions you want to install in the builtins namespace in addition to _(). Supported names are 'gettext', 'ngettext', 'lgettext' and 'lngettext'.

Note that this is only one way, albeit the most convenient way, to make the _() function available to your application. Because it affects the entire application globally, and specifically the built-in namespace, localized modules should never install _(). Instead, they should use this code to make _() available to their module:

```python
import gettext
t = gettext.translation('mymodule', ...)_
  = t.gettext
```

This puts _() only in the module’s global namespace and so only affects calls within this module.
23.1.2.2. The **GNUTranslations** class

The **gettext** module provides one additional class derived from **NullTranslations**: **GNUTranslations**. This class overrides `_parse()` to enable reading GNU **gettext** format .mo files in both big-endian and little-endian format.

**GNUTranslations** parses optional meta-data out of the translation catalog. It is convention with GNU **gettext** to include meta-data as the translation for the empty string. This meta-data is in **RFC 822**-style key: value pairs, and should contain the Project-Id-Version key. If the key Content-Type is found, then the charset property is used to initialize the “protected” _charset instance variable, defaulting to None if not found. If the charset encoding is specified, then all message ids and message strings read from the catalog are converted to Unicode using this encoding, else ASCII encoding is assumed.

Since message ids are read as Unicode strings too, all *gettext() methods will assume message ids as Unicode strings, not byte strings.

The entire set of key/value pairs are placed into a dictionary and set as the “protected” _info instance variable.

If the .mo file's magic number is invalid, the major version number is unexpected, or if other problems occur while reading the file, instantiating a **GNUTranslations** class can raise **OSError**.

**class gettext.GNUTranslations**

The following methods are overridden from the base class implementation:
gettext(message)
Look up the message id in the catalog and return the corresponding message string, as a Unicode string. If there is no entry in the catalog for the message id, and a fallback has been set, the look up is forwarded to the fallback's gettext() method. Otherwise, the message id is returned.

ngettext(singular, plural, n)
Do a plural-forms lookup of a message id. singular is used as the message id for purposes of lookup in the catalog, while n is used to determine which plural form to use. The returned message string is a Unicode string.

If the message id is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback's ngettext() method. Otherwise, when n is 1 singular is returned, and plural is returned in all other cases.

Here is an example:

```python
n = len(os.listdir('.'))
cat = GNUTranslations(somefile)
message = cat.ngettext(
    'There is %(num)d file in this directory',
    'There are %(num)d files in this directory',
    n) % {'num': n}
```

lgettext(message)

lngettext(singular, plural, n)
Equivalent to gettext() and ngettext(), but the translation is returned as a byte string encoded in the preferred system encoding if no encoding was explicitly set with
set_output_charset().

**Warning:** These methods should be avoided in Python 3. See the warning for the `lgettext()` function.

### 23.1.2.3. Solaris message catalog support

The Solaris operating system defines its own binary `.mo` file format, but since no documentation can be found on this format, it is not supported at this time.

### 23.1.2.4. The Catalog constructor

GNOME uses a version of the `gettext` module by James Henstridge, but this version has a slightly different API. Its documented usage was:

```python
import gettext
cat = gettext.Catalog(domain, localedir)
_ = cat.gettext
print(_('hello world'))
```

For compatibility with this older module, the function `Catalog()` is an alias for the `translation()` function described above.

One difference between this module and Henstridge’s: his catalog objects supported access through a mapping API, but this appears to be unused and so is not currently supported.
23.1.3. Internationalizing your programs and modules

Internationalization (I18N) refers to the operation by which a program is made aware of multiple languages. Localization (L10N) refers to the adaptation of your program, once internationalized, to the local language and cultural habits. In order to provide multilingual messages for your Python programs, you need to take the following steps:

1. prepare your program or module by specially marking translatable strings
2. run a suite of tools over your marked files to generate raw messages catalogs
3. create language specific translations of the message catalogs
4. use the gettext module so that message strings are properly translated

In order to prepare your code for I18N, you need to look at all the strings in your files. Any string that needs to be translated should be marked by wrapping it in `_('...')` — that is, a call to the function `_()`. For example:

```python
filename = 'mylog.txt'
message = _('writing a log message')
fp = open(filename, 'w')
fp.write(message)
fp.close()
```

In this example, the string `writing a log message` is marked as a candidate for translation, while the strings `mylog.txt` and `w` are not.
There are a few tools to extract the strings meant for translation. The original GNU gettext only supported C or C++ source code but its extended version xgettext scans code written in a number of languages, including Python, to find strings marked as translatable. Babel is a Python internationalization library that includes a pybabel script to extract and compile message catalogs. François Pinard's program called xpot does a similar job and is available as part of his po-utils package.

(Python also includes pure-Python versions of these programs, called pygettext.py and msgfmt.py; some Python distributions will install them for you. pygettext.py is similar to xgettext, but only understands Python source code and cannot handle other programming languages such as C or C++. pygettext.py supports a command-line interface similar to xgettext; for details on its use, run pygettext.py --help. msgfmt.py is binary compatible with GNU msgfmt. With these two programs, you may not need the GNU gettext package to internationalize your Python applications.)

xgettext, pygettext, and similar tools generate .po files that are message catalogs. They are structured human-readable files that contain every marked string in the source code, along with a placeholder for the translated versions of these strings.

Copies of these .po files are then handed over to the individual human translators who write translations for every supported natural language. They send back the completed language-specific versions as a <language-name>.po file that's compiled into a machine-readable .mo binary catalog file using the msgfmt program. The .mo files are used by the gettext module for the actual translation processing at run-time.
How you use the `gettext` module in your code depends on whether you are internationalizing a single module or your entire application. The next two sections will discuss each case.

### 23.1.3.1. Localizing your module

If you are localizing your module, you must take care not to make global changes, e.g. to the built-in namespace. You should not use the GNU `gettext` API but instead the class-based API.

Let's say your module is called “spam” and the module's various natural language translation `.mo` files reside in `/usr/share/locale` in GNU `gettext` format. Here's what you would put at the top of your module:

```python
import gettext
t = gettext.translation('spam', '/usr/share/locale')
_ = t.gettext
```

### 23.1.3.2. Localizing your application

If you are localizing your application, you can install the `_()` function globally into the built-in namespace, usually in the main driver file of your application. This will let all your application-specific files just use `_('...')` without having to explicitly install it in each file.

In the simple case then, you need only add the following bit of code to the main driver file of your application:

```python
import gettext
gettext.install('myapplication')
```
If you need to set the locale directory, you can pass it into the `install()` function:

```python
import gettext
gettext.install('myapplication', '/usr/share/locale')
```

### 23.1.3.3. Changing languages on the fly

If your program needs to support many languages at the same time, you may want to create multiple translation instances and then switch between them explicitly, like so:

```python
import gettext

lang1 = gettext.translation('myapplication', languages=['en'])
lang2 = gettext.translation('myapplication', languages=['es'])
lang3 = gettext.translation('myapplication', languages=['fr'])

# start by using language 1
lang1.install()

# ... time goes by, user selects language 2
lang2.install()

# ... more time goes by, user selects language 3
lang3.install()
```

### 23.1.3.4. Deferred translations

In most coding situations, strings are translated where they are coded. Occasionally however, you need to mark strings for translation, but defer actual translation until later. A classic example is:
Here, you want to mark the strings in the `animals` list as being translatable, but you don’t actually want to translate them until they are printed.

Here is one way you can handle this situation:

```python
def _(message): return message

animals = [_("mollusk"),
         _("albatross"),
         _("rat"),
         _("penguin"),
         _("python"), ]

del _

# ...
for a in animals:   
    print(_(a))
```

This works because the dummy definition of `_()` simply returns the string unchanged. And this dummy definition will temporarily override any definition of `_()` in the built-in namespace (until the `del` command). Take care, though if you have a previous definition of `_()` in the local namespace.
Note that the second use of \_() will not identify “a” as being translatable to the \_gettext\ program, because the parameter is not a string literal.

Another way to handle this is with the following example:

```python
def N_(message): return message

animals = [N_('mollusk'),
           N_('albatross'),
           N_('rat'),
           N_('penguin'),
           N_('python'), ]

# ...
for a in animals:
    print(_(a))
```

In this case, you are marking translatable strings with the function \_N\_(\), which won’t conflict with any definition of \_()\). However, you will need to teach your message extraction program to look for translatable strings marked with \_N\_(\). \_xgettext\, \_pygettext\, \_pybabel\\_extract\, and \_xpot\ all support this through the use of the \_k\ command-line switch. The choice of \_N\_(\) here is totally arbitrary; it could have just as easily been \_MarkThisStringForTranslation\().
23.1.4. Acknowledgements

The following people contributed code, feedback, design suggestions, previous implementations, and valuable experience to the creation of this module:

- Peter Funk
- James Henstridge
- Juan David Ibáñez Palomar
- Marc-André Lemburg
- Martin von Löwis
- François Pinard
- Barry Warsaw
- Gustavo Niemeyer

Footnotes

The default locale directory is system dependent; for example, on RedHat Linux it is /usr/share/locale, but on Solaris it is /usr/lib/locale. The gettext module does not try to support these system dependent defaults; instead its default is sys.prefix/share/locale. For this reason, it is always best to call bindtextdomain() with an explicit absolute path at the start of your application.

[1] See the footnote for bindtextdomain() above.
23.2. `locale` —
Internationalization services

**Source code:** [Lib/locale.py](#)

The `locale` module opens access to the POSIX locale database and functionality. The POSIX locale mechanism allows programmers to deal with certain cultural issues in an application, without requiring the programmer to know all the specifics of each country where the software is executed.

The `locale` module is implemented on top of the `_locale` module, which in turn uses an ANSI C locale implementation if available.

The `locale` module defines the following exception and functions:

- **exception** `locale.Error`
  
  Exception raised when the locale passed to `setlocale()` is not recognized.

- `locale.setlocale(category, locale=None)`
  
  If *locale* is given and not `None`, `setlocale()` modifies the locale setting for the *category*. The available categories are listed in the data description below. `locale` may be a string, or an iterable of two strings (language code and encoding). If it's an iterable, it's converted to a locale name using the locale aliasing engine. An empty string specifies the user's default settings. If the modification of the locale fails, the exception `Error` is raised. If successful, the new locale setting is returned.
If `locale` is omitted or `None`, the current setting for `category` is returned.

`setlocale()` is not thread-safe on most systems. Applications typically start with a call of

```python
import locale
locale.setlocale(locale.LC_ALL, '')
```

This sets the locale for all categories to the user’s default setting (typically specified in the `LANG` environment variable). If the locale is not changed thereafter, using multithreading should not cause problems.

`locale.localeconv()`

Returns the database of the local conventions as a dictionary. This dictionary has the following strings as keys:

<table>
<thead>
<tr>
<th>Category</th>
<th>Key</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>LC_NUMERIC</td>
<td>'decimal_point'</td>
<td>Dec character</td>
</tr>
<tr>
<td></td>
<td>'grouping'</td>
<td>Sequence of numbers specifying which relative positions the 'thousands_sep' is expected. The sequence is terminated with CHAR_MAX further grouping is performed. If the sequence terminates with a</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>'thousands_sep'</td>
<td>Character used between groups.</td>
<td></td>
</tr>
<tr>
<td><strong>LC_MONETARY</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>'int_curr_symbol'</td>
<td>International currency symbol.</td>
<td></td>
</tr>
<tr>
<td>'currency_symbol'</td>
<td>Local currency symbol.</td>
<td></td>
</tr>
<tr>
<td>'p_cs_precedes/n_cs_precedes'</td>
<td>Whether the currency symbol precedes the value (for positive resp. negative)</td>
<td></td>
</tr>
<tr>
<td>'p_sep_by_space/n_sep_by_space'</td>
<td>Whether the currency symbol is separated from the value (for positive resp. negative)</td>
<td></td>
</tr>
<tr>
<td>'mon_decimal_point'</td>
<td>Decimal point used for monetary values.</td>
<td></td>
</tr>
<tr>
<td>'frac_digits'</td>
<td>Number of fractional digits used in local formatting of monetary values.</td>
<td></td>
</tr>
<tr>
<td>'int_frac_digits'</td>
<td>Number of fractional digits used in international formatting of monetary values.</td>
<td></td>
</tr>
<tr>
<td>'mon_thousands_sep'</td>
<td>Group separator used for monetary values.</td>
<td></td>
</tr>
</tbody>
</table>
'mon_grouping'
Equivalent to 'grouping' for monetary values.

'positive_sign'
Symbol used to annotate a positive monetary value.

'negative_sign'
Symbol used to annotate a negative monetary value.

'p_sign_posn/n_sign_posn'
The position of the sign (for positive resp. negative values), see below.

All numeric values can be set to CHAR_MAX to indicate that there is no value specified in this locale.

The possible values for 'p_sign_posn' and 'n_sign_posn' are given below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Currency and value are surrounded by parentheses.</td>
</tr>
<tr>
<td>1</td>
<td>The sign should precede the value and currency symbol.</td>
</tr>
<tr>
<td>2</td>
<td>The sign should follow the value and currency symbol.</td>
</tr>
<tr>
<td>3</td>
<td>The sign should immediately precede the value.</td>
</tr>
<tr>
<td>4</td>
<td>The sign should immediately follow the value.</td>
</tr>
<tr>
<td>CHAR_MAX</td>
<td>Nothing is specified in this locale.</td>
</tr>
</tbody>
</table>

The function sets temporarily the LC_CTYPE locale to the
LC_NUMERIC locale to decode decimal_point and thousands_sep byte strings if they are non-ASCII or longer than 1 byte, and the LC_NUMERIC locale is different than the LC_CTYPE locale. This temporary change affects other threads.

*Changed in version 3.7:* The function now sets temporarily the LC_CTYPE locale to the LC_NUMERIC locale in some cases.

**locale.nl_langinfo(option)**

Return some locale-specific information as a string. This function is not available on all systems, and the set of possible options might also vary across platforms. The possible argument values are numbers, for which symbolic constants are available in the locale module.

The `nl_langinfo()` function accepts one of the following keys. Most descriptions are taken from the corresponding description in the GNU C library.

**locale.CODESET**

Get a string with the name of the character encoding used in the selected locale.

**locale.D_T_FMT**

Get a string that can be used as a format string for `time.strftime()` to represent date and time in a locale-specific way.

**locale.D_FMT**

Get a string that can be used as a format string for `time.strftime()` to represent a date in a locale-specific way.
locale. **T_FMT**
Get a string that can be used as a format string for `time.strftime()` to represent a time in a locale-specific way.

locale. **T_FMT_AMPM**
Get a format string for `time.strftime()` to represent time in the am/pm format.

**DAY_1 ... DAY_7**
Get the name of the n-th day of the week.

**Notes:** This follows the US convention of `DAY_1` being Sunday, not the international convention (ISO 8601) that Monday is the first day of the week.

**ABDAY_1 ... ABDAY_7**
Get the abbreviated name of the n-th day of the week.

**MON_1 ... MON_12**
Get the name of the n-th month.

**ABMON_1 ... ABMON_12**
Get the abbreviated name of the n-th month.

locale. **RADIXCHAR**
Get the radix character (decimal dot, decimal comma, etc.).

locale. **THOUSEP**
Get the separator character for thousands (groups of three digits).

locale. **YESEXPR**
Get a regular expression that can be used with the regex function to recognize a positive response to a yes/no question.

**Note:** The expression is in the syntax suitable for the `regex()` function from the C library, which might differ from the syntax used in `re`.

locale. **NOEXPR**
Get a regular expression that can be used with the `regex(3)` function to recognize a negative response to a yes/no question.

locale. **CRNCYSTR**
Get the currency symbol, preceded by “-” if the symbol should appear before the value, “+” if the symbol should appear after the value, or “.” if the symbol should replace the radix character.

locale. **ERA**
Get a string that represents the era used in the current locale.

Most locales do not define this value. An example of a locale which does define this value is the Japanese one. In Japan, the traditional representation of dates includes the name of the era corresponding to the then-emperor’s reign.

Normally it should not be necessary to use this value directly. Specifying the E modifier in their format strings causes the `time.strftime()` function to use this information. The format of the returned string is not specified, and therefore you should not assume knowledge of it on different systems.

locale. **ERA_D_T_FMT**
Get a format string for `time.strftime()` to represent date and time in a locale-specific era-based way.
locale.**ERA_D_FMT**

Get a format string for `time.strftime()` to represent a date in a locale-specific era-based way.

locale.**ERA_T_FMT**

Get a format string for `time.strftime()` to represent a time in a locale-specific era-based way.

locale.**ALT_DIGITS**

Get a representation of up to 100 values used to represent the values 0 to 99.

locale.**getdefaultlocale([envvars])**

Tries to determine the default locale settings and returns them as a tuple of the form `(language code, encoding)`.

According to POSIX, a program which has not called `setlocale(LC_ALL, '')` runs using the portable 'C' locale. Calling `setlocale(LC_ALL, '')` lets it use the default locale as defined by the LANG variable. Since we do not want to interfere with the current locale setting we thus emulate the behavior in the way described above.

To maintain compatibility with other platforms, not only the LANG variable is tested, but a list of variables given as envvars parameter. The first found to be defined will be used. envvars defaults to the search path used in GNU gettext; it must always contain the variable name 'LANG'. The GNU gettext search path contains 'LC_ALL', 'LC_CTYPE', 'LANG' and 'LANGUAGE', in that order.

Except for the code 'C', the language code corresponds to RFC
**1766.** *language code* and *encoding* may be `None` if their values cannot be determined.

`locale.getlocale(category=LC_CTYPE)`

Returns the current setting for the given locale category as sequence containing *language code*, *encoding*. *category* may be one of the LC_* values except LC_ALL. It defaults to LC_CTYPE.

Except for the code 'C', the language code corresponds to RFC 1766. *language code* and *encoding* may be `None` if their values cannot be determined.

`locale.getpreferredencoding(do_setlocale=True)`

Return the encoding used for text data, according to user preferences. User preferences are expressed differently on different systems, and might not be available programmatically on some systems, so this function only returns a guess.

On some systems, it is necessary to invoke `setlocale()` to obtain the user preferences, so this function is not thread-safe. If invoking `setlocale()` is not necessary or desired, `do_setlocale` should be set to `False`.

On Android or in the UTF-8 mode (`-X utf8` option), always return 'UTF-8', the locale and the `do_setlocale` argument are ignored.

*Changed in version 3.7:* The function now always returns UTF-8 on Android or if the UTF-8 mode is enabled.

`locale.normalize(localename)`

Returns a normalized locale code for the given locale name. The returned locale code is formatted for use with `setlocale()`. If normalization fails, the original name is returned unchanged.
If the given encoding is not known, the function defaults to the default encoding for the locale code just like \texttt{setlocale()}.

\texttt{locale.resetlocale(category=LC\_ALL)}

Sets the locale for \texttt{category} to the default setting.

The default setting is determined by calling \texttt{getdefaultlocale()}. \texttt{category} defaults to \texttt{LC\_ALL}.

\texttt{locale.strcoll(string1, string2)}

Compares two strings according to the current \texttt{LC\_COLLATE} setting. As any other compare function, returns a negative, or a positive value, or 0, depending on whether \texttt{string1} collates before or after \texttt{string2} or is equal to it.

\texttt{locale.strxfrm(string)}

Transforms a string to one that can be used in locale-aware comparisons. For example, \texttt{strxfrm(s1) < strxfrm(s2)} is equivalent to \texttt{strcoll(s1, s2) < 0}. This function can be used when the same string is compared repeatedly, e.g. when collating a sequence of strings.

\texttt{locale.format_string(format, val, grouping=False, monetary=False)}

Formats a number \texttt{val} according to the current \texttt{LC\_NUMERIC} setting. The format follows the conventions of the \texttt{%} operator. For floating point values, the decimal point is modified if appropriate. If \texttt{grouping} is true, also takes the grouping into account.

If \texttt{monetary} is true, the conversion uses monetary thousands separator and grouping strings.
Processes formatting specifiers as in `format % val`, but takes the current locale settings into account.

*Changed in version 3.7:* The `monetary` keyword parameter was added.

```python
locale.format(format, val, grouping=False, monetary=False)
```

Please note that this function works like `format_string()` but will only work for exactly one `%char` specifier. For example, `'%f'` and `'.0f'` are both valid specifiers, but `'%f KiB'` is not.

For whole format strings, use `format_string()`.

*Deprecated since version 3.7:* Use `format_string()` instead.

```python
locale.currency(val, symbol=True, grouping=False, international=False)
```

Formats a number `val` according to the current `LC_MONETARY` settings.

The returned string includes the currency symbol if `symbol` is true, which is the default. If `grouping` is true (which is not the default), grouping is done with the value. If `international` is true (which is not the default), the international currency symbol is used.

Note that this function will not work with the ‘C’ locale, so you have to set a locale via `setlocale()` first.

```python
locale.str(float)
```

Formats a floating point number using the same format as the built-in function `str(float)`, but takes the decimal point into account.

```python
locale.delocalize(string)
```
Converts a string into a normalized number string, following the \texttt{LC\_NUMERIC} settings.

\textit{New in version 3.5.}

\texttt{locale.atof(string)}

Converts a string to a floating point number, following the \texttt{LC\_NUMERIC} settings.

\texttt{locale.atoi(string)}

Converts a string to an integer, following the \texttt{LC\_NUMERIC} conventions.

\texttt{locale.LC\_CTYPE}

Locale category for the character type functions. Depending on the settings of this category, the functions of module \texttt{string} dealing with case change their behaviour.

\texttt{locale.LC\_COLLATE}

Locale category for sorting strings. The functions \texttt{strcoll()} and \texttt{strxfrm()} of the \texttt{locale} module are affected.

\texttt{locale.LC\_TIME}

Locale category for the formatting of time. The function \texttt{time.strftime()} follows these conventions.

\texttt{locale.LC\_MONETARY}

Locale category for formatting of monetary values. The available options are available from the \texttt{localeconv()} function.

\texttt{locale.LC\_MESSAGES}

Locale category for message display. Python currently does not support application specific locale-aware messages. Messages
displayed by the operating system, like those returned by \texttt{os.strerror()} might be affected by this category.

\textbf{locale.} \texttt{LC\_NUMERIC}
Locale category for formatting numbers. The functions \texttt{format()}, \texttt{atoi()}, \texttt{atof()} and \texttt{str()} of the \texttt{locale} module are affected by that category. All other numeric formatting operations are not affected.

\textbf{locale.} \texttt{LC\_ALL}
Combination of all locale settings. If this flag is used when the locale is changed, setting the locale for all categories is attempted. If that fails for any category, no category is changed at all. When the locale is retrieved using this flag, a string indicating the setting for all categories is returned. This string can be later used to restore the settings.

\textbf{locale.} \texttt{CHAR\_MAX}
This is a symbolic constant used for different values returned by \texttt{localeconv()}.  

Example:

```
>>> import locale
>>> loc = locale.getlocale()  # get current locale
# use German locale; name might vary with platform
>>> locale.setlocale(locale.LC\_ALL, 'de\_DE')
>>> locale.strcoll('f\xe4n', 'foo')  # compare a string
>>> locale.setlocale(locale.LC\_ALL, '')  # use user
>>> locale.setlocale(locale.LC\_ALL, 'C')  # use default
>>> locale.setlocale(locale.LC\_ALL, loc)  # restore
```
23.2.1. Background, details, hints, tips and caveats

The C standard defines the locale as a program-wide property that may be relatively expensive to change. On top of that, some implementation are broken in such a way that frequent locale changes may cause core dumps. This makes the locale somewhat painful to use correctly.

Initially, when a program is started, the locale is the C locale, no matter what the user’s preferred locale is. There is one exception: the LC_CTYPE category is changed at startup to set the current locale encoding to the user’s preferred locale encoding. The program must explicitly say that it wants the user’s preferred locale settings for other categories by calling `setlocale(LC_ALL, '')`.

It is generally a bad idea to call `setlocale()` in some library routine, since as a side effect it affects the entire program. Saving and restoring it is almost as bad: it is expensive and affects other threads that happen to run before the settings have been restored.

If, when coding a module for general use, you need a locale independent version of an operation that is affected by the locale (such as certain formats used with `time.strftime()`), you will have to find a way to do it without using the standard library routine. Even better is convincing yourself that using locale settings is okay. Only as a last resort should you document that your module is not compatible with non-C locale settings.

The only way to perform numeric operations according to the locale is to use the special functions defined by this module: `atof()`, `atoi()`,...
There is no way to perform case conversions and character classifications according to the locale. For (Unicode) text strings these are done according to the character value only, while for byte strings, the conversions and classifications are done according to the ASCII value of the byte, and bytes whose high bit is set (i.e., non-ASCII bytes) are never converted or considered part of a character class such as letter or whitespace.
23.2.2. For extension writers and programs that embed Python

Extension modules should never call `setlocale()`, except to find out what the current locale is. But since the return value can only be used portably to restore it, that is not very useful (except perhaps to find out whether or not the locale is C).

When Python code uses the `locale` module to change the locale, this also affects the embedding application. If the embedding application doesn't want this to happen, it should remove the `_locale` extension module (which does all the work) from the table of built-in modules in the `config.c` file, and make sure that the `_locale` module is not accessible as a shared library.
23.2.3. Access to message catalogs

locale.**gettext**(*msg*)
locale.**dgettext**(*domain, msg*)
locale.**dcgettext**(*domain, msg, category*)
locale.**textdomain**(*domain*)
locale.**bindtextdomain**(*domain, dir*)

The locale module exposes the C library's gettext interface on systems that provide this interface. It consists of the functions gettext(), dgettext(), dcgettext(), textdomain(), bindtextdomain(), and bind_textdomain_codeset(). These are similar to the same functions in the gettext module, but use the C library's binary format for message catalogs, and the C library's search algorithms for locating message catalogs.

Python applications should normally find no need to invoke these functions, and should use gettext instead. A known exception to this rule are applications that link with additional C libraries which internally invoke gettext() or dcgettext(). For these applications, it may be necessary to bind the text domain, so that the libraries can properly locate their message catalogs.
24. Program Frameworks

The modules described in this chapter are frameworks that will largely dictate the structure of your program. Currently the modules described here are all oriented toward writing command-line interfaces.

The full list of modules described in this chapter is:

24.1. **turtle** — Turtle graphics

**Source code:** Lib/turtle.py
24.1.1. Introduction

Turtle graphics is a popular way for introducing programming to kids. It was part of the original Logo programming language developed by Wally Feurzig and Seymour Papert in 1966.

Imagine a robotic turtle starting at (0, 0) in the x-y plane. After an import turtle, give it the command turtle.forward(15), and it moves (on-screen!) 15 pixels in the direction it is facing, drawing a line as it moves. Give it the command turtle.right(25), and it rotates in-place 25 degrees clockwise.

By combining together these and similar commands, intricate shapes and pictures can easily be drawn.

The turtle module is an extended reimplementation of the same-named module from the Python standard distribution up to version Python 2.5.

It tries to keep the merits of the old turtle module and to be (nearly) 100% compatible with it. This means in the first place to enable the learning programmer to use all the commands, classes and methods interactively when using the module from within IDLE run with the -n switch.

The turtle module provides turtle graphics primitives, in both object-
oriented and procedure-oriented ways. Because it uses tkinter for the underlying graphics, it needs a version of Python installed with Tk support.

The object-oriented interface uses essentially two+two classes:

1. The **TurtleScreen** class defines graphics windows as a playground for the drawing turtles. Its constructor needs a tkinter.Canvas or a ScrolledCanvas as argument. It should be used when turtle is used as part of some application.

   The function **Screen()** returns a singleton object of a TurtleScreen subclass. This function should be used when turtle is used as a standalone tool for doing graphics. As a singleton object, inheriting from its class is not possible.

   All methods of TurtleScreen/Screen also exist as functions, i.e. as part of the procedure-oriented interface.

2. **RawTurtle** (alias: **RawPen**) defines Turtle objects which draw on a TurtleScreen. Its constructor needs a Canvas, ScrolledCanvas or TurtleScreen as argument, so the RawTurtle objects know where to draw.

   Derived from RawTurtle is the subclass **Turtle** (alias: Pen), which draws on “the” Screen instance which is automatically created, if not already present.

   All methods of RawTurtle/Turtle also exist as functions, i.e. part of
the procedure-oriented interface.

The procedural interface provides functions which are derived from the methods of the classes `Screen` and `Turtle`. They have the same names as the corresponding methods. A screen object is automatically created whenever a function derived from a Screen method is called. An (unnamed) turtle object is automatically created whenever any of the functions derived from a Turtle method is called.

To use multiple turtles on a screen one has to use the object-oriented interface.

**Note:** In the following documentation the argument list for functions is given. Methods, of course, have the additional first argument `self` which is omitted here.
24.1.2. Overview of available Turtle and Screen methods

24.1.2.1. Turtle methods

Turtle motion

Move and draw

- forward() | fd()
- backward() | bk() | back()
- right() | rt()
- left() | lt()
- goto() | setpos() | setposition()
- setx()
- sety()
- setheading() | seth()
- home()
- circle()
- dot()
- stamp()
- clearstamp()
- clearstamps()
- undo()
- speed()

Tell Turtle's state

- position() | pos()
- towards()
- xcor()
- ycor()
- heading()
- distance()
Setting and measurement

    degrees()
    radians()

Pen control

    Drawing state

    pendown() | pd() | down()
    penup() | pu() | up()
    pensize() | width()
    pen()
    isdown()

Color control

    color()
    pencolor()
    fillcolor()

Filling

    filling()
    begin_fill()
    end_fill()

More drawing control

    reset()
    clear()
    write()

Turtle state

    Visibility

    showturtle() | st()
hideturtle() | ht()
isvisible()

Appearance

shape()
resizemode()
shapesize() | turtlesize()
shearfactor()
settiltangle()

24.1.2.2. Methods of TurtleScreen/Screen

Window control
bgcolor()
bgpic()
clear() | clearscren()
reset() | resetscreen()
screensize()
setworldcoordinates()

Animation control

delay()
tracer()
update()

Using screen events

listen()
onkey() | onkeyrelease()
onkeypress()
onclick() | onscreenclick()
ontimer()
mainloop() | done()

Settings and special methods

mode()
colormode()
getcanvas()
getchapes()
register_shape() | addshape()
turtles()
window_height()
window_width()

Input methods

textinput()
numinput()

Methods specific to Screen

bye()
exitonclick()
setup()
title()
24.1.3. Methods of RawTurtle/Turtle and corresponding functions

Most of the examples in this section refer to a Turtle instance called turtle.

24.1.3.1. Turtle motion

turtle. \texttt{forward}(distance)
turtle. \texttt{fd}(distance)

\begin{verbatim}
Parameters: distance – a number (integer or float)
\end{verbatim}

Move the turtle forward by the specified distance, in the direction the turtle is headed.

```python
>>> turtle.position()
(0.00, 0.00)
>>> turtle.forward(25)
>>> turtle.position()
(25.00, 0.00)
>>> turtle.forward(-75)
>>> turtle.position()
(-50.00, 0.00)
```

turtle. \texttt{back}(distance)
turtle. \texttt{bk}(distance)
turtle. \texttt{backward}(distance)

\begin{verbatim}
Parameters: distance – a number
\end{verbatim}

Move the turtle backward by distance, opposite to the direction the turtle is headed. Do not change the turtle's heading.
turtle.\texttt{right}(\texttt{angle}) 
turtle.\texttt{rt}(\texttt{angle}) 

\begin{tabular}{|l|}
\hline
\textbf{Parameters:} & \textbf{angle} \textendash{} a number (integer or float) \\
\hline
\end{tabular}

Turn turtle right by \texttt{angle} units. (Units are by default degrees, but can be set via the \texttt{degrees()} and \texttt{radians()} functions.) Angle orientation depends on the turtle mode, see \texttt{mode()}. 

turtle.\texttt{left}(\texttt{angle}) 
turtle.\texttt{lt}(\texttt{angle}) 

\begin{tabular}{|l|}
\hline
\textbf{Parameters:} & \textbf{angle} \textendash{} a number (integer or float) \\
\hline
\end{tabular}

Turn turtle left by \texttt{angle} units. (Units are by default degrees, but can be set via the \texttt{degrees()} and \texttt{radians()} functions.) Angle orientation depends on the turtle mode, see \texttt{mode()}. 

```python
>>> turtle.position()
(0.00, 0.00)
>>> turtle.backward(30)
>>> turtle.position()
(-30.00, 0.00)

>>> turtle.right(45)
>>> turtle.heading()
337.0

>>> turtle.left(45)
>>> turtle.heading()
67.0
```
turtle.\texttt{goto}(x, y=\text{None})
turtle.\texttt{setpos}(x, y=\text{None})
turtle.\texttt{setposition}(x, y=\text{None})

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>• \texttt{x} – a number or a pair/vector of numbers</td>
<td></td>
</tr>
<tr>
<td>• \texttt{y} – a number or \texttt{None}</td>
<td></td>
</tr>
</tbody>
</table>

If \texttt{y} is \texttt{None}, \texttt{x} must be a pair of coordinates or a \texttt{Vec2D} (e.g. as returned by \texttt{pos()}).

Move turtle to an absolute position. If the pen is down, draw line. Do not change the turtle's orientation.

```python
>>> tp = turtle.pos()
>>> tp
(0.00,0.00)
>>> turtle.setpos(60,30)
>>> turtle.pos()
(60.00,30.00)
>>> turtle.setpos((20,80))
>>> turtle.pos()
(20.00,80.00)
>>> turtle.setpos(tp)
>>> turtle.pos()
(0.00,0.00)
```

turtle.\texttt{setx}(x)

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{x} – a number (integer or float)</td>
<td></td>
</tr>
</tbody>
</table>

Set the turtle's first coordinate to \texttt{x}, leave second coordinate unchanged.

```python
>>> turtle.position()
(0.00,240.00)
>>> turtle.setx(10)
```
turtle.sety(y)

Parameters: y – a number (integer or float)

Set the turtle’s second coordinate to y, leave first coordinate unchanged.

turtle.setheading(to_angle)
turtle.seth(to_angle)

Parameters: to_angle – a number (integer or float)

Set the orientation of the turtle to to_angle. Here are some common directions in degrees:

<table>
<thead>
<tr>
<th>standard mode</th>
<th>logo mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - east</td>
<td>0 - north</td>
</tr>
<tr>
<td>90 - north</td>
<td>90 - east</td>
</tr>
<tr>
<td>180 - west</td>
<td>180 - south</td>
</tr>
<tr>
<td>270 - south</td>
<td>270 - west</td>
</tr>
</tbody>
</table>

>>> turtle.setheading(90)
>>> turtle.heading()
90.0
turtle.**home**()  

Move turtle to the origin – coordinates (0,0) – and set its heading to its start-orientation (which depends on the mode, see `mode()`).

```python  
>>> turtle.heading()  
90.0  
>>> turtle.position()  
(0.00,-10.00)  
>>> turtle.home()  
>>> turtle.position()  
(0.00,0.00)  
>>> turtle.heading()  
0.0  
```

**turtle.**circle*(radius, extent=None, steps=None)*

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>radius</code></td>
<td>a number</td>
</tr>
<tr>
<td><code>extent</code></td>
<td>a number (or None)</td>
</tr>
<tr>
<td><code>steps</code></td>
<td>an integer (or None)</td>
</tr>
</tbody>
</table>

Draw a circle with given `radius`. The center is `radius` units left of the turtle; `extent` – an angle – determines which part of the circle is drawn. If `extent` is not given, draw the entire circle. If `extent` is not a full circle, one endpoint of the arc is the current pen position. Draw the arc in counterclockwise direction if `radius` is positive, otherwise in clockwise direction. Finally the direction of the turtle is changed by the amount of `extent`.

As the circle is approximated by an inscribed regular polygon, `steps` determines the number of steps to use. If not given, it will be calculated automatically. May be used to draw regular polygons.

```python  
>>> turtle.home()  
>>> turtle.position()  
```
(0.00, 0.00)
>>> turtle.heading()
0.0
>>> turtle.circle(50)
>>> turtle.position()
(-0.00, 0.00)
>>> turtle.heading()
0.0
>>> turtle.circle(120, 180)  # draw a semicircle
>>> turtle.position()
(0.00, 240.00)
>>> turtle.heading()
180.0

turtle.dot(size=None, *color)

**Parameters:**
- **size** – an integer >= 1 (if given)
- **color** – a colorstring or a numeric color tuple

Draw a circular dot with diameter *size*, using *color*. If *size* is not given, the maximum of pensize+4 and 2*pensize* is used.

>>> turtle.home()
>>> turtle.dot()
>>> turtle.fd(50); turtle.dot(20, "blue"); turtle
>>> turtle.position()
(100.00, -0.00)
>>> turtle.heading()
0.0

turtle.stamp()

Stamp a copy of the turtle shape onto the canvas at the current turtle position. Return a stamp_id for that stamp, which can be used to delete it by calling clearstamp(stamp_id).
turtle.
  color("blue")
  stamp()
11
  fd(50)

turtle.
  clearstamp(stampid)

Parameters:
  stampid – an integer, must be return value of
  previous stamp() call

Delete stamp with given stampid.

turtle.
  position()
(150.00,-0.00)
  color("blue")
  astamp = turtle.
  stamp()
  fd(50)
  position()
(200.00,-0.00)
  clearstamp(astamp)
  position()
(200.00,-0.00)

turtle.
  clearstamps(n=None)

Parameters:
  n – an integer (or None)

Delete all or first/last n of turtle's stamps. If n is None, delete all
stamps, if n > 0 delete first n stamps, else if n < 0 delete last n
stamps.

for i in range(8):
  ...   turtle.
  stamp(); turtle.
  fd(30)
turtle.clearstamps(2)
turtle.clearstamps(-2)
turtle.clearstamps()

turtle.undo()
Undo (repeatedly) the last turtle action(s). Number of available undo actions is determined by the size of the undobuffer.

for i in range(4):
    turtle.fd(50); turtle.lt(80)

for i in range(8):
    turtle.undo()

turtle.speed(speed=None)

Parameters:

speed – an integer in the range 0..10 or a speedstring (see below)

Set the turtle's speed to an integer value in the range 0..10. If no argument is given, return current speed.

If input is a number greater than 10 or smaller than 0.5, speed is set to 0. Speedstrings are mapped to speedvalues as follows:

- “fastest”: 0
- “fast”: 10
- “normal”: 6
- “slow”: 3
- “slowest”: 1
Speeds from 1 to 10 enforce increasingly faster animation of line drawing and turtle turning.

Attention: \textit{speed} = 0 means that \textit{no} animation takes place. forward/back makes turtle jump and likewise left/right make the turtle turn instantly.

\begin{Verbatim}
>>> turtle.speed()
3
>>> turtle.speed('normal')
>>> turtle.speed()
6
>>> turtle.speed(9)
>>> turtle.speed()
9
\end{Verbatim}

24.1.3.2. Tell Turtle’s state

\begin{verbatim}
turtle.\texttt{position()}
turtle.\texttt{pos()}
\end{verbatim}

Return the turtle’s current location (x,y) (as a \texttt{Vec2D} vector).

\begin{Verbatim}
>>> turtle.pos()
(440.00, -0.00)
\end{Verbatim}

\begin{verbatim}
turtle.\texttt{towards(x, y=\texttt{None})}
\end{verbatim}

\begin{tabular}{|c|c|}
\hline
\textbf{Parameters:} & \textbullet~x – a number or a pair/vector of numbers or a turtle instance \\
\hline & \textbullet~y – a number if x is a number, else \texttt{None} \\
\hline
\end{tabular}

Return the angle between the line from turtle position to position specified by (x,y), the vector or the other turtle. This depends on the turtle’s start orientation which depends on the mode -
turtle.goto(10, 10)
turtle.towards(0, 0)
225.0

turtle.xcor()
Return the turtle's x coordinate.

>>> turtle.home()
>>> turtle.left(50)
>>> turtle.forward(100)
>>> turtle.pos()
(64.28, 76.60)
>>> print(round(turtle.xcor(), 5))
64.27876

turtle.ycor()
Return the turtle's y coordinate.

>>> turtle.home()
>>> turtle.left(60)
>>> turtle.forward(100)
>>> print(turtle.pos())
(50.00, 86.60)
>>> print(round(turtle.ycor(), 5))
86.60254

turtle.heading()
Return the turtle's current heading (value depends on the turtle mode, see mode()).

>>> turtle.home()
>>> turtle.left(67)
>>> turtle.heading()
turtle.distance(x, y=None)

**Parameters:**
- **x** – a number or a pair/vector of numbers or a turtle instance
- **y** – a number if x is a number, else None

Return the distance from the turtle to (x,y), the given vector, or the given other turtle, in turtle step units.

```python
>>> turtle.home()
>>> turtle.distance(30, 40)
50.0
>>> turtle.distance((30, 40))
50.0
>>> joe = Turtle()
>>> joe.forward(77)
>>> turtle.distance(joe)
77.0
```

24.1.3.3. Settings for measurement

turtle.degrees(fullcircle=360.0)

**Parameters:**
- **fullcircle** – a number

Set angle measurement units, i.e. set number of “degrees” for a full circle. Default value is 360 degrees.

```python
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.heading()
90.0
```

Change angle measurement unit to grad (also known as gon,
grade, or gradiant and equals 1/100-th of the right angle.

```python
>>> turtle.degrees(400.0)
>>> turtle.headng()
100.0
>>> turtle.degrees(360)
>>> turtle.headng()
90.0
```

turtle. **radians()**

Set the angle measurement units to radians. Equivalent to `degrees(2*math.pi)`.

```python
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.headng()
90.0
>>> turtle.radians()
>>> turtle.headng()
1.5707963267948966
```

## 24.1.3.4. Pen control

### 24.1.3.4.1. Drawing state

turtle. **pendown()**

turtle. **pd()**

turtle. **down()**

Pull the pen down – drawing when moving.

```python
>>> turtle.pendown()
```

turtle. **penup()**

turtle. **pu()**

turtle. **up()**

Pull the pen up – no drawing when moving.
turtle.**pensize**(width=None)
turtle.**width**(width=None)

**Parameters:**

| width | – a positive number |

Set the line thickness to *width* or return it. If resizemode is set to “auto” and turtleshape is a polygon, that polygon is drawn with the same line thickness. If no argument is given, the current pensize is returned.

```python
>>> turtle.pensize()
1
>>> print(turtle.pensize(10))  # from here on lines of
```

turtle.**pen**(pen=None,**pendict**)

**Parameters:**

| pen | – a dictionary with some or all of the below listed keys |

Return or set the pen’s attributes in a “pen-dictionary” with the following key/value pairs:

- “shown”: True/False
- “pendown”: True/False
- “pencolor”: color-string or color-tuple
- “fillcolor”: color-string or color-tuple
- “pensize”: positive number
- “speed”: number in range 0..10
- “resizemode”: “auto” or “user” or “noresize”
- “stretchfactor”: (positive number, positive number)
- “outline”: positive number
- “tilt”: number
This dictionary can be used as argument for a subsequent call to `pen()` to restore the former pen-state. Moreover one or more of these attributes can be provided as keyword-arguments. This can be used to set several pen attributes in one statement.

```python
>>> turtle.pen(fillcolor="black", pencolor="red",
...
>>> sorted(turtle.pen().items())
[('fillcolor', 'black'), ('outline', 1), ('pencolor',
... ('pendown', True), ('pensize', 10), ('resizemode
... ('shearfactor', 0.0), ('shown', True), ('speed',,
... ('stretchfactor', (1.0, 1.0)), ('tilt', 0.0))
>>> penstate=turtle.pen()
>>> turtle.color("yellow", ")
>>> turtle.penup()
>>> sorted(turtle.pen().items())[:3]
[('fillcolor', ''), ('outline', 1), ('pencolor',,
>>> turtle.pen(penstate, fillcolor="green")
>>> sorted(turtle.pen().items())[:3]
[('fillcolor', 'green'), ('outline', 1), ('pencolor,
```

turtle. `isdown()`

Return True if pen is down, False if it's up.

```python
>>> turtle.pendown()
>>> turtle.isdown()
False
>>> turtle.pendown()
>>> turtle.isdown()
True
```

### 24.1.3.4.2. Color control

turtle. `pencolor(*args)`

Return or set the pencolor.
Four input formats are allowed:

`pencolor()`
Return the current pencolor as color specification string or as a tuple (see example). May be used as input to another color/pencolor/fillcolor call.

`pencolor(colorstring)`
Set pencolor to `colorstring`, which is a Tk color specification string, such as "red", "yellow", or "#33cc8c".

`pencolor((r, g, b))`
Set pencolor to the RGB color represented by the tuple of `r`, `g`, and `b`. Each of `r`, `g`, and `b` must be in the range 0..colormode, where colormode is either 1.0 or 255 (see `colormode()`).

`pencolor(r, g, b)`
Set pencolor to the RGB color represented by `r`, `g`, and `b`. Each of `r`, `g`, and `b` must be in the range 0..colormode.

If turtleshape is a polygon, the outline of that polygon is drawn with the newly set pencolor.

```python
>>> colormode()
1.0
>>> turtle.pencolor()
'red'
>>> turtle.pencolor("brown")
>>> turtle.pencolor()
'brown'
>>> tup = (0.2, 0.8, 0.55)
>>> turtle.pencolor(tup)
>>> turtle.pencolor()
(0.2, 0.8, 0.5490196078431373)
>>> colormode(255)
>>> turtle.pencolor()
(51.0, 204.0, 140.0)
```
turtle.pencolor('\#32c18f')
>>> turtle.pencolor()
(50.0, 193.0, 143.0)

turtle.fillcolor(*args)
Return or set the fillcolor.

Four input formats are allowed:

fillcolor()
Return the current fillcolor as color specification string, possibly in tuple format (see example). May be used as input to another color/pencolor/fillcolor call.

fillcolor(colorstring)
Set fillcolor to colorstring, which is a Tk color specification string, such as "red", "yellow", or "\#33cc8c".

fillcolor((r, g, b))
Set fillcolor to the RGB color represented by the tuple of r, g, and b. Each of r, g, and b must be in the range 0..colormode, where colormode is either 1.0 or 255 (see colormode()).

fillcolor(r, g, b)
Set fillcolor to the RGB color represented by r, g, and b. Each of r, g, and b must be in the range 0..colormode.

If turtleshape is a polygon, the interior of that polygon is drawn with the newly set fillcolor.

>>> turtle.fillcolor("violet")
>>> turtle.fillcolor()
'violet'
>>> turtle.pencolor()
(50.0, 193.0, 143.0)
>>> turtle.fillcolor((50, 193, 143))  # Integers,
turtle.color(*args)

Return or set pencolor and fillcolor.

Several input formats are allowed. They use 0 to 3 arguments as follows:

color()

Return the current pencolor and the current fillcolor as a pair of color specification strings or tuples as returned by pencolor() and fillcolor().

color(colorstring), color((r, g, b)), color(r, g, b)

Inputs as in pencolor(), set both, fillcolor and pencolor, to the given value.

color(colorstring1, colorstring2),
color((r1, g1, b1), (r2, g2, b2))

Equivalent to pencolor(colorstring1) and fillcolor(colorstring2) and analogously if the other input format is used.

If turtleshape is a polygon, outline and interior of that polygon is drawn with the newly set colors.
See also: Screen method `colormode()`.

24.1.3.4.3. Filling

turtle. **filling**()

Return fillstate (True if filling, False else).

```python
>>> turtle.begin_fill()
>>> if turtle.filling():
...    turtle.pensize(5)
... else:
...    turtle.pensize(3)
```

turtle. **begin_fill**()

To be called just before drawing a shape to be filled.

turtle. **end_fill**()

Fill the shape drawn after the last call to `begin_fill()`.

```python
>>> turtle.color("black", "red")
>>> turtle.begin_fill()
>>> turtle.circle(80)
>>> turtle.end_fill()
```

24.1.3.4.4. More drawing control

turtle. **reset**()

Delete the turtle’s drawings from the screen, re-center the turtle and set variables to the default values.

```python
>>> turtle.goto(0, -22)
```
turtle.\texttt{clear()}\n
Delete the turtle's drawings from the screen. Do not move turtle. State and position of the turtle as well as drawings of other turtles are not affected.

turtle.\texttt{write}(arg, move=False, align="left", font=("Arial", 8, "normal"))

<table>
<thead>
<tr>
<th>Parameters:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{arg}</td>
<td>object to be written to the TurtleScreen</td>
</tr>
<tr>
<td>\texttt{move}</td>
<td>True/False</td>
</tr>
<tr>
<td>\texttt{align}</td>
<td>one of the strings “left”, “center” or right”</td>
</tr>
<tr>
<td>\texttt{font}</td>
<td>a triple (fontname, fontsize, fonttype)</td>
</tr>
</tbody>
</table>

Write text - the string representation of \texttt{arg} - at the current turtle position according to \texttt{align} (“left”, “center” or right”) and with the given font. If \texttt{move} is true, the pen is moved to the bottom-right corner of the text. By default, \texttt{move} is False.

>>> turtle.write("Home = ", \texttt{True}, align="center")
>>> turtle.write((0,0), \texttt{True})

24.1.3.5. Turtle state
24.1.3.5.1. Visibility

turtle. **hideturtle**()
turtle. **ht**()

Make the turtle invisible. It's a good idea to do this while you're in the middle of doing some complex drawing, because hiding the turtle speeds up the drawing observably.

```python
>>> turtle.hideturtle()
```

```python
turtle. **showturtle**()
turtle. **st**()

Make the turtle visible.

```python
>>> turtle.showturtle()
```

```python
turtle. **isvisible**()

Return `True` if the Turtle is shown, `False` if it's hidden.

```python
>>> turtle.hideturtle()
>>> turtle.isvisible()
False
>>> turtle.showturtle()
>>> turtle.isvisible()
True
```

24.1.3.5.2. Appearance

turtle. **shape**(*name=*_None*)

**Parameters:**  
name – a string which is a valid shapename

Set turtle shape to shape with given name or, if name is not given,
return name of current shape. Shape with name must exist in the TurtleScreen's shape dictionary. Initially there are the following polygon shapes: “arrow”, “turtle”, “circle”, “square”, “triangle”, “classic”. To learn about how to deal with shapes see Screen method register_shape().

```python
>>> turtle.shape()
'classic'
>>> turtle.shape("turtle")
>>> turtle.shape()
'turtle'
```

turtle.resizemode(rmode=None)

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>rmode – one of the strings “auto”, “user”, “noresize”</th>
</tr>
</thead>
</table>

Set resizemode to one of the values: “auto”, “user”, “noresize”. If rmode is not given, return current resizemode. Different resizemodes have the following effects:

- “auto”: adapts the appearance of the turtle corresponding to the value of pensize.
- “user”: adapts the appearance of the turtle according to the values of stretchfactor and outlinewidth (outline), which are set by shapesize().
- “noresize”: no adaption of the turtle's appearance takes place.

resizemode("user") is called by shapesize() when used with arguments.

```python
>>> turtle.resizemode()
'noresize'
>>> turtle.resizemode("auto")
>>> turtle.resizemode()
'auto'
```
turtle.shapesize(stretch_wid=None, stretch_len=None, outline=None)
turtle.turtlesize(stretch_wid=None, stretch_len=None, outline=None)

<table>
<thead>
<tr>
<th>Parameters:</th>
</tr>
</thead>
</table>
| • stretch_wid – positive number  
| • stretch_len – positive number  
| • outline – positive number |

Return or set the pen’s attributes x/y-stretchfactors and/or outline. Set resizemode to “user”. If and only if resizemode is set to “user”, the turtle will be displayed stretched according to its stretchfactors: stretch_wid is stretchfactor perpendicular to its orientation, stretch_len is stretchfactor in direction of its orientation, outline determines the width of the shapes's outline.

```python
>>> turtle.shapesize()
(1.0, 1.0, 1)
>>> turtle.resizemode("user")
>>> turtle.shapesize(5, 5, 12)
>>> turtle.shapesize()
(5, 5, 12)
>>> turtle.shapesize(outline=8)
>>> turtle.shapesize()
(5, 5, 8)
```

turtle.shearfactor(shear=None)

<table>
<thead>
<tr>
<th>Parameters:</th>
</tr>
</thead>
<tbody>
<tr>
<td>shear – number (optional)</td>
</tr>
</tbody>
</table>

Set or return the current shearfactor. Shear the turtleshape according to the given shearfactor shear, which is the tangent of the shear angle. Do not change the turtle’s heading (direction of movement). If shear is not given: return the current shearfactor, i.
e. the tangent of the shear angle, by which lines parallel to the heading of the turtle are sheared.

```python
>>> turtle.shape("circle")
>>> turtle.shapesize(5, 2)
>>> turtle.shearfactor(0.5)
>>> turtle.shearfactor()

0.5
```

turtle.**tilt**(angle)

**Parameters:**  
angle – a number

Rotate the turtleshape by angle from its current tilt-angle, but do not change the turtle's heading (direction of movement).

```python
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5, 2)
>>> turtle.tilt(30)
>>> turtle.fd(50)
>>> turtle.tilt(30)
>>> turtle.fd(50)
```

turtle.**settiltangle**(angle)

**Parameters:**  
angle – a number

Rotate the turtleshape to point in the direction specified by angle, regardless of its current tilt-angle. Do not change the turtle's heading (direction of movement).

```python
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5, 2)
>>> turtle.settiltangle(45)
```
>>> turtle.fd(50)
>>> turtle.settiltangle(-45)
>>> turtle.fd(50)

Deprecated since version 3.1.

turtle.\texttt{tiltangle}(\texttt{angle=none})

\begin{center}
\begin{tabular}{|l|}
\hline
| Parameters: | angle – a number (optional) |
\hline
\end{tabular}
\end{center}

Set or return the current tilt-angle. If angle is given, rotate the
turtleshape to point in the direction specified by angle, regardless
of its current tilt-angle. Do \textit{not} change the turtle's heading (direction
of movement). If angle is not given: return the current tilt-angle, i. e.
the angle between the orientation of the turtleshape and the
heading of the turtle (its direction of movement).

>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.tilt(45)
>>> turtle.tiltangle()
45.0

turtle.\texttt{shapetransform}(t11=none, t12=none, t21=none,
t22=none)

\begin{center}
\begin{tabular}{|l|}
\hline
| Parameters: |
| t11 – a number (optional) |
| t12 – a number (optional) |
| t21 – a number (optional) |
| t12 – a number (optional) |
\hline
\end{tabular}
\end{center}

Set or return the current transformation matrix of the turtle shape.

If none of the matrix elements are given, return the transformation
matrix as a tuple of 4 elements. Otherwise set the given elements
and transform the turtleshape according to the matrix consisting of first row $t_{11}$, $t_{12}$ and second row $t_{21}$, $t_{22}$. The determinant $t_{11} * t_{22} - t_{12} * t_{21}$ must not be zero, otherwise an error is raised. Modify stretchfactor, shearfactor and tiltangle according to the given matrix.

```python
>>> turtle = Turtle()
>>> turtle.shape("square")
>>> turtle.shapesize(4, 2)
>>> turtle.shearfactor(-0.5)
>>> turtle.shapetransform((4.0, -1.0, -0.0, 2.0))
```

turtle.<math>get_shapepoly</math>()

Return the current shape polygon as tuple of coordinate pairs. This can be used to define a new shape or components of a compound shape.

```python
>>> turtle.shape("square")
>>> turtle.shapetransform(4, -1, 0, 2)
>>> turtle.get_shapepoly()
((50, -20), (30, 20), (-50, 20), (-30, -20))
```

24.1.3.6. Using events

turtle.<math>onclick</math>(<var>fun</var>, <var>btn</var>=1, <var>add</var>=None)

**Parameters:**
- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – True or False – if True, a new binding will be added, otherwise it will replace
a former binding

Bind \textit{fun} to mouse-click events on this turtle. If \textit{fun} is \texttt{None}, existing bindings are removed. Example for the anonymous turtle, i.e. the procedural way:

\begin{verbatim}
>>> def turn(x, y):
...     left(180)
... >>> onclick(turn)  # Now clicking into the turtle
>>> onclick(None)  # event-binding will be removed
\end{verbatim}

\texttt{turtle.onrelease}(\textit{fun, btn=1, add=None})

\begin{tabular}{|l|}
\hline
\textbf{Parameters:} & \begin{itemize}
\item \textit{fun} – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
\item \textit{num} – number of the mouse-button, defaults to 1 (left mouse button)
\item \textit{add} – \texttt{True} or \texttt{False} – if \texttt{True}, a new binding will be added, otherwise it will replace a former binding
\end{itemize} \\
\hline
\end{tabular}

Bind \textit{fun} to mouse-button-release events on this turtle. If \textit{fun} is \texttt{None}, existing bindings are removed.

\begin{verbatim}
>>> class MyTurtle(Turtle):
...     def glow(self, x, y):
...         self.fillcolor("red")
...     def unglow(self, x, y):
...         self.fillcolor("")
... >>> turtle = MyTurtle()
>>> turtle.onclick(turtle.glow)  # clicking on
>>> turtle.onrelease(turtle.unglow)  # releasing t
\end{verbatim}
turtle.ondrag(fun, btn=1, add=None)

**Parameters:**

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – **True** or **False** – if **True**, a new binding will be added, otherwise it will replace a former binding

Bind *fun* to mouse-move events on this turtle. If *fun* is **None**, existing bindings are removed.

Remark: Every sequence of mouse-move-events on a turtle is preceded by a mouse-click event on that turtle.

```python
>>> turtle.ondrag(turtle.goto)
```

Subsequently, clicking and dragging the Turtle will move it across the screen thereby producing handdrawings (if pen is down).

### 24.1.3.7. Special Turtle methods

**turtle.begin_poly()**

Start recording the vertices of a polygon. Current turtle position is first vertex of polygon.

**turtle.end_poly()**

Stop recording the vertices of a polygon. Current turtle position is last vertex of polygon. This will be connected with the first vertex.
turtle. **get_poly()**

Return the last recorded polygon.

```python
>>> turtle.home()
>>> turtle.begin_poly()
>>> turtle.fd(100)
>>> turtle.left(20)
>>> turtle.fd(30)
>>> turtle.left(60)
>>> turtle.fd(50)
>>> turtle.end_poly()
>>> p = turtle.get_poly()
>>> register_shape("myFavouriteShape", p)
```

turtle. **clone()**

Create and return a clone of the turtle with same position, heading and turtle properties.

```python
>>> mick = Turtle()
>>> joe = mick.clone()
```

turtle. **getturtle()**

turtle. **getpen()**

Return the Turtle object itself. Only reasonable use: as a function to return the “anonymous turtle”:

```python
>>> pet = getturtle()
>>> pet.fd(50)
>>> pet
<turtle.Turtle object at 0x...>
```

turtle. **getscreen()**

Return the TurtleScreen object the turtle is drawing on. TurtleScreen methods can then be called for that object.
```python
>>> ts = turtle.getscreen()
>>> ts
<turtle._Screen object at 0x...>
>>> ts.bgcolor("pink")
```

turtle.setundobuffer(size)

**Parameters:**

<table>
<thead>
<tr>
<th>size – an integer or None</th>
</tr>
</thead>
</table>

Set or disable undobuffer. If `size` is an integer an empty undobuffer of given size is installed. `size` gives the maximum number of turtle actions that can be undone by the `undo()` method/function. If `size` is `None`, the undobuffer is disabled.

```python
>>> turtle.setundobuffer(42)
```

turtle.undobufferentries()

Return number of entries in the undobuffer.

```python
>>> while undobufferentries():
    ...
    undo()
```

24.1.3.8. Compound shapes

To use compound turtle shapes, which consist of several polygons of different color, you must use the helper class `Shape` explicitly as described below:

1. Create an empty Shape object of type “compound”.

2. Add as many components to this object as desired, using the `addcomponent()` method.

For example:
3. Now add the Shape to the Screen’s shapelist and use it:

```py
>>> register_shape("myshape", s)
>>> shape("myshape")
```

**Note:** The `Shape` class is used internally by the `register_shape()` method in different ways. The application programmer has to deal with the Shape class *only* when using compound shapes like shown above!
24.1.4. Methods of TurtleScreen/Screen and corresponding functions

Most of the examples in this section refer to a TurtleScreen instance called `screen`.

24.1.4.1. Window control

turtle. `bgcolor(*args)`

| Parameters: | args – a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers |

Set or return background color of the TurtleScreen.

```python
>>> screen.bgcolor("orange")
'orange'
>>> screen.bgcolor()
(128.0, 0.0, 128.0)
```

turtle. `bgpic(picname=None)`

| Parameters: | picname – a string, name of a gif-file or "nopic", or None |

Set background image or return name of current backgroundimage. If `picname` is a filename, set the corresponding image as background. If `picname` is "nopic", delete background image, if present. If `picname` is None, return the filename of the current backgroundimage.
turtle.clear()
turtle.clearscreen()

Delete all drawings and all turtles from the TurtleScreen. Reset the now empty TurtleScreen to its initial state: white background, no background image, no event bindings and tracing on.

**Note:** This TurtleScreen method is available as a global function only under the name clearscreen. The global function clear is a different one derived from the Turtle method clear.

turtle.reset()
turtle.resetscreen()

Reset all Turtles on the Screen to their initial state.

**Note:** This TurtleScreen method is available as a global function only under the name resetscreen. The global function reset is another one derived from the Turtle method reset.

turtle.screensize(canvwidth=None, canvheight=None, bg=None)

**Parameters:**
- **canvwidth** – positive integer, new width of canvas in pixels
- **canvheight** – positive integer, new height of canvas in pixels
- **bg** – colorstring or color-tuple, new
If no arguments are given, return current (canvaswidth, canvashheight). Else resize the canvas the turtles are drawing on. Do not alter the drawing window. To observe hidden parts of the canvas, use the scrollbars. With this method, one can make visible those parts of a drawing which were outside the canvas before.

```python
>>> screen.screensize()
(400, 300)
>>> screen.screensize(2000, 1500)
>>> screen.screensize()
(2000, 1500)
```

E.g. to search for an erroneously escaped turtle ;-)

**turtle.setworldcoordinates(llx, lly, urx, ury)**

- **llx** – a number, x-coordinate of lower left corner of canvas
- **lly** – a number, y-coordinate of lower left corner of canvas
- **urx** – a number, x-coordinate of upper right corner of canvas
- **ury** – a number, y-coordinate of upper right corner of canvas

Set up user-defined coordinate system and switch to mode “world” if necessary. This performs a `screen.reset()`. If mode “world” is already active, all drawings are redrawn according to the new coordinates.

**ATTENTION:** in user-defined coordinate systems angles may appear distorted.
>>> screen.reset()
>>> screen.setworldcoordinates(-50, -7.5, 50, 7.5)
>>> for _ in range(72):
...    left(10)
...
>>> for _ in range(8):
...    left(45); fd(2)  # a regular octagon

24.1.4.2. Animation control

turtle.\texttt{delay}(*\texttt{delay}*=\texttt{None})

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>delay – positive integer</th>
</tr>
</thead>
</table>

Set or return the drawing \textit{delay} in milliseconds. (This is approximately the time interval between two consecutive canvas updates.) The longer the drawing delay, the slower the animation.

Optional argument:

>>> screen.delay()
10
>>> screen.delay(5)
>>> screen.delay()
5

turtle.\texttt{tracer}(*\texttt{n}*=	exttt{None}, \texttt{delay}=	exttt{None})

| Parameters: | • \texttt{n} – nonnegative integer
|             | • \texttt{delay} – nonnegative integer |

Turn turtle animation on/off and set delay for update drawings. If \texttt{n} is given, only each \texttt{n}-th regular screen update is really performed. (Can be used to accelerate the drawing of complex graphics.) When called without arguments, returns the currently stored value
of n. Second argument sets delay value (see `delay()`).

```python
>>> screen.tracer(8, 25)
>>> dist = 2
>>> for i in range(200):
...    fd(dist)
...    rt(90)
...    dist += 2
```

turtle.**update**()

Perform a TurtleScreen update. To be used when tracer is turned off.

See also the RawTurtle/Turtle method `speed()`.

### 24.1.4.3. Using screen events

**turtle.**listen**(xdummy=None, ydummy=None)**

Set focus on TurtleScreen (in order to collect key-events). Dummy arguments are provided in order to be able to pass `listen()` to the onclick method.

**turtle.**onkey**(fun, key)**

**turtle.**onkeyrelease**(fun, key)**

<table>
<thead>
<tr>
<th>Parameters:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>fun</strong> – a function with no arguments or <code>None</code></td>
</tr>
<tr>
<td>• <strong>key</strong> – a string: key (e.g. “a”) or key-symbol (e.g. “space”)</td>
</tr>
</tbody>
</table>

Bind *fun* to key-release event of *key*. If *fun* is `None`, event bindings are removed. Remark: in order to be able to register key-events, TurtleScreen must have the focus. (See method `listen()`.)

```python
>>> def f():
...    fd(50)
...    lt(60)
...>>> screen.onkey(f, "Up")
>>> screen.listen()
```

turtle.onkeypress(fun, key=None)

**Parameters:**
- **fun** – a function with no arguments or `None`
- **key** – a string: key (e.g. “a”) or key-symbol (e.g. “space”)

Bind *fun* to key-press event of *key* if *key* is given, or to any key-press-event if no *key* is given. Remark: in order to be able to register key-events, TurtleScreen must have focus. (See method `listen()`.)

```python
>>> def f():
...    fd(50)
...>>> screen.onkey(f, "Up")
>>> screen.listen()
```

turtle.onclick(fun, btn=1, add=None)
turtle.onscreenclick(fun, btn=1, add=None)

**Parameters:**
- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – True or False – if True, a new binding will be added, otherwise it will replace a former binding
Bind `fun` to mouse-click events on this screen. If `fun` is `None`, existing bindings are removed.

Example for a TurtleScreen instance named `screen` and a Turtle instance named `turtle`:

```python
>>> screen.onclick(turtle.goto)  # Subsequently clicking into the TurtleScreen will make the turtle move to the clicked point.
>>> screen.onclick(None)  # remove event binding again
```

**Note:** This TurtleScreen method is available as a global function only under the name `onscreenclick`. The global function `onclick` is another one derived from the Turtle method `onclick`.

```
turtle.ontimer(fun, t=0)
```

**Parameters:**
- `fun` – a function with no arguments
- `t` – a number $\geq 0$

Install a timer that calls `fun` after `t` milliseconds.

```python
>>> running = True
>>> def f():
...     if running:
...         fd(50)
...         lt(60)
...     screen.ontimer(f, 250)
>>> f()  # makes the turtle march around
>>> running = False
```

turtle.mainloop()
turtle.done()
Starts event loop - calling Tkinter's mainloop function. Must be the last statement in a turtle graphics program. Must not be used if a script is run from within IDLE in -n mode (No subprocess) - for interactive use of turtle graphics.

```python
>>> screen.mainloop()
```

24.1.4.4. Input methods

turtle.**textinput**(title, prompt)

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>title – string</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>prompt – string</td>
</tr>
</tbody>
</table>

Pop up a dialog window for input of a string. Parameter title is the title of the dialog window, prompt is a text mostly describing what information to input. Return the string input. If the dialog is canceled, return None.

```python
>>> screen.textinput("NIM", "Name of first player:")
```

turtle.**numinput**(title, prompt, default=None, minval=None, maxval=None)

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>title – string</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>prompt – string</td>
</tr>
<tr>
<td></td>
<td>default – number (optional)</td>
</tr>
<tr>
<td></td>
<td>minval – number (optional)</td>
</tr>
<tr>
<td></td>
<td>maxval – number (optional)</td>
</tr>
</tbody>
</table>

Pop up a dialog window for input of a number. title is the title of the dialog window, prompt is a text mostly describing what numerical information to input. default: default value, minval: minimum value, maxval: maximum value.
for input, maxval: maximum value for input The number input must be in the range minval .. maxval if these are given. If not, a hint is issued and the dialog remains open for correction. Return the number input. If the dialog is canceled, return None.

```python
>>> screen.numinput("Poker", "Your stakes:", 1000
```

24.1.4.5. Settings and special methods

turtle. mode(mode=None)

<table>
<thead>
<tr>
<th>Parameters:</th>
<th>mode – one of the strings “standard”, “logo” or “world”</th>
</tr>
</thead>
</table>

Set turtle mode (“standard”, “logo” or “world”) and perform reset. If mode is not given, current mode is returned.

Mode “standard” is compatible with old turtle. Mode “logo” is compatible with most Logo turtle graphics. Mode “world” uses user-defined “world coordinates”. Attention: in this mode angles appear distorted if x/y unit-ratio doesn’t equal 1.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Initial turtle heading</th>
<th>positive angles</th>
</tr>
</thead>
<tbody>
<tr>
<td>“standard”</td>
<td>to the right (east)</td>
<td>counterclockwise</td>
</tr>
<tr>
<td>“logo”</td>
<td>upward (north)</td>
<td>clockwise</td>
</tr>
</tbody>
</table>

```python
>>> mode("logo")  # resets turtle heading to nor
```  

```python
>>> mode()

'logo'
```

turtle. colormode(cmode=None)

```python
```
Parameters:  
**cmode** – one of the values 1.0 or 255

Return the colormode or set it to 1.0 or 255. Subsequently $r$, $g$, $b$ values of color triples have to be in the range 0..$cmode$.

```python
>>> screen.colormode(1)
>>> turtle.pencolor(240, 160, 80)
Traceback (most recent call last):
   ...  
TurtleGraphicsError: bad color sequence: (240, 16
>>> screen.colormode()
1.0
>>> screen.colormode(255)
255
>>> turtle.pencolor(240, 160, 80)
```

turtle.**getcanvas**()

Return the Canvas of this TurtleScreen. Useful for insiders who know what to do with a Tkinter Canvas.

```python
>>> cv = screen.getcanvas()
>>> cv
<turtle.ScrolledCanvas object ...>
```

turtle.**getshapes**()

Return a list of names of all currently available turtle shapes.

```python
>>> screen.getshapes()
['arrow', 'blank', 'circle', ..., 'turtle']
```

turtle.**register_shape**(name, shape=None)  
turtle.**addshape**(name, shape=None)

There are three different ways to call this function:
1. *name* is the name of a gif-file and *shape* is `None`: Install the corresponding image shape.

```python
>>> screen.register_shape("turtle.gif")
```

**Note:** Image shapes *do not* rotate when turning the turtle, so they do not display the heading of the turtle!

2. *name* is an arbitrary string and *shape* is a tuple of pairs of coordinates: Install the corresponding polygon shape.

```python
>>> screen.register_shape("triangle", ((5,-3),
```

3. *name* is an arbitrary string and *shape* is a (compound) `Shape` object: Install the corresponding compound shape.

Add a turtle shape to TurtleScreen’s shapelist. Only thusly registered shapes can be used by issuing the command `shape(shapename)`.

```python
turtle.turtles()

Return the list of turtles on the screen.

```python
>>> for turtle in screen.turtles():
...    turtle.color("red")
```

```python
turtle.window_height()

Return the height of the turtle window.

```python
>>> screen.window_height()
480
```

```python
turtle.window_width()
```
Return the width of the turtle window.

```python
>>> screen.window_width()
640
```

24.1.4.6. Methods specific to Screen, not inherited from TurtleScreen

```python
turtle.bye()
```
Shut the turtlegraphics window.

```python
turtle.exitonclick()
```
Bind `bye()` method to mouse clicks on the Screen.

If the value “using_IDLE” in the configuration dictionary is `False` (default value), also enter mainloop. Remark: If IDLE with the `-n` switch (no subprocess) is used, this value should be set to `True` in `turtle.cfg`. In this case IDLE’s own mainloop is active also for the client script.

```python
turtle.setup(width=_CFG["width"], height=_CFG["height"],
            startx=_CFG["leftright"], starty=_CFG["topbottom"])
```
Set the size and position of the main window. Default values of arguments are stored in the configuration dictionary and can be changed via a `turtle.cfg` file.

- `width` – if an integer, a size in pixels, if a float, a fraction of the screen; default is 50% of screen
- `height` – if an integer, the height in pixels, if a float, a fraction of the screen; default is 75% of screen
Parameters:
- **startx** – if positive, starting position in pixels from the left edge of the screen, if negative from the right edge, if None, center window horizontally
- **starty** – if positive, starting position in pixels from the top edge of the screen, if negative from the bottom edge, if None, center window vertically

```python
>>> screen.setup (width=200, height=200, startx=0
>>> # sets window to 200x200 pixels,
>>> screen.setup(width=.75, height=0.5, startx=None
>>> # sets window to 75% of screen b
```

turtle.**title**(titlestring)

Parameters:
- **titlestring** – a string that is shown in the titlebar of the turtle graphics window

Set title of turtle window to *titlestring*.

```python
>>> screen.title("Welcome to the turtle zoo!"")
```
24.1.5. Public classes

class turtle.RawTurtle(canvas)
class turtle.RawPen(canvas)

| Parameters: | canvas – a tkinter.Canvas, a ScrolledCanvas or a TurtleScreen |

Create a turtle. The turtle has all methods described above as “methods of Turtle/RawTurtle”.

class turtle.Turtle

Subclass of RawTurtle, has the same interface but draws on a default Screen object created automatically when needed for the first time.

class turtle.TurtleScreen(cv)

| Parameters: | cv – a tkinter.Canvas |

Provides screen oriented methods like setbg() etc. that are described above.

class turtle.Screen

Subclass of TurtleScreen, with four methods added.

class turtle.ScrolledCanvas(master)

| Parameters: | master – some Tkinter widget to contain the ScrolledCanvas, i.e. a Tkinter-canvas with scrollbars added |

Used by class Screen, which thus automatically provides a ScrolledCanvas as playground for the turtles.
class turtle. **Shape**(type_, data)

**Parameters:**

<table>
<thead>
<tr>
<th>type_</th>
<th>data</th>
</tr>
</thead>
<tbody>
<tr>
<td>“polygon”</td>
<td>a polygon-tuple, i.e. a tuple of pairs of coordinates</td>
</tr>
<tr>
<td>“image”</td>
<td>an image (in this form only used internally!)</td>
</tr>
<tr>
<td>“compound”</td>
<td>None (a compound shape has to be constructed using the <code>addcomponent()</code> method)</td>
</tr>
</tbody>
</table>

Data structure modeling shapes. The pair `(type_, data)` must follow this specification:

```
addcomponent(poly, fill, outline=None)
```

**Parameters:**

- **poly** – a polygon, i.e. a tuple of pairs of numbers
- **fill** – a color the `poly` will be filled with
- **outline** – a color for the poly’s outline (if given)

Example:

```python
>>> poly = ((0, 0), (10, -5), (0, -10), (-10, -5))
>>> s = Shape("compound")
>>> s.addcomponent(poly, "red", "blue")
>>> # ... add more components and then use register_shape()
```

See [Compound shapes](#).

class turtle. **Vec2D**(x, y)

A two-dimensional vector class, used as a helper class for implementing turtle graphics. May be useful for turtle graphics
programs too. Derived from tuple, so a vector is a tuple!

Provides (for \(a, b\) vectors, \(k\) number):

- \(a + b\) vector addition
- \(a - b\) vector subtraction
- \(a \cdot b\) inner product
- \(k \cdot a\) and \(a \cdot k\) multiplication with scalar
- \(\text{abs}(a)\) absolute value of \(a\)
- \(a.\text{rotate}(\text{angle})\) rotation
24.1.6. Help and configuration

24.1.6.1. How to use help

The public methods of the Screen and Turtle classes are documented extensively via docstrings. So these can be used as online-help via the Python help facilities:

- When using IDLE, tooltips show the signatures and first lines of the docstrings of typed in function-/method calls.

- Calling `help()` on methods or functions displays the docstrings:

```python
>>> help(Screen.bgcolor)
Help on method bgcolor in module turtle:

bgcolor(self, *args) unbound turtle.Screen method
    Set or return backgroundcolor of the TurtleScreen

    Arguments (if given): a color string or three in the range 0..colormode or a 3-tuple of such

>>> screen.bgcolor("orange")
>>> screen.bgcolor()
"orange"
>>> screen.bgcolor(0.5,0,0.5)
>>> screen.bgcolor()
"#800080"
```

```python
>>> help(Turtle.penup)
Help on method penup in module turtle:

penup(self) unbound turtle.Turtle method
    Pull the pen up -- no drawing when moving.
```
Aliases: penup | pu | up

No argument

>>> turtle.penup()

• The docstrings of the functions which are derived from methods have a modified form:

>>> help(bgcolor)
Help on function bgcolor in module turtle:

bgcolor(*args)
    Set or return backgroundcolor of the TurtleScreen.

    Arguments (if given): a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers.

    Example::

        >>> bgcolor("orange")
        >>> bgcolor()
        "orange"
        >>> bgcolor(0.5,0,0.5)
        >>> bgcolor()
        "#800080"

>>> help(penup)
Help on function penup in module turtle:

penup()
    Pull the pen up -- no drawing when moving.

    Aliases: penup | pu | up
These modified docstrings are created automatically together with the function definitions that are derived from the methods at import time.

24.1.6.2. Translation of docstrings into different languages

There is a utility to create a dictionary the keys of which are the method names and the values of which are the docstrings of the public methods of the classes Screen and Turtle.

```
turtle.write_docstringdict(filename="turtle_docstringdict"

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>filename – a string, used as filename</td>
<td></td>
</tr>
</tbody>
</table>
```

Create and write docstring-dictionary to a Python script with the given filename. This function has to be called explicitly (it is not used by the turtle graphics classes). The docstring dictionary will be written to the Python script `filename.py`. It is intended to serve as a template for translation of the docstrings into different languages.

If you (or your students) want to use `turtle` with online help in your native language, you have to translate the docstrings and save the resulting file as e.g. `turtle_docstringdict_german.py`.

If you have an appropriate entry in your `turtle.cfg` file this dictionary will be read in at import time and will replace the original English docstrings.
At the time of this writing there are docstring dictionaries in German and in Italian. (Requests please to glingl@aon.at.)

24.1.6.3. How to configure Screen and Turtles

The built-in default configuration mimics the appearance and behaviour of the old turtle module in order to retain best possible compatibility with it.

If you want to use a different configuration which better reflects the features of this module or which better fits to your needs, e.g. for use in a classroom, you can prepare a configuration file `turtle.cfg` which will be read at import time and modify the configuration according to its settings.

The built in configuration would correspond to the following `turtle.cfg`:

```plaintext
width = 0.5
height = 0.75
leftright = None
topbottom = None
canvwidth = 400
canvheight = 300
mode = standard
colormode = 1.0
delay = 10
undobuffersize = 1000
shape = classic
pencolor = black
fillcolor = black
resizemode = noresize
visible = True
language = english
exampleturtle = turtle
examplescreen = screen
```
Short explanation of selected entries:

- The first four lines correspond to the arguments of the `Screen.setup()` method.
- Line 5 and 6 correspond to the arguments of the method `Screen.screensize()`.
- `shape` can be any of the built-in shapes, e.g: arrow, turtle, etc. For more info try `help(shape)`.
- If you want to use no fillcolor (i.e. make the turtle transparent), you have to write `fillcolor = ""` (but all nonempty strings must not have quotes in the `cfg-file`).
- If you want to reflect the turtle its state, you have to use `resizemode = auto`.
- If you set e.g. `language = italian` the docstringdict `turtle_docstringdict_italian.py` will be loaded at import time (if present on the import path, e.g. in the same directory as `turtle`.
- The entries `exampleturtle` and `examplescreen` define the names of these objects as they occur in the docstrings. The transformation of method-docstrings to function-docstrings will delete these names from the docstrings.
- `using_IDLE`: Set this to True if you regularly work with IDLE and its -n switch (“no subprocess”). This will prevent `exitonclick()` to enter the mainloop.

There can be a `turtle.cfg` file in the directory where `turtle` is stored and an additional one in the current working directory. The latter will override the settings of the first one.

The `Lib/turtledemo` directory contains a `turtle.cfg` file. You can study it as an example and see its effects when running the
demos (preferably not from within the demo-viewer).
24.1.7. **turtledemo — Demo scripts**

The **turtledemo** package includes a set of demo scripts. These scripts can be run and viewed using the supplied demo viewer as follows:

```python
python -m turtledemo
```

Alternatively, you can run the demo scripts individually. For example,

```python
python -m turtledemo.bytedesign
```

The **turtledemo** package directory contains:

- A demo viewer `__main__.py` which can be used to view the sourcecode of the scripts and run them at the same time.
- Multiple scripts demonstrating different features of the **turtle** module. Examples can be accessed via the Examples menu. They can also be run standalone.
- A `turtle.cfg` file which serves as an example of how to write and use such files.

The demo scripts are:

Have fun!
24.1.8. Changes since Python 2.6

- The methods `Turtle.tracer()`, `Turtle.window_width()` and `Turtle.window_height()` have been eliminated. Methods with these names and functionality are now available only as methods of `Screen`. The functions derived from these remain available. (In fact already in Python 2.6 these methods were merely duplications of the corresponding `TurtleScreen`/`Screen`-methods.)
- The method `Turtle.fill()` has been eliminated. The behaviour of `begin_fill()` and `end_fill()` have changed slightly: now every filling-process must be completed with an `end_fill()` call.
- A method `Turtle.filling()` has been added. It returns a boolean value: `True` if a filling process is under way, `False` otherwise. This behaviour corresponds to a `fill()` call without arguments in Python 2.6.
24.1.9. Changes since Python 3.0

- The methods `Turtle.shearfactor()`, `Turtle.shapetransform()` and `Turtle.get_shapepoly()` have been added. Thus the full range of regular linear transforms is now available for transforming turtle shapes. `Turtle.tiltangle()` has been enhanced in functionality: it now can be used to get or set the tiltangle. `Turtle.settiltangle()` has been deprecated.
- The method `Screen.onkeypress()` has been added as a complement to `Screen.onkey()` which in fact binds actions to the keyrelease event. Accordingly the latter has got an alias: `Screen.onkeyrelease()`.
- The method `Screen.mainloop()` has been added. So when working only with Screen and Turtle objects one must not additionally import `mainloop()` anymore.
- Two input methods has been added `Screen.textinput()` and `Screen.numinput()`. These popup input dialogs and return strings and numbers respectively.
- Two example scripts `tdemo_nim.py` and `tdemo_round_dance.py` have been added to the Lib/turtledemo directory.
24.2. cmd — Support for line-oriented command interpreters

Source code: Lib/cmd.py

The Cmd class provides a simple framework for writing line-oriented command interpreters. These are often useful for test harnesses, administrative tools, and prototypes that will later be wrapped in a more sophisticated interface.

```python
class cmd.Cmd(completekey='tab', stdin=None, stdout=None)
```

A Cmd instance or subclass instance is a line-oriented interpreter framework. There is no good reason to instantiate Cmd itself; rather, it's useful as a superclass of an interpreter class you define yourself in order to inherit Cmd's methods and encapsulate action methods.

The optional argument completekey is the readline name of a completion key; it defaults to Tab. If completekey is not None and readline is available, command completion is done automatically.

The optional arguments stdin and stdout specify the input and output file objects that the Cmd instance or subclass instance will use for input and output. If not specified, they will default to sys.stdin and sys.stdout.

If you want a given stdin to be used, make sure to set the instance's use_rawinput attribute to False, otherwise stdin will
be ignored.
24.2.1. Cmd Objects

A `Cmd` instance has the following methods:

```python
Cmd.cmdloop(intro=None)
```

Repeatedly issue a prompt, accept input, parse an initial prefix off the received input, and dispatch to action methods, passing them the remainder of the line as argument.

The optional argument is a banner or intro string to be issued before the first prompt (this overrides the `intro` class attribute).

If the `readline` module is loaded, input will automatically inherit `bash`-like history-list editing (e.g. `Control-P` scrolls back to the last command, `Control-N` forward to the next one, `Control-F` moves the cursor to the right non-destructively, `Control-B` moves the cursor to the left non-destructively, etc.).

An end-of-file on input is passed back as the string `'EOF'`.

An interpreter instance will recognize a command name `foo` if and only if it has a method `do_foo()`. As a special case, a line beginning with the character `'?` is dispatched to the method `do_help()`. As another special case, a line beginning with the character `''!''` is dispatched to the method `do_shell()` (if such a method is defined).

This method will return when the `postcmd()` method returns a true value. The `stop` argument to `postcmd()` is the return value from the command's corresponding `do_*()` method.

If completion is enabled, completing commands will be done
automatically, and completing of commands args is done by calling complete_foo() with arguments text, line, begidx, and endidx. text is the string prefix we are attempting to match: all returned matches must begin with it. line is the current input line with leading whitespace removed, begidx and endidx are the beginning and ending indexes of the prefix text, which could be used to provide different completion depending upon which position the argument is in.

All subclasses of Cmd inherit a predefined do_help(). This method, called with an argument 'bar', invokes the corresponding method help_bar(), and if that is not present, prints the docstring of do_bar(), if available. With no argument, do_help() lists all available help topics (that is, all commands with corresponding help_*() methods or commands that have docstrings), and also lists any undocumented commands.

Cmd.onecmd(str)
Interpret the argument as though it had been typed in response to the prompt. This may be overridden, but should not normally need to be; see the precmd() and postcmd() methods for useful execution hooks. The return value is a flag indicating whether interpretation of commands by the interpreter should stop. If there is a do_*( ) method for the command str, the return value of that method is returned, otherwise the return value from the default() method is returned.

Cmd.emptyline()
Method called when an empty line is entered in response to the prompt. If this method is not overridden, it repeats the last nonempty command entered.
**Cmd. `default(line)`**
Method called on an input line when the command prefix is not recognized. If this method is not overridden, it prints an error message and returns.

**Cmd. `completesdefault(text, line, begidx, endidx)`**
Method called to complete an input line when no command-specific `complete_*()` method is available. By default, it returns an empty list.

**Cmd. `precmd(line)`**
Hook method executed just before the command line `line` is interpreted, but after the input prompt is generated and issued. This method is a stub in `Cmd`; it exists to be overridden by subclasses. The return value is used as the command which will be executed by the `onecmd()` method; the `precmd()` implementation may re-write the command or simply return `line` unchanged.

**Cmd. `postcmd(stop, line)`**
Hook method executed just after a command dispatch is finished. This method is a stub in `Cmd`; it exists to be overridden by subclasses. `line` is the command line which was executed, and `stop` is a flag which indicates whether execution will be terminated after the call to `postcmd()`; this will be the return value of the `onecmd()` method. The return value of this method will be used as the new value for the internal flag which corresponds to `stop`; returning false will cause interpretation to continue.

**Cmd. `preloop()`**
Hook method executed once when `cmdloop()` is called. This method is a stub in `Cmd`; it exists to be overridden by subclasses.
**Cmd. `postloop()`**
Hook method executed once when `cmdloop()` is about to return. This method is a stub in `Cmd`; it exists to be overridden by subclasses.

Instances of `Cmd` subclasses have some public instance variables:

**Cmd. `prompt`**
The prompt issued to solicit input.

**Cmd. `identchars`**
The string of characters accepted for the command prefix.

**Cmd. `lastcmd`**
The last nonempty command prefix seen.

**Cmd. `cmdqueue`**
A list of queued input lines. The `cmdqueue` list is checked in `cmdloop()` when new input is needed; if it is nonempty, its elements will be processed in order, as if entered at the prompt.

**Cmd. `intro`**
A string to issue as an intro or banner. May be overridden by giving the `cmdloop()` method an argument.

**Cmd. `doc_header`**
The header to issue if the help output has a section for documented commands.

**Cmd. `misc_header`**
The header to issue if the help output has a section for miscellaneous help topics (that is, there are `help_*()` methods
without corresponding do_*( ) methods).

Cmd. **undoc_header**
The header to issue if the help output has a section for undocumented commands (that is, there are do_*( ) methods without corresponding help_*( ) methods).

Cmd. **ruler**
The character used to draw separator lines under the help-message headers. If empty, no ruler line is drawn. It defaults to '='.

Cmd. **use_rawinput**
A flag, defaulting to true. If true, cmdloop() uses input( ) to display a prompt and read the next command; if false, sys.stdout.write( ) and sys.stdin.readline( ) are used. (This means that by importing readline, on systems that support it, the interpreter will automatically support Emacs-like line editing and command-history keystrokes.)
24.2.2. Cmd Example

The cmd module is mainly useful for building custom shells that let a user work with a program interactively.

This section presents a simple example of how to build a shell around a few of the commands in the turtle module.

Basic turtle commands such as forward() are added to a Cmd subclass with method named do_forward(). The argument is converted to a number and dispatched to the turtle module. The docstring is used in the help utility provided by the shell.

The example also includes a basic record and playback facility implemented with the precmd() method which is responsible for converting the input to lowercase and writing the commands to a file. The do_playback() method reads the file and adds the recorded commands to the cmdqueue for immediate playback:

```python
import cmd, sys
from turtle import *

class TurtleShell(cmd.Cmd):
    intro = 'Welcome to the turtle shell. Type help or ? to list commands.
    prompt = '(turtle) '
    file = None

    # ----- basic turtle commands -----
    def do_forward(self, arg):
        'Move the turtle forward by the specified distance:
        forward(*parse(arg))
    def do_right(self, arg):
        'Turn turtle right by given number of degrees
        right(*parse(arg))
```
right(*parse(arg))
def do_left(self, arg):
    'Turn turtle left by given number of degrees'
    left(*parse(arg))
def do_goto(self, arg):
    'Move turtle to an absolute position with changing orientation'
    goto(*parse(arg))
def do_home(self, arg):
    'Return turtle to the home position: HOME'
    home()
def do_circle(self, arg):
    'Draw circle with given radius an options except center'
    circle(*parse(arg))
def do_position(self, arg):
    'Print the current turtle position: POSITION'
    print('Current position is %d %d\n' % position)
def do_heading(self, arg):
    'Print the current turtle heading in degrees'
    print('Current heading is %d\n' % (heading()))
def do_color(self, arg):
    'Set the color: COLOR BLUE'
    color(arg.lower())
def do_undo(self, arg):
    'Undo (repeatedly) the last turtle action(s)'
def do_reset(self, arg):
    'Clear the screen and return turtle to center'
    reset()
def do_bye(self, arg):
    'Stop recording, close the turtle window, and exit'
    print('Thank you for using Turtle')
    self.close()
    bye()
    return True

# ----- record and playback -----
def do_record(self, arg):
    'Save future commands to filename: RECORD rose.cmd'
self.file = open(arg, 'w')

def do_playback(self, arg):
    'Playback commands from a file: PLAYBACK rose.cmd'
    self.close()
    with open(arg) as f:
        self.cmdqueue.extend(f.read().splitlines)

def precmd(self, line):
    line = line.lower()
    if self.file and 'playback' not in line:
        print(line, file=self.file)
    return line

def close(self):
    if self.file:
        self.file.close()
        self.file = None

def parse(arg):
    'Convert a series of zero or more numbers to an argument tuple'
    return tuple(map(int, arg.split()))

if __name__ == '__main__':
    TurtleShell().cmdloop()

Here is a sample session with the turtle shell showing the help functions, using blank lines to repeat commands, and the simple record and playback facility:

Welcome to the turtle shell. Type help or ? to list commands.
(turtle) ?

Documented commands (type help <topic>):

Current position is 0 0

Current heading is 0

Current heading is 180

(turtle) bye
Thank you for using Turtle
24.3. **shlex** — Simple lexical analysis

**Source code:** Lib/shlex.py

The `shlex` class makes it easy to write lexical analyzers for simple syntaxes resembling that of the Unix shell. This will often be useful for writing minilanguages, (for example, in run control files for Python applications) or for parsing quoted strings.

The `shlex` module defines the following functions:

**shlex.split(s, comments=False, posix=True)**

Split the string `s` using shell-like syntax. If `comments` is `False` (the default), the parsing of comments in the given string will be disabled (setting the `commenters` attribute of the `shlex` instance to the empty string). This function operates in POSIX mode by default, but uses non-POSIX mode if the `posix` argument is false.

**Note:** Since the `split()` function instantiates a `shlex` instance, passing `None` for `s` will read the string to split from standard input.

**shlex.quote(s)**

Return a shell-escaped version of the string `s`. The returned value is a string that can safely be used as one token in a shell command line, for cases where you cannot use a list.

This idiom would be unsafe:
quote() lets you plug the security hole:

```
>>> from shlex import quote
>>> command = 'ls -l {}'.format(quote(filename))
>>> print(command)
ls -l 'somefile; rm -rf ~'
```

The quoting is compatible with UNIX shells and with `split()`:

```
>>> from shlex import split
>>> remote_command = 'ssh home {}'.format(quote(command))
>>> print(remote_command)
ssh home 'ls -l """'somefile; rm -rf ~"""'
```

```
New in version 3.3.
```

The `shlex` module defines the following class:

```
class shlex.shlex(instream=None, infile=None, posix=False, punctuation_chars=False)
```

A `shlex` instance or subclass instance is a lexical analyzer object. The initialization argument, if present, specifies where to read characters from. It must be a file-/stream-like object with `read()`
and `readline()` methods, or a string. If no argument is given, input will be taken from `sys.stdin`. The second optional argument is a filename string, which sets the initial value of the `infile` attribute. If the `instream` argument is omitted or equal to `sys.stdin`, this second argument defaults to “stdin”. The `posix` argument defines the operational mode: when `posix` is not true (default), the `shlex` instance will operate in compatibility mode. When operating in POSIX mode, `shlex` will try to be as close as possible to the POSIX shell parsing rules. The `punctuation_chars` argument provides a way to make the behaviour even closer to how real shells parse. This can take a number of values: the default value, `False`, preserves the behaviour seen under Python 3.5 and earlier. If set to `True`, then parsing of the characters `();<>|&` is changed: any run of these characters (considered punctuation characters) is returned as a single token. If set to a non-empty string of characters, those characters will be used as the punctuation characters. Any characters in the `wordchars` attribute that appear in `punctuation_chars` will be removed from `wordchars`. See Improved Compatibility with Shells for more information.

`Changed in version 3.6:` The `punctuation_chars` parameter was added.

**See also:**

**Module** `configparser`

Parser for configuration files similar to the Windows `.ini` files.
24.3.1. shlex Objects

A `shlex` instance has the following methods:

**shlex.get_token()**

Return a token. If tokens have been stacked using `push_token()`, pop a token off the stack. Otherwise, read one from the input stream. If reading encounters an immediate end-of-file, `eof` is returned (the empty string (`''`) in non-POSIX mode, and `None` in POSIX mode).

**shlex.push_token(str)**

Push the argument onto the token stack.

**shlex.read_token()**

Read a raw token. Ignore the pushback stack, and do not interpret source requests. (This is not ordinarily a useful entry point, and is documented here only for the sake of completeness.)

**shlex.sourcehook(filename)**

When `shlex` detects a source request (see `source` below) this method is given the following token as argument, and expected to return a tuple consisting of a filename and an open file-like object.

Normally, this method first strips any quotes off the argument. If the result is an absolute pathname, or there was no previous source request in effect, or the previous source was a stream (such as `sys.stdin`), the result is left alone. Otherwise, if the result is a relative pathname, the directory part of the name of the file immediately before it on the source inclusion stack is prepended (this behavior is like the way the C preprocessor handles
The result of the manipulations is treated as a filename, and returned as the first component of the tuple, with `open()` called on it to yield the second component. (Note: this is the reverse of the order of arguments in instance initialization!)

This hook is exposed so that you can use it to implement directory search paths, addition of file extensions, and other namespace hacks. There is no corresponding 'close' hook, but a shlex instance will call the `close()` method of the sourced input stream when it returns EOF.

For more explicit control of source stacking, use the `push_source()` and `pop_source()` methods.

```python
shlex.push_source(newstream, newfile=None)
```

Push an input source stream onto the input stack. If the filename argument is specified it will later be available for use in error messages. This is the same method used internally by the `sourcehook()` method.

```python
shlex.pop_source()
```

Pop the last-pushed input source from the input stack. This is the same method used internally when the lexer reaches EOF on a stacked input stream.

```python
shlex.error_leader(infile=None, lineno=None)
```

This method generates an error message leader in the format of a Unix C compiler error label; the format is "%%s", line %d: ", where the %%s is replaced with the name of the current source file and the %d with the current input line number (the optional
arguments can be used to override these).

This convenience is provided to encourage shlex users to generate error messages in the standard, parseable format understood by Emacs and other Unix tools.

Instances of shlex subclasses have some public instance variables which either control lexical analysis or can be used for debugging:

shlex.commenters

The string of characters that are recognized as comment beginners. All characters from the comment beginner to end of line are ignored. Includes just '#' by default.

shlex.wordchars

The string of characters that will accumulate into multi-character tokens. By default, includes all ASCII alphanumerics and underscore. In POSIX mode, the accented characters in the Latin-1 set are also included. If punctuation_chars is not empty, the characters ~-./*?=, which can appear in filename specifications and command line parameters, will also be included in this attribute, and any characters which appear in punctuation_chars will be removed from wordchars if they are present there.

shlex.whitespace

Characters that will be considered whitespace and skipped. Whitespace bounds tokens. By default, includes space, tab, linefeed and carriage-return.

shlex.escape

Characters that will be considered as escape. This will be only used in POSIX mode, and includes just '\' by default.
shlex.\texttt{quotes}

Characters that will be considered string quotes. The token accumulates until the same quote is encountered again (thus, different quote types protect each other as in the shell.) By default, includes ASCII single and double quotes.

shlex.\texttt{escapedquotes}

Characters in \texttt{quotes} that will interpret escape characters defined in \texttt{escape}. This is only used in POSIX mode, and includes just `' by default.

shlex.\texttt{whitespace\_split}

If \texttt{True}, tokens will only be split in whitespaces. This is useful, for example, for parsing command lines with \texttt{shlex}, getting tokens in a similar way to shell arguments. If this attribute is \texttt{True}, \texttt{punctuation\_chars} will have no effect, and splitting will happen only on whitespaces. When using \texttt{punctuation\_chars}, which is intended to provide parsing closer to that implemented by shells, it is advisable to leave \texttt{whitespace\_split} as \texttt{False} (the default value).

shlex.\texttt{in\_file}

The name of the current input file, as initially set at class instantiation time or stacked by later source requests. It may be useful to examine this when constructing error messages.

shlex.\texttt{in\_stream}

The input stream from which this \texttt{shlex} instance is reading characters.

shlex.\texttt{source}

This attribute is \texttt{None} by default. If you assign a string to it, that
string will be recognized as a lexical-level inclusion request similar to the `source` keyword in various shells. That is, the immediately following token will be opened as a filename and input will be taken from that stream until EOF, at which point the `close()` method of that stream will be called and the input source will again become the original input stream. Source requests may be stacked any number of levels deep.

**shlex.** **debug**

If this attribute is numeric and 1 or more, a `shlex` instance will print verbose progress output on its behavior. If you need to use this, you can read the module source code to learn the details.

**shlex.** **lineno**

Source line number (count of newlines seen so far plus one).

**shlex.** **token**

The token buffer. It may be useful to examine this when catching exceptions.

**shlex.** **eof**

Token used to determine end of file. This will be set to the empty string (`''`), in non-POSIX mode, and to `None` in POSIX mode.

**shlex.** **punctuation_chars**

Characters that will be considered punctuation. Runs of punctuation characters will be returned as a single token. However, note that no semantic validity checking will be performed: for example, `>>>` could be returned as a token, even though it may not be recognised as such by shells.

*New in version 3.6.*
24.3.2. Parsing Rules

When operating in non-POSIX mode, shlex will try to obey to the following rules.

- Quote characters are not recognized within words (Do"Not"Separate is parsed as the single word Do"Not"Separate);
- Escape characters are not recognized;
- Enclosing characters in quotes preserve the literal value of all characters within the quotes;
- Closing quotes separate words ("Do"Separate is parsed as "Do" and Separate);
- If whitespace_split is False, any character not declared to be a word character, whitespace, or a quote will be returned as a single-character token. If it is True, shlex will only split words in whitespaces;
- EOF is signaled with an empty string ('');
- It’s not possible to parse empty strings, even if quoted.

When operating in POSIX mode, shlex will try to obey to the following parsing rules.

- Quotes are stripped out, and do not separate words ("Do"Not"Separate" is parsed as the single word DoNotSeparate);
- Non-quoted escape characters (e.g. '\') preserve the literal value of the next character that follows;
- Enclosing characters in quotes which are not part of escapedquotes (e.g. "\") preserve the literal value of all characters within the quotes;
- Enclosing characters in quotes which are part of
escapedquotes (e.g. "'") preserves the literal value of all characters within the quotes, with the exception of the characters mentioned in escape. The escape characters retain its special meaning only when followed by the quote in use, or the escape character itself. Otherwise the escape character will be considered a normal character.

- EOF is signaled with a None value;
- Quoted empty strings ('') are allowed.
24.3.3. Improved Compatibility with Shells

*New in version 3.6.*

The `shlex` class provides compatibility with the parsing performed by common Unix shells like `bash`, `dash`, and `sh`. To take advantage of this compatibility, specify the `punctuation_chars` argument in the constructor. This defaults to `False`, which preserves pre-3.6 behaviour. However, if it is set to `True`, then parsing of the characters `();<>|&` is changed: any run of these characters is returned as a single token. While this is short of a full parser for shells (which would be out of scope for the standard library, given the multiplicity of shells out there), it does allow you to perform processing of command lines more easily than you could otherwise. To illustrate, you can see the difference in the following snippet:

```python
>>> import shlex
>>> text = "a && b; c && d || e; f >'abc'; (def "ghi")
>>> list(shlex.shlex(text))
['a', '&', '&', 'b', ';', 'c', '&', '&', 'd', '||', 'e', '>', 'abc', ']', '(', 'def', 'ghi', ')
```

Of course, tokens will be returned which are not valid for shells, and you'll need to implement your own error checks on the returned tokens.

Instead of passing `True` as the value for the `punctuation_chars` parameter, you can pass a string with specific characters, which will be used to determine which characters constitute punctuation. For
example:

```python
>>> import shlex
>>> s = shlex.shlex("a && b || c", punctuation_chars=True)
>>> list(s)
["a", ",", ",", ",b", ",||", ",c"]
```

**Note:** When punctuation_chars is specified, the `wordchars` attribute is augmented with the characters `~ . / * ? =`. That is because these characters can appear in file names (including wildcards) and command-line arguments (e.g. `--color=auto`). Hence:

```python
>>> import shlex
>>> s = shlex.shlex("~/a && b-c --color=auto || d ...
... punctuation_chars=True)
>>> list(s)
["~/a", ",&&", ",b-c", ",--color=auto", ",||", ",d", ",*
```

For best effect, `punctuation_chars` should be set in conjunction with `posix=True`. (Note that `posix=False` is the default for `shlex`.)
25. Graphical User Interfaces with Tk

Tk/Tcl has long been an integral part of Python. It provides a robust and platform independent windowing toolkit, that is available to Python programmers using the \texttt{tkinter} package, and its extension, the \texttt{tkinter.tix} and the \texttt{tkinter.ttk} modules.

The \texttt{tkinter} package is a thin object-oriented layer on top of Tcl/Tk. To use \texttt{tkinter}, you don't need to write Tcl code, but you will need to consult the Tk documentation, and occasionally the Tcl documentation. \texttt{tkinter} is a set of wrappers that implement the Tk widgets as Python classes. In addition, the internal module \_\texttt{tkinter} provides a threadsafe mechanism which allows Python and Tcl to interact.

\texttt{tkinter}'s chief virtues are that it is fast, and that it usually comes bundled with Python. Although its standard documentation is weak, good material is available, which includes: references, tutorials, a book and others. \texttt{tkinter} is also famous for having an outdated look and feel, which has been vastly improved in Tk 8.5. Nevertheless, there are many other GUI libraries that you could be interested in. For more information about alternatives, see the \texttt{Other Graphical User Interface Packages} section.

25.1. **tkinter — Python interface to Tcl/Tk**

Source code: Lib/tkinter/__init__.py

The `tkinter` package ("Tk interface") is the standard Python interface to the Tk GUI toolkit. Both Tk and `tkinter` are available on most Unix platforms, as well as on Windows systems. (Tk itself is not part of Python; it is maintained at ActiveState.) You can check that `tkinter` is properly installed on your system by running `python -m tkinter` from the command line; this should open a window demonstrating a simple Tk interface.

**Python and Tkinter Programming**  
25.1.1. Tkinter Modules

Most of the time, `tkinter` is all you really need, but a number of additional modules are available as well. The Tk interface is located in a binary module named `_tkinter`. This module contains the low-level interface to Tk, and should never be used directly by application programmers. It is usually a shared library (or DLL), but might in some cases be statically linked with the Python interpreter.

In addition to the Tk interface module, `tkinter` includes a number of Python modules, `tkinter.constants` being one of the most important. Importing `tkinter` will automatically import `tkinter.constants`, so, usually, to use Tkinter all you need is a simple import statement:

```python
import tkinter
```

Or, more often:

```python
from tkinter import *
```

class `tkinter.Tk`(screenName=None, baseName=None, className='Tk', useTk=1)

        The `Tk` class is instantiated without arguments. This creates a toplevel widget of Tk which usually is the main window of an application. Each instance has its own associated Tcl interpreter.

tkinter.Tcl(screenName=None, baseName=None, className='Tk', useTk=0)

        The `Tcl()` function is a factory function which creates an object much like that created by the `Tk` class, except that it does not
initialize the Tk subsystem. This is most often useful when driving the Tcl interpreter in an environment where one doesn’t want to create extraneous toplevel windows, or where one cannot (such as Unix/Linux systems without an X server). An object created by the Tcl() object can have a Toplevel window created (and the Tk subsystem initialized) by calling its loadtk() method.

Other modules that provide Tk support include:

```
tkinter.scrolledtext
    Text widget with a vertical scroll bar built in.
tkinter.colorchooser
    Dialog to let the user choose a color.
tkinter.commondialog
    Base class for the dialogs defined in the other modules listed here.
tkinter.filedialog
    Common dialogs to allow the user to specify a file to open or save.
tkinter.font
    Utilities to help work with fonts.
tkinter.messagebox
    Access to standard Tk dialog boxes.
tkinter.simpledialog
    Basic dialogs and convenience functions.
tkinter.dnd
    Drag-and-drop support for tkinter. This is experimental and should become deprecated when it is replaced with the Tk DND.
turtle
    Turtle graphics in a Tk window.
```
25.1.2. Tkinter Life Preserver

This section is not designed to be an exhaustive tutorial on either Tk or Tkinter. Rather, it is intended as a stop gap, providing some introductory orientation on the system.

Credits:

- Tk was written by John Ousterhout while at Berkeley.
- Tkinter was written by Steen Lumholt and Guido van Rossum.
- This Life Preserver was written by Matt Conway at the University of Virginia.
- The HTML rendering, and some liberal editing, was produced from a FrameMaker version by Ken Manheimer.
- Fredrik Lundh elaborated and revised the class interface descriptions, to get them current with Tk 4.2.
- Mike Clarkson converted the documentation to LaTeX, and compiled the User Interface chapter of the reference manual.

25.1.2.1. How To Use This Section

This section is designed in two parts: the first half (roughly) covers background material, while the second half can be taken to the keyboard as a handy reference.

When trying to answer questions of the form “how do I do blah”, it is often best to find out how to do “blah” in straight Tk, and then convert this back into the corresponding tkinter call. Python programmers can often guess at the correct Python command by looking at the Tk documentation. This means that in order to use Tkinter, you will have to know a little bit about Tk. This document can’t fulfill that role, so the best we can do is point you to the best documentation that exists.
Here are some hints:

- The authors strongly suggest getting a copy of the Tk man pages. Specifically, the man pages in the `manN` directory are most useful. The `man3` man pages describe the C interface to the Tk library and thus are not especially helpful for script writers.
- Addison-Wesley publishes a book called Tcl and the Tk Toolkit by John Ousterhout (ISBN 0-201-63337-X) which is a good introduction to Tcl and Tk for the novice. The book is not exhaustive, and for many details it defers to the man pages.
- `tkinter/__init__.py` is a last resort for most, but can be a good place to go when nothing else makes sense.

25.1.2.2. A Simple Hello World Program

```python
import tkinter as tk

class Application(tk.Frame):
    def __init__(self, master=None):
        super().__init__(master)
        self.pack()
        self.create_widgets()
```
def create_widgets(self):
    self.hi_there = tk.Button(self)
    self.hi_there["text"] = "Hello World
(click me)"
    self.hi_there["command"] = self.say_hi
    self.hi_there.pack(side="top")

    self.quit = tk.Button(self, text="QUIT", fg=command=root.destroy)
    self.quit.pack(side="bottom")

def say_hi(self):
    print("hi there, everyone!")

root = tk.Tk()
app = Application(master=root)
app.mainloop()
25.1.3. A (Very) Quick Look at Tcl/Tk

The class hierarchy looks complicated, but in actual practice, application programmers almost always refer to the classes at the very bottom of the hierarchy.

Notes:

- These classes are provided for the purposes of organizing certain functions under one namespace. They aren’t meant to be instantiated independently.
- The Tk class is meant to be instantiated only once in an application. Application programmers need not instantiate one explicitly, the system creates one whenever any of the other classes are instantiated.
- The Widget class is not meant to be instantiated, it is meant only for subclassing to make “real” widgets (in C++, this is called an ‘abstract class’).

To make use of this reference material, there will be times when you will need to know how to read short passages of Tk and how to identify the various parts of a Tk command. (See section Mapping Basic Tk into Tkinter for the tkinter equivalents of what’s below.)

Tk scripts are Tcl programs. Like all Tcl programs, Tk scripts are just lists of tokens separated by spaces. A Tk widget is just its class, the options that help configure it, and the actions that make it do useful things.

To make a widget in Tk, the command is always of the form:

classCommand newPathname options
**classCommand**

denotes which kind of widget to make (a button, a label, a menu…)

**newPathname**

is the new name for this widget. All names in Tk must be unique. To help enforce this, widgets in Tk are named with *pathnames*, just like files in a file system. The top level widget, the *root*, is called (period) and children are delimited by more periods. For example, `.myApp.controlPanel.okButton` might be the name of a widget.

**options**

configure the widget’s appearance and in some cases, its behavior. The options come in the form of a list of flags and values. Flags are preceded by a ‘-‘, like Unix shell command flags, and values are put in quotes if they are more than one word.

For example:

```
button .fred -fg red -text "hi there"
```

Once created, the pathname to the widget becomes a new command. This new *widget command* is the programmer’s handle for getting the new widget to perform some *action*. In C, you’d express this as `someAction(fred, someOptions)`, in C++, you would express this as `fred.someAction(someOptions)`, and in Tk, you say:

```
.fred someAction someOptions
```

Note that the object name, `.fred`, starts with a dot.
As you’d expect, the legal values for *someAction* will depend on the widget’s class: `.fred disable` works if fred is a button (fred gets greyed out), but does not work if fred is a label (disabling of labels is not supported in Tk).

The legal values of *someOptions* is action dependent. Some actions, like `disable`, require no arguments, others, like a text-entry box’s `delete` command, would need arguments to specify what range of text to delete.
25.1.4. Mapping Basic Tk into Tkinter

Class commands in Tk correspond to class constructors in Tkinter.

```
button .fred          ======>  fred = Button()
```

The master of an object is implicit in the new name given to it at creation time. In Tkinter, masters are specified explicitly.

```
button .panel.fred    ======>  fred = Button(panel)
```

The configuration options in Tk are given in lists of hyphenated tags followed by values. In Tkinter, options are specified as keyword-arguments in the instance constructor, and keyword-args for configure calls or as instance indices, in dictionary style, for established instances. See section Setting Options on setting options.

```
button .fred -fg red  ======>  fred = Button(panel)
.fred configure -fg red ======>  fred["fg"] = red
OR ==>  fred.config(fg='red')
```

In Tk, to perform an action on a widget, use the widget name as a command, and follow it with an action name, possibly with arguments (options). In Tkinter, you call methods on the class instance to invoke actions on the widget. The actions (methods) that a given widget can perform are listed in `tkinter/__init__.py`.

```
.fred invoke          ======>  fred.invoke()
```

To give a widget to the packer (geometry manager), you call pack with optional arguments. In Tkinter, the Pack class holds all this
functionality, and the various forms of the pack command are implemented as methods. All widgets in tkinter are subclassed from the Packer, and so inherit all the packing methods. See the tkinter.tix module documentation for additional information on the Form geometry manager.

pack .fred -side left ======> fred.pack(side='
25.1.5. How Tk and Tkinter are Related

From the top down:

Your App Here (Python)
A Python application makes a `tkinter` call.

tkinter (Python Package)
This call (say, for example, creating a button widget), is implemented in the `tkinter` package, which is written in Python. This Python function will parse the commands and the arguments and convert them into a form that makes them look as if they had come from a Tk script instead of a Python script.

ltkinter (C)
These commands and their arguments will be passed to a C function in the `ltkinter` - note the underscore - extension module.

Tk Widgets (C and Tcl)
This C function is able to make calls into other C modules, including the C functions that make up the Tk library. Tk is implemented in C and some Tcl. The Tcl part of the Tk widgets is used to bind certain default behaviors to widgets, and is executed once at the point where the Python `tkinter` package is imported. (The user never sees this stage).

Tk (C)
The Tk part of the Tk Widgets implement the final mapping to ...

Xlib (C)
the Xlib library to draw graphics on the screen.
25.1.6. Handy Reference

25.1.6.1. Setting Options

Options control things like the color and border width of a widget. Options can be set in three ways:

At object creation time, using keyword arguments

```python
fred = Button(self, fg="red", bg="blue")
```

After object creation, treating the option name like a dictionary index

```python
fred["fg"] = "red"
fred["bg"] = "blue"
```

Use the config() method to update multiple attrs subsequent to object creation

```python
fred.config(fg="red", bg="blue")
```

For a complete explanation of a given option and its behavior, see the Tk man pages for the widget in question.

Note that the man pages list “STANDARD OPTIONS” and “WIDGET SPECIFIC OPTIONS” for each widget. The former is a list of options that are common to many widgets, the latter are the options that are idiosyncratic to that particular widget. The Standard Options are documented on the options(3) man page.

No distinction between standard and widget-specific options is made in this document. Some options don’t apply to some kinds of widgets. Whether a given widget responds to a particular option depends on the class of the widget; buttons have a command option, labels do not.
The options supported by a given widget are listed in that widget's man page, or can be queried at runtime by calling the `config()` method without arguments, or by calling the `keys()` method on that widget. The return value of these calls is a dictionary whose key is the name of the option as a string (for example, `'relief'`) and whose values are 5-tuples.

Some options, like `bg` are synonyms for common options with long names (`bg` is shorthand for “background”). Passing the `config()` method the name of a shorthand option will return a 2-tuple, not 5-tuple. The 2-tuple passed back will contain the name of the synonym and the “real” option (such as `('bg', 'background')`).

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>option name</td>
<td>'relief'</td>
</tr>
<tr>
<td>1</td>
<td>option name for database lookup</td>
<td>'relief'</td>
</tr>
<tr>
<td>2</td>
<td>option class for database lookup</td>
<td>'Relief'</td>
</tr>
<tr>
<td>3</td>
<td>default value</td>
<td>'raised'</td>
</tr>
<tr>
<td>4</td>
<td>current value</td>
<td>'groove'</td>
</tr>
</tbody>
</table>

Example:

```python
>>> print(fred.config())
{'relief': ('relief', 'relief', 'Relief', 'raised', 'groove')}
```

Of course, the dictionary printed will include all the options available and their values. This is meant only as an example.

25.1.6.2. The Packer
The packer is one of Tk's geometry-management mechanisms. Geometry managers are used to specify the relative positioning of the positioning of widgets within their container - their mutual master. In contrast to the more cumbersome placer (which is used less commonly, and we do not cover here), the packer takes qualitative relationship specification - above, to the left of, filling, etc - and works everything out to determine the exact placement coordinates for you.

The size of any master widget is determined by the size of the “slave widgets” inside. The packer is used to control where slave widgets appear inside the master into which they are packed. You can pack widgets into frames, and frames into other frames, in order to achieve the kind of layout you desire. Additionally, the arrangement is dynamically adjusted to accommodate incremental changes to the configuration, once it is packed.

Note that widgets do not appear until they have had their geometry specified with a geometry manager. It's a common early mistake to leave out the geometry specification, and then be surprised when the widget is created but nothing appears. A widget will appear only after it has had, for example, the packer’s pack() method applied to it.

The pack() method can be called with keyword-option/value pairs that control where the widget is to appear within its container, and how it is to behave when the main application window is resized. Here are some examples:

```python
fred.pack()  # defaults to side =
fred.pack(side="left")
fred.pack(expand=1)
```

25.1.6.3. Packer Options
For more extensive information on the packer and the options that it can take, see the man pages and page 183 of John Ousterhout's book.

anchor

Anchor type. Denotes where the packer is to place each slave in its parcel.

expand

Boolean, 0 or 1.

fill

Legal values: 'x', 'y', 'both', 'none'.

ipadx and ipady

A distance - designating internal padding on each side of the slave widget.

padx and pady

A distance - designating external padding on each side of the slave widget.

side

Legal values are: 'left', 'right', 'top', 'bottom'.

25.1.6.4. Coupling Widget Variables

The current-value setting of some widgets (like text entry widgets) can be connected directly to application variables by using special options. These options are variable, textvariable, onvalue, offvalue, and value. This connection works both ways: if the variable changes for any reason, the widget it's connected to will be updated to reflect the new value.

Unfortunately, in the current implementation of tkinter it is not possible to hand over an arbitrary Python variable to a widget through
a variable or textvariable option. The only kinds of variables for which this works are variables that are subclassed from a class called Variable, defined in tkinter.

There are many useful subclasses of Variable already defined: StringVar, IntVar, DoubleVar, and BooleanVar. To read the current value of such a variable, call the get() method on it, and to change its value you call the set() method. If you follow this protocol, the widget will always track the value of the variable, with no further intervention on your part.

For example:

class App(Frame):
    def __init__(self, master=None):
        super().__init__(master)
        self.pack()

        self.entrythingy = Entry()
        self.entrythingy.pack()

        # here is the application variable
        self.contents = StringVar()
        # set it to some value
        self.contents.set("this is a variable")
        # tell the entry widget to watch this variable
        self.entrythingy["textvariable"] = self.contents

        # and here we get a callback when the user hits return
        # we will have the program print out the value of the application variable when the user hits return
        self.entrythingy.bind('<Key-Return>',
            self.print_contents)

    def print_contents(self, event):

25.1.6.5. The Window Manager

In Tk, there is a utility command, `wm`, for interacting with the window manager. Options to the `wm` command allow you to control things like titles, placement, icon bitmaps, and the like. In `tkinter`, these commands have been implemented as methods on the `Wm` class. Toplevel widgets are subclassed from the `Wm` class, and so can call the `Wm` methods directly.

To get at the toplevel window that contains a given widget, you can often just refer to the widget's master. Of course if the widget has been packed inside of a frame, the master won't represent a toplevel window. To get at the toplevel window that contains an arbitrary widget, you can call the `_root()` method. This method begins with an underscore to denote the fact that this function is part of the implementation, and not an interface to Tk functionality.

Here are some examples of typical usage:

```python
import tkinter as tk

class App(tk.Frame):
    def __init__(self, master=None):
        super().__init__(master)
        self.pack()

# create the application
myapp = App()
```
# here are method calls to the window manager class
#
myapp.master.title("My Do-Nothing Application")
myapp.master.maxsize(1000, 400)

# start the program
myapp.mainloop()

25.1.6.6. Tk Option Data Types

anchor
Legal values are points of the compass: "n", "ne", "e", "se", "s", "sw", "w", "nw", and also "center".

bitmap
There are eight built-in, named bitmaps: 'error', 'gray25', 'gray50', 'hourglass', 'info', 'questhead', 'question', 'warning'. To specify an X bitmap filename, give the full path to the file, preceded with an @, as in "@/usr/contrib(bitmap/gumby.bit".

boolean
You can pass integers 0 or 1 or the strings "yes" or "no".

callback
This is any Python function that takes no arguments. For example:

```
def print_it():
    print("hi there")
    fred["command"] = print_it
```

color
Colors can be given as the names of X colors in the rgb.txt file, or as strings representing RGB values in 4 bit: "#RGB", 8 bit: "#RRGGBB", 12 bit "#RRRGGGBBB", or 16 bit

cursor
The standard X cursor names from cursorfont.h can be used, without the XC_ prefix. For example to get a hand cursor (XC_hand2), use the string "hand2". You can also specify a bitmap and mask file of your own. See page 179 of Ousterhout's book.

distance
Screen distances can be specified in either pixels or absolute distances. Pixels are given as numbers and absolute distances as strings, with the trailing character denoting units: c for centimetres, i for inches, m for millimetres, p for printer's points. For example, 3.5 inches is expressed as "3.5i".

font
Tk uses a list font name format, such as {courier 10 bold}. Font sizes with positive numbers are measured in points; sizes with negative numbers are measured in pixels.

geometry
This is a string of the form widthxheight, where width and height are measured in pixels for most widgets (in characters for widgets displaying text). For example: fred["geometry"] = "200x100".

justify
Legal values are the strings: "left", "center", "right", and "fill".

region
This is a string with four space-delimited elements, each of which is a legal distance (see above). For example: "2 3 4 5" and "3i 2i 4.5i 2i" and "3c 2c 4c 10.43c" are all legal regions.
relief
Determine what the border style of a widget will be. Legal values are: "raised", "sunken", "flat", "groove", and "ridge".

scrollcommand
This is almost always the set() method of some scrollbar widget, but can be any widget method that takes a single argument.

wrap:
Must be one of: "none", "char", or "word".

25.1.6.7. Bindings and Events

The bind method from the widget command allows you to watch for certain events and to have a callback function trigger when that event type occurs. The form of the bind method is:

```python
def bind(self, sequence, func, add=' '):
```

where:

sequence
is a string that denotes the target kind of event. (See the bind man page and page 201 of John Ousterhout’s book for details).

func
is a Python function, taking one argument, to be invoked when the event occurs. An Event instance will be passed as the argument. (Functions deployed this way are commonly known as callbacks.)

add
is optional, either '' or '+'. Passing an empty string denotes that this binding is to replace any other bindings that this event is associated with. Passing a '+' means that this function is to be added to the list of functions bound to this event type.
def turn_red(self, event):
    event.widget["activeforeground"] = "red"

self.button.bind("<Enter>", self.turn_red)

Notice how the widget field of the event is being accessed in the `turn_red()` callback. This field contains the widget that caught the X event. The following table lists the other event fields you can access, and how they are denoted in Tk, which can be useful when referring to the Tk man pages.

<table>
<thead>
<tr>
<th>Tk</th>
<th>Tkinter Event Field</th>
<th>Tk</th>
<th>Tkinter Event Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>%f</td>
<td>focus</td>
<td>%A</td>
<td>char</td>
</tr>
<tr>
<td>%h</td>
<td>height</td>
<td>%E</td>
<td>send_event</td>
</tr>
<tr>
<td>%k</td>
<td>keycode</td>
<td>%K</td>
<td>keysym</td>
</tr>
<tr>
<td>%s</td>
<td>state</td>
<td>%N</td>
<td>keysym_num</td>
</tr>
<tr>
<td>%t</td>
<td>time</td>
<td>%T</td>
<td>type</td>
</tr>
<tr>
<td>%w</td>
<td>width</td>
<td>%W</td>
<td>widget</td>
</tr>
<tr>
<td>%x</td>
<td>x</td>
<td>%X</td>
<td>x_root</td>
</tr>
<tr>
<td>%y</td>
<td>y</td>
<td>%Y</td>
<td>y_root</td>
</tr>
</tbody>
</table>

25.1.6.8. The index Parameter

A number of widgets require “index” parameters to be passed. These are used to point at a specific place in a Text widget, or to particular characters in an Entry widget, or to particular menu items in a Menu widget.

Entry widget indexes (index, view index, etc.)
Entry widgets have options that refer to character positions in the text being displayed. You can use these tkinter functions to access these special points in text widgets:

Text widget indexes

The index notation for Text widgets is very rich and is best described in the Tk man pages.

Menu indexes (menu.invoke(), menu.entryconfig(), etc.)

Some options and methods for menus manipulate specific menu entries. Anytime a menu index is needed for an option or a parameter, you may pass in:

- an integer which refers to the numeric position of the entry in the widget, counted from the top, starting with 0;
- the string "active", which refers to the menu position that is currently under the cursor;
- the string "last" which refers to the last menu item;
- An integer preceded by @, as in @6, where the integer is interpreted as a y pixel coordinate in the menu's coordinate system;
- the string "none", which indicates no menu entry at all, most often used with menu.activate() to deactivate all entries, and finally,
- a text string that is pattern matched against the label of the menu entry, as scanned from the top of the menu to the bottom. Note that this index type is considered after all the others, which means that matches for menu items labelled last, active, or none may be interpreted as the above literals, instead.

25.1.6.9. Images

Bitmap/Pixelmap images can be created through the subclasses of
tkinter.Image:

- BitmapImage can be used for X11 bitmap data.
- PhotoImage can be used for GIF and PPM/PGM color bitmaps.

Either type of image is created through either the `file` or the `data` option (other options are available as well).

The image object can then be used wherever an `image` option is supported by some widget (e.g. labels, buttons, menus). In these cases, Tk will not keep a reference to the image. When the last Python reference to the image object is deleted, the image data is deleted as well, and Tk will display an empty box wherever the image was used.
25.1.7. File Handlers

Tk allows you to register and unregister a callback function which will be called from the Tk mainloop when I/O is possible on a file descriptor. Only one handler may be registered per file descriptor. Example code:

```python
import tkinter
widget = tkinter.Tk()
mask = tkinter.READABLE | tkinter.WRITABLE
widget.tk.createfilehandler(file, mask, callback)
...
widget.tk.deletefilehandler(file)
```

This feature is not available on Windows.

Since you don’t know how many bytes are available for reading, you may not want to use the `BufferedIOBase` or `TextIOBase` `read()` or `readline()` methods, since these will insist on reading a predefined number of bytes. For sockets, the `recv()` or `recvfrom()` methods will work fine; for other files, use raw reads or `os.read(file.fileno(), maxbytecount)`.

`Widget.tk.createfilehandler(file, mask, func)`

Registers the file handler callback function `func`. The `file` argument may either be an object with a `fileno()` method (such as a file or socket object), or an integer file descriptor. The `mask` argument is an ORed combination of any of the three constants below. The callback is called as follows:

`callback(file, mask)`
Widget.tk. **deletefilehandler**(*file*)

Unregisters a file handler.

tkinter. **READABLE**
tkinter. **WRITABLE**
tkinter. **EXCEPTION**

Constants used in the *mask* arguments.
25.2. **tkinter.ttk** — Tk themed widgets

Source code: Lib/tkinter/ttk.py

The `tkinter.ttk` module provides access to the Tk themed widget set, introduced in Tk 8.5. If Python has not been compiled against Tk 8.5, this module can still be accessed if `Tile` has been installed. The former method using Tk 8.5 provides additional benefits including anti-aliased font rendering under X11 and window transparency (requiring a composition window manager on X11).

The basic idea for `tkinter.ttk` is to separate, to the extent possible, the code implementing a widget's behavior from the code implementing its appearance.

See also:

Tk Widget Styling Support

A document introducing theming support for Tk
25.2.1. Using Ttk

To start using Ttk, import its module:

```python
from tkinter import ttk
```

To override the basic Tk widgets, the import should follow the Tk import:

```python
from tkinter import *
from tkinter.ttk import *
```

That code causes several `tkinter.ttk` widgets (Button, Checkbutton, Entry, Frame, Label, LabelFrame, Menubutton, PanedWindow, Radiobutton, Scale and Scrollbar) to automatically replace the Tk widgets.

This has the direct benefit of using the new widgets which gives a better look and feel across platforms; however, the replacement widgets are not completely compatible. The main difference is that widget options such as “fg”, “bg” and others related to widget styling are no longer present in Ttk widgets. Instead, use the `ttk.Style` class for improved styling effects.

See also:

**Converting existing applications to use Tile widgets**

A monograph (using Tcl terminology) about differences typically encountered when moving applications to use the new widgets.
25.2.2. Ttk Widgets

Ttk comes with 17 widgets, eleven of which already existed in tkinter: Button, Checkbutton, Entry, Frame, Label, LabelFrame, Menubutton, PanedWindow, Radiobutton, Scale and Scrollbar. The other six are new: Combobox, Notebook, Progressbar, Separator, Sizegrip and Treeview. And all them are subclasses of Widget.

Using the Ttk widgets gives the application an improved look and feel. As discussed above, there are differences in how the styling is coded.

Tk code:

```python
l1 = tkinter.Label(text="Test", fg="black", bg="white")
l2 = tkinter.Label(text="Test", fg="black", bg="white")
```

Ttk code:

```python
style = ttk.Style()
style.configure("BW.TLabel", foreground="black", background="white")
l1 = ttk.Label(text="Test", style="BW.TLabel")
l2 = ttk.Label(text="Test", style="BW.TLabel")
```

For more information about TtkStyling, see the Style class documentation.
25.2.3. Widget

ttk.Widget defines standard options and methods supported by Tk themed widgets and is not supposed to be directly instantiated.

25.2.3.1. Standard Options

All the ttk Widgets accepts the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td>Specifies the window class. The class is used when querying the option database for the window's other options, to determine the default bindtags for the window, and to select the widget's default layout and style. This option is read-only, and may only be specified when the window is created.</td>
</tr>
<tr>
<td>cursor</td>
<td>Specifies the mouse cursor to be used for the widget. If set to the empty string (the default), the cursor is inherited for the parent widget.</td>
</tr>
<tr>
<td>takefocus</td>
<td>Determines whether the window accepts the focus during keyboard traversal. 0, 1 or an empty string is returned. If 0 is returned, it means that the window should be skipped entirely during keyboard traversal. If 1, it means that the window should receive the input focus as long as it is viewable. And an empty string means that the traversal scripts make the decision about whether or not to focus on the window.</td>
</tr>
<tr>
<td>style</td>
<td>May be used to specify a custom widget style.</td>
</tr>
</tbody>
</table>

25.2.3.2. Scrollable Widget Options
The following options are supported by widgets that are controlled by a scrollbar.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xscrollcommand</td>
<td>Used to communicate with horizontal scrollbars. When the view in the widget's window change, the widget will generate a Tcl command based on the scrollcommand. Usually this option consists of the method Scrollbar.set() of some scrollbar. This will cause the scrollbar to be updated whenever the view in the window changes.</td>
</tr>
<tr>
<td>yscrollcommand</td>
<td>Used to communicate with vertical scrollbars. For some more information, see above.</td>
</tr>
</tbody>
</table>

25.2.3.3. Label Options

The following options are supported by labels, buttons and other button-like widgets.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>Specifies a text string to be displayed inside the widget.</td>
</tr>
<tr>
<td>textvariable</td>
<td>Specifies a name whose value will be used in place of the text option resource.</td>
</tr>
<tr>
<td>underline</td>
<td>If set, specifies the index (0-based) of a character to underline in the text string. The underline</td>
</tr>
</tbody>
</table>
character is used for mnemonic activation.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>image</td>
<td>Specifies an image to display. This is a list of 1 or more elements. The first element is the default image name. The rest of the list if a sequence of statespec/value pairs as defined by <code>Style.map()</code>, specifying different images to use when the widget is in a particular state or a combination of states. All images in the list should have the same size.</td>
</tr>
<tr>
<td>compound</td>
<td>Specifies how to display the image relative to the text, in the case both text and images options are present. Valid values are:</td>
</tr>
<tr>
<td></td>
<td>- text: display text only</td>
</tr>
<tr>
<td></td>
<td>- image: display image only</td>
</tr>
<tr>
<td></td>
<td>- top, bottom, left, right: display image above, below, left of, or right of the text, respectively.</td>
</tr>
<tr>
<td></td>
<td>- none: the default. display the image if present, otherwise the text.</td>
</tr>
<tr>
<td>width</td>
<td>If greater than zero, specifies how much space, in character widths, to allocate for the text label, if less than zero, specifies a minimum width. If zero or unspecified, the natural width of the text label is used.</td>
</tr>
</tbody>
</table>

25.2.3.4. Compatibility Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>state</td>
<td>May be set to “normal” or “disabled” to control the “disabled” state bit. This is a write-only option: setting it changes the widget state, but the <code>Widget.state()</code> method does not affect this option.</td>
</tr>
</tbody>
</table>
25.2.3.5. Widget States

The widget state is a bitmap of independent state flags.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>The mouse cursor is over the widget and pressing a mouse button will cause some action to occur</td>
</tr>
<tr>
<td>disabled</td>
<td>Widget is disabled under program control</td>
</tr>
<tr>
<td>focus</td>
<td>Widget has keyboard focus</td>
</tr>
<tr>
<td>pressed</td>
<td>Widget is being pressed</td>
</tr>
<tr>
<td>selected</td>
<td>“On”, “true”, or “current” for things like Checkbuttons and radiobuttons</td>
</tr>
<tr>
<td>background</td>
<td>Windows and Mac have a notion of an “active” or foreground window. The background state is set for widgets in a background window, and cleared for those in the foreground window</td>
</tr>
<tr>
<td>readonly</td>
<td>Widget should not allow user modification</td>
</tr>
<tr>
<td>alternate</td>
<td>A widget-specific alternate display format</td>
</tr>
<tr>
<td>invalid</td>
<td>The widget’s value is invalid</td>
</tr>
</tbody>
</table>

A state specification is a sequence of state names, optionally prefixed with an exclamation point indicating that the bit is off.

25.2.3.6. ttk.Widget

Besides the methods described below, the ttk.Widget supports the methods `tkinter.Widget.cget()` and `tkinter.Widget.configure()`.
class tkinter.ttk.Widget

identify(x, y)
  Returns the name of the element at position x, y, or the empty string if the point does not lie within any element.

  x and y are pixel coordinates relative to the widget.

instate(statespec, callback=callback, *args, **kw)
  Test the widget's state. If a callback is not specified, returns True if the widget state matches statespec and False otherwise. If callback is specified then it is called with args if widget state matches statespec.

state(statespec=None)
  Modify or inquire widget state. If statespec is specified, sets the widget state according to it and return a new statespec indicating which flags were changed. If statespec is not specified, returns the currently-enabled state flags.

statespec will usually be a list or a tuple.
25.2.4. Combobox

The `ttk.Combobox` widget combines a text field with a pop-down list of values. This widget is a subclass of `Entry`.

Besides the methods inherited from `Widget`: `Widget.cget()`, `Widget.configure()`, `Widget.identify()`, `Widget.instate()` and `Widget.state()`, and the following inherited from `Entry`: `Entry.bbox()`, `Entry.delete()`, `Entry.icursor()`, `Entry.index()`, `Entry.insert()`, `Entry.selection()`, `Entry.xview()`, it has some other methods, described at `ttk.Combobox`.

25.2.4.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>exportselection</code></td>
<td>Boolean value. If set, the widget selection is linked to the Window Manager selection (which can be returned by invoking Misc.selection_get, for example).</td>
</tr>
<tr>
<td><code>justify</code></td>
<td>Specifies how the text is aligned within the widget. One of “left”, “center”, or “right”.</td>
</tr>
<tr>
<td><code>height</code></td>
<td>Specifies the height of the pop-down listbox, in rows.</td>
</tr>
<tr>
<td><code>postcommand</code></td>
<td>A script (possibly registered with Misc.register) that is called immediately before displaying the values. It may specify which values to display.</td>
</tr>
<tr>
<td>state</td>
<td>One of “normal”, “readonly”, or “disabled”. In the “readonly” state, the value may not be edited directly, and the user can only selection of the values from the dropdown list. In the “normal” state, the text field is directly editable. In the “disabled” state, no interaction is possible.</td>
</tr>
<tr>
<td>textvariable</td>
<td>Specifies a name whose value is linked to the widget value. Whenever the value associated with that name changes, the widget value is updated, and vice versa. See tkinter.StringVar.</td>
</tr>
<tr>
<td>values</td>
<td>Specifies the list of values to display in the drop-down listbox.</td>
</tr>
<tr>
<td>width</td>
<td>Specifies an integer value indicating the desired width of the entry window, in average-size characters of the widget’s font.</td>
</tr>
</tbody>
</table>

25.2.4.2. Virtual events

The combobox widgets generates a <<ComboboxSelected>> virtual event when the user selects an element from the list of values.

25.2.4.3. ttk.Combobox

class tkinter.ttk.Combobox
current(newindex=None)

If newindex is specified, sets the combobox value to the element position newindex. Otherwise, returns the index of the current value or -1 if the current value is not in the values list.

get()

Returns the current value of the combobox.
**set**(*value*)

Sets the value of the combobox to *value*. 
25.2.5. Notebook

Ttk Notebook widget manages a collection of windows and displays a single one at a time. Each child window is associated with a tab, which the user may select to change the currently-displayed window.

25.2.5.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>height</td>
<td>If present and greater than zero, specifies the desired height of the pane area (not including internal padding or tabs). Otherwise, the maximum height of all panes is used.</td>
</tr>
<tr>
<td>padding</td>
<td>Specifies the amount of extra space to add around the outside of the notebook. The padding is a list up to four length specifications left top right bottom. If fewer than four elements are specified, bottom defaults to top, right defaults to left, and top defaults to left.</td>
</tr>
<tr>
<td>width</td>
<td>If present and greater than zero, specified the desired width of the pane area (not including internal padding). Otherwise, the maximum width of all panes is used.</td>
</tr>
</tbody>
</table>

25.2.5.2. Tab Options

There are also specific options for tabs:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>state</td>
<td>Either “normal”, “disabled” or “hidden”. If “disabled”, then the tab is not selectable. If “hidden”, then the tab is not shown.</td>
</tr>
<tr>
<td>-----------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sticky</td>
<td>Specifies how the child window is positioned within the pane area. Value is a string containing zero or more of the characters “n”, “s”, “e” or “w”. Each letter refers to a side (north, south, east or west) that the child window will stick to, as per the grid() geometry manager.</td>
</tr>
<tr>
<td>padding</td>
<td>Specifies the amount of extra space to add between the notebook and this pane. Syntax is the same as for the option padding used by this widget.</td>
</tr>
<tr>
<td>text</td>
<td>Specifies a text to be displayed in the tab.</td>
</tr>
<tr>
<td>image</td>
<td>Specifies an image to display in the tab. See the option image described in Widget.</td>
</tr>
<tr>
<td>compound</td>
<td>Specifies how to display the image relative to the text, in the case both options text and image are present. See Label Options for legal values.</td>
</tr>
<tr>
<td>underline</td>
<td>Specifies the index (0-based) of a character to underline in the text string. The underlined character is used for mnemonic activation if Notebook.enable_traversal() is called.</td>
</tr>
</tbody>
</table>

25.2.5.3. Tab Identifiers

The tab_id present in several methods of ttk.Notebook may take any of the following forms:

- An integer between zero and the number of tabs
- The name of a child window
- A positional specification of the form “@x,y”, which identifies the tab
- The literal string “current”, which identifies the currently-selected tab
- The literal string “end”, which returns the number of tabs (only valid for Notebook.index( ))

25.2.5.4. Virtual Events

This widget generates a «NotebookTabChanged>> virtual event after a new tab is selected.

25.2.5.5. ttk.Notebook

```python
class tkinter.ttk.Notebook
    add(child, **kw)
        Adds a new tab to the notebook.

        If window is currently managed by the notebook but hidden, it is restored to its previous position.

        See Tab Options for the list of available options.

    forget(tab_id)
        Removes the tab specified by tab_id, unmaps and unmanages the associated window.

    hide(tab_id)
        Hides the tab specified by tab_id.

        The tab will not be displayed, but the associated window remains managed by the notebook and its configuration remembered. Hidden tabs may be restored with the add() command.
```
**identify**

Returns the name of the tab element at position \( x, y \), or the empty string if none.

**index**

Returns the numeric index of the tab specified by \( \text{tab\_id} \), or the total number of tabs if \( \text{tab\_id} \) is the string “end”.

**insert**

Inserts a pane at the specified position.

\( pos \) is either the string “end”, an integer index, or the name of a managed child. If \( child \) is already managed by the notebook, moves it to the specified position.

See **Tab Options** for the list of available options.

**select**

Selects the specified \( \text{tab\_id} \).

The associated child window will be displayed, and the previously-selected window (if different) is unmapped. If \( \text{tab\_id} \) is omitted, returns the widget name of the currently selected pane.

**tab**

Query or modify the options of the specific \( \text{tab\_id} \).

If \( kw \) is not given, returns a dictionary of the tab option values. If \( option \) is specified, returns the value of that \( option \). Otherwise, sets the options to the corresponding values.

**tabs**
Returns a list of windows managed by the notebook.

**enable_traversal()**

Enable keyboard traversal for a toplevel window containing this notebook.

This will extend the bindings for the toplevel window containing the notebook as follows:

- **Control-Tab**: selects the tab following the currently selected one.
- **Shift-Control-Tab**: selects the tab preceding the currently selected one.
- **Alt-K**: where K is the mnemonic (underlined) character of any tab, will select that tab.

Multiple notebooks in a single toplevel may be enabled for traversal, including nested notebooks. However, notebook traversal only works properly if all panes have the notebook they are in as master.
25.2.6. Progressbar

The ttk.Progressbar widget shows the status of a long-running operation. It can operate in two modes: 1) the determinate mode which shows the amount completed relative to the total amount of work to be done and 2) the indeterminate mode which provides an animated display to let the user know that work is progressing.

25.2.6.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orient</td>
<td>One of “horizontal” or “vertical”. Specifies the orientation of the progress bar.</td>
</tr>
<tr>
<td>length</td>
<td>Specifies the length of the long axis of the progress bar (width if horizontal, height if vertical).</td>
</tr>
<tr>
<td>mode</td>
<td>One of “determinate” or “indeterminate”.</td>
</tr>
<tr>
<td>maximum</td>
<td>A number specifying the maximum value. Defaults to 100.</td>
</tr>
<tr>
<td>value</td>
<td>The current value of the progress bar. In “determinate” mode, this represents the amount of work completed. In “indeterminate” mode, it is interpreted as modulo maximum; that is, the progress bar completes one “cycle” when its value increases by maximum.</td>
</tr>
<tr>
<td>variable</td>
<td>A name which is linked to the option value. If specified, the value of the progress bar is automatically set to the value of this name whenever the latter is modified.</td>
</tr>
<tr>
<td></td>
<td>Read-only option. The widget periodically</td>
</tr>
</tbody>
</table>
phase | increments the value of this option whenever its value is greater than 0 and, in determinate mode, less than maximum. This option may be used by the current theme to provide additional animation effects.

25.2.6.2. ttk.Progressbar

class tkinter.ttk.Progressbar

    start(interval=None)
    
    Begin autoincrement mode: schedules a recurring timer event that calls Progressbar.step() every interval milliseconds. If omitted, interval defaults to 50 milliseconds.

    step(amount=None)
    
    Increments the progress bar’s value by amount.

    amount defaults to 1.0 if omitted.

    stop()
    
    Stop autoincrement mode: cancels any recurring timer event initiated by Progressbar.start() for this progress bar.
25.2.7. Separator

The `ttk.Separator` widget displays a horizontal or vertical separator bar.

It has no other methods besides the ones inherited from `ttk.Widget`.

25.2.7.1. Options

This widget accepts the following specific option:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orient</td>
<td>One of “horizontal” or “vertical”. Specifies the orientation of the separator.</td>
</tr>
</tbody>
</table>
25.2.8. Sizegrip

The ttk.Sizegrip widget (also known as a grow box) allows the user to resize the containing toplevel window by pressing and dragging the grip.

This widget has neither specific options nor specific methods, besides the ones inherited from ttk.Widget.

25.2.8.1. Platform-specific notes

- On MacOS X, toplevel windows automatically include a built-in size grip by default. Adding a Sizegrip is harmless, since the built-in grip will just mask the widget.

25.2.8.2. Bugs

- If the containing toplevel’s position was specified relative to the right or bottom of the screen (e.g. ….), the Sizegrip widget will not resize the window.
- This widget supports only “southeast” resizing.
25.2.9. Treeview

The ttk.Treeview widget displays a hierarchical collection of items. Each item has a textual label, an optional image, and an optional list of data values. The data values are displayed in successive columns after the tree label.

The order in which data values are displayed may be controlled by setting the widget option `displaycolumns`. The tree widget can also display column headings. Columns may be accessed by number or symbolic names listed in the widget option columns. See Column Identifiers.

Each item is identified by a unique name. The widget will generate item IDs if they are not supplied by the caller. There is a distinguished root item, named `{}`. The root item itself is not displayed; its children appear at the top level of the hierarchy.

Each item also has a list of tags, which can be used to associate event bindings with individual items and control the appearance of the item.

The Treeview widget supports horizontal and vertical scrolling, according to the options described in Scrollable Widget Options and the methods Treeview.xview() and Treeview.yview().

25.2.9.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns</td>
<td>A list of column identifiers, specifying the number of columns and their names.</td>
</tr>
<tr>
<td><strong>displaycolumns</strong></td>
<td>A list of column identifiers (either symbolic or integer indices) specifying which data columns are displayed and the order in which they appear, or the string “#all”.</td>
</tr>
<tr>
<td><strong>height</strong></td>
<td>Specifies the number of rows which should be visible. Note: the requested width is determined from the sum of the column widths.</td>
</tr>
<tr>
<td><strong>padding</strong></td>
<td>Specifies the internal padding for the widget. The padding is a list of up to four length specifications.</td>
</tr>
<tr>
<td><strong>selectmode</strong></td>
<td>Controls how the built-in class bindings manage the selection. One of “extended”, “browse” or “none”. If set to “extended” (the default), multiple items may be selected. If “browse”, only a single item will be selected at a time. If “none”, the selection will not be changed. Note that the application code and tag bindings can set the selection however they wish, regardless of the value of this option.</td>
</tr>
<tr>
<td><strong>show</strong></td>
<td>A list containing zero or more of the following values, specifying which elements of the tree to display.</td>
</tr>
<tr>
<td></td>
<td>- tree: display tree labels in column #0.</td>
</tr>
<tr>
<td></td>
<td>- headings: display the heading row.</td>
</tr>
<tr>
<td></td>
<td>The default is “tree headings”, i.e., show all elements.</td>
</tr>
</tbody>
</table>
Note: Column #0 always refers to the tree column, even if show="tree" is not specified.

25.2.9.2. Item Options

The following item options may be specified for items in the insert and item widget commands.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>The textual label to display for the item.</td>
</tr>
<tr>
<td>image</td>
<td>A Tk Image, displayed to the left of the label.</td>
</tr>
<tr>
<td>values</td>
<td>The list of values associated with the item. Each item should have the same number of values as the widget option columns. If there are fewer values than columns, the remaining values are assumed empty. If there are more values than columns, the extra values are ignored.</td>
</tr>
<tr>
<td>open</td>
<td>True/False value indicating whether the item's children should be displayed or hidden.</td>
</tr>
<tr>
<td>tags</td>
<td>A list of tags associated with this item.</td>
</tr>
</tbody>
</table>

25.2.9.3. Tag Options

The following options may be specified on tags:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreground</td>
<td>Specifies the text foreground color.</td>
</tr>
<tr>
<td>background</td>
<td>Specifies the cell or item background color.</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>font</td>
<td>Specifies the font to use when drawing text.</td>
</tr>
<tr>
<td>image</td>
<td>Specifies the item image, in case the item’s image option is empty.</td>
</tr>
</tbody>
</table>

### 25.2.9.4. Column Identifiers

Column identifiers take any of the following forms:

- A symbolic name from the list of columns option.
- An integer \( n \), specifying the \( n \)th data column.
- A string of the form \(#n\) where \( n \) is an integer, specifying the \( n \)th display column.

**Notes:**

- Item’s option values may be displayed in a different order than the order in which they are stored.
- Column \#0 always refers to the tree column, even if show="tree" is not specified.

A data column number is an index into an item’s option values list; a display column number is the column number in the tree where the values are displayed. Tree labels are displayed in column \#0. If option displaycolumns is not set, then data column \( n \) is displayed in column \#n+1. Again, **column \#0 always refers to the tree column.**

### 25.2.9.5. Virtual Events

The Treeview widget generates the following virtual events.

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
</table>

Generated whenever the selection changes.

Generated just before settings the focus item to open=True.

Generated just after setting the focus item to open=False.

The `Treeview.focus()` and `Treeview.selection()` methods can be used to determine the affected item or items.

### 25.2.9.6. ttk.Treeview

```python
class tkinter.ttk.Treeview
    bbox(item, column=None)
    Returns the bounding box (relative to the treeview widget's window) of the specified item in the form (x, y, width, height).

    If column is specified, returns the bounding box of that cell. If the item is not visible (i.e., if it is a descendant of a closed item or is scrolled offscreen), returns an empty string.

    get_children(item=None)
    Returns the list of children belonging to item.

    If item is not specified, returns root children.

    set_children(item, *newchildren)
    Replaces item's child with newchildren.

    Children present in item that are not present in newchildren are detached from the tree. No items in newchildren may be an ancestor of item. Note that not specifying newchildren results in
detaching item’s children.

**column**(column, option=None, **kw)

Query or modify the options for the specified column.

If kw is not given, returns a dict of the column option values. If option is specified then the value for that option is returned. Otherwise, sets the options to the corresponding values.

The valid options/values are:

- id
  Returns the column name. This is a read-only option.

- anchor: One of the standard Tk anchor values.
  Specifies how the text in this column should be aligned with respect to the cell.

- minwidth: width
  The minimum width of the column in pixels. The treeview widget will not make the column any smaller than specified by this option when the widget is resized or the user drags a column.

- stretch: True/False
  Specifies whether the column’s width should be adjusted when the widget is resized.

- width: width
  The width of the column in pixels.

To configure the tree column, call this with column = “#0"

**delete**(items)

Delete all specified items and all their descendants.
The root item may not be deleted.

**detach(*items)**
Unlinks all of the specified *items* from the tree.

The items and all of their descendants are still present, and may be reinserted at another point in the tree, but will not be displayed.

The root item may not be detached.

**exists(*item)**
Returns True if the specified *item* is present in the tree.

**focus(*item=None)**
If *item* is specified, sets the focus item to *item*. Otherwise, returns the current focus item, or "" if there is none.

**heading(*column, option=None, **kw)**
Query or modify the heading options for the specified *column*.

If *kw* is not given, returns a dict of the heading option values. If *option* is specified then the value for that *option* is returned. Otherwise, sets the options to the corresponding values.

The valid options/values are:

- **text**: text
  The text to display in the column heading.

- **image**: imageName
  Specifies an image to display to the right of the column heading.

- **anchor**: anchor
Specifies how the heading text should be aligned. One of the standard Tk anchor values.

- command: callback
  A callback to be invoked when the heading label is pressed.

To configure the tree column heading, call this with column = “#0”.

**identify**(component, x, y)
Returns a description of the specified component under the point given by x and y, or the empty string if no such component is present at that position.

**identify_row**(y)
Returns the item ID of the item at position y.

**identify_column**(x)
Returns the data column identifier of the cell at position x.

The tree column has ID #0.

**identify_region**(x, y)
Returns one of:

<table>
<thead>
<tr>
<th>region</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>heading</td>
<td>Tree heading area.</td>
</tr>
<tr>
<td>separator</td>
<td>Space between two columns headings.</td>
</tr>
<tr>
<td>tree</td>
<td>The tree area.</td>
</tr>
<tr>
<td>cell</td>
<td>A data cell.</td>
</tr>
</tbody>
</table>

Availability: Tk 8.6.
**identify_element**(x, y)

Returns the element at position x, y.

Availability: Tk 8.6.

**index**(item)

Returns the integer index of item within its parent's list of children.

**insert**(parent, index, iid=None, **kw)

Creates a new item and returns the item identifier of the newly created item.

*parent* is the item ID of the parent item, or the empty string to create a new top-level item. *index* is an integer, or the value “end”, specifying where in the list of parent’s children to insert the new item. If *index* is less than or equal to zero, the new node is inserted at the beginning; if *index* is greater than or equal to the current number of children, it is inserted at the end. If *iid* is specified, it is used as the item identifier; *iid* must not already exist in the tree. Otherwise, a new unique identifier is generated.

See Item Options for the list of available points.

**item**(item, option=None, **kw)

Query or modify the options for the specified item.

If no options are given, a dict with options/values for the item is returned. If *option* is specified then the value for that option is returned. Otherwise, sets the options to the corresponding values as given by *kw*. 
**move**(item, parent, index)
Moves item to position index in parent’s list of children.

It is illegal to move an item under one of its descendants. If index is less than or equal to zero, item is moved to the beginning; if greater than or equal to the number of children, it is moved to the end. If item was detached it is reattached.

**next**(item)
Returns the identifier of item's next sibling, or '' if item is the last child of its parent.

**parent**(item)
Returns the ID of the parent of item, or '' if item is at the top level of the hierarchy.

**prev**(item)
Returns the identifier of item's previous sibling, or '' if item is the first child of its parent.

**reattach**(item, parent, index)
An alias for Treeview.move().

**see**(item)
Ensure that item is visible.

Sets all of item’s ancestors open option to True, and scrolls the widget if necessary so that item is within the visible portion of the tree.

**selection**(selop=None, items=None)
If selop is not specified, returns selected items. Otherwise, it will act according to the following selection methods.
Deprecated since version 3.6, will be removed in version 3.8: Using `selection()` for changing the selection state is deprecated. Use the following selection methods instead.

**selection_set(**items**)

*items* becomes the new selection.

*Changed in version 3.6:* *items* can be passed as separate arguments, not just as a single tuple.

**selection_add(**items**)

Add *items* to the selection.

*Changed in version 3.6:* *items* can be passed as separate arguments, not just as a single tuple.

**selection_remove(**items**)

Remove *items* from the selection.

*Changed in version 3.6:* *items* can be passed as separate arguments, not just as a single tuple.

**selection_toggle(**items**)

Toggle the selection state of each item in *items*.

*Changed in version 3.6:* *items* can be passed as separate arguments, not just as a single tuple.

**set**(item, column=None, value=None)

With one argument, returns a dictionary of column/value pairs for the specified *item*. With two arguments, returns the current value of the specified *column*. With three arguments, sets the value of given *column* in given *item* to the specified *value*. 
tag_bind(tagname, sequence=None, callback=None)

Bind a callback for the given event sequence to the tag tagname. When an event is delivered to an item, the callbacks for each of the item’s tags option are called.

tag_configure(tagname, option=None, **kw)

Query or modify the options for the specified tagname. If kw is not given, returns a dict of the option settings for tagname. If option is specified, returns the value for that option for the specified tagname. Otherwise, sets the options to the corresponding values for the given tagname.

tag_has(tagname, item=None)

If item is specified, returns 1 or 0 depending on whether the specified item has the given tagname. Otherwise, returns a list of all items that have the specified tag.

Availability: Tk 8.6

xview(*args)

Query or modify horizontal position of the treeview.

yview(*args)

Query or modify vertical position of the treeview.
25.2.10. Ttk Styling

Each widget in ttk is assigned a style, which specifies the set of elements making up the widget and how they are arranged, along with dynamic and default settings for element options. By default the style name is the same as the widget's class name, but it may be overridden by the widget's style option. If you don't know the class name of a widget, use the method Misc.winfo_class() (somewidget.winfo_class()).

See also:

Tcl'2004 conference presentation
This document explains how the theme engine works

class tkinter.ttk.Style
This class is used to manipulate the style database.

configure(style, query_opt=None, **kw)
Query or set the default value of the specified option(s) in style.

Each key in kw is an option and each value is a string identifying the value for that option.

For example, to change every default button to be a flat button with some padding and a different background color:

```python
from tkinter import ttk
import tkinter

root = tkinter.Tk()
```
map(style, query_opt=None, **kw)
Query or sets dynamic values of the specified option(s) in style.

Each key in kw is an option and each value should be a list or a tuple (usually) containing statespecs grouped in tuples, lists, or some other preference. A statespec is a compound of one or more states and then a value.

An example may make it more understandable:

```python
import tkinter
from tkinter import ttk

root = tkinter.Tk()

style = ttk.Style()
style.map("C.TButton",
    foreground=[('pressed', 'red'), ('active',
    background=[('pressed', '!disabled', 'black')
]

colored_btn = ttk.Button(text="Test", style="C.
root.mainloop()
```

Note that the order of the (states, value) sequences for an
option does matter, if the order is changed to [('active', 'blue'), ('pressed', 'red')] in the foreground option, for example, the result would be a blue foreground when the widget were in active or pressed states.

**lookup(style, option, state=None, default=None)**

Returns the value specified for option in style.

If state is specified, it is expected to be a sequence of one or more states. If the default argument is set, it is used as a fallback value in case no specification for option is found.

To check what font a Button uses by default:

```python
from tkinter import ttk
print(ttk.Style().lookup("TButton", "font"))
```

**layout(style, layoutspec=None)**

Define the widget layout for given style. If layoutspec is omitted, return the layout specification for given style.

`layoutspec`, if specified, is expected to be a list or some other sequence type (excluding strings), where each item should be a tuple and the first item is the layout name and the second item should have the format described in Layouts.

To understand the format, see the following example (it is not intended to do anything useful):

```python
from tkinter import ttk
import tkinter

root = tkinter.Tk()
```
```python
style = ttk.Style()
style.layout("TMenubutton", [
    ("Menubutton.background", None),
    ("Menubutton.button", {"children":
        ["Menubutton.focus", {"children":
            ["Menubutton.padding", {"children":
                ["Menubutton.label", {"side": "
                    
                }]
            }
        ]
    }
],
])

mbtn = ttk.Menubutton(text='Text')
mbtn.pack()
root.mainloop()
```

**element_create(elementname, etype, *args, **kw)**

Create a new element in the current theme, of the given *etype* which is expected to be either “image”, “from” or “vsapi”. The latter is only available in Tk 8.6a for Windows XP and Vista and is not described here.

If “image” is used, *args should contain the default image name followed by statespec/value pairs (this is the imagespec), and **kw may have the following options:

- **border=padding**
  
  padding is a list of up to four integers, specifying the left, top, right, and bottom borders, respectively.

- **height=height**

  Specifies a minimum height for the element. If less than zero, the base image's height is used as a default.
- **padding=padding**
  Specifies the element’s interior padding. Defaults to border’s value if not specified.

- **sticky=spec**
  Specifies how the image is placed within the final parcel. spec contains zero or more characters “n”, “s”, “w”, or “e”.

- **width=width**
  Specifies a minimum width for the element. If less than zero, the base image’s width is used as a default.

If “from” is used as the value of etype, `element_create()` will clone an existing element. `args` is expected to contain a themename, from which the element will be cloned, and optionally an element to clone from. If this element to clone from is not specified, an empty element will be used. `kw` is discarded.

**element_names()**
Returns the list of elements defined in the current theme.

**element_options(elementname)**
Returns the list of elementname’s options.

**theme_create(themename, parent=None, settings=None)**
Create a new theme.

It is an error if themename already exists. If parent is specified, the new theme will inherit styles, elements and layouts from the parent theme. If settings are present they are expected to have the same syntax used for theme_settings().
theme_settings(themename, settings)

Temporarily sets the current theme to themename, apply specified settings and then restore the previous theme.

Each key in settings is a style and each value may contain the keys ‘configure’, ‘map’, ‘layout’ and ‘element create’ and they are expected to have the same format as specified by the methods Style.configure(), Style.map(), Style.layout() and Style.element_create() respectively.

As an example, let's change the Combobox for the default theme a bit:

```python
from tkinter import ttk
import tkinter

root = tkinter.Tk()

style = ttk.Style()
style.theme_settings("default", {
    "TCombobox": {
        "configure": {"padding": 5},
        "map": {
            "background": ["active", "green2"],
            "!disabled": "green4",
            "fieldbackground": ["!disabled", "grey800"],
            "foreground": ["focus", "OliveDrab1",
                            "!disabled", "OliveDrab1"]
        }
    }
})

combo = ttk.Combobox().pack()
```
theme_names()

Returns a list of all known themes.

theme_use(themename=None)

If themename is not given, returns the theme in use. Otherwise, sets the current theme to themename, refreshes all widgets and emits a <<ThemeChanged>> event.

25.2.10.1. Layouts

A layout can be just None, if it takes no options, or a dict of options specifying how to arrange the element. The layout mechanism uses a simplified version of the pack geometry manager: given an initial cavity, each element is allocated a parcel. Valid options/values are:

- side: whichside
  Specifies which side of the cavity to place the element; one of top, right, bottom or left. If omitted, the element occupies the entire cavity.

- sticky: nswe
  Specifies where the element is placed inside its allocated parcel.

- unit: 0 or 1
  If set to 1, causes the element and all of its descendants to be treated as a single element for the purposes of Widget.identify() et al. It's used for things like scrollbar thumbs with grips.

- children: [sublayout...]
Specifies a list of elements to place inside the element. Each element is a tuple (or other sequence type) where the first item is the layout name, and the other is a Layout.
25.3. `tkinter.tix` — Extension widgets for Tk

**Source code:** Lib/tkinter/tix.py

*Deprecated since version 3.6:* This Tk extension is unmaintained and should not be used in new code. Use `tkinter.ttk` instead.

The `tkinter.tix` (Tk Interface Extension) module provides an additional rich set of widgets. Although the standard Tk library has many useful widgets, they are far from complete. The `tkinter.tix` library provides most of the commonly needed widgets that are missing from standard Tk: `HList`, `ComboBox`, `Control` (a.k.a. `SpinBox`) and an assortment of scrollable widgets. `tkinter.tix` also includes many more widgets that are generally useful in a wide range of applications: `NoteBook`, `FileEntry`, `PanedWindow`, etc; there are more than 40 of them.

With all these new widgets, you can introduce new interaction techniques into applications, creating more useful and more intuitive user interfaces. You can design your application by choosing the most appropriate widgets to match the special needs of your application and users.

**See also:**

**Tix Homepage**

The home page for Tix. This includes links to additional documentation and downloads.
**Tix Man Pages**
On-line version of the man pages and reference material.

**Tix Programming Guide**
On-line version of the programmer’s reference material.

**Tix Development Applications**
Tix applications for development of Tix and Tkinter programs. Tide applications work under Tk or Tkinter, and include **TixInspect**, an inspector to remotely modify and debug Tix/Tk/Tkinter applications.
25.3.1. Using Tix

class tkinter.tix.Tk(screenName=None, baseName=None, className='Tix')

Toplevel widget of Tix which represents mostly the main window of an application. It has an associated Tcl interpreter.

Classes in the tkinter.tix module subclasses the classes in the tkinter. The former imports the latter, so to use tkinter.tix with Tkinter, all you need to do is to import one module. In general, you can just import tkinter.tix, and replace the toplevel call to tkinter.Tk with tix.Tk:

```
from tkinter import tix
from tkinter.constants import *
root = tix.Tk()
```

To use tkinter.tix, you must have the Tix widgets installed, usually alongside your installation of the Tk widgets. To test your installation, try the following:

```
from tkinter import tix
root = tix.Tk()
root.tk.eval('package require Tix')
```

If this fails, you have a Tk installation problem which must be resolved before proceeding. Use the environment variable TIX_LIBRARY to point to the installed Tix library directory, and make sure you have the dynamic object library (tix8183.dll or libtix8183.so) in the same directory that contains your Tk dynamic object library (tk8183.dll or libtk8183.so). The directory with the dynamic
object library should also have a file called `pkgIndex.tcl` (case sensitive), which contains the line:

```
package ifneeded Tix 8.1 [list load "[file join $dir tix8183.dll]"
```
25.3.2. Tix Widgets

Tix introduces over 40 widget classes to the tkinter repertoire.

25.3.2.1. Basic Widgets

class tkinter.tix.Balloon
  A Balloon that pops up over a widget to provide help. When the user moves the cursor inside a widget to which a Balloon widget has been bound, a small pop-up window with a descriptive message will be shown on the screen.

class tkinter.tix.ButtonBox
  The ButtonBox widget creates a box of buttons, such as is commonly used for Ok Cancel.

class tkinter.tix.ComboBox
  The ComboBox widget is similar to the combo box control in MS Windows. The user can select a choice by either typing in the entry subwidget or selecting from the listbox subwidget.

class tkinter.tix.Control
  The Control widget is also known as the SpinBox widget. The user can adjust the value by pressing the two arrow buttons or by entering the value directly into the entry. The new value will be checked against the user-defined upper and lower limits.

class tkinter.tix.LabelEntry
  The LabelEntry widget packages an entry widget and a label into one mega widget. It can be used to simplify the creation of “entry-form” type of interface.
class tkinter.tix.LabelFrame

The LabelFrame widget packages a frame widget and a label into one mega widget. To create widgets inside a LabelFrame widget, one creates the new widgets relative to the frame subwidget and manage them inside the frame subwidget.

class tkinter.tix.Meter

The Meter widget can be used to show the progress of a background job which may take a long time to execute.

class tkinter.tix.OptionMenu

The OptionMenu creates a menu button of options.

class tkinter.tix.PopupMenu

The PopupMenu widget can be used as a replacement of the tk_popup command. The advantage of the Tix PopupMenu widget is it requires less application code to manipulate.

class tkinter.tix.Select

The Select widget is a container of button subwidgets. It can be used to provide radio-box or check-box style of selection options for the user.

class tkinter.tix.StdButtonBox

The StdButtonBox widget is a group of standard buttons for Motif-like dialog boxes.

25.3.2.2. File Selectors

class tkinter.tix.DirList

The DirList widget displays a list view of a directory, its previous directories and its sub-directories. The user can choose one of the
directories displayed in the list or change to another directory.

*class* tkinter.tix.*DirTree*

The DirTree widget displays a tree view of a directory, its previous directories and its sub-directories. The user can choose one of the directories displayed in the list or change to another directory.

*class* tkinter.tix.*DirSelectDialog*

The DirSelectDialog widget presents the directories in the file system in a dialog window. The user can use this dialog window to navigate through the file system to select the desired directory.

*class* tkinter.tix.*DirSelectBox*

The DirSelectBox is similar to the standard Motif(TM) directory-selection box. It is generally used for the user to choose a directory. DirSelectBox stores the directories mostly recently selected into a ComboBox widget so that they can be quickly selected again.

*class* tkinter.tix.*ExFileSelectBox*

The ExFileSelectBox widget is usually embedded in a tixExFileSelectDialog widget. It provides a convenient method for the user to select files. The style of the ExFileSelectBox widget is very similar to the standard file dialog on MS Windows 3.1.

*class* tkinter.tix.*FileSelectBox*

The FileSelectBox is similar to the standard Motif(TM) file-selection box. It is generally used for the user to choose a file. FileSelectBox stores the files mostly recently selected into a ComboBox widget so that they can be quickly selected again.

*class* tkinter.tix.*FileEntry*

The FileEntry widget can be used to input a filename. The user can type in the filename manually. Alternatively, the user can press the
button widget that sits next to the entry, which will bring up a file selection dialog.

25.3.2.3. Hierarchical ListBox

class tkinter.tix.HList

The HList widget can be used to display any data that have a hierarchical structure, for example, file system directory trees. The list entries are indented and connected by branch lines according to their places in the hierarchy.

class tkinter.tix.CheckList

The CheckList widget displays a list of items to be selected by the user. CheckList acts similarly to the Tk checkbutton or radiobutton widgets, except it is capable of handling many more items than checkbuttons or radiobuttons.

class tkinter.tix.Tree

The Tree widget can be used to display hierarchical data in a tree form. The user can adjust the view of the tree by opening or closing parts of the tree.

25.3.2.4. Tabular ListBox

class tkinter.tix.TList

The TList widget can be used to display data in a tabular format. The list entries of a TList widget are similar to the entries in the Tk listbox widget. The main differences are (1) the TList widget can display the list entries in a two dimensional format and (2) you can use graphical images as well as multiple colors and fonts for the list entries.
25.3.2.5. Manager Widgets

`class tkinter.tix.PanedWindow`

The `PanedWindow` widget allows the user to interactively manipulate the sizes of several panes. The panes can be arranged either vertically or horizontally. The user changes the sizes of the panes by dragging the resize handle between two panes.

`class tkinter.tix.ListNoteBook`

The `ListNoteBook` widget is very similar to the TixNoteBook widget: it can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages (windows). At one time only one of these pages can be shown. The user can navigate through these pages by choosing the name of the desired page in the hlist subwidget.

`class tkinter.tix.NoteBook`

The `NoteBook` widget can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages. At one time only one of these pages can be shown. The user can navigate through these pages by choosing the visual “tabs” at the top of the NoteBook widget.

25.3.2.6. Image Types

The `tkinter.tix` module adds:

- `pixmap` capabilities to all `tkinter.tix` and `tkinter` widgets to create color images from XPM files.
- `Compound` image types can be used to create images that consists of multiple horizontal lines; each line is composed of a series of items (texts, bitmaps, images or spaces) arranged from
left to right. For example, a compound image can be used to display a bitmap and a text string simultaneously in a Tk Button widget.

25.3.2.7. Miscellaneous Widgets

class tkinter.tix.**InputOnly**

The **InputOnly** widgets are to accept inputs from the user, which can be done with the *bind* command (Unix only).

25.3.2.8. Form Geometry Manager

In addition, *tkinter.tix* augments *tkinter* by providing:

class tkinter.tix.**Form**

The **Form** geometry manager based on attachment rules for all Tk widgets.
25.3.3. Tix Commands

class tkinter.tix.tixCommand

The `tix commands` provide access to miscellaneous elements of Tix's internal state and the Tix application context. Most of the information manipulated by these methods pertains to the application as a whole, or to a screen or display, rather than to a particular window.

To view the current settings, the common usage is:

```python
from tkinter import tix
root = tix.Tk()
print(root.tix_configure())
```

tixCommand.tix_configure(cnf=None, **kw)

Query or modify the configuration options of the Tix application context. If no option is specified, returns a dictionary all of the available options. If option is specified with no value, then the method returns a list describing the one named option (this list will be identical to the corresponding sublist of the value returned if no option is specified). If one or more option-value pairs are specified, then the method modifies the given option(s) to have the given value(s); in this case the method returns an empty string. Option may be any of the configuration options.

tixCommand.tix_cget(option)

Returns the current value of the configuration option given by `option`. Option may be any of the configuration options.

tixCommand.tix_getbitmap(name)

Locates a bitmap file of the name `name.xpm` or `name` in one of the
bitmap directories (see the `tix_addbitmapdir()` method). By using `tix_getbitmap()`, you can avoid hard coding the pathnames of the bitmap files in your application. When successful, it returns the complete pathname of the bitmap file, prefixed with the character @. The returned value can be used to configure the bitmap option of the Tk and Tix widgets.

**tixCommand.** `tix_addbitmapdir(directory)`

Tix maintains a list of directories under which the `tix_getimage()` and `tix_getbitmap()` methods will search for image files. The standard bitmap directory is `$TIX_LIBRARY/bitmaps`. The `tix_addbitmapdir()` method adds `directory` into this list. By using this method, the image files of an application can also be located using the `tix_getimage()` or `tix_getbitmap()` method.

**tixCommand.** `tix Filedialog([dlgclass])`

Returns the file selection dialog that may be shared among different calls from this application. This method will create a file selection dialog widget when it is called the first time. This dialog will be returned by all subsequent calls to `tixFiledialog()`. An optional `dlgclass` parameter can be passed as a string to specify what type of file selection dialog widget is desired. Possible options are `tix`, `FileSelectDialog` or `tixExFileSelectDialog`.

**tixCommand.** `tix_getimage(self, name)`

Locates an image file of the name `name.xpm`, `name.xbm` or `name.ppm` in one of the bitmap directories (see the `tix_addbitmapdir()` method above). If more than one file with the same name (but different extensions) exist, then the image type
is chosen according to the depth of the X display: xbm images are chosen on monochrome displays and color images are chosen on color displays. By using \texttt{tix\_getimage()}, you can avoid hard coding the pathnames of the image files in your application. When successful, this method returns the name of the newly created image, which can be used to configure the \texttt{image} option of the Tk and Tix widgets.

\texttt{tixCommand.tix\_option\_get(name)}

Gets the options maintained by the Tix scheme mechanism.

\texttt{tixCommand.tix\_resetoptions(newScheme, newFontSet[, newScmPrio])}

Resets the scheme and fontset of the Tix application to \texttt{newScheme} and \texttt{newFontSet}, respectively. This affects only those widgets created after this call. Therefore, it is best to call the \texttt{resetoptions} method before the creation of any widgets in a Tix application.

The optional parameter \texttt{newScmPrio} can be given to reset the priority level of the Tk options set by the Tix schemes.

Because of the way Tk handles the X option database, after Tix has been has imported and initd, it is not possible to reset the color schemes and font sets using the \texttt{tix\_config()} method. Instead, the \texttt{tix\_resetoptions()} method must be used.
25.4. `tkinter.scrolledtext` — Scrolled Text Widget

Source code: Lib/tkinter/scrolledtext.py

The `tkinter.scrolledtext` module provides a class of the same name which implements a basic text widget which has a vertical scrollbar configured to do the “right thing.” Using the ScrolledText class is a lot easier than setting up a text widget and scrollbar directly. The constructor is the same as that of the `tkinter.Text` class.

The text widget and scrollbar are packed together in a Frame, and the methods of the Grid and Pack geometry managers are acquired from the Frame object. This allows the ScrolledText widget to be used directly to achieve most normal geometry management behavior.

Should more specific control be necessary, the following attributes are available:

`ScrolledText.frame`

The frame which surrounds the text and scrollbar widgets.

`ScrolledText.vbar`

The scrollbar widget.
25.5. IDLE

Source code: Lib/idlelib/

IDLE is Python’s Integrated Development and Learning Environment.

IDLE has the following features:

- coded in 100% pure Python, using the tkinter GUI toolkit
- cross-platform: works mostly the same on Windows, Unix, and Mac OS X
- Python shell window (interactive interpreter) with colorizing of code input, output, and error messages
- multi-window text editor with multiple undo, Python colorizing, smart indent, call tips, auto completion, and other features
- search within any window, replace within editor windows, and search through multiple files (grep)
- debugger with persistent breakpoints, stepping, and viewing of global and local namespaces
- configuration, browsers, and other dialogs
25.5.1. Menus

IDLE has two main window types, the Shell window and the Editor window. It is possible to have multiple editor windows simultaneously. Output windows, such as used for Edit / Find in Files, are a subtype of edit window. They currently have the same top menu as Editor windows but a different default title and context menu.

IDLE’s menus dynamically change based on which window is currently selected. Each menu documented below indicates which window type it is associated with.

25.5.1.1. File menu (Shell and Editor)

New File
  Create a new file editing window.

Open…
  Open an existing file with an Open dialog.

Recent Files
  Open a list of recent files. Click one to open it.

Open Module…
  Open an existing module (searches sys.path).

Class Browser
  Show functions, classes, and methods in the current Editor file in a tree structure. In the shell, open a module first.

Path Browser
  Show sys.path directories, modules, functions, classes and methods in a tree structure.

Save
  Save the current window to the associated file, if there is one.
Windows that have been changed since being opened or last saved have a * before and after the window title. If there is no associated file, do Save As instead.

Save As…
Save the current window with a Save As dialog. The file saved becomes the new associated file for the window.

Save Copy As…
Save the current window to different file without changing the associated file.

Print Window
Print the current window to the default printer.

Close
Close the current window (ask to save if unsaved).

Exit
Close all windows and quit IDLE (ask to save unsaved windows).

25.5.1.2. Edit menu (Shell and Editor)

Undo
Undo the last change to the current window. A maximum of 1000 changes may be undone.

Redo
Redo the last undone change to the current window.

Cut
Copy selection into the system-wide clipboard; then delete the selection.

Copy
Copy selection into the system-wide clipboard.

Paste
Insert contents of the system-wide clipboard into the current
The clipboard functions are also available in context menus.

Select All
   Select the entire contents of the current window.

Find…
   Open a search dialog with many options

Find Again
   Repeat the last search, if there is one.

Find Selection
   Search for the currently selected string, if there is one.

Find in Files…
   Open a file search dialog. Put results in a new output window.

Replace…
   Open a search-and-replace dialog.

Go to Line
   Move cursor to the line number requested and make that line visible.

Show Completions
   Open a scrollable list allowing selection of keywords and attributes. See Completions in the Tips sections below.

Expand Word
   Expand a prefix you have typed to match a full word in the same window; repeat to get a different expansion.

Show call tip
   After an unclosed parenthesis for a function, open a small window with function parameter hints.

Show surrounding parens
   Highlight the surrounding parenthesis.
25.5.1.3. Format menu (Editor window only)

Indent Region
  Shift selected lines right by the indent width (default 4 spaces).

Dedent Region
  Shift selected lines left by the indent width (default 4 spaces).

Comment Out Region
  Insert ## in front of selected lines.

Uncomment Region
  Remove leading # or ## from selected lines.

Tabify Region
  Turn leading stretches of spaces into tabs. (Note: We recommend using 4 space blocks to indent Python code.)

Untabify Region
  Turn all tabs into the correct number of spaces.

Toggle Tabs
  Open a dialog to switch between indenting with spaces and tabs.

New Indent Width
  Open a dialog to change indent width. The accepted default by the Python community is 4 spaces.

Format Paragraph
  Reformat the current blank-line-delimited paragraph in comment block or multiline string or selected line in a string. All lines in the paragraph will be formatted to less than N columns, where N defaults to 72.

Strip trailing whitespace
  Remove trailing space and other whitespace characters after the last non-whitespace character of a line by applying str.rstrip to each line, including lines within multiline strings.
25.5.1.4. Run menu (Editor window only)

Python Shell
Open or wake up the Python Shell window.

Check Module
Check the syntax of the module currently open in the Editor window. If the module has not been saved IDLE will either prompt the user to save or autosave, as selected in the General tab of the Idle Settings dialog. If there is a syntax error, the approximate location is indicated in the Editor window.

Run Module
Do Check Module (above). If no error, restart the shell to clean the environment, then execute the module. Output is displayed in the Shell window. Note that output requires use of `print` or `write`. When execution is complete, the Shell retains focus and displays a prompt. At this point, one may interactively explore the result of execution. This is similar to executing a file with `python -i file` at a command line.

25.5.1.5. Shell menu (Shell window only)

View Last Restart
Scroll the shell window to the last Shell restart.

Restart Shell
Restart the shell to clean the environment.

Interrupt Execution
Stop a running program.

25.5.1.6. Debug menu (Shell window only)

Go to File/Line
Look on the current line, with the cursor, and the line above for a filename and line number. If found, open the file if not already open, and show the line. Use this to view source lines referenced in an exception traceback and lines found by Find in Files. Also available in the context menu of the Shell window and Output windows.

Debugger (toggle)
When activated, code entered in the Shell or run from an Editor will run under the debugger. In the Editor, breakpoints can be set with the context menu. This feature is still incomplete and somewhat experimental.

Stack Viewer
Show the stack traceback of the last exception in a tree widget, with access to locals and globals.

Auto-open Stack Viewer
Toggle automatically opening the stack viewer on an unhandled exception.

25.5.1.7. Options menu (Shell and Editor)

Configure IDLE
Open a configuration dialog and change preferences for the following: fonts, indentation, keybindings, text color themes, startup windows and size, additional help sources, and extensions (see below). On OS X, open the configuration dialog by selecting Preferences in the application menu. To use a new built-in color theme (IDLE Dark) with older IDLEs, save it as a new custom theme.

Non-default user settings are saved in a .idlerc directory in the user’s home directory. Problems caused by bad user configuration files are solved by editing or deleting one or more of the files in
.idlerc.

Code Context (toggle)(Editor Window only)
Open a pane at the top of the edit window which shows the block context of the code which has scrolled above the top of the window.

25.5.1.8. Window menu (Shell and Editor)

Zoom Height
Toggles the window between normal size and maximum height. The initial size defaults to 40 lines by 80 chars unless changed on the General tab of the Configure IDLE dialog.

The rest of this menu lists the names of all open windows; select one to bring it to the foreground (deiconifying it if necessary).

25.5.1.9. Help menu (Shell and Editor)

About IDLE
Display version, copyright, license, credits, and more.

IDLE Help
Display a help file for IDLE detailing the menu options, basic editing and navigation, and other tips.

Python Docs
Access local Python documentation, if installed, or start a web browser and open docs.python.org showing the latest Python documentation.

Turtle Demo
Run the turtledemo module with example python code and turtle drawings.

Additional help sources may be added here with the Configure IDLE
dialog under the General tab.

25.5.1.10. Context Menus

Open a context menu by right-clicking in a window (Control-click on OS X). Context menus have the standard clipboard functions also on the Edit menu.

Cut
   Copy selection into the system-wide clipboard; then delete the selection.

Copy
   Copy selection into the system-wide clipboard.

Paste
   Insert contents of the system-wide clipboard into the current window.

Editor windows also have breakpoint functions. Lines with a breakpoint set are specially marked. Breakpoints only have an effect when running under the debugger. Breakpoints for a file are saved in the user’s .idlerc directory.

Set Breakpoint
   Set a breakpoint on the current line.

Clear Breakpoint
   Clear the breakpoint on that line.

Shell and Output windows have the following.

Go to file/line
   Same as in Debug menu.
25.5.2. Editing and navigation

In this section, ‘C’ refers to the Control key on Windows and Unix and the Command key on Mac OSX.

- **Backspace** deletes to the left; **Del** deletes to the right
- **C-Backspace** delete word left; **C-Del** delete word to the right
- Arrow keys and Page Up/Page Down to move around
- **C-LeftArrow** and **C-RightArrow** moves by words
- Home/End go to begin/end of line
- **C-Home**/C-**End** go to begin/end of file
- Some useful Emacs bindings are inherited from Tcl/Tk:
  - **C-a** beginning of line
  - **C-e** end of line
  - **C-k** kill line (but doesn’t put it in clipboard)
  - **C-l** center window around the insertion point
  - **C-b** go backward one character without deleting (usually you can also use the cursor key for this)
  - **C-f** go forward one character without deleting (usually you can also use the cursor key for this)
  - **C-p** go up one line (usually you can also use the cursor key for this)
  - **C-d** delete next character

Standard keybindings (like **C-c** to copy and **C-v** to paste) may work. Keybindings are selected in the Configure IDLE dialog.
25.5.2.1. Automatic indentation

After a block-opening statement, the next line is indented by 4 spaces (in the Python Shell window by one tab). After certain keywords (break, return etc.) the next line is dedented. In leading indentation, Backspace deletes up to 4 spaces if they are there. Tab inserts spaces (in the Python Shell window one tab), number depends on Indent width. Currently, tabs are restricted to four spaces due to Tcl/Tk limitations.

See also the indent/dedent region commands in the edit menu.

25.5.2.2. Completions

Completions are supplied for functions, classes, and attributes of classes, both built-in and user-defined. Completions are also provided for filenames.

The AutoCompleteWindow (ACW) will open after a predefined delay (default is two seconds) after a ‘.’ or (in a string) an os.sep is typed. If after one of those characters (plus zero or more other characters) a tab is typed the ACW will open immediately if a possible continuation is found.

If there is only one possible completion for the characters entered, a Tab will supply that completion without opening the ACW.

‘Show Completions’ will force open a completions window, by default the C-space will open a completions window. In an empty string, this will contain the files in the current directory. On a blank line, it will contain the built-in and user-defined functions and classes in the current namespaces, plus any modules imported. If some characters
have been entered, the ACW will attempt to be more specific.

If a string of characters is typed, the ACW selection will jump to the entry most closely matching those characters. Entering a tab will cause the longest non-ambiguous match to be entered in the Editor window or Shell. Two tab in a row will supply the current ACW selection, as will return or a double click. Cursor keys, Page Up/Down, mouse selection, and the scroll wheel all operate on the ACW.

“Hidden” attributes can be accessed by typing the beginning of hidden name after a ‘.’, e.g. ‘.’. This allows access to modules with __all__ set, or to class-private attributes.

Completions and the ‘Expand Word’ facility can save a lot of typing!

Completions are currently limited to those in the namespaces. Names in an Editor window which are not via __main__ and sys.modules will not be found. Run the module once with your imports to correct this situation. Note that IDLE itself places quite a few modules in sys.modules, so much can be found by default, e.g. the re module.

If you don’t like the ACW popping up unbidden, simply make the delay longer or disable the extension.

25.5.2.3. Calltips

A calltip is shown when one types ( after the name of an accessible function. A name expression may include dots and subscripts. A calltip remains until it is clicked, the cursor is moved out of the argument area, or ) is typed. When the cursor is in the argument part of a definition, the menu or shortcut display a calltip.

A calltip consists of the function signature and the first line of the
docstring. For builtins without an accessible signature, the calltip consists of all lines up the fifth line or the first blank line. These details may change.

The set of accessible functions depends on what modules have been imported into the user process, including those imported by Idle itself, and what definitions have been run, all since the last restart.

For example, restart the Shell and enter `itertools.count()`. A calltip appears because Idle imports itertools into the user process for its own use. (This could change.) Enter `turtle.write()` and nothing appears. Idle does not import turtle. The menu or shortcut do nothing either. Enter `import turtle` and then `turtle.write()` will work.

In an editor, import statements have no effect until one runs the file. One might want to run a file after writing the import statements at the top, or immediately run an existing file before editing.

### 25.5.2.4. Python Shell window

- **C-c** interrupts executing command
- **C-d** sends end-of-file; closes window if typed at a `>>>` prompt
- **Alt-/'** (Expand word) is also useful to reduce typing

Command history

- **Alt-p** retrieves previous command matching what you have typed. On OS X use **C-p**.
- **Alt-n** retrieves next. On OS X use **C-n**.
- **Return** while on any previous command retrieves that command
25.5.2.5. Text colors

Idle defaults to black on white text, but colors text with special meanings. For the shell, these are shell output, shell error, user output, and user error. For Python code, at the shell prompt or in an editor, these are keywords, built-in class and function names, names following `class` and `def`, strings, and comments. For any text window, these are the cursor (when present), found text (when possible), and selected text.

Text coloring is done in the background, so uncolorized text is occasionally visible. To change the color scheme, use the Configure IDLE dialog Highlighting tab. The marking of debugger breakpoint lines in the editor and text in popups and dialogs is not user-configurable.
25.5.3. Startup and code execution

Upon startup with the `-s` option, IDLE will execute the file referenced by the environment variables IDLESTARTUP or PYTHONSTARTUP. IDLE first checks for IDLESTARTUP; if IDLESTARTUP is present the file referenced is run. If IDLESTARTUP is not present, IDLE checks for PYTHONSTARTUP. Files referenced by these environment variables are convenient places to store functions that are used frequently from the IDLE shell, or for executing import statements to import common modules.

In addition, Tk also loads a startup file if it is present. Note that the Tk file is loaded unconditionally. This additional file is .Idle.py and is looked for in the user’s home directory. Statements in this file will be executed in the Tk namespace, so this file is not useful for importing functions to be used from IDLE’s Python shell.

25.5.3.1. Command line usage

```
```

- `-c command` run command in the shell window
- `-d` enable debugger and open shell window
- `-e` open editor window
- `-h` print help message with legal combinations
- `-i` open shell window
- `-r file` run file in shell window
- `-s` run $IDLESTARTUP or $PYTHONSTARTUP first
- `-t title` set title of shell window
- `-` run stdin in shell (- must be last option)
If there are arguments:

- If `-`, `-c`, or `-r` is used, all arguments are placed in `sys.argv[1:]` and `sys.argv[0]` is set to `'`, `-c`, or `-r`. No editor window is opened, even if that is the default set in the Options dialog.
- Otherwise, arguments are files opened for editing and `sys.argv` reflects the arguments passed to IDLE itself.

### 25.5.3.2. Startup failure

IDLE uses a socket to communicate between the IDLE GUI process and the user code execution process. A connection must be established whenever the Shell starts or restarts. (The latter is indicated by a divider line that says ‘RESTART’). If the user process fails to connect to the GUI process, it displays a Tk error box with a ‘cannot connect’ message that directs the user here. It then exits.

A common cause of failure is a user-written file with the same name as a standard library module, such as `random.py` and `tkinter.py`. When such a file is located in the same directory as a file that is about to be run, IDLE cannot import the stdlib file. The current fix is to rename the user file.

Though less common than in the past, an antivirus or firewall program may stop the connection. If the program cannot be taught to allow the connection, then it must be turned off for IDLE to work. It is safe to allow this internal connection because no data is visible on external ports. A similar problem is a network mis-configuration that blocks connections.

Python installation issues occasionally stop IDLE: multiple versions can clash, or a single installation might need admin access. If one
undo the clash, or cannot or does not want to run as admin, it might be easiest to completely remove Python and start over.

A zombie pythonw.exe process could be a problem. On Windows, use Task Manager to detect and stop one. Sometimes a restart initiated by a program crash or Keyboard Interrupt (control-C) may fail to connect. Dismissing the error box or Restart Shell on the Shell menu may fix a temporary problem.

When IDLE first starts, it attempts to read user configuration files in ~/.idlerc/ (~ is one’s home directory). If there is a problem, an error message should be displayed. Leaving aside random disk glitches, this can be prevented by never editing the files by hand, using the configuration dialog, under Options, instead Options. Once it happens, the solution may be to delete one or more of the configuration files.

If IDLE quits with no message, and it was not started from a console, try starting from a console (python -m idlelib) and see if a message appears.

25.5.3.3. IDLE-console differences

With rare exceptions, the result of executing Python code with IDLE is intended to be the same as executing the same code in a console window. However, the different interface and operation occasionally affect visible results. For instance, `sys.modules` starts with more entries.

IDLE also replaces `sys.stdin`, `sys.stdout`, and `sys.stderr` with objects that get input from and send output to the Shell window. When Shell has the focus, it controls the keyboard and screen. This is normally transparent, but functions that directly access the keyboard
and screen will not work. If `sys` is reset with `importlib.reload(sys)`, IDLE's changes are lost and things like `input`, `raw_input`, and `print` will not work correctly.

With IDLE’s Shell, one enters, edits, and recalls complete statements. Some consoles only work with a single physical line at a time. IDLE uses `exec` to run each statement. As a result, `['__builtins__']` is always defined for each statement.

25.5.3.4. Developing tkinter applications

IDLE is intentionally different from standard Python in order to facilitate development of tkinter programs. Enter `import tkinter as tk; root = tk.Tk()` in standard Python and nothing appears. Enter the same in IDLE and a tk window appears. In standard Python, one must also enter `root.update()` to see the window. IDLE does the equivalent in the background, about 20 times a second, which is about every 50 milliseconds. Next enter `b = tk.Button(root, text='button'); b.pack()`. Again, nothing visibly changes in standard Python until one enters `root.update()`.

Most tkinter programs run `root.mainloop()`, which usually does not return until the tk app is destroyed. If the program is run with `python -i` or from an IDLE editor, a `>>>` shell prompt does not appear until `mainloop()` returns, at which time there is nothing left to interact with.

When running a tkinter program from an IDLE editor, one can comment out the mainloop call. One then gets a shell prompt immediately and can interact with the live application. One just has to remember to re-enable the mainloop call when running in standard
25.5.3.5. Running without a subprocess

By default, IDLE executes user code in a separate subprocess via a socket, which uses the internal loopback interface. This connection is not externally visible and no data is sent to or received from the Internet. If firewall software complains anyway, you can ignore it.

If the attempt to make the socket connection fails, Idle will notify you. Such failures are sometimes transient, but if persistent, the problem may be either a firewall blocking the connection or misconfiguration of a particular system. Until the problem is fixed, one can run Idle with the -n command line switch.

If IDLE is started with the -n command line switch it will run in a single process and will not create the subprocess which runs the RPC Python execution server. This can be useful if Python cannot create the subprocess or the RPC socket interface on your platform. However, in this mode user code is not isolated from IDLE itself. Also, the environment is not restarted when Run/Run Module (F5) is selected. If your code has been modified, you must reload() the affected modules and re-import any specific items (e.g. from foo import baz) if the changes are to take effect. For these reasons, it is preferable to run IDLE with the default subprocess if at all possible.

*Deprecated since version 3.4.*
25.5.4. Help and preferences

25.5.4.1. Additional help sources

IDLE includes a help menu entry called “Python Docs” that will open the extensive sources of help, including tutorials, available at docs.python.org. Selected URLs can be added or removed from the help menu at any time using the Configure IDLE dialog. See the IDLE help option in the help menu of IDLE for more information.

25.5.4.2. Setting preferences

The font preferences, highlighting, keys, and general preferences can be changed via Configure IDLE on the Option menu. Keys can be user defined; IDLE ships with four built-in key sets. In addition, a user can create a custom key set in the Configure IDLE dialog under the keys tab.

25.5.4.3. Extensions

IDLE contains an extension facility. Preferences for extensions can be changed with the Extensions tab of the preferences dialog. See the beginning of config-extensions.def in the idlelib directory for further information. The only current default extension is zzdummy, an example also used for testing.
25.6. Other Graphical User Interface Packages

Major cross-platform (Windows, Mac OS X, Unix-like) GUI toolkits are available for Python:

See also:

PyGObject
PyGObject provides introspection bindings for C libraries using GObject. One of these libraries is the GTK+ 3 widget set. GTK+ comes with many more widgets than Tkinter provides. An online Python GTK+ 3 Tutorial is available.

PyGTK
PyGTK provides bindings for an older version of the library, GTK+ 2. It provides an object oriented interface that is slightly higher level than the C one. There are also bindings to GNOME. An online tutorial is available.

PyQt
PyQt is a sip-wrapped binding to the Qt toolkit. Qt is an extensive C++ GUI application development framework that is available for Unix, Windows and Mac OS X. sip is a tool for generating bindings for C++ libraries as Python classes, and is specifically designed for Python.

PySide
PySide is a newer binding to the Qt toolkit, provided by Nokia. Compared to PyQt, its licensing scheme is friendlier to non-open source applications.

wxPython
wxPython is a cross-platform GUI toolkit for Python that is built
around the popular **wxWidgets** (formerly wxWindows) C++ toolkit. It provides a native look and feel for applications on Windows, Mac OS X, and Unix systems by using each platform’s native widgets where ever possible, (GTK+ on Unix-like systems). In addition to an extensive set of widgets, wxPython provides classes for online documentation and context sensitive help, printing, HTML viewing, low-level device context drawing, drag and drop, system clipboard access, an XML-based resource format and more, including an ever growing library of user-contributed modules.

PyGTK, PyQt, and wxPython, all have a modern look and feel and more widgets than Tkinter. In addition, there are many other GUI toolkits for Python, both cross-platform, and platform-specific. See the GUI Programming page in the Python Wiki for a much more complete list, and also for links to documents where the different GUI toolkits are compared.
26. Development Tools

The modules described in this chapter help you write software. For example, the pydoc module takes a module and generates documentation based on the module’s contents. The doctest and unittest modules contains frameworks for writing unit tests that automatically exercise code and verify that the expected output is produced. 2to3 can translate Python 2.x source code into valid Python 3.x code.

The list of modules described in this chapter is:

- **26.1. typing — Support for type hints**
  - 26.1.1. Type aliases
  - 26.1.2. NewType
  - 26.1.3. Callable
  - 26.1.4. Generics
  - 26.1.5. User-defined generic types
  - 26.1.6. The Any type
  - 26.1.7. Classes, functions, and decorators
- **26.2. pydoc — Documentation generator and online help system**
- **26.3. doctest — Test interactive Python examples**
  - 26.3.1. Simple Usage: Checking Examples in Docstrings
  - 26.3.2. Simple Usage: Checking Examples in a Text File
  - 26.3.3. How It Works
    - 26.3.3.1. Which Docstrings Are Examined?
    - 26.3.3.2. How are Docstring Examples Recognized?
    - 26.3.3.3. What’s the Execution Context?
    - 26.3.3.4. What About Exceptions?
    - 26.3.3.5. Option Flags
    - 26.3.3.6. Directives
    - 26.3.3.7. Warnings
• 26.3.4. Basic API
• 26.3.5. Unittest API
• 26.3.6. Advanced API
  ■ 26.3.6.1. DocTest Objects
  ■ 26.3.6.2. Example Objects
  ■ 26.3.6.3. DocTestFinder objects

26.1. typing — Support for type hints

New in version 3.5.

Source code: Lib/typing.py

Note: The typing module has been included in the standard library on a provisional basis. New features might be added and API may change even between minor releases if deemed necessary by the core developers.

This module supports type hints as specified by PEP 484 and PEP 526. The most fundamental support consists of the types Any, Union, Tuple, Callable, TypeVar, and Generic. For full specification please see PEP 484. For a simplified introduction to type hints see PEP 483.

The function below takes and returns a string and is annotated as follows:

```python
def greeting(name: str) -> str:
    return 'Hello ' + name
```

In the function greeting, the argument name is expected to be of type str and the return type str. Subtypes are accepted as arguments.
26.1.1. Type aliases

A type alias is defined by assigning the type to the alias. In this example, `Vector` and `List[float]` will be treated as interchangeable synonyms:

```python
from typing import List
Vector = List[float]

def scale(scalar: float, vector: Vector) -> Vector:
    return [scalar * num for num in vector]

# typechecks; a list of floats qualifies as a Vector
new_vector = scale(2.0, [1.0, -4.2, 5.4])
```

Type aliases are useful for simplifying complex type signatures. For example:

```python
from typing import Dict, Tuple, List

ConnectionOptions = Dict[str, str]
Address = Tuple[str, int]
Server = Tuple[Address, ConnectionOptions]

def broadcast_message(message: str, servers: List[Server]...)

# The static type checker will treat the previous type
# being exactly equivalent to this one.
def broadcast_message(
    message: str,
    servers: List[Tuple[Tuple[str, int], Dict[str, str]]]
...)
```
Note that `None` as a type hint is a special case and is replaced by `type(None)`.
26.1.2. NewType

Use the `NewType()` helper function to create distinct types:

```python
from typing import NewType

UserId = NewType('UserId', int)
some_id = UserId(524313)
```

The static type checker will treat the new type as if it were a subclass of the original type. This is useful in helping catch logical errors:

```python
def get_user_name(user_id: UserId) -> str:
    ...

# typechecks
user_a = get_user_name(UserId(42351))

# does not typecheck; an int is not a UserId
user_b = get_user_name(-1)
```

You may still perform all int operations on a variable of type `UserId`, but the result will always be of type `int`. This lets you pass in a `UserId` wherever an `int` might be expected, but will prevent you from accidentally creating a `UserId` in an invalid way:

```python
# 'output' is of type 'int', not 'UserId'
output = UserId(23413) + UserId(54341)
```

Note that these checks are enforced only by the static type checker. At runtime the statement `Derived = NewType('Derived', Base)` will make `Derived` a function that immediately returns whatever parameter you pass it. That means the expression
Derived(some_value) does not create a new class or introduce any overhead beyond that of a regular function call.

More precisely, the expression `some_value is Derived(some_value)` is always true at runtime.

This also means that it is not possible to create a subtype of `Derived` since it is an identity function at runtime, not an actual type:

```python
from typing import NewType

UserId = NewType('UserId', int)

# Fails at runtime and does not typecheck
class AdminUserId(UserId): pass
```

However, it is possible to create a `NewType()` based on a 'derived' `NewType`:

```python
from typing import NewType

UserId = NewType('UserId', int)

ProUserId = NewType('ProUserId', UserId)
```

and typechecking for `ProUserId` will work as expected.

See PEP 484 for more details.

**Note:** Recall that the use of a type alias declares two types to be `equivalent` to one another. Doing `Alias = Original` will make the static type checker treat `Alias` as being `exactly equivalent` to `Original` in all cases. This is useful when you want to simplify complex type signatures.
In contrast, NewType declares one type to be a *subtype* of another. Doing `Derived = NewType('Derived', Original)` will make the static type checker treat Derived as a *subclass* of Original, which means a value of type Original cannot be used in places where a value of type Derived is expected. This is useful when you want to prevent logic errors with minimal runtime cost.

*New in version 3.5.2.*
26.1.3. Callable

Frameworks expecting callback functions of specific signatures might be type hinted using `Callable[[Arg1Type, Arg2Type], ReturnType]`.

For example:

```python
from typing import Callable

def feeder(get_next_item: Callable[[], str]) -> None:
    # Body

def async_query(on_success: Callable[[int], None],
                 on_error: Callable[[int, Exception],
                                    None],
    # Body
```

It is possible to declare the return type of a callable without specifying the call signature by substituting a literal ellipsis for the list of arguments in the type hint: `Callable[..., ReturnType]`. 
26.1.4. Generics

Since type information about objects kept in containers cannot be statically inferred in a generic way, abstract base classes have been extended to support subscription to denote expected types for container elements.

```python
from typing import Mapping, Sequence

def notify_by_email(employees: Sequence[Employee], overrides: Mapping[str, str]) -> ...
```

Generics can be parametrized by using a new factory available in typing called `TypeVar`.

```python
from typing import Sequence, TypeVar
T = TypeVar('T')  # Declare type variable
def first(l: Sequence[T]) -> T:  # Generic function
    return l[0]
```
26.1.5. User-defined generic types

A user-defined class can be defined as a generic class.

```python
from typing import TypeVar, Generic
from logging import Logger

T = TypeVar('T')

class LoggedVar(Generic[T]):
    def __init__(self, value: T, name: str, logger: Logger):
        self.name = name
        self.logger = logger
        self.value = value

    def set(self, new: T) -> None:
        self.log('Set ' + repr(self.value))
        self.value = new

    def get(self) -> T:
        self.log('Get ' + repr(self.value))
        return self.value

    def log(self, message: str) -> None:
        self.logger.info('%s: %s', self.name, message)
```

Generic[T] as a base class defines that the class LoggedVar takes a single type parameter T. This also makes T valid as a type within the class body.

The Generic base class uses a metaclass that defines __getitem__() so that LoggedVar[t] is valid as a type:

```python
from typing import Iterable
```
A generic type can have any number of type variables, and type variables may be constrained:

```python
from typing import TypeVar, Generic
...
T = TypeVar('T')
S = TypeVar('S', int, str)

class StrangePair(Generic[T, S]):
    ...
```

Each type variable argument to `Generic` must be distinct. This is thus invalid:

```python
from typing import TypeVar, Generic
...
T = TypeVar('T')

class Pair(Generic[T, T]):  # INVALID
    ...
```

You can use multiple inheritance with `Generic`:

```python
from typing import TypeVar, Generic, Sized
T = TypeVar('T')

class LinkedList(Sized, Generic[T]):
```
When inheriting from generic classes, some type variables could be fixed:

```python
from typing import TypeVar, Mapping

T = TypeVar('T')

class MyDict(Mapping[str, T]):
    ...
```

In this case `MyDict` has a single parameter, `T`.

Using a generic class without specifying type parameters assumes `Any` for each position. In the following example, `MyIterable` is not generic but implicitly inherits from `Iterable[Any]`:

```python
from typing import Iterable

class MyIterable(Iterable):  # Same as Iterable[Any]
    ...
```

User defined generic type aliases are also supported. Examples:

```python
from typing import TypeVar, Iterable, Tuple, Union

S = TypeVar('S')
Response = Union[Iterable[S], int]

# Return type here is same as Union[Iterable[str], int]
def response(query: str) -> Response[str]:
    ...

T = TypeVar('T', int, float, complex)
Vec = Iterable[Tuple[T, T]]
```
The metaclass used by `Generic` is a subclass of `abc.ABCMeta`. A generic class can be an ABC by including abstract methods or properties, and generic classes can also have ABCs as base classes without a metaclass conflict. Generic metaclasses are not supported. The outcome of parameterizing generics is cached, and most types in the typing module are hashable and comparable for equality.
26.1.6. The **Any** type

A special kind of type is **Any**. A static type checker will treat every type as being compatible with **Any** and **Any** as being compatible with every type.

This means that it is possible to perform any operation or method call on a value of type on **Any** and assign it to any variable:

```python
from typing import Any

a = None  # type: Any
a = []    # OK
a = 2     # OK

s = ''    # type: str
s = a     # OK

def foo(item: Any) -> int:
    # Typechecks; 'item' could be any type,
    # and that type might have a 'bar' method
    item.bar()
...
```

Notice that no typechecking is performed when assigning a value of type **Any** to a more precise type. For example, the static type checker did not report an error when assigning `a` to `s` even though `s` was declared to be of type **str** and receives an **int** value at runtime!

Furthermore, all functions without a return type or parameter types will implicitly default to using **Any**:

```python
def legacy_parser(text):
```
...  
    return data

# A static type checker will treat the above  
# as having the same signature as:  
def legacy_parser(text: Any) -> Any:  
    ...  
    return data

This behavior allows Any to be used as an escape hatch when you  
need to mix dynamically and statically typed code.

Contrast the behavior of Any with the behavior of object. Similar to  
Any, every type is a subtype of object. However, unlike Any, the  
reverse is not true: object is not a subtype of every other type.

That means when the type of a value is object, a type checker will  
reject almost all operations on it, and assigning it to a variable (or  
using it as a return value) of a more specialized type is a type error.  
For example:

def hash_a(item: object) -> int:  
    # Fails; an object does not have a 'magic' method  
    item.magic()  
    ...

def hash_b(item: Any) -> int:  
    # Typechecks  
    item.magic()  
    ...

# Typechecks, since ints and strs are subclasses of  
hash_a(42)  
hash_a("foo")
Use `object` to indicate that a value could be any type in a typesafe manner. Use `Any` to indicate that a value is dynamically typed.
26.1.7. Classes, functions, and decorators

The module defines the following classes, functions and decorators:

class typing. **TypeVar**

Type variable.

Usage:

```python
T = TypeVar('T')    # Can be anything
A = TypeVar('A', str, bytes)  # Must be str or by
```

Type variables exist primarily for the benefit of static type checkers. They serve as the parameters for generic types as well as for generic function definitions. See class Generic for more information on generic types. Generic functions work as follows:

```python
def repeat(x: T, n: int) -> Sequence[T]:
    """Return a list containing n references to x"
    return [x] * n

def longest(x: A, y: A) -> A:
    """Return the longest of two strings.""
    return x if len(x) >= len(y) else y
```

The latter example's signature is essentially the overloading of
(str, str) -> str and (bytes, bytes) -> bytes. Also note that if the arguments are instances of some subclass of str, the return type is still plain str.

At runtime, `isinstance(x, T)` will raise `TypeError`. In general, `isinstance()` and `issubclass()` should not be used
with types.

Type variables may be marked covariant or contravariant by passing covariant=True or contravariant=True. See PEP 484 for more details. By default type variables are invariant. Alternatively, a type variable may specify an upper bound using bound=<type>. This means that an actual type substituted (explicitly or implicitly) for the type variable must be a subclass of the boundary type, see PEP 484.

```python
class typing.Generictyping.
Abstract base class for generic types.

A generic type is typically declared by inheriting from an instantiation of this class with one or more type variables. For example, a generic mapping type might be defined as:

class Mapping(Generic[KT, VT]):
    def __getitem__(self, key: KT) -> VT:
        ...
        # Etc.
```

This class can then be used as follows:

```python
X = TypeVar('X')
Y = TypeVar('Y')

def lookup_name(mapping: Mapping[X, Y], key: X, default: Y):
    try:
        return mapping[key]
    except KeyError:
        return default

class typing.TypeGeneric[CT_co])```
A variable annotated with $C$ may accept a value of type $C$. In contrast, a variable annotated with $\text{Type}[C]$ may accept values that are classes themselves – specifically, it will accept the class object of $C$. For example:

```python
a = 3           # Has type 'int'
b = int          # Has type 'Type[int]'
c = type(a)      # Also has type 'Type[int]'
```

Note that $\text{Type[}C\text{]}$ is covariant:

```python
class User: ...
class BasicUser(User): ...
class ProUser(User): ...
class TeamUser(User): ...

# Accepts User, BasicUser, ProUser, TeamUser, ...
def make_new_user(user_class: Type[User]) -> User
    # ...
    return user_class()
```

The fact that $\text{Type[}C\text{]}$ is covariant implies that all subclasses of $C$ should implement the same constructor signature and class method signatures as $C$. The type checker should flag violations of this, but should also allow constructor calls in subclasses that match the constructor calls in the indicated base class. How the type checker is required to handle this particular case may change in future revisions of PEP 484.

The only legal parameters for $\text{Type}$ are classes, unions of classes, and $\text{Any}$. For example:

```python
def new_non_team_user(user_class: Type[Union[Base}
```
Type[Any] is equivalent to Type which in turn is equivalent to type, which is the root of Python's metaclass hierarchy.

*New in version 3.5.2.*

class typing.Iterable(Generic[T_co])

A generic version of collections.abc.Iterable.

class typing.Iterator(Iterable[T_co])

A generic version of collections.abc.Iterator.

class typing.Reversible(Iterable[T_co])

A generic version of collections.abc.Reversible.

class typing.SupportsInt

An ABC with one abstract method __int__.

class typing.SupportsFloat

An ABC with one abstract method __float__.

class typing.SupportsComplex

An ABC with one abstract method __complex__.

class typing.SupportsBytes

An ABC with one abstract method __bytes__.

class typing.SupportsAbs

An ABC with one abstract method __abs__ that is covariant in its return type.

class typing.SupportsRound

An ABC with one abstract method __round__ that is covariant in
its return type.

```python
class typing.Container(Generic[T_co])
    A generic version of collections.abc.Container.

class typing.Hashable
    An alias to collections.abc.Hashable

class typing.Sized
    An alias to collections.abc.Sized

class typing.Collection(Sized, Iterable[T_co], Container[T_co])
    A generic version of collections.abc.Collection

    New in version 3.6.

class typing.AbstractSet(Sized, Collection[T_co])
    A generic version of collections.abc.Set.

class typing.MutableSet(AbstractSet[T])
    A generic version of collections.abc.MutableSet.

class typing.Mapping(Sized, Collection[KT], Generic[VT_co])
    A generic version of collections.abc.Mapping.

class typing.MutableMapping(Mapping[KT, VT])
    A generic version of collections.abc.MutableMapping.

class typing.Sequence(Reversible[T_co], Collection[T_co])
    A generic version of collections.abc.Sequence.

class typing.MutableSequence(Sequence[T])
```
A generic version of `collections.abc.MutableSequence`.

class typing.**ByteString**(Sequence[int])
A generic version of `collections.abc.ByteString`.

This type represents the types `bytes`, `bytearray`, and `memoryview`.

As a shorthand for this type, `bytes` can be used to annotate arguments of any of the types mentioned above.

class typing.**Deque**(deque, MutableSequence[T])
A generic version of `collections.deque`.

*New in version 3.6.1.*

class typing.**List**(list, MutableSequence[T])
Generic version of `list`. Useful for annotating return types. To annotate arguments it is preferred to use abstract collection types such as `Mapping`, `Sequence`, or `AbstractSet`.

This type may be used as follows:

```python
T = TypeVar('T', int, float)

def vec2(x: T, y: T) -> List[T]:
    return [x, y]

def keep_positives(vector: Sequence[T]) -> List[T]:
    return [item for item in vector if item > 0]
```

class typing.**Set**(set, MutableSet[T])
A generic version of `builtins.set`. 
class typing.FrozenSet(frozenset, AbstractSet[T_co])
A generic version of builtins.frozenset.

class typing.MappingView(Sized, Iterable[T_co])
A generic version of collections.abc.MappingView.

class typing.KeysView(MappingView[KT_co], AbstractSet[KT_co])
A generic version of collections.abc.KeysView.

class typing.ItemsView(MappingView, Generic[KT_co, VT_co])
A generic version of collections.abc.ItemsView.

class typing.ValuesView(MappingView[VT_co])
A generic version of collections.abc.ValuesView.

class typing.Awaitable(Generic[T_co])
A generic version of collections.abc.Awaitable.

class typingCoroutine(Awaitable[V_co], Generic[T_co T_contra, V_co])
A generic version of collections.abcCoroutine. The variance and order of type variables correspond to those of Generator, for example:

```python
from typing import List, Coroutine
c = None  # type: Coroutine[List[str], str, int]
...
x = c.send('hi')  # type: List[str]
async def bar() -> None:
x = await c  # type: int
```

class typing.AsyncIterable(Generic[T_co])
A generic version of `collections.abc.AsyncIterable`.

```python
class typing.AsyncIterator(AsyncIterable[T_co])
```
A generic version of `collections.abc.AsyncIterator`.

```python
class typing.ContextManager(Generic[T_co])
```
A generic version of `contextlib.AbstractContextManager`.

*New in version 3.6.*

```python
class typing.Dict(dict, MutableMapping[KT, VT])
```
A generic version of `dict`. The usage of this type is as follows:

```python
def get_position_in_index(word_list: Dict[str, int]) -> int:
    return word_list[word]
```

```
class typing.DefaultDict(collections.defaultdict, 
MutableMapping[KT, VT])
```
A generic version of `collections.defaultdict`.

*New in version 3.5.2.*

```python
class typing.Counter(collections.Counter, Dict[T, int])
```
A generic version of `collections.Counter`.

*New in version 3.6.1.*

```python
class typing.ChainMap(collections.ChainMap, 
MutableMapping[KT, VT])
```
A generic version of `collections.ChainMap`.

*New in version 3.6.1.*
A generator can be annotated by the generic type `Generator[YieldType, SendType, ReturnType]`. For example:

```python
def echo_round() -> Generator[int, float, str]:
    sent = yield 0
    while sent >= 0:
        sent = yield round(sent)
    return 'Done'
```

Note that unlike many other generics in the typing module, the `SendType` of `Generator` behaves contravariantly, not covariantly or invariantly.

If your generator will only yield values, set the `SendType` and `ReturnType` to `None`:

```python
def infinite_stream(start: int) -> Generator[int, None, None]:
    while True:
        yield start
        start += 1
```

Alternatively, annotate your generator as having a return type of either `Iterable[YieldType]` or `Iterator[YieldType]`:

```python
def infinite_stream(start: int) -> Iterator[int]:
    while True:
        yield start
        start += 1
```

`class typing.AsyncGenerator(AsyncIterator[T_co],`
"Generic[T_co, T_contra]"

An async generator can be annotated by the generic type AsyncGenerator[YieldType, SendType]. For example:

```python
async def echo_round() -> AsyncGenerator[int, float]:
    sent = yield 0
    while sent >= 0.0:
        rounded = await round(sent)
        sent = yield rounded
```

Unlike normal generators, async generators cannot return a value, so there is no ReturnType type parameter. As with Generator, the SendType behaves contravariantly.

If your generator will only yield values, set the SendType to None:

```python
async def infinite_stream(start: int) -> AsyncGenerator:
    while True:
        yield start
        start = await increment(start)
```

Alternatively, annotate your generator as having a return type of either AsyncIterable[YieldType] or AsyncIterator[YieldType]:

```python
async def infinite_stream(start: int) -> AsyncIterator:
    while True:
        yield start
        start = await increment(start)
```

New in version 3.5.4.
class typing. **Text**

Text is an alias for `str`. It is provided to supply a forward compatible path for Python 2 code: in Python 2, Text is an alias for `unicode`.

Use Text to indicate that a value must contain a unicode string in a manner that is compatible with both Python 2 and Python 3:

```python
def add_unicode_checkmark(text: Text) -> Text:
    return text + u' ✓'
```

*New in version 3.5.2.*

class typing. **io**

Wrapper namespace for I/O stream types.

This defines the generic type `IO[AnyStr]` and subclasses `TextIO` and `BinaryIO`, deriving from `IO[str]` and `IO[bytes]`, respectively. These represent the types of I/O streams such as returned by `open()`.

These types are also accessible directly as `typing.IO`, `typing.TextIO`, and `typing.BinaryIO`.

class typing. **re**

Wrapper namespace for regular expression matching types.

This defines the type aliases `Pattern` and `Match` which correspond to the return types from `re.compile()` and `re.match()`. These types (and the corresponding functions) are generic in `AnyStr` and can be made specific by writing `Pattern[str]`, `Pattern[bytes]`, `Match[str]`, or `Match[bytes]`.  

These types are also accessible directly as `typing.Pattern` and `typing.Match`.

```python
class typing.NamedTuple

Typed version of namedtuple.

Usage:

class Employee(NamedTuple):
    name: str
    id: int

This is equivalent to:

```collections.namedtuple('Employee', ['name', 'id'])```

To give a field a default value, you can assign to it in the class body:

```python
class Employee(NamedTuple):
    name: str
    id: int = 3

employee = Employee('Guido')
assert employee.id == 3
```

Fields with a default value must come after any fields without a default.

The resulting class has two extra attributes: `_field_types`, giving a dict mapping field names to types, and `_field_defaults`, a dict mapping field names to default values. (The field names are in the `_fields` attribute, which is part of the
NamedTuple subclasses can also have docstrings and methods:

```python
class Employee(NamedTuple):
    """Represents an employee."""
    name: str
    id: int = 3

    def __repr__(self) -> str:
        return f'<Employee {self.name}, id={self.id}>
```

Backward-compatible usage:

```python
Employee = NamedTuple('Employee', [('name', str),
```

*Changed in version 3.6:* Added support for [PEP 526](https://www.python.org/dev/peps/pep-0526) variable annotation syntax.

*Changed in version 3.6.1:* Added support for default values, methods, and docstrings.

**typing.** [NewType](https://docs.python.org/3/library/typing.html#typing.NewType)**(typ)**

A helper function to indicate a distinct types to a typechecker, see [NewType](https://docs.python.org/3/library/typing.html#typing.NewType). At runtime it returns a function that returns its argument.

**Usage:**

```python
UserId = NewType('UserId', int)
first_user = UserId(1)
```

*New in version 3.5.2.*

**typing.** [cast](https://docs.python.org/3/library/typing.html#typing.cast)**(typ, val)**
Cast a value to a type.

This returns the value unchanged. To the type checker this signals that the return value has the designated type, but at runtime we intentionally don’t check anything (we want this to be as fast as possible).

```
typing.get_type_hints(obj[, globals[, locals]])
```

Return a dictionary containing type hints for a function, method, module or class object.

This is often the same as `obj.__annotations__`. In addition, forward references encoded as string literals are handled by evaluating them in `globals` and `locals` namespaces. If necessary, `Optional[t]` is added for function and method annotations if a default value equal to `None` is set. For a class `C`, return a dictionary constructed by merging all the `__annotations__ along `C.__mro__ in reverse order.

```
@typing.overload
```

The `@overload` decorator allows describing functions and methods that support multiple different combinations of argument types. A series of `@overload-decorated definitions must be followed by exactly one non-@overload-decorated definition (for the same function/method). The `@overload-decorated definitions are for the benefit of the type checker only, since they will be overwritten by the non-@overload-decorated definition, while the latter is used at runtime but should be ignored by a type checker. At runtime, calling a `@overload-decorated function directly will raise `NotImplementedError`. An example of overload that gives a more precise type than can be expressed using a union or a type variable:
@overload
def process(response: None) -> None:
    ...
@overload
def process(response: int) -> Tuple[int, str]:
    ...
@overload
def process(response: bytes) -> str:
    ...
def process(response):
    <actual implementation>

See PEP 484 for details and comparison with other typing semantics.

@typing.no_type_check
Decorator to indicate that annotations are not type hints.

This works as class or function decorator. With a class, it applies recursively to all methods defined in that class (but not to methods defined in its superclasses or subclasses).

This mutates the function(s) in place.

@typing.no_type_check_decorator
Decorator to give another decorator the no_type_check() effect.

This wraps the decorator with something that wraps the decorated function in no_type_check().

typing.Any
Special type indicating an unconstrained type.

- Every type is compatible with Any.
- Any is compatible with every type.
**typing.** **Union**

Union type; `Union[X, Y]` means either `X` or `Y`.

To define a union, use e.g. `Union[int, str]`. Details:

- The arguments must be types and there must be at least one.
- Unions of unions are flattened, e.g.:

  ```python
  Union[Union[int, str], float] == Union[int, str]
  ```

- Unions of a single argument vanish, e.g.:

  ```python
  Union[int] == int  # The constructor actually returns int
  ```

- Redundant arguments are skipped, e.g.:

  ```python
  Union[int, str, int] == Union[int, str]
  ```

- When comparing unions, the argument order is ignored, e.g.:

  ```python
  Union[int, str] == Union[str, int]
  ```

- When a class and its subclass are present, the latter is skipped, e.g.:

  ```python
  Union[int, object] == object
  ```

- You cannot subclass or instantiate a union.
- You cannot write `Union[X][Y]`.
- You can use `Optional[X]` as a shorthand for `Union[X,

```
typing. **Optional**

Optional type.

`Optional[X]` is equivalent to `Union[X, None]`.

Note that this is not the same concept as an optional argument, which is one that has a default. An optional argument with a default needn’t use the `Optional` qualifier on its type annotation (although it is inferred if the default is `None`). A mandatory argument may still have an `Optional` type if an explicit value of `None` is allowed.

typing. **Tuple**

Tuple type; `Tuple[X, Y]` is the type of a tuple of two items with the first item of type `X` and the second of type `Y`.

Example: `Tuple[T1, T2]` is a tuple of two elements corresponding to type variables `T1` and `T2`. `Tuple[int, float, str]` is a tuple of an int, a float and a string.

To specify a variable-length tuple of homogeneous type, use literal ellipsis, e.g. `Tuple[int, ...]`. A plain `Tuple` is equivalent to `Tuple[Any, ...]`, and in turn to `tuple`.

typing. **Callable**

Callable type; `Callable[[int], str]` is a function of `(int) -> str`.

The subscription syntax must always be used with exactly two values: the argument list and the return type. The argument list must be a list of types or an ellipsis; the return type must be a
single type.

There is no syntax to indicate optional or keyword arguments; such function types are rarely used as callback types. Callable[..., ReturnType] (literal ellipsis) can be used to type hint a callable taking any number of arguments and returning ReturnType. A plain Callable is equivalent to Callable[..., Any], and in turn to collections.abc.Callable.

typing. ClassVar

Special type construct to mark class variables.

As introduced in PEP 526, a variable annotation wrapped in ClassVar indicates that a given attribute is intended to be used as a class variable and should not be set on instances of that class. Usage:

```python
class Starship:
    stats: ClassVar[Dict[str, int]] = {}  # class variable
    damage: int = 10  # instance variable
```

ClassVar accepts only types and cannot be further subscribed.

ClassVar is not a class itself, and should not be used with isinstance() or issubclass(). ClassVar does not change Python runtime behavior, but it can be used by third-party type checkers. For example, a type checker might flag the following code as an error:

```python
enterprise_d = Starship(3000)
enterprise_d.stats = {}  # Error, setting class variable
Starship.stats = {}  # This is OK
```
New in version 3.5.3.

typing. **AnyStr**

AnyStr is a type variable defined as `AnyStr = TypeVar('AnyStr', str, bytes)`.

It is meant to be used for functions that may accept any kind of string without allowing different kinds of strings to mix. For example:

```python
def concat(a: AnyStr, b: AnyStr) -> AnyStr:
    return a + b

concat(u"foo", u"bar")  # Ok, output has type 'unicode'
concat(b"foo", b"bar")  # Ok, output has type 'bytes'
concat(u"foo", b"bar")  # Error, cannot mix unicode and bytes
```

typing. **TYPE_CHECKING**

A special constant that is assumed to be `True` by 3rd party static type checkers. It is `False` at runtime. Usage:

```python
if TYPE_CHECKING:
    import expensive_mod

def fun(arg: 'expensive_mod.SomeType') -> None:
    local_var: expensive_mod.AnotherType = other_
```

Note that the first type annotation must be enclosed in quotes, making it a “forward reference”, to hide the `expensive_mod` reference from the interpreter runtime. Type annotations for local variables are not evaluated, so the second annotation does not need to be enclosed in quotes.
26.2. **pydoc** — Documentation generator and online help system

**Source code:** Lib/pydoc.py

The `pydoc` module automatically generates documentation from Python modules. The documentation can be presented as pages of text on the console, served to a Web browser, or saved to HTML files.

For modules, classes, functions and methods, the displayed documentation is derived from the docstring (i.e. the `__doc__` attribute) of the object, and recursively of its documentable members. If there is no docstring, `pydoc` tries to obtain a description from the block of comment lines just above the definition of the class, function or method in the source file, or at the top of the module (see `inspect.getcomments()`).

The built-in function `help()` invokes the online help system in the interactive interpreter, which uses `pydoc` to generate its documentation as text on the console. The same text documentation can also be viewed from outside the Python interpreter by running `pydoc` as a script at the operating system’s command prompt. For example, running

```
pydoc sys
```

at a shell prompt will display documentation on the `sys` module, in a style similar to the manual pages shown by the Unix `man` command. The argument to `pydoc` can be the name of a function, module, or
package, or a dotted reference to a class, method, or function within a module or module in a package. If the argument to `pydoc` looks like a path (that is, it contains the path separator for your operating system, such as a slash in Unix), and refers to an existing Python source file, then documentation is produced for that file.

**Note:** In order to find objects and their documentation, `pydoc` imports the module(s) to be documented. Therefore, any code on module level will be executed on that occasion. Use an `if __name__ == '__main__':` guard to only execute code when a file is invoked as a script and not just imported.

When printing output to the console, `pydoc` attempts to paginate the output for easier reading. If the PAGER environment variable is set, `pydoc` will use its value as a pagination program.

Specifying a `-w` flag before the argument will cause HTML documentation to be written out to a file in the current directory, instead of displaying text on the console.

Specifying a `-k` flag before the argument will search the synopsis lines of all available modules for the keyword given as the argument, again in a manner similar to the Unix `man` command. The synopsis line of a module is the first line of its documentation string.

You can also use `pydoc` to start an HTTP server on the local machine that will serve documentation to visiting Web browsers. `pydoc -p 1234` will start a HTTP server on port 1234, allowing you to browse the documentation at `http://localhost:1234/` in your preferred Web browser. Specifying `0` as the port number will select an arbitrary unused port.
**pydoc -n <hostname>** will start the server listening at the given hostname. By default the hostname is 'localhost' but if you want the server to be reached from other machines, you may want to change the host name that the server responds to. During development this is especially useful if you want to run pydoc from within a container.

**pydoc -b** will start the server and additionally open a web browser to a module index page. Each served page has a navigation bar at the top where you can Get help on an individual item, Search all modules with a keyword in their synopsis line, and go to the Module index, Topics and Keywords pages.

When **pydoc** generates documentation, it uses the current environment and path to locate modules. Thus, invoking **pydoc spam** documents precisely the version of the module you would get if you started the Python interpreter and typed `import spam`.

Module docs for core modules are assumed to reside in https://docs.python.org/X.Y/library/ where X and Y are the major and minor version numbers of the Python interpreter. This can be overridden by setting the PYTHONDOCS environment variable to a different URL or to a local directory containing the Library Reference Manual pages.

*Changed in version 3.2:* Added the `-b` option.

*Changed in version 3.3:* The `-g` command line option was removed.

*Changed in version 3.4:* **pydoc** now uses `inspect.signature()` rather than `inspect.getfullargspec()` to extract signature information from callables.

*Changed in version 3.7:* Added the `-n` option.
26.3. doctest — Test interactive Python examples

Source code: Lib/doctest.py

The doctest module searches for pieces of text that look like interactive Python sessions, and then executes those sessions to verify that they work exactly as shown. There are several common ways to use doctest:

- To check that a module’s docstrings are up-to-date by verifying that all interactive examples still work as documented.
- To perform regression testing by verifying that interactive examples from a test file or a test object work as expected.
- To write tutorial documentation for a package, liberally illustrated with input-output examples. Depending on whether the examples or the expository text are emphasized, this has the flavor of “literate testing” or “executable documentation”.

Here’s a complete but small example module:

```python
""
This is the "example" module.

The example module supplies one function, factorial().

>>> factorial(5)
120
""

def factorial(n):
    """Return the factorial of n, an exact integer >
```
>>> [factorial(n) for n in range(6)]
[1, 1, 2, 6, 24, 120]
>>> factorial(30)
2652528598121910586363084800000000
>>> factorial(-1)
Traceback (most recent call last):
...
ValueError: n must be >= 0

Factorials of floats are OK, but the float must
>>> factorial(30.1)
Traceback (most recent call last):
...
ValueError: n must be exact integer
>>> factorial(30.0)
2652528598121910586363084800000000

It must also not be ridiculously large:
>>> factorial(1e100)
Traceback (most recent call last):
...
OverflowError: n too large

import math
if not n >= 0:
    raise ValueError("n must be >= 0")
if math.floor(n) != n:
    raise ValueError("n must be exact integer")
if n+1 == n:  # catch a value like 1e300
    raise OverflowError("n too large")
result = 1
factor = 2
while factor <= n:
    result *= factor
    factor += 1
If you run `example.py` directly from the command line, `doctest` works its magic:

```
$ python example.py
```

There's no output! That's normal, and it means all the examples worked. Pass `-v` to the script, and `doctest` prints a detailed log of what it's trying, and prints a summary at the end:

```
$ python example.py -v
Trying:
  factorial(5)
Expecting:
  120
 ok
Trying:
  [factorial(n) for n in range(6)]
Expecting:
  [1, 1, 2, 6, 24, 120]
 ok

And so on, eventually ending with:

```
Trying:
  factorial(1e100)
Expecting:
  Traceback (most recent call last):
```
...  
  OverflowError: n too large
ok
2 items passed all tests:
  1 tests in __main__
  8 tests in __main__.factorial
9 tests in 2 items.
9 passed and 0 failed.
Test passed.
$

That's all you need to know to start making productive use of doctest! Jump in. The following sections provide full details. Note that there are many examples of doctests in the standard Python test suite and libraries. Especially useful examples can be found in the standard test file lib/test/test_doctest.py.
26.3.1. Simple Usage: Checking Examples in Docstrings

The simplest way to start using doctest (but not necessarily the way you'll continue to do it) is to end each module M with:

```python
if __name__ == '__main__':
    import doctest
    doctest.testmod()
```

doctest then examines docstrings in module M.

Running the module as a script causes the examples in the docstrings to get executed and verified:

```shell
python M.py
```

This won't display anything unless an example fails, in which case the failing example(s) and the cause(s) of the failure(s) are printed to stdout, and the final line of output is ***Test Failed*** N failures., where N is the number of examples that failed.

Run it with the `-v` switch instead:

```shell
python M.py -v
```

and a detailed report of all examples tried is printed to standard output, along with assorted summaries at the end.

You can force verbose mode by passing `verbose=True` to `testmod()`, or prohibit it by passing `verbose=False`. In either of those cases, `sys.argv` is not examined by `testmod()` (so passing
There is also a command line shortcut for running `testmod()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the module name(s) on the command line:

```
python -m doctest -v example.py
```

This will import `example.py` as a standalone module and run `testmod()` on it. Note that this may not work correctly if the file is part of a package and imports other submodules from that package.

For more information on `testmod()`, see section `Basic API`.
26.3.2. Simple Usage: Checking Examples in a Text File

Another simple application of doctest is testing interactive examples in a text file. This can be done with the `testfile()` function:

```python
import doctest
doctest.testfile("example.txt")
```

That short script executes and verifies any interactive Python examples contained in the file `example.txt`. The file content is treated as if it were a single giant docstring; the file doesn’t need to contain a Python program! For example, perhaps `example.txt` contains this:

```
The ``example`` module
======================

Using ``factorial``
-----------------

This is an example text file in reStructuredText for ``factorial`` from the ``example`` module:

    >>> from example import factorial

Now use it:

    >>> factorial(6)
    120
```

Running `doctest.testfile("example.txt")` then finds the
error in this documentation:

```
File "./example.txt", line 14, in example.txt
Failed example:
    factorial(6)
Expected:
    120
Got:
    720
```

As with `testmod()`, `testfile()` won't display anything unless an example fails. If an example does fail, then the failing example(s) and the cause(s) of the failure(s) are printed to stdout, using the same format as `testmod()`.

By default, `testfile()` looks for files in the calling module's directory. See section Basic API for a description of the optional arguments that can be used to tell it to look for files in other locations.

Like `testmod()`, `testfile()`'s verbosity can be set with the `-v` command-line switch or with the optional keyword argument `verbose`.

There is also a command line shortcut for running `testfile()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the file name(s) on the command line:

```
python -m doctest -v example.txt
```

Because the file name does not end with `.py`, `doctest` infers that it must be run with `testfile()`, not `testmod()`.

For more information on `testfile()`, see section Basic API.
26.3.3. How It Works

This section examines in detail how doctest works: which docstrings it looks at, how it finds interactive examples, what execution context it uses, how it handles exceptions, and how option flags can be used to control its behavior. This is the information that you need to know to write doctest examples; for information about actually running doctest on these examples, see the following sections.

26.3.3.1. Which Docstrings Are Examined?

The module docstring, and all function, class and method docstrings are searched. Objects imported into the module are not searched.

In addition, if M.__test__ exists and “is true”, it must be a dict, and each entry maps a (string) name to a function object, class object, or string. Function and class object docstrings found from M.__test__ are searched, and strings are treated as if they were docstrings. In output, a key K in M.__test__ appears with name

<name of M>.__test__.K

Any classes found are recursively searched similarly, to test docstrings in their contained methods and nested classes.

CPython implementation detail: Prior to version 3.4, extension modules written in C were not fully searched by doctest.

26.3.3.2. How are Docstring Examples Recognized?

In most cases a copy-and-paste of an interactive console session
works fine, but doctest isn’t trying to do an exact emulation of any specific Python shell.

```python
>>> # comments are ignored
>>> x = 12
>>> x
12
>>> if x == 13:
...     print("yes")
... else:
...     print("no")
...     print("NO")
...     print("NO!!!")
no
NO
NO!!!
```  

Any expected output must immediately follow the final `>>>` or `...` line containing the code, and the expected output (if any) extends to the next `>>>` or all-whitespace line.

The fine print:

- Expected output cannot contain an all-whitespace line, since such a line is taken to signal the end of expected output. If expected output does contain a blank line, put `<BLANKLINE>` in your doctest example each place a blank line is expected.

- All hard tab characters are expanded to spaces, using 8-column tab stops. Tabs in output generated by the tested code are not modified. Because any hard tabs in the sample output are expanded, this means that if the code output includes hard tabs, the only way the doctest can pass is if the
NORMALIZE_WHITESPACE option or directive is in effect. Alternatively, the test can be rewritten to capture the output and compare it to an expected value as part of the test. This handling of tabs in the source was arrived at through trial and error, and has proven to be the least error prone way of handling them. It is possible to use a different algorithm for handling tabs by writing a custom DocTestParser class.

- Output to stdout is captured, but not output to stderr (exception tracebacks are captured via a different means).

- If you continue a line via backslashing in an interactive session, or for any other reason use a backslash, you should use a raw docstring, which will preserve your backslashes exactly as you type them:

```python
>>> def f(x):
...     r'''Backslashes in a raw docstring: m\n'''
>>> print(f.__doc__)
Backslashes in a raw docstring: m
```

Otherwise, the backslash will be interpreted as part of the string. For example, the `\n` above would be interpreted as a newline character. Alternatively, you can double each backslash in the doctest version (and not use a raw string):

```python
>>> def f(x):
...     '''Backslashes in a raw docstring: m\n'''
>>> print(f.__doc__)
Backslashes in a raw docstring: m
```

- The starting column doesn’t matter:
and as many leading whitespace characters are stripped from the expected output as appeared in the initial \texttt{\textgreater大于\textless小于} line that started the example.

26.3.3.3. What's the Execution Context?

By default, each time \texttt{doctest} finds a docstring to test, it uses a \textit{shallow copy} of \texttt{M}'s globals, so that running tests doesn't change the module's real globals, and so that one test in \texttt{M} can't leave behind crumbs that accidentally allow another test to work. This means examples can freely use any names defined at top-level in \texttt{M}, and names defined earlier in the docstring being run. Examples cannot see names defined in other docstrings.

You can force use of your own dict as the execution context by passing \texttt{globs=your\_dict} to \texttt{testmod()} or \texttt{testfile()} instead.

26.3.3.4. What About Exceptions?

No problem, provided that the traceback is the only output produced by the example: just paste in the traceback. \cite{1} Since tracebacks contain details that are likely to change rapidly (for example, exact file paths and line numbers), this is one case where doctest works hard to be flexible in what it accepts.

Simple example:
That doctest succeeds if `ValueError` is raised, with the `list.remove(x): x not in list` detail as shown.

The expected output for an exception must start with a traceback header, which may be either of the following two lines, indented the same as the first line of the example:

```
Traceback (most recent call last):
Traceback (innermost last):
```

The traceback header is followed by an optional traceback stack, whose contents are ignored by doctest. The traceback stack is typically omitted, or copied verbatim from an interactive session.

The traceback stack is followed by the most interesting part: the line(s) containing the exception type and detail. This is usually the last line of a traceback, but can extend across multiple lines if the exception has a multi-line detail:

```
>>> raise ValueError('multi
  line\ndetail')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: multi
  line
detail
```

The last three lines (starting with `ValueError`) are compared against the exception’s type and detail, and the rest are ignored.
Best practice is to omit the traceback stack, unless it adds significant documentation value to the example. So the last example is probably better as:

```python
>>> raise ValueError('multi\n   line\ndetail')
Traceback (most recent call last):
  ...
ValueError: multi
   line
detail
```

Note that tracebacks are treated very specially. In particular, in the rewritten example, the use of `...` is independent of doctest's `ELLIPSIS` option. The ellipsis in that example could be left out, or could just as well be three (or three hundred) commas or digits, or an indented transcript of a Monty Python skit.

Some details you should read once, but won't need to remember:

- Doctest can't guess whether your expected output came from an exception traceback or from ordinary printing. So, e.g., an example that expects `ValueError: 42 is prime` will pass whether `ValueError` is actually raised or if the example merely prints that traceback text. In practice, ordinary output rarely begins with a traceback header line, so this doesn't create real problems.

- Each line of the traceback stack (if present) must be indented further than the first line of the example, or start with a non-alphanumeric character. The first line following the traceback header indented the same and starting with an alphanumeric is taken to be the start of the exception detail. Of course this does the right thing for genuine tracebacks.
• When the `IGNORE_EXCEPTION_DETAIL` doctest option is specified, everything following the leftmost colon and any module information in the exception name is ignored.

• The interactive shell omits the traceback header line for some `SyntaxError` s. But doctest uses the traceback header line to distinguish exceptions from non-exceptions. So in the rare case where you need to test a `SyntaxError` that omits the traceback header, you will need to manually add the traceback header line to your test example.

• For some `SyntaxError` s, Python displays the character position of the syntax error, using a `^` marker:

```python
>>> 1 1
 File "<stdin>", line 1
   1 1
 ^
SyntaxError: invalid syntax
```

Since the lines showing the position of the error come before the exception type and detail, they are not checked by doctest. For example, the following test would pass, even though it puts the `^` marker in the wrong location:

```python
>>> 1 1
 File "<stdin>", line 1
   1 1
 ^
SyntaxError: invalid syntax
```

26.3.3.5. Option Flags
A number of option flags control various aspects of doctest’s behavior. Symbolic names for the flags are supplied as module constants, which can be bitwise ORed together and passed to various functions. The names can also be used in doctest directives, and may be passed to the doctest command line interface via the `-o` option.

*New in version 3.4:* The `-o` command line option.

The first group of options define test semantics, controlling aspects of how doctest decides whether actual output matches an example’s expected output:

**doctest.\texttt{DONT\_ACCEPT\_TRUE\_FOR\_1}**

By default, if an expected output block contains just 1, an actual output block containing just 1 or just `True` is considered to be a match, and similarly for 0 versus `False`. When `DONT_ACCEPT_TRUE_FOR_1` is specified, neither substitution is allowed. The default behavior caters to that Python changed the return type of many functions from integer to boolean; doctests expecting “little integer” output still work in these cases. This option will probably go away, but not for several years.

**doctest.\texttt{DONT\_ACCEPT\_BLANKLINE}**

By default, if an expected output block contains a line containing only the string `<BLANKLINE>`, then that line will match a blank line in the actual output. Because a genuinely blank line delimits the expected output, this is the only way to communicate that a blank line is expected. When `DONT_ACCEPT_BLANKLINE` is specified, this substitution is not allowed.

**doctest.\texttt{NORMALIZE\_WHITESPACE}**

When specified, all sequences of whitespace (blanks and
newlines) are treated as equal. Any sequence of whitespace within
the expected output will match any sequence of whitespace within
the actual output. By default, whitespace must match exactly.
NORMALIZE_WHITESPACE is especially useful when a line of
expected output is very long, and you want to wrap it across
multiple lines in your source.

doctest.ELLIPSIS
When specified, an ellipsis marker (…) in the expected output
can match any substring in the actual output. This includes
substrings that span line boundaries, and empty substrings, so it’s
best to keep usage of this simple. Complicated uses can lead to
the same kinds of “oops, it matched too much!” surprises that .* is
prone to in regular expressions.

doctest.IGNORE_EXCEPTION_DETAIL
When specified, an example that expects an exception passes if an
exception of the expected type is raised, even if the exception
detail does not match. For example, an example expecting
ValueError: 42 will pass if the actual exception raised is
ValueError: 3*14, but will fail, e.g., if TypeError is raised.

It will also ignore the module name used in Python 3 doctest
reports. Hence both of these variations will work with the flag
specified, regardless of whether the test is run under Python 2.7 or
Python 3.2 (or later versions):

```python
>>> raise CustomError('message')
Traceback (most recent call last):
CustomError: message
```

```python
>>> raise CustomError('message')
Traceback (most recent call last):
```
Note that **ELLIPSIS** can also be used to ignore the details of the exception message, but such a test may still fail based on whether or not the module details are printed as part of the exception name. Using **IGNORE_EXCEPTION_DETAIL** and the details from Python 2.3 is also the only clear way to write a doctest that doesn’t care about the exception detail yet continues to pass under Python 2.3 or earlier (those releases do not support **doctest directives** and ignore them as irrelevant comments). For example:

```python
>>> (1, 2)[3] = 'moo'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: object doesn't support item assignment
```

passes under Python 2.3 and later Python versions with the flag specified, even though the detail changed in Python 2.4 to say “does not” instead of “doesn’t”.

*Changed in version 3.2*: **IGNORE_EXCEPTION_DETAIL** now also ignores any information relating to the module containing the exception under test.

**doctest.SKIP**

When specified, do not run the example at all. This can be useful in contexts where doctest examples serve as both documentation and test cases, and an example should be included for documentation purposes, but should not be checked. E.g., the example’s output might be random; or the example might depend on resources which would be unavailable to the test driver.

The SKIP flag can also be used for temporarily “commenting out”
examples.

doctest.COMPARISON_FLAGS

A bitmask or'ing together all the comparison flags above.

The second group of options controls how test failures are reported:

doctest.REPORT_UDIFF

When specified, failures that involve multi-line expected and actual outputs are displayed using a unified diff.

doctest.REPORT_CDIFF

When specified, failures that involve multi-line expected and actual outputs will be displayed using a context diff.

doctest.REPORT_NDIFF

When specified, differences are computed by difflib.Differ, using the same algorithm as the popular ndiff.py utility. This is the only method that marks differences within lines as well as across lines. For example, if a line of expected output contains digit 1 where actual output contains letter l, a line is inserted with a caret marking the mismatching column positions.

doctest.REPORT_ONLY_FIRST_FAILURE

When specified, display the first failing example in each doctest, but suppress output for all remaining examples. This will prevent doctest from reporting correct examples that break because of earlier failures; but it might also hide incorrect examples that fail independently of the first failure. When REPORT_ONLY_FIRST_FAILURE is specified, the remaining examples are still run, and still count towards the total number of failures reported; only the output is suppressed.
doctest. **FAIL_FAST**

When specified, exit after the first failing example and don’t attempt to run the remaining examples. Thus, the number of failures reported will be at most 1. This flag may be useful during debugging, since examples after the first failure won’t even produce debugging output.

The doctest command line accepts the option `-f` as a shorthand for `-o FAIL_FAST`.

*New in version 3.4.*

**doctest. REPORTING_FLAGS**

A bitmask or'ing together all the reporting flags above.

There is also a way to register new option flag names, though this isn't useful unless you intend to extend doctest internals via subclassing:

**doctest. register_optionflag**(*name*)

Create a new option flag with a given name, and return the new flag's integer value. `register_optionflag()` can be used when subclassing `OutputChecker` or `DocTestRunner` to create new options that are supported by your subclasses. `register_optionflag()` should always be called using the following idiom:

```
MY_FLAG = register_optionflag('MY_FLAG')
```

### 26.3.3.6. Directives

Doctest directives may be used to modify the option flags for an individual example. Doctest directives are special Python comments...
following an example's source code:

```
directive ::= "#" "doctest:" directive
directive_options ::= directive_option ("," directive_option)
directive_option ::= on_or_off directive_option_name
don_or_off ::= "+" | "-"
directive_option_name ::= "DONT_ACCEPT_BLANKLINE" 
```

Whitespace is not allowed between the `+` or `-` and the directive option name. The directive option name can be any of the option flag names explained above.

An example's doctest directives modify doctest's behavior for that single example. Use `+` to enable the named behavior, or `-` to disable it.

For example, this test passes:

```
>>> print(list(range(20))) # doctest: +NORMALIZE_WHITESPACE
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19]
```

Without the directive it would fail, both because the actual output doesn’t have two blanks before the single-digit list elements, and because the actual output is on a single line. This test also passes, and also requires a directive to do so:

```
>>> print(list(range(20))) # doctest: +ELLIPSIS
[0, 1, ..., 18, 19]
```

Multiple directives can be used on a single physical line, separated by commas:
If multiple directive comments are used for a single example, then they are combined:

```python
>>> print(list(range(20)))  # doctest: +ELLIPSIS, +NORMALIZE_WHITESPACE
[0, 1, ..., 18, 19]
```

As the previous example shows, you can add `...` lines to your example containing only directives. This can be useful when an example is too long for a directive to comfortably fit on the same line:

```python
>>> print(list(range(20)))  # doctest: +ELLIPSIS
...  # doctest: +NORMALIZE_WHITESPACE
[0, 1, ..., 18, 19]
```

Note that since all options are disabled by default, and directives apply only to the example they appear in, enabling options (via `+` in a directive) is usually the only meaningful choice. However, option flags can also be passed to functions that run doctests, establishing different defaults. In such cases, disabling an option via `-` in a directive can be useful.

26.3.3.7. Warnings

doctest is serious about requiring exact matches in expected output. If even a single character doesn’t match, the test fails. This will probably surprise you a few times, as you learn exactly what Python does and doesn’t guarantee about output. For example, when printing
a dict, Python doesn’t guarantee that the key-value pairs will be printed in any particular order, so a test like

```python
>>> foo()
{'Hermione': 'hippogryph', 'Harry': 'broomstick'}
```

is vulnerable! One workaround is to do

```python
>>> foo() == {'Hermione': 'hippogryph', 'Harry': 'broomstick'}
True
```

instead. Another is to do

```python
>>> d = sorted(foo().items())
>>> d
[('Harry', 'broomstick'), ('Hermione', 'hippogryph')]
```

There are others, but you get the idea.

Another bad idea is to print things that embed an object address, like

```python
>>> id(1.0)  # certain to fail some of the time
7948648
>>> class C: pass
>>> C()  # the default repr() for instances embeds
<__main__.C instance at 0x00AC18F0>
```

The `ELLIPSIS` directive gives a nice approach for the last example:

```python
>>> C()  # doctest: +ELLIPSIS
<__main__.C instance at 0x...>
```

Floating-point numbers are also subject to small output variations
across platforms, because Python defers to the platform C library for float formatting, and C libraries vary widely in quality here.

```python
>>> 1./7  # risky
0.14285714285714285
>>> print(1./7)  # safer
0.142857142857
>>> print(round(1./7, 6))  # much safer
0.142857
```

Numbers of the form $\frac{I}{2.**J}$ are safe across all platforms, and I often contrive doctest examples to produce numbers of that form:

```python
>>> 3./4  # utterly safe
0.75
```

Simple fractions are also easier for people to understand, and that makes for better documentation.
26.3.4. Basic API

The functions `testmod()` and `testfile()` provide a simple interface to doctest that should be sufficient for most basic uses. For a less formal introduction to these two functions, see sections Simple Usage: Checking Examples in Docstrings and Simple Usage: Checking Examples in a Text File.

```python
doctest.testfile(filename, module_relative=True, name=None, package=None, globs=None, verbose=None, report=True, optionflags=0, extraglobs=None, raise_on_error=False, parser=DocTestParser(), encoding=None)
```

All arguments except `filename` are optional, and should be specified in keyword form.

Test examples in the file named `filename`. Return `(failure_count, test_count)`.

Optional argument `module_relative` specifies how the filename should be interpreted:

- If `module_relative` is `True` (the default), then `filename` specifies an OS-independent module-relative path. By default, this path is relative to the calling module’s directory; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, `filename` should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If `module_relative` is `False`, then `filename` specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.
Optional argument *name* gives the name of the test; by default, or if None, `os.path.basename(filename)` is used.

Optional argument *package* is a Python package or the name of a Python package whose directory should be used as the base directory for a module-relative filename. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify *package* if *module_relative* is False.

Optional argument *globs* gives a dict to be used as the globals when executing examples. A new shallow copy of this dict is created for the doctest, so its examples start with a clean slate. By default, or if None, a new empty dict is used.

Optional argument *extraglobs* gives a dict merged into the globals used to execute examples. This works like `dict.update()`: if *globs* and *extraglobs* have a common key, the associated value in *extraglobs* appears in the combined dict. By default, or if None, no extra globals are used. This is an advanced feature that allows parameterization of doctests. For example, a doctest can be written for a base class, using a generic name for the class, then reused to test any number of subclasses by passing an *extraglobs* dict mapping the generic name to the subclass to be tested.

Optional argument *verbose* prints lots of stuff if true, and prints only failures if false; by default, or if None, it's true if and only if '-v' is in `sys.argv`.

Optional argument *report* prints a summary at the end when true, else prints nothing at the end. In verbose mode, the summary is detailed, else the summary is very brief (in fact, empty if all tests passed).
Optional argument *optionflags* (default value 0) takes the bitwise OR of option flags. See section *Option Flags*.

Optional argument *raise_on_error* defaults to false. If true, an exception is raised upon the first failure or unexpected exception in an example. This allows failures to be post-mortem debugged. Default behavior is to continue running examples.

Optional argument *parser* specifies a *DocTestParser* (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., *DocTestParser()*).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

```
doctest.testmod(m=None, name=None, globs=None, verbose=None, report=True, optionflags=0, extraglobs=None, raise_on_error=False, exclude_empty=False)
```

All arguments are optional, and all except for *m* should be specified in keyword form.

Test examples in docstrings in functions and classes reachable from module *m* (or module *__main__* if *m* is not supplied or is *None*), starting with *m.__doc__*.

Also test examples reachable from dict *m.__test__*, if it exists and is not *None*. *m.__test__* maps names (strings) to functions, classes and strings; function and class docstrings are searched for examples; strings are searched directly, as if they were docstrings.

Only docstrings attached to objects belonging to module *m* are searched.

Return (*failure_count*, *test_count*).
Optional argument *name* gives the name of the module; by default, or if None, `m.__name__` is used.

Optional argument *exclude_empty* defaults to false. If true, objects for which no doctests are found are excluded from consideration. The default is a backward compatibility hack, so that code still using `doctest.master.summarize()` in conjunction with `testmod()` continues to get output for objects with no tests. The `exclude_empty` argument to the newer `DocTestFinder` constructor defaults to true.

Optional arguments *extraglobs*, *verbose*, *report*, *optionflags*, *raise_on_error*, and *globs* are the same as for function `testfile()` above, except that *globs* defaults to `m.__dict__`.

```python
doctest.run_docstring_examples(f, globs, verbose=False, name="NoName", compileflags=None, optionflags=0)
```

Test examples associated with object *f*; for example, *f* may be a string, a module, a function, or a class object.

A shallow copy of dictionary argument *globs* is used for the execution context.

Optional argument *name* is used in failure messages, and defaults to "NoName".

If optional argument *verbose* is true, output is generated even if there are no failures. By default, output is generated only in case of an example failure.

Optional argument *compileflags* gives the set of flags that should be used by the Python compiler when running the examples. By
default, or if None, flags are deduced corresponding to the set of future features found in globs.

Optional argument optionflags works as for function testfile() above.
26.3.5. Unittest API

As your collection of doctest'ed modules grows, you'll want a way to run all their doctests systematically. doctest provides two functions that can be used to create unittest test suites from modules and text files containing doctests. To integrate with unittest test discovery, include a load_tests() function in your test module:

```python
import unittest
import doctest
import my_module_with_doctests

def load_tests(loader, tests, ignore):
    tests.addTests(doctest.DocTestSuite(my_module_with_doctests))
    return tests
```

There are two main functions for creating unittest.TestSuite instances from text files and modules with doctests:

```python
doctest.DocFileSuite(*paths, module_relative=True, package=None, setUp=None, tearDown=None, globs=None, optionflags=0, parser=DocTestParser(), encoding=None)
```

Convert doctest tests from one or more text files to a unittest.TestSuite.

The returned unittest.TestSuite is to be run by the unittest framework and runs the interactive examples in each file. If an example in any file fails, then the synthesized unit test fails, and a failureException exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Pass one or more paths (as strings) to text files to be examined.
Options may be provided as keyword arguments:

Optional argument `module_relative` specifies how the filenames in `paths` should be interpreted:

- If `module_relative` is `True` (the default), then each filename in `paths` specifies an OS-independent module-relative path. By default, this path is relative to the calling module’s directory; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, each filename should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If `module_relative` is `False`, then each filename in `paths` specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument `package` is a Python package or the name of a Python package whose directory should be used as the base directory for module-relative filenames in `paths`. If no package is specified, then the calling module’s directory is used as the base directory for module-relative filenames. It is an error to specify `package` if `module_relative` is `False`.

Optional argument `setUp` specifies a set-up function for the test suite. This is called before running the tests in each file. The `setUp` function will be passed a `DocTest` object. The setUp function can access the test globals as the `globs` attribute of the test passed.

Optional argument `tearDown` specifies a tear-down function for the test suite. This is called after running the tests in each file. The `tearDown` function will be passed a `DocTest` object. The tearDown function can access the test globals as the `globs` attribute of the test passed.
Optional argument *globs* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globs* is a new empty dictionary.

Optional argument *optionflags* specifies the default doctest options for the tests, created by or-ing together individual option flags. See section **Option Flags**. See function `set_unittest_reportflags()` below for a better way to set reporting options.

Optional argument *parser* specifies a `DocTestParser` (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

The global `__file__` is added to the globals provided to doctests loaded from a text file using `DocFileSuite()`.

```python
doctest.DocTestSuite(module=None, globs=None, extraglobs=None, test_finder=None, setUp=None, tearDown=None, checker=None)
```

Convert doctest tests for a module to a `unittest.TestCase`.

The returned `unittest.TestCase` is to be run by the unittest framework and runs each doctest in the module. If any of the doctests fail, then the synthesized unit test fails, and a `failureException` exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Optional argument *module* provides the module to be tested. It can be a module object or a (possibly dotted) module name. If not
specified, the module calling this function is used.

Optional argument *globs* is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, *globs* is a new empty dictionary.

Optional argument *extraglobs* specifies an extra set of global variables, which is merged into *globs*. By default, no extra globals are used.

Optional argument *test_finder* is the *DocTestFinder* object (or a drop-in replacement) that is used to extract doctests from the module.

Optional arguments *setUp*, *tearDown*, and *optionflags* are the same as for function *DocFileSuite()* above.

This function uses the same search technique as *testmod()*.

*Changed in version 3.5:* *DocTestSuite()* returns an empty *unittest.TestSuite* if *module* contains no docstrings instead of raising *ValueError*.

Under the covers, *DocTestSuite()* creates a *unittest.TestSuite* out of *doctest.DocTestCase* instances, and *DocTestCase* is a subclass of *unittest.TestCase*. *DocTestCase* isn't documented here (it's an internal detail), but studying its code can answer questions about the exact details of *unittest* integration.

Similarly, *DocFileSuite()* creates a *unittest.TestSuite* out of *doctest.DocFileCase* instances, and *DocFileCase* is a subclass of *DocTestCase*. 
So both ways of creating a `unittest.TestSuite` run instances of `DocTestTestCase`. This is important for a subtle reason: when you run `doctest` functions yourself, you can control the `doctest` options in use directly, by passing option flags to `doctest` functions. However, if you're writing a `unittest` framework, `unittest` ultimately controls when and how tests get run. The framework author typically wants to control `doctest` reporting options (perhaps, e.g., specified by command line options), but there's no way to pass options through `unittest` to `doctest` test runners.

For this reason, `doctest` also supports a notion of `doctest` reporting flags specific to `unittest` support, via this function:

```python
doctest.set_unittest_reportflags(flags)
```

Set the `doctest` reporting flags to use.

Argument `flags` takes the bitwise OR of option flags. See section `Option Flags`. Only “reporting flags” can be used.

This is a module-global setting, and affects all future doctests run by module `unittest`: the `runTest()` method of `DocTestTestCase` looks at the option flags specified for the test case when the `DocTestTestCase` instance was constructed. If no reporting flags were specified (which is the typical and expected case), `doctest`'s `unittest` reporting flags are bitwise ORed into the option flags, and the option flags so augmented are passed to the `DocTestRunner` instance created to run the doctest. If any reporting flags were specified when the `DocTestTestCase` instance was constructed, `doctest`'s `unittest` reporting flags are ignored.

The value of the `unittest` reporting flags in effect before the
function was called is returned by the function.
26.3.6. Advanced API

The basic API is a simple wrapper that’s intended to make doctest easy to use. It is fairly flexible, and should meet most users’ needs; however, if you require more fine-grained control over testing, or wish to extend doctest’s capabilities, then you should use the advanced API.

The advanced API revolves around two container classes, which are used to store the interactive examples extracted from doctest cases:

- **Example**: A single Python statement, paired with its expected output.
- **DocTest**: A collection of Examples, typically extracted from a single docstring or text file.

Additional processing classes are defined to find, parse, and run, and check doctest examples:

- **DocTestFinder**: Finds all docstrings in a given module, and uses a DocTestParser to create a DocTest from every docstring that contains interactive examples.
- **DocTestParser**: Creates a DocTest object from a string (such as an object’s docstring).
- **DocTestRunner**: Executes the examples in a DocTest, and uses an OutputChecker to verify their output.
- **OutputChecker**: Compares the actual output from a doctest example with the expected output, and decides whether they match.

The relationships among these processing classes are summarized in the following diagram:
26.3.6.1. DocTest Objects

class doctest.**DocTest**(**examples**, **globs**, **name**, **filename**, **lineno**, **docstring**)  

A collection of doctest examples that should be run in a single namespace. The constructor arguments are used to initialize the attributes of the same names.

**DocTest** defines the following attributes. They are initialized by the constructor, and should not be modified directly.

**examples**

A list of **Example** objects encoding the individual interactive Python examples that should be run by this test.

**globs**

The namespace (aka globals) that the examples should be run in. This is a dictionary mapping names to values. Any changes to the namespace made by the examples (such as binding new variables) will be reflected in **globs** after the test is run.

**name**

A string name identifying the **DocTest**. Typically, this is the
name of the object or file that the test was extracted from.

**filename**
The name of the file that this `DocTest` was extracted from; or None if the filename is unknown, or if the `DocTest` was not extracted from a file.

**lineno**
The line number within `filename` where this `DocTest` begins, or None if the line number is unavailable. This line number is zero-based with respect to the beginning of the file.

**docstring**
The string that the test was extracted from, or None if the string is unavailable, or if the test was not extracted from a string.

### 26.3.6.2. Example Objects

```python
class doctest.Example(source, want, exc_msg=None, lineno=0, indent=0, options=None)
```
A single interactive example, consisting of a Python statement and its expected output. The constructor arguments are used to initialize the attributes of the same names.

`Example` defines the following attributes. They are initialized by the constructor, and should not be modified directly.

**source**
A string containing the example’s source code. This source code consists of a single Python statement, and always ends with a newline; the constructor adds a newline when necessary.
**want**

The expected output from running the example's source code (either from stdout, or a traceback in case of exception). **want** ends with a newline unless no output is expected, in which case it's an empty string. The constructor adds a newline when necessary.

**exc_msg**

The exception message generated by the example, if the example is expected to generate an exception; or `None` if it is not expected to generate an exception. This exception message is compared against the return value of `traceback.format_exception_only()`. **exc_msg** ends with a newline unless it's `None`. The constructor adds a newline if needed.

**lineno**

The line number within the string containing this example where the example begins. This line number is zero-based with respect to the beginning of the containing string.

**indent**

The example's indentation in the containing string, i.e., the number of space characters that precede the example's first prompt.

**options**

A dictionary mapping from option flags to `True` or `False`, which is used to override default options for this example. Any option flags not contained in this dictionary are left at their default value (as specified by the `DocTestRunner`'s `optionflags`). By default, no options are set.
26.3.6.3. DocTestFinder objects

class doctest.DocTestFinder(verbos=False,
parser=DocTestParser(), recurse=True, exclude_empty=True)

A processing class used to extract the DocTests that are relevant to a given object, from its docstring and the docstrings of its contained objects. DocTests can be extracted from modules, classes, functions, methods, staticmethods, classmethods, and properties.

The optional argument verbose can be used to display the objects searched by the finder. It defaults to False (no output).

The optional argument parser specifies the DocTestParser object (or a drop-in replacement) that is used to extract doctests from docstrings.

If the optional argument recurse is false, then DocTestFinder.find() will only examine the given object, and not any contained objects.

If the optional argument exclude_empty is false, then DocTestFinder.find() will include tests for objects with empty docstrings.

DocTestFinder defines the following method:

find(obj[, name][, module][, globs][, extraglobs])

Return a list of the DocTests that are defined by obj’s docstring, or by any of its contained objects’ docstrings.

The optional argument name specifies the object’s name; this
name will be used to construct names for the returned DocTests. If name is not specified, then \texttt{obj.__name__} is used.

The optional parameter \textit{module} is the module that contains the given object. If the module is not specified or is \texttt{None}, then the test finder will attempt to automatically determine the correct module. The object’s module is used:

- As a default namespace, if \texttt{globs} is not specified.
- To prevent the DocTestFinder from extracting DocTests from objects that are imported from other modules. (Contained objects with modules other than \textit{module} are ignored.)
- To find the name of the file containing the object.
- To help find the line number of the object within its file.

If \textit{module} is \texttt{False}, no attempt to find the module will be made. This is obscure, of use mostly in testing doctest itself: if \textit{module} is \texttt{False}, or is \texttt{None} but cannot be found automatically, then all objects are considered to belong to the (non-existent) module, so all contained objects will (recursively) be searched for doctests.

The globals for each \texttt{DocTest} is formed by combining \texttt{globs} and \texttt{extraglobs} (bindings in \texttt{extraglobs} override bindings in \texttt{globs}). A new shallow copy of the globals dictionary is created for each \texttt{DocTest}. If \texttt{globs} is not specified, then it defaults to the module’s \texttt{__dict__}, if specified, or \texttt{[]} otherwise. If \texttt{extraglobs} is not specified, then it defaults to \texttt{[]}.

\textbf{26.3.6.4. DocTestParser objects}
class doctest.**DocTestParser**

A processing class used to extract interactive examples from a string, and use them to create a **DocTest** object.

**DocTestParser** defines the following methods:

**get_doctest** (*string, globs, name, filename, lineno*)

Extract all doctest examples from the given string, and collect them into a **DocTest** object.

`globs`, `name`, `filename`, and `lineno` are attributes for the new **DocTest** object. See the documentation for **DocTest** for more information.

**get_examples** (*string, name='<string>'*)

Extract all doctest examples from the given string, and return them as a list of **Example** objects. Line numbers are 0-based. The optional argument `name` is a name identifying this string, and is only used for error messages.

**parse** (*string, name='<string>'*)

Divide the given string into examples and intervening text, and return them as a list of alternating **Examples** and strings. Line numbers for the **Examples** are 0-based. The optional argument `name` is a name identifying this string, and is only used for error messages.

### 26.3.6.5. DocTestRunner objects

**class doctest.**DocTestRunner(*checker=None, verbose=None, optionflags=0*)

A processing class used to execute and verify the interactive
examples in a DocTest.

The comparison between expected outputs and actual outputs is done by an OutputChecker. This comparison may be customized with a number of option flags; see section Option Flags for more information. If the option flags are insufficient, then the comparison may also be customized by passing a subclass of OutputChecker to the constructor.

The test runner’s display output can be controlled in two ways. First, an output function can be passed to TestRunner.run(); this function will be called with strings that should be displayed. It defaults to sys.stdout.write. If capturing the output is not sufficient, then the display output can be also customized by subclassing DocTestRunner, and overriding the methods report_start(), report_success(), report_unexpected_exception(), and report_failure().

The optional keyword argument checker specifies the OutputChecker object (or drop-in replacement) that should be used to compare the expected outputs to the actual outputs of doctest examples.

The optional keyword argument verbose controls the DocTestRunner’s verbosity. If verbose is True, then information is printed about each example, as it is run. If verbose is False, then only failures are printed. If verbose is unspecified, or None, then verbose output is used iff the command-line switch -v is used.

The optional keyword argument optionflags can be used to control
how the test runner compares expected output to actual output, and how it displays failures. For more information, see section Option Flags.

DocTestParser defines the following methods:

report_start(out, test, example)
Report that the test runner is about to process the given example. This method is provided to allow subclasses of DocTestRunner to customize their output; it should not be called directly.

example is the example about to be processed. test is the test containing example. out is the output function that was passed to DocTestRunner.run().

report_success(out, test, example, got)
Report that the given example ran successfully. This method is provided to allow subclasses of DocTestRunner to customize their output; it should not be called directly.

example is the example about to be processed. got is the actual output from the example. test is the test containing example. out is the output function that was passed to DocTestRunner.run().

report_failure(out, test, example, got)
Report that the given example failed. This method is provided to allow subclasses of DocTestRunner to customize their output; it should not be called directly.

example is the example about to be processed. got is the actual output from the example. test is the test containing example.
out is the output function that was passed to DocTestRunner.run().

report_unexpected_exception(out, test, example, exc_info)
Report that the given example raised an unexpected exception. This method is provided to allow subclasses of DocTestRunner to customize their output; it should not be called directly.

element is the example about to be processed. exc_info is a tuple containing information about the unexpected exception (as returned by sys.exc_info()). test is the test containing example. out is the output function that was passed to DocTestRunner.run().

run(test, compileflags=None, out=None, clear_globs=True)
Run the examples in test (a DocTest object), and display the results using the writer function out.

The examples are run in the namespace test.globs. If clear_globs is true (the default), then this namespace will be cleared after the test runs, to help with garbage collection. If you would like to examine the namespace after the test completes, then use clear_globs=False.

compileflags gives the set of flags that should be used by the Python compiler when running the examples. If not specified, then it will default to the set of future-import flags that apply to globs.

The output of each example is checked using the DocTestRunner's output checker, and the results are
formatted by the DocTestRunner.report_*( ) methods.

**summarize**(verbose=None)

Print a summary of all the test cases that have been run by this DocTestRunner, and return a named tuple 
TestResults(failed, attempted).

The optional verbose argument controls how detailed the summary is. If the verbosity is not specified, then the DocTestRunner’s verbosity is used.

26.3.6.6. OutputChecker objects

class doctest.**OutputChecker**

A class used to check the whether the actual output from a doctest example matches the expected output. OutputChecker defines two methods: check_output(), which compares a given pair of outputs, and returns true if they match; and output_difference(), which returns a string describing the differences between two outputs.

**OutputChecker** defines the following methods:

**check_output**(want, got, optionflags)

Return True iff the actual output from an example (got) matches the expected output (want). These strings are always considered to match if they are identical; but depending on what option flags the test runner is using, several non-exact match types are also possible. See section **Option Flags** for more information about option flags.

**output_difference**(example, got, optionflags)
Return a string describing the differences between the expected output for a given example (example) and the actual output (got). optionflags is the set of option flags used to compare want and got.
26.3.7. Debugging

Doctest provides several mechanisms for debugging doctest examples:

- Several functions convert doctests to executable Python programs, which can be run under the Python debugger, `pdb`.

- The `DebugRunner` class is a subclass of `DocTestRunner` that raises an exception for the first failing example, containing information about that example. This information can be used to perform post-mortem debugging on the example.

- The `unittest` cases generated by `DocTestSuite()` support the `debug()` method defined by `unittest.TestCase`.

- You can add a call to `pdb.set_trace()` in a doctest example, and you'll drop into the Python debugger when that line is executed. Then you can inspect current values of variables, and so on. For example, suppose `a.py` contains just this module docstring:

```python
""
>>> def f(x):
...    g(x*2)
>>> def g(x):
...    print(x+3)
...    import pdb; pdb.set_trace()
>>> f(3)
g
""
```

Then an interactive Python session may look like this:
>>> import a, doctest
>>> doctest.testmod(a)
--Return--
> <doctest a[1]>(3)g()->None
-> import pdb; pdb.set_trace()
(Pdb) list
  1    def g(x):
  2         print(x+3)
  3    ->    import pdb; pdb.set_trace()
[EOF]
(Pdb) p x
6
(Pdb) step
--Return--
> <doctest a[0]>(2)f()->None
-> g(x*2)
(Pdb) list
  1    def f(x):
  2    ->    g(x*2)
[EOF]
(Pdb) p x
3
(Pdb) step
--Return--
> <doctest a[2]>(1)?()->None
-> f(3)
(Pdb) cont
(0, 3)

Functions that convert doctests to Python code, and possibly run the synthesized code under the debugger:

doctest..script_from_examples(s)

    Convert text with examples to a script.
Argument \texttt{s} is a string containing doctest examples. The string is converted to a Python script, where doctest examples in \texttt{s} are converted to regular code, and everything else is converted to Python comments. The generated script is returned as a string. For example,

```
import doctest
print(doctest.script_from_examples(r""
    Set \texttt{x} and \texttt{y} to 1 and 2.
    >>> \texttt{x}, \texttt{y} = 1, 2

    Print their sum:
    >>> print(\texttt{x+y})
    3
""))
```

displays:

```
\# Set \texttt{x} and \texttt{y} to 1 and 2.
\texttt{x}, \texttt{y} = 1, 2
\#
\#	Print their sum:
\texttt{print(\texttt{x+y})}
\#	Expected:
##
\#	3
```

This function is used internally by other functions (see below), but can also be useful when you want to transform an interactive Python session into a Python script.

\texttt{doctest.testsource(module, name)}

Convert the doctest for an object to a script.

Argument \texttt{module} is a module object, or dotted name of a module, containing the object whose doctests are of interest. Argument
name is the name (within the module) of the object with the doctests of interest. The result is a string, containing the object's docstring converted to a Python script, as described for script_from_examples() above. For example, if module a.py contains a top-level function f(), then

```python
import a, doctest
print(doctest.testsource(a, "a.f"))
```

prints a script version of function f()'s docstring, with doctests converted to code, and the rest placed in comments.

```python
doctest.debug(module, name, pm=False)
```

Debug the doctests for an object.

The module and name arguments are the same as for function testsource() above. The synthesized Python script for the named object's docstring is written to a temporary file, and then that file is run under the control of the Python debugger, pdb.

A shallow copy of module.__dict__ is used for both local and global execution context.

Optional argument pm controls whether post-mortem debugging is used. If pm has a true value, the script file is run directly, and the debugger gets involved only if the script terminates via raising an unhandled exception. If it does, then post-mortem debugging is invoked, via pdb.post_mortem(), passing the traceback object from the unhandled exception. If pm is not specified, or is false, the script is run under the debugger from the start, via passing an appropriate exec() call to pdb.run().

```python
doctest.debug_src(src, pm=False,lobs=None)
```
Debug the doctests in a string.

This is like function `debug()` above, except that a string containing doctest examples is specified directly, via the `src` argument.

Optional argument `pm` has the same meaning as in function `debug()` above.

Optional argument `globs` gives a dictionary to use as both local and global execution context. If not specified, or `None`, an empty dictionary is used. If specified, a shallow copy of the dictionary is used.

The `DebugRunner` class, and the special exceptions it may raise, are of most interest to testing framework authors, and will only be sketched here. See the source code, and especially `DebugRunner`'s docstring (which is a doctest!) for more details:

```python
class doctest.DebugRunner (checker=None, verbose=None, optionflags=0)

A subclass of `DocTestRunner` that raises an exception as soon as a failure is encountered. If an unexpected exception occurs, an `UnexpectedException` exception is raised, containing the test, the example, and the original exception. If the output doesn't match, then a `DocTestFailure` exception is raised, containing the test, the example, and the actual output.

For information about the constructor parameters and methods, see the documentation for `DocTestRunner` in section Advanced API.

There are two exceptions that may be raised by `DebugRunner`
instances:

*exception* doctest.*DocTestFailure*(test, example, got)

An exception raised by *DocTestRunner* to signal that a doctest example’s actual output did not match its expected output. The constructor arguments are used to initialize the attributes of the same names.

*DocTestFailure* defines the following attributes:

*DocTestFailure*.test

The *DocTest* object that was being run when the example failed.

*DocTestFailure*.example

The *Example* that failed.

*DocTestFailure*.got

The example’s actual output.

*exception* doctest.*UnexpectedException*(test, example, exc_info)

An exception raised by *DocTestRunner* to signal that a doctest example raised an unexpected exception. The constructor arguments are used to initialize the attributes of the same names.

*UnexpectedException* defines the following attributes:

*UnexpectedException*.test

The *DocTest* object that was being run when the example failed.

*UnexpectedException*.example

The *Example* that failed.
UnexpectedException.exc_info

A tuple containing information about the unexpected exception, as returned by `sys.exc_info()`.
26.3.8. Soapbox

As mentioned in the introduction, *doctest* has grown to have three primary uses:

1. Checking examples in docstrings.
2. Regression testing.
3. Executable documentation / literate testing.

These uses have different requirements, and it is important to distinguish them. In particular, filling your docstrings with obscure test cases makes for bad documentation.

When writing a docstring, choose docstring examples with care. There's an art to this that needs to be learned—it may not be natural at first. Examples should add genuine value to the documentation. A good example can often be worth many words. If done with care, the examples will be invaluable for your users, and will pay back the time it takes to collect them many times over as the years go by and things change. I'm still amazed at how often one of my *doctest* examples stops working after a “harmless” change.

Doctest also makes an excellent tool for regression testing, especially if you don’t skimp on explanatory text. By interleaving prose and examples, it becomes much easier to keep track of what’s actually being tested, and why. When a test fails, good prose can make it much easier to figure out what the problem is, and how it should be fixed. It’s true that you could write extensive comments in code-based testing, but few programmers do. Many have found that using doctest approaches instead leads to much clearer tests. Perhaps this is simply because doctest makes writing prose a little easier than writing code, while writing comments in code is a little harder. I think it goes deeper
than just that: the natural attitude when writing a doctest-based test is that you want to explain the fine points of your software, and illustrate them with examples. This in turn naturally leads to test files that start with the simplest features, and logically progress to complications and edge cases. A coherent narrative is the result, instead of a collection of isolated functions that test isolated bits of functionality seemingly at random. It's a different attitude, and produces different results, blurring the distinction between testing and explaining.

Regression testing is best confined to dedicated objects or files. There are several options for organizing tests:

- Write text files containing test cases as interactive examples, and test the files using `testfile()` or `DocFileSuite()`. This is recommended, although is easiest to do for new projects, designed from the start to use doctest.
- Define functions named `_regrtest_topic` that consist of single docstrings, containing test cases for the named topics. These functions can be included in the same file as the module, or separated out into a separate test file.
- Define a `__test__` dictionary mapping from regression test topics to docstrings containing test cases.

When you have placed your tests in a module, the module can itself be the test runner. When a test fails, you can arrange for your test runner to re-run only the failing doctest while you debug the problem. Here is a minimal example of such a test runner:

```python
if __name__ == '__main__':
    import doctest
    flags = doctest.REPORT_NDIFF|doctest.FAIL_FAST
    if len(sys.argv) > 1:
        name = sys.argv[1]
        if name in globals():
```
Footnotes

[1] Examples containing both expected output and an exception are not supported. Trying to guess where one ends and the other begins is too error-prone, and that also makes for a confusing test.
26.4. unittest — Unit testing framework

Source code: Lib/unittest/__init__.py

(If you are already familiar with the basic concepts of testing, you might want to skip to the list of assert methods.)

The unittest unit testing framework was originally inspired by JUnit and has a similar flavor as major unit testing frameworks in other languages. It supports test automation, sharing of setup and shutdown code for tests, aggregation of tests into collections, and independence of the tests from the reporting framework.

To achieve this, unittest supports some important concepts in an object-oriented way:

**test fixture**

A test fixture represents the preparation needed to perform one or more tests, and any associate cleanup actions. This may involve, for example, creating temporary or proxy databases, directories, or starting a server process.

**test case**

A test case is the individual unit of testing. It checks for a specific response to a particular set of inputs. unittest provides a base class, TestCase, which may be used to create new test cases.

**test suite**

A test suite is a collection of test cases, test suites, or both. It is used to aggregate tests that should be executed together.

**test runner**
A test runner is a component which orchestrates the execution of tests and provides the outcome to the user. The runner may use a graphical interface, a textual interface, or return a special value to indicate the results of executing the tests.

Testing in Python Mailing List
A special-interest-group for discussion of testing, and testing tools, in Python.

The script `Tools/unittestgui/unittestgui.py` in the Python source distribution is a GUI tool for test discovery and execution. This is intended largely for ease of use for those new to unit testing. For production environments it is recommended that tests be driven by a continuous integration system such as Buildbot, Jenkins or Hudson.
26.4.1. Basic example

The `unittest` module provides a rich set of tools for constructing and running tests. This section demonstrates that a small subset of the tools suffice to meet the needs of most users.

Here is a short script to test three string methods:

```python
import unittest
class TestStringMethods(unittest.TestCase):
    def test_upper(self):
        self.assertEqual('foo'.upper(), 'FOO')

    def test_isupper(self):
        self.assertTrue('FOO'.isupper())
        self.assertFalse('Foo'.isupper())

    def test_split(self):
        s = 'hello world'
        self.assertEqual(s.split(), ['hello', 'world'])
        # check that s.split fails when the separator is not a string
        with self.assertRaises(TypeError):
            s.split(2)

if __name__ == '__main__':
    unittest.main()
```

A testcase is created by subclassing `unittest.TestCase`. The three individual tests are defined with methods whose names start with the letters `test`. This naming convention informs the test runner about which methods represent tests.
The crux of each test is a call to `assertEqual()` to check for an expected result; `assertTrue()` or `assertFalse()` to verify a condition; or `assertRaises()` to verify that a specific exception gets raised. These methods are used instead of the `assert` statement so the test runner can accumulate all test results and produce a report.

The `setUp()` and `tearDown()` methods allow you to define instructions that will be executed before and after each test method. They are covered in more detail in the section Organizing test code.

The final block shows a simple way to run the tests. `unittest.main()` provides a command-line interface to the test script. When run from the command line, the above script produces an output that looks like this:

```
... 
Ran 3 tests in 0.000s
OK
```

Passing the `-v` option to your test script will instruct `unittest.main()` to enable a higher level of verbosity, and produce the following output:

```
test_isupper (__main__.TestStringMethods) ... ok
test_split (__main__.TestStringMethods) ... ok
test_upper (__main__.TestStringMethods) ... ok

Ran 3 tests in 0.001s
OK
```
The above examples show the most commonly used `unittest` features which are sufficient to meet many everyday testing needs. The remainder of the documentation explores the full feature set from first principles.
26.4.2. Command-Line Interface

The unittest module can be used from the command line to run tests from modules, classes or even individual test methods:

```
python -m unittest test_module1 test_module2
python -m unittest test_module.TestClass
python -m unittest test_module.TestClass.test_method
```

You can pass in a list with any combination of module names, and fully qualified class or method names.

Test modules can be specified by file path as well:

```
python -m unittest tests/test_something.py
```

This allows you to use the shell filename completion to specify the test module. The file specified must still be importable as a module. The path is converted to a module name by removing the `.py` and converting path separators into `.`. If you want to execute a test file that isn't importable as a module you should execute the file directly instead.

You can run tests with more detail (higher verbosity) by passing in the `-v` flag:

```
python -m unittest -v test_module
```

When executed without arguments Test Discovery is started:

```
python -m unittest
```
For a list of all the command-line options:

```
python -m unittest -h
```

*Changed in version 3.2:* In earlier versions it was only possible to run individual test methods and not modules or classes.

### 26.4.2.1. Command-line options

`unittest` supports these command-line options:

**-b, --buffer**

The standard output and standard error streams are buffered during the test run. Output during a passing test is discarded. Output is echoed normally on test fail or error and is added to the failure messages.

**-c, --catch**

`Control-C` during the test run waits for the current test to end and then reports all the results so far. A second `Control-C` raises the normal `KeyboardInterrupt` exception.

See [Signal Handling](#) for the functions that provide this functionality.

**-f, --failfast**

Stop the test run on the first error or failure.

**-k**

Only run test methods and classes that match the pattern or substring. This option may be used multiple times, in which case all test cases that match of the given patterns are included.

Patterns that contain a wildcard character (`*`) are matched against
the test name using `fnmatch.fnmatchcase()`; otherwise simple case-sensitive substring matching is used.

Patterns are matched against the fully qualified test method name as imported by the test loader.

For example, `-k foo` matches `foo_tests.SomeTest.test_something`, `bar_tests.SomeTest.test_foo`, but not `bar_tests.FooTest.test_something`.

**--locals**

Show local variables in tracebacks.

*New in version 3.2:* The command-line options `-b`, `-c` and `-f` were added.

*New in version 3.5:* The command-line option `--locals`.

*New in version 3.7:* The command-line option `-k`.

The command line can also be used for test discovery, for running all of the tests in a project or just a subset.
26.4.3. Test Discovery

*New in version 3.2.*

Unittest supports simple test discovery. In order to be compatible with test discovery, all of the test files must be modules or packages (including namespace packages) importable from the top-level directory of the project (this means that their filenames must be valid identifiers).

Test discovery is implemented in `TestLoader.discover()`, but can also be used from the command line. The basic command-line usage is:

```
$ cd project_directory
$ python -m unittest discover
```

**Note:** As a shortcut, `python -m unittest` is the equivalent of `python -m unittest discover`. If you want to pass arguments to test discovery the `discover` sub-command must be used explicitly.

The `discover` sub-command has the following options:

- `-v, --verbose`
  
  Verbose output

- `-s, --start-directory directory`
  
  Directory to start discovery (`<directory>`, default)

- `-p, --pattern pattern`
  
  Pattern to match test files (`test*.py` default)
-t, --top-level-directory directory
  Top level directory of project (defaults to start directory)

The -s, -p, and -t options can be passed in as positional arguments in that order. The following two command lines are equivalent:

```bash
python -m unittest discover -s project_directory -p
python -m unittest discover project_directory "*_test.py"
```

As well as being a path it is possible to pass a package name, for example `myproject.subpackage.test`, as the start directory. The package name you supply will then be imported and its location on the filesystem will be used as the start directory.

**Caution:** Test discovery loads tests by importing them. Once test discovery has found all the test files from the start directory you specify it turns the paths into package names to import. For example `foo/bar/baz.py` will be imported as `foo.bar.baz`.

If you have a package installed globally and attempt test discovery on a different copy of the package then the import could happen from the wrong place. If this happens test discovery will warn you and exit.

If you supply the start directory as a package name rather than a path to a directory then discover assumes that whichever location it imports from is the location you intended, so you will not get the warning.

Test modules and packages can customize test loading and discovery by through the `load_tests` protocol.

*Changed in version 3.4:* Test discovery supports namespace
packages.
26.4.4. Organizing test code

The basic building blocks of unit testing are test cases — single scenarios that must be set up and checked for correctness. In `unittest`, test cases are represented by `unittest.TestCase` instances. To make your own test cases you must write subclasses of `TestCase` or use `FunctionTestCase`.

The testing code of a `TestCase` instance should be entirely self contained, such that it can be run either in isolation or in arbitrary combination with any number of other test cases.

The simplest `TestCase` subclass will simply implement a test method (i.e. a method whose name starts with `test`) in order to perform specific testing code:

```python
import unittest
class DefaultWidgetSizeTestCase(unittest.TestCase):
    def test_default_widget_size(self):
        widget = Widget('The widget')
        self.assertEqual(widget.size(), (50, 50))
```

Note that in order to test something, we use one of the `assert*()` methods provided by the `TestCase` base class. If the test fails, an exception will be raised, and `unittest` will identify the test case as a `failure`. Any other exceptions will be treated as `errors`.

Tests can be numerous, and their set-up can be repetitive. Luckily, we can factor out set-up code by implementing a method called `setUp()`, which the testing framework will automatically call for every single test we run:
```python
import unittest

class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def test_default_widget_size(self):
        self.assertEqual(self.widget.size(), (50, 50), 'incorrect default size')

    def test_widget_resize(self):
        self.widget.resize(100, 150)
        self.assertEqual(self.widget.size(), (100, 150), 'wrong size after resize')

Note: The order in which the various tests will be run is determined by sorting the test method names with respect to the built-in ordering for strings.

If the setUp() method raises an exception while the test is running, the framework will consider the test to have suffered an error, and the test method will not be executed.

Similarly, we can provide a tearDown() method that tidies up after the test method has been run:
```
```
If `setUp()` succeeded, `tearDown()` will be run whether the test method succeeded or not.

Such a working environment for the testing code is called a **fixture**.

Test case instances are grouped together according to the features they test. `unittest` provides a mechanism for this: the **test suite**, represented by `unittest`'s `TestSuite` class. In most cases, calling `unittest.main()` will do the right thing and collect all the module's test cases for you, and then execute them.

However, should you want to customize the building of your test suite, you can do it yourself:

```python
def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('test_default_widget_size'))
    suite.addTest(WidgetTestCase('test_widget_resize'))
    return suite

if __name__ == '__main__':
    runner = unittest.TextTestRunner()
    runner.run(suite())
```

You can place the definitions of test cases and test suites in the same modules as the code they are to test (such as `widget.py`), but there are several advantages to placing the test code in a separate module, such as `test_widget.py`:

- The test module can be run standalone from the command line.
- The test code can more easily be separated from shipped code.
- There is less temptation to change test code to fit the code it tests without a good reason.
- Test code should be modified much less frequently than the code
it tests.

- Tested code can be refactored more easily.
- Tests for modules written in C must be in separate modules anyway, so why not be consistent?
- If the testing strategy changes, there is no need to change the source code.
26.4.5. Re-using old test code

Some users will find that they have existing test code that they would like to run from `unittest`, without converting every old test function to a `TestCase` subclass.

For this reason, `unittest` provides a `FunctionTestCase` class. This subclass of `TestCase` can be used to wrap an existing test function. Set-up and tear-down functions can also be provided.

Given the following test function:

```python
def testSomething():
    something = makeSomething()
    assert something.name is not None
    # ...
```

one can create an equivalent test case instance as follows, with optional set-up and tear-down methods:

```python
testcase = unittest.FunctionTestCase(testSomething,
        setUp=makeSomethingDB,
        tearDown=deleteSomethingDB)
```

**Note:** Even though `FunctionTestCase` can be used to quickly convert an existing test base over to a `unittest`-based system, this approach is not recommended. Taking the time to set up proper `TestCase` subclasses will make future test refactorings infinitely easier.

In some cases, the existing tests may have been written using the
doctest module. If so, doctest provides a DocTestSuite class that can automatically build unittest.TestSuite instances from the existing doctest-based tests.
26.4.6. Skipping tests and expected failures

New in version 3.1.

Unittest supports skipping individual test methods and even whole classes of tests. In addition, it supports marking a test as an “expected failure,” a test that is broken and will fail, but shouldn’t be counted as a failure on a TestResult.

Skipping a test is simply a matter of using the skip() decorator or one of its conditional variants.

Basic skipping looks like this:

```python
class MyTestCase(unittest.TestCase):
    @unittest.skip("demonstrating skipping")
    def test_nothing(self):
        self.fail("shouldn't happen")

    @unittest.skipIf(mylib.__version__ < (1, 3), "not supported in this library")
    def test_format(self):
        # Tests that work for only a certain version
        pass

    @unittest.skipUnless(sys.platform.startswith("wi"))
    def test_windows_support(self):
        # windows specific testing code
        pass
```

This is the output of running the example above in verbose mode:
Classes can be skipped just like methods:

```python
@unittest.skip("showing class skipping")
class MySkippedTestCase(unittest.TestCase):
    def test_not_run(self):
        pass
```

`TestCase.setUp()` can also skip the test. This is useful when a resource that needs to be set up is not available.

Expected failures use the `expectedFailure()` decorator.

```python
class ExpectedFailureTestCase(unittest.TestCase):
    @unittest.expectedFailure
def test_fail(self):
        self.assertEqual(1, 0, "broken")
```

It's easy to roll your own skipping decorators by making a decorator that calls `skip()` on the test when it wants it to be skipped. This decorator skips the test unless the passed object has a certain attribute:

```python
def skipUnlessHasattr(obj, attr):
    if hasattr(obj, attr):
        return lambda func: func
```
The following decorators implement test skipping and expected failures:

`@unittest.skip(reason)`

Unconditionally skip the decorated test. `reason` should describe why the test is being skipped.

`@unittest.skipIf(condition, reason)`

Skip the decorated test if `condition` is true.

`@unittest.skipUnless(condition, reason)`

Skip the decorated test unless `condition` is true.

`@unittest.expectedFailure`  
Mark the test as an expected failure. If the test fails when run, the test is not counted as a failure.

`exception unittest.SkipTest(reason)`  
This exception is raised to skip a test.

Usually you can use `TestCase.skipTest()` or one of the skipping decorators instead of raising this directly.

Skipped tests will not have `setUp()` or `tearDown()` run around them. Skipped classes will not have `setUpClass()` or `tearDownClass()` run. Skipped modules will not have `setUpModule()` or `tearDownModule()` run.
26.4.7. Distinguishing test iterations using subtests

*New in version 3.4.*

When some of your tests differ only by a some very small differences, for instance some parameters, unittest allows you to distinguish them inside the body of a test method using the `subTest()` context manager.

For example, the following test:

```python
class NumbersTest(unittest.TestCase):
    def test_even(self):
        """
        Test that numbers between 0 and 5 are all even
        """
        for i in range(0, 6):
            with self.subTest(i=i):
                self.assertEqual(i % 2, 0)
```

will produce the following output:

```
FAIL: test_even (__main__.NumbersTest) (i=1)

Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0
```
FAIL: test_even (__main__.NumbersTest) (i=3)

Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0

FAIL: test_even (__main__.NumbersTest) (i=5)

Traceback (most recent call last):
  File "subtests.py", line 32, in test_even
    self.assertEqual(i % 2, 0)
AssertionError: 1 != 0

Without using a subtest, execution would stop after the first failure, and the error would be less easy to diagnose because the value of i wouldn’t be displayed:
26.4.8. Classes and functions

This section describes in depth the API of unittest.

26.4.8.1. Test cases

```python
class unittest.TestCase(methodName='runTest')
```

Instances of the `TestCase` class represent the logical test units in the `unittest` universe. This class is intended to be used as a base class, with specific tests being implemented by concrete subclasses. This class implements the interface needed by the test runner to allow it to drive the tests, and methods that the test code can use to check for and report various kinds of failure.

Each instance of `TestCase` will run a single base method: the method named `methodName`. In most uses of `TestCase`, you will neither change the `methodName` nor reimplement the default `runTest()` method.

`Changed in version 3.2:` `TestCase` can be instantiated successfully without providing a `methodName`. This makes it easier to experiment with `TestCase` from the interactive interpreter.

`TestCase` instances provide three groups of methods: one group used to run the test, another used by the test implementation to check conditions and report failures, and some inquiry methods allowing information about the test itself to be gathered.

Methods in the first group (running the test) are:

```python
setUp()
```
Method called to prepare the test fixture. This is called immediately before calling the test method; other than \texttt{AssertionError} or \texttt{SkipTest}, any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

\texttt{tearDown()}

Method called immediately after the test method has been called and the result recorded. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception, other than \texttt{AssertionError} or \texttt{SkipTest}, raised by this method will be considered an additional error rather than a test failure (thus increasing the total number of reported errors). This method will only be called if the \texttt{setUp()} succeeds, regardless of the outcome of the test method. The default implementation does nothing.

\texttt{setUpClass()}

A class method called before tests in an individual class run. \texttt{setUpClass} is called with the class as the only argument and must be decorated as a \texttt{classmethod}:

\begin{verbatim}
@classmethod
def setUpClass(cls):
    ...
\end{verbatim}

See \texttt{Class and Module Fixtures} for more details.

\textit{New in version 3.2.}

\texttt{tearDownClass()}

A class method called after tests in an individual class have run.
tearDownClass is called with the class as the only argument and must be decorated as a `classmethod()`:

```python
@classmethod
def tearDownClass(cls):
    ...
```

See [Class and Module Fixtures](#) for more details.

*New in version 3.2.*

**run** *(result=None)*

Run the test, collecting the result into the `TestResult` object passed as `result`. If `result` is omitted or `None`, a temporary result object is created (by calling the `defaultTestResult()` method) and used. The result object is returned to `run()`'s caller.

The same effect may be had by simply calling the `TestCase` instance.

*Changed in version 3.3:* Previous versions of `run` did not return the result. Neither did calling an instance.

**skipTest** *(reason)*

Calling this during a test method or `setUp()` skips the current test. See [Skipping tests and expected failures](#) for more information.

*New in version 3.1.*

**subTest** *(msg=None, **params)*

Return a context manager which executes the enclosed code
block as a subtest. *msg* and *params* are optional, arbitrary values which are displayed whenever a subtest fails, allowing you to identify them clearly.

A test case can contain any number of subtest declarations, and they can be arbitrarily nested.

See [Distinguishing test iterations using subtests](#) for more information.

*New in version 3.4.*

d**ebug()**

Run the test without collecting the result. This allows exceptions raised by the test to be propagated to the caller, and can be used to support running tests under a debugger.

The **TestCase** class provides several assert methods to check for and report failures. The following table lists the most commonly used methods (see the tables below for more assert methods):

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertEqual(a, b)</code></td>
<td><code>a == b</code></td>
<td></td>
</tr>
<tr>
<td><code>assertNotEqual(a, b)</code></td>
<td><code>a != b</code></td>
<td></td>
</tr>
<tr>
<td><code>assertTrue(x)</code></td>
<td><code>bool(x) is True</code></td>
<td></td>
</tr>
<tr>
<td><code>assertFalse(x)</code></td>
<td><code>bool(x) is False</code></td>
<td></td>
</tr>
<tr>
<td><code>assertIs(a, b)</code></td>
<td><code>a is b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertIsNot(a, b)</code></td>
<td><code>a is not b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertIsNone(x)</code></td>
<td><code>x is None</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertIsNotNone(x)</code></td>
<td><code>x is not None</code></td>
<td>3.1</td>
</tr>
</tbody>
</table>
assertIn(a, b)  
\[ a \text{ in } b \]  
3.1

assertNotIn(a, b)  
\[ a \text{ not in } b \]  
3.1

assertIsInstance(a, b)  
\[ \text{isinstance}(a, b) \]  
3.2

assertNotIsInstance(a, b)  
\[ \text{not } \text{isinstance}(a, b) \]  
3.2

All the assert methods accept a msg argument that, if specified, is used as the error message on failure (see also longMessage). Note that the msg keyword argument can be passed to assertRaises(), assertRaisesRegex(), assertWarns(), assertWarnsRegex() only when they are used as a context manager.

**assertEqual** \((first, second, msg=None)\)

Test that \(first\) and \(second\) are equal. If the values do not compare equal, the test will fail.

In addition, if \(first\) and \(second\) are the exact same type and one of list, tuple, dict, set, frozenset or str or any type that a subclass registers with addTypeEqualityFunc() the type-specific equality function will be called in order to generate a more useful default error message (see also the list of type-specific methods).

*Changed in version 3.1:* Added the automatic calling of type-specific equality function.

*Changed in version 3.2:* assertMultiLineEqual() added as the default type equality function for comparing strings.
**assertNotEqual** *(first, second, msg=None)*

Test that *first* and *second* are not equal. If the values do compare equal, the test will fail.

**assertTrue** *(expr, msg=None)*
**assertFalse** *(expr, msg=None)*

Test that *expr* is true (or false).

Note that this is equivalent to `bool(expr) is True` and not to `expr is True` (use `assertIs(expr, True)` for the latter). This method should also be avoided when more specific methods are available (e.g. `assertEqual(a, b)` instead of `assertTrue(a == b)`), because they provide a better error message in case of failure.

**assertIs** *(first, second, msg=None)*
**assertIsNot** *(first, second, msg=None)*

Test that *first* and *second* evaluate (or don’t evaluate) to the same object.

*New in version 3.1.*

**assertIsNone** *(expr, msg=None)*
**assertIsNotNone** *(expr, msg=None)*

Test that *expr* is (or is not) None.

*New in version 3.1.*

**assertIn** *(first, second, msg=None)*
**assertNotIn** *(first, second, msg=None)*

Test that *first* is (or is not) in *second*.

*New in version 3.1.*
**assertIsInstance**(obj, cls, msg=None)

**assertNotIsInstance**(obj, cls, msg=None)

Test that obj is (or is not) an instance of cls (which can be a class or a tuple of classes, as supported by `isinstance()`).

To check for the exact type, use `assertIs(type(obj), cls)`.

*New in version 3.2.*

It is also possible to check the production of exceptions, warnings, and log messages using the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertRaises(exc, fun, *args, **kwds)</code></td>
<td><code>fun(*args, **kwds) raises exc</code></td>
<td></td>
</tr>
<tr>
<td><code>assertRaisesRegex(exc, r, fun, *args, **kwds)</code></td>
<td><code>fun(*args, **kwds) raises exc and the message matches regex r</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertWarns(warn, fun, *args, **kwds)</code></td>
<td><code>fun(*args, **kwds) raises warn</code></td>
<td>3.2</td>
</tr>
<tr>
<td><code>assertWarnsRegex(warn, r, fun, *args, **kwds)</code></td>
<td><code>fun(*args, **kwds) raises warn and the message matches regex r</code></td>
<td>3.2</td>
</tr>
<tr>
<td><code>assertLogs(logger, level)</code></td>
<td>The with block logs on logger with minimum <code>level</code></td>
<td>3.4</td>
</tr>
</tbody>
</table>

**assertRaises**(exception, callable, *args, **kwds)

**assertRaises**(exception, msg=None)

Test that an exception is raised when callable is called with any
positional or keyword arguments that are also passed to `assertRaises()`. The test passes if `exception` is raised, is an error if another exception is raised, or fails if no exception is raised. To catch any of a group of exceptions, a tuple containing the exception classes may be passed as `exception`.

If only the `exception` and possibly the `msg` arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```python
with self.assertRaises(SomeException):
    do_something()
```

When used as a context manager, `assertRaises()` accepts the additional keyword argument `msg`.

The context manager will store the caught exception object in its `exception` attribute. This can be useful if the intention is to perform additional checks on the exception raised:

```python
with self.assertRaises(SomeException) as cm:
    do_something()

the_exception = cm.exception
self.assertEqual(the_exception.error_code, 3)
```

*Changed in version 3.1:* Added the ability to use `assertRaises()` as a context manager.

*Changed in version 3.2:* Added the `exception` attribute.

*Changed in version 3.3:* Added the `msg` keyword argument when used as a context manager.
assertRaisesRegex(exception, regex, callable, *args, **kwds)
assertRaisesRegex(exception, regex, msg=None)

Like assertRaises() but also tests that regex matches on the string representation of the raised exception. regex may be a regular expression object or a string containing a regular expression suitable for use by re.search(). Examples:

```python
self.assertRaisesRegex(ValueError, "invalid literal for.*XYZ'"
int, 'XYZ')
```

or:

```python
with self.assertRaisesRegex(ValueError, 'literal'
int('XYZ')
```

*New in version 3.1:* under the name assertRaisesRegexp.

*Changed in version 3.2:* Renamed to assertRaisesRegex().

*Changed in version 3.3:* Added the msg keyword argument when used as a context manager.

assertWarns(warning, callable, *args, **kwds)
assertWarns(warning, msg=None)

Test that a warning is triggered when callable is called with any positional or keyword arguments that are also passed to assertWarns(). The test passes if warning is triggered and fails if it isn't. Any exception is an error. To catch any of a group of warnings, a tuple containing the warning classes may be passed as warnings.
If only the `warning` and possibly the `msg` arguments are given, return a context manager so that the code under test can be written inline rather than as a function:

```python
with self.assertWarns(SomeWarning):
    do_something()
```

When used as a context manager, `assertWarns()` accepts the additional keyword argument `msg`.

The context manager will store the caught warning object in its `warning` attribute, and the source line which triggered the warnings in the `filename` and `lineno` attributes. This can be useful if the intention is to perform additional checks on the warning caught:

```python
with self.assertWarns(SomeWarning) as cm:
    do_something()
    self.assertIn('myfile.py', cm.filename)
    self.assertEqual(320, cm.lineno)
```

This method works regardless of the warning filters in place when it is called.

*New in version 3.2.*

*Changed in version 3.3:* Added the `msg` keyword argument when used as a context manager.

```python
assertWarnsRegex(warning, regex, callable, *args, **kwds)
```

```python
assertWarnsRegex(warning, regex, msg=None)
```

Like `assertWarns()` but also tests that `regex` matches on the message of the triggered warning. `regex` may be a regular
expression object or a string containing a regular expression suitable for use by `re.search()`. Example:

```python
self.assertWarnsRegex(DeprecationWarning, r'legacy_function\(\) is legacy_function, 'XYZ')
```

or:

```python
with self.assertWarnsRegex(RuntimeWarning, 'unsafe frobnicating') as msg:
frobnicate('/etc/passwd')
```

*New in version 3.2.*

*Changed in version 3.3:* Added the `msg` keyword argument when used as a context manager.

**assertLogs** *(logger=None, level=None)*

A context manager to test that at least one message is logged on the `logger` or one of its children, with at least the given `level`.

If given, `logger` should be a `logging.Logger` object or a `str` giving the name of a logger. The default is the root logger, which will catch all messages.

If given, `level` should be either a numeric logging level or its string equivalent (for example either "ERROR" or `logging.ERROR`). The default is `logging.INFO`.

The test passes if at least one message emitted inside the `with` block matches the `logger` and `level` conditions, otherwise it fails.
The object returned by the context manager is a recording helper which keeps tracks of the matching log messages. It has two attributes:

**records**

A list of `logging.LogRecord` objects of the matching log messages.

**output**

A list of `str` objects with the formatted output of matching messages.

Example:

```python
with self.assertLogs('foo', level='INFO') as cm:
    logging.getLogger('foo').info('first message')
    logging.getLogger('foo.bar').error('second message')
self.assertEqual(cm.output, ['INFO:foo:first message', 'ERROR:foo.bar:second message'])
```

*New in version 3.4.*

There are also other methods used to perform more specific checks, such as:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertAlmostEqual(a, b)</code></td>
<td><code>round(a-b, 7) == 0</code></td>
<td>3.4</td>
</tr>
<tr>
<td><code>assertNotAlmostEqual(a, b)</code></td>
<td><code>round(a-b, 7) != 0</code></td>
<td></td>
</tr>
<tr>
<td><code>assertGreater(a, b)</code></td>
<td><code>a &gt; b</code></td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertGreaterEqual(a, b)</code></td>
<td><code>a &gt;= b</code></td>
<td>3.1</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Version</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td><code>assertLess(a, b)</code></td>
<td>a &lt; b</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertLessEqual(a, b)</code></td>
<td>a &lt;= b</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertRegex(s, r)</code></td>
<td>r.search(s)</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertNotRegex(s, r)</code></td>
<td>not r.search(s)</td>
<td>3.2</td>
</tr>
<tr>
<td><code>assertCountEqual(a, b)</code></td>
<td>a and b have the same elements in the same number, regardless of their order</td>
<td>3.2</td>
</tr>
</tbody>
</table>

### assertAlmostEqual

```python
assertAlmostEqual(first, second, places=7, msg=None, delta=None)
```

Test that `first` and `second` are approximately (or not approximately) equal by computing the difference, rounding to the given number of decimal `places` (default 7), and comparing to zero. Note that these methods round the values to the given number of decimal places (i.e. like the `round()` function) and not significant digits.

If `delta` is supplied instead of `places` then the difference between `first` and `second` must be less or equal to (or greater than) `delta`.

Supplying both `delta` and `places` raises a `TypeError`.

**Changed in version 3.2:** `assertAlmostEqual()` automatically considers almost equal objects that compare equal. `assertNotAlmostEqual()` automatically fails if the objects compare equal. Added the `delta` keyword argument.
**assertGreater** *(first, second, msg=None)*
**assertGreaterEqual** *(first, second, msg=None)*
**assertLess** *(first, second, msg=None)*
**assertLessEqual** *(first, second, msg=None)*

Test that *first* is respectively >, >=, < or <= than *second* depending on the method name. If not, the test will fail:

```python
>>> self.assertGreaterEqual(3, 4)
AssertionError: "3" unexpectedly not greater than or equal to "4"
```

*New in version 3.1.*

**assertRegex** *(text, regex, msg=None)*
**assertNotRegex** *(text, regex, msg=None)*

Test that a *regex* search matches (or does not match) *text*. In case of failure, the error message will include the pattern and the *text* (or the pattern and the part of *text* that unexpectedly matched). *regex* may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`.

*New in version 3.1:* under the name `assertRegexpMatches`.

*Changed in version 3.2:* The method `assertRegexpMatches()` has been renamed to `assertRegex()`.

*New in version 3.2:* `assertNotRegex()`.

*New in version 3.5:* The name `assertNotRegexpMatches` is a deprecated alias for `assertNotRegex()`.
**assertCountEqual**(first, second, msg=None)

Test that sequence first contains the same elements as second, regardless of their order. When they don’t, an error message listing the differences between the sequences will be generated.

Duplicate elements are *not* ignored when comparing first and second. It verifies whether each element has the same count in both sequences. Equivalent to:

```python
assertEqual(Counter(list(first)), Counter(list(second)))
```

but works with sequences of unhashable objects as well.

*New in version 3.2.*

The **assertEqual()** method dispatches the equality check for objects of the same type to different type-specific methods. These methods are already implemented for most of the built-in types, but it’s also possible to register new methods using **addTypeEqualityFunc()**:

**addTypeEqualityFunc**(typeobj, function)

Registers a type-specific method called by assertEqual() to check if two objects of exactly the same typeobj (not subclasses) compare equal. function must take two positional arguments and a third msg=None keyword argument just as assertEqual() does. It must raise self.failureException(msg) when inequality between the first two parameters is detected – possibly providing useful information and explaining the inequalities in details in the error message.
New in version 3.1.

The list of type-specific methods automatically used by `assertEqual()` are summarized in the following table. Note that it’s usually not necessary to invoke these methods directly.

<table>
<thead>
<tr>
<th>Method</th>
<th>Used to compare</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertMultiLineEqual(a, b)</code></td>
<td>strings</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertSequenceEqual(a, b)</code></td>
<td>sequences</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertListEqual(a, b)</code></td>
<td>lists</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertTupleEqual(a, b)</code></td>
<td>tuples</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertSetEqual(a, b)</code></td>
<td>sets or frozensets</td>
<td>3.1</td>
</tr>
<tr>
<td><code>assertDictEqual(a, b)</code></td>
<td>dicts</td>
<td>3.1</td>
</tr>
</tbody>
</table>

**assertMultiLineEqual**(first, second, msg=None)

Test that the multiline string `first` is equal to the string `second`. When not equal a diff of the two strings highlighting the differences will be included in the error message. This method is used by default when comparing strings with `assertEqual()`.

New in version 3.1.

**assertSequenceEqual**(first, second, msg=None, seq_type=None)

Tests that two sequences are equal. If a `seq_type` is supplied, both `first` and `second` must be instances of `seq_type` or a failure will be raised. If the sequences are different an error message is constructed that shows the difference between the two.
This method is not called directly by `assertEqual()`, but it’s used to implement `assertListEqual()` and `assertTupleEqual()`.

*New in version 3.1.*

**assertListEqual** *(first, second, msg=None)*

**assertTupleEqual** *(first, second, msg=None)*

Tests that two lists or tuples are equal. If not, an error message is constructed that shows only the differences between the two. An error is also raised if either of the parameters are of the wrong type. These methods are used by default when comparing lists or tuples with `assertEqual()`.

*New in version 3.1.*

**assertSetEqual** *(first, second, msg=None)*

Tests that two sets are equal. If not, an error message is constructed that lists the differences between the sets. This method is used by default when comparing sets or frozensets with `assertEqual()`.

Fails if either of `first` or `second` does not have a `set.difference()` method.

*New in version 3.1.*

**assertDictEqual** *(first, second, msg=None)*

Test that two dictionaries are equal. If not, an error message is constructed that shows the differences in the dictionaries. This method will be used by default to compare dictionaries in calls to `assertEqual()`.
Finally the `TestCase` provides the following methods and attributes:

**fail** *(msg=None)*

Signals a test failure unconditionally, with `msg` or `None` for the error message.

**failureException**

This class attribute gives the exception raised by the test method. If a test framework needs to use a specialized exception, possibly to carry additional information, it must subclass this exception in order to “play fair” with the framework. The initial value of this attribute is `AssertionError`.

**longMessage**

This class attribute determines what happens when a custom failure message is passed as the `msg` argument to an `assertXYY` call that fails. `True` is the default value. In this case, the custom message is appended to the end of the standard failure message. When set to `False`, the custom message replaces the standard message.

The class setting can be overridden in individual test methods by assigning an instance attribute, `self.longMessage`, to `True` or `False` before calling the assert methods.

The class setting gets reset before each test call.

*New in version 3.1.*
**maxDiff**

This attribute controls the maximum length of diffs output by assert methods that report diffs on failure. It defaults to 80*8 characters. Assert methods affected by this attribute are `assertSequenceEqual()` (including all the sequence comparison methods that delegate to it), `assertDictEqual()` and `assertMultiLineEqual()`.

Setting `maxDiff` to `None` means that there is no maximum length of diffs.

*New in version 3.2.*

Testing frameworks can use the following methods to collect information on the test:

**countTestCases()**

Return the number of tests represented by this test object. For `TestCase` instances, this will always be 1.

**defaultTestResult()**

Return an instance of the test result class that should be used for this test case class (if no other result instance is provided to the `run()` method).

For `TestCase` instances, this will always be an instance of `TestResult`; subclasses of `TestCase` should override this as necessary.

**id()**

Return a string identifying the specific test case. This is usually the full name of the test method, including the module and class name.
**shortDescription()**

Returns a description of the test, or None if no description has been provided. The default implementation of this method returns the first line of the test method's docstring, if available, or None.

*Changed in version 3.1:* In 3.1 this was changed to add the test name to the short description even in the presence of a docstring. This caused compatibility issues with unittest extensions and adding the test name was moved to the TextTestResult in Python 3.2.

**addCleanup(function, *args, **kwargs)**

Add a function to be called after tearDown() to cleanup resources used during the test. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into addCleanup() when they are added.

If setUp() fails, meaning that tearDown() is not called, then any cleanup functions added will still be called.

*New in version 3.1.*

**doCleanups()**

This method is called unconditionally after tearDown(), or after setUp() if setUp() raises an exception.

It is responsible for calling all the cleanup functions added by addCleanup(). If you need cleanup functions to be called prior to tearDown() then you can call doCleanups() yourself.
doCleanups() pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

*New in version 3.1.*

class unittest.FunctionTestCase(testFunc, setUp=None, tearDown=None, description=None)

This class implements the portion of the `TestCase` interface which allows the test runner to drive the test, but does not provide the methods which test code can use to check and report errors. This is used to create test cases using legacy test code, allowing it to be integrated into a `unittest`-based test framework.

### 26.4.8.1.1. Deprecated aliases

For historical reasons, some of the `TestCase` methods had one or more aliases that are now deprecated. The following table lists the correct names along with their deprecated aliases:

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Deprecated alias</th>
<th>Deprecated alias</th>
<th>Deprecated alias</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertEqual()</code></td>
<td><code>failUnlessEqual</code></td>
<td><code>assertEquals</code></td>
<td></td>
</tr>
<tr>
<td><code>assertNotEqual()</code></td>
<td><code>failIfEqual</code></td>
<td><code>assertNotEquals</code></td>
<td></td>
</tr>
<tr>
<td><code>assertTrue()</code></td>
<td><code>failUnless</code></td>
<td><code>assert_</code></td>
<td></td>
</tr>
<tr>
<td><code>assertFalse()</code></td>
<td><code>failIf</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>assertRaises()</code></td>
<td><code>failUnlessRaises</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>assertAlmostEqual()</code></td>
<td><code>failUnlessAlmostEqual</code></td>
<td><code>assertAlmostEquals</code></td>
<td></td>
</tr>
<tr>
<td><code>assertNotAlmostEqual()</code></td>
<td><code>failIfAlmostEqual</code></td>
<td><code>assertNotAlmostEquals</code></td>
<td></td>
</tr>
<tr>
<td><code>assertRegex()</code></td>
<td></td>
<td><code>assertReg</code></td>
<td></td>
</tr>

assertRaisesRegex()

Deprecation since version 3.1: the fail* aliases listed in the second column.

Deprecation since version 3.2: the assert* aliases listed in the third column.

Deprecation since version 3.2: assertRegexpMatches and assertRaisesRegexp have been renamed to assertRegex() and assertRaisesRegex().

Deprecation since version 3.5: the assertNotRegexpMatches name in favor of assertNotRegex().

26.4.8.2. Grouping tests

class unittest.TestSuite(tests=())

This class represents an aggregation of individual test cases and test suites. The class presents the interface needed by the test runner to allow it to be run as any other test case. Running a TestSuite instance is the same as iterating over the suite, running each test individually.

If tests is given, it must be an iterable of individual test cases or other test suites that will be used to build the suite initially. Additional methods are provided to add test cases and suites to the collection later on.

TestSuite objects behave much like TestCase objects, except they do not actually implement a test. Instead, they are used to aggregate tests into groups of tests that should be run together.
Some additional methods are available to add tests to `TestSuite` instances:

**addTest(test)**

Add a `TestCase` or `TestSuite` to the suite.

**addTests(tests)**

Add all the tests from an iterable of `TestCase` and `TestSuite` instances to this test suite.

This is equivalent to iterating over `tests`, calling `addTest()` for each element.

`TestSuite` shares the following methods with `TestCase`:

**run(result)**

Run the tests associated with this suite, collecting the result into the test result object passed as `result`. Note that unlike `TestCase.run()`, `TestSuite.run()` requires the result object to be passed in.

**debug()**

Run the tests associated with this suite without collecting the result. This allows exceptions raised by the test to be propagated to the caller and can be used to support running tests under a debugger.

**countTestCases()**

Return the number of tests represented by this test object, including all individual tests and sub-suites.

**__iter__()**

Tests grouped by a `TestSuite` are always accessed by
iteration. Subclasses can lazily provide tests by overriding \texttt{\_\_iter\_()}\texttt{().} Note that this method may be called several times on a single suite (for example when counting tests or comparing for equality) so the tests returned by repeated iterations before \texttt{TestSuite.run()} must be the same for each call iteration. After \texttt{TestSuite.run()}, callers should not rely on the tests returned by this method unless the caller uses a subclass that overrides \texttt{TestSuite._\_removeTestAtIndex()} to preserve test references.

\textit{Changed in version 3.2:} In earlier versions the \texttt{TestSuite} accessed tests directly rather than through iteration, so overriding \texttt{\_\_iter\_()} wasn’t sufficient for providing tests.

\textit{Changed in version 3.4:} In earlier versions the \texttt{TestSuite} held references to each \texttt{TestCase} after \texttt{TestSuite.run()}. Subclasses can restore that behavior by overriding \texttt{TestSuite._\_removeTestAtIndex()}.

In the typical usage of a \texttt{TestSuite} object, the \texttt{run()} method is invoked by a TestRunner rather than by the end-user test harness.

\section*{26.4.8.3. Loading and running tests}

\texttt{\textbf{class unittest.\_\_TestLoader\_\_}}

The \texttt{TestLoader} class is used to create test suites from classes and modules. Normally, there is no need to create an instance of this class; the \texttt{unittest} module provides an instance that can be shared as \texttt{unittest.defaultTestLoader}. Using a subclass or
instance, however, allows customization of some configurable properties.

**TestLoader** objects have the following attributes:

**errors**
A list of the non-fatal errors encountered while loading tests. Not reset by the loader at any point. Fatal errors are signalled by the relevant a method raising an exception to the caller. Non-fatal errors are also indicated by a synthetic test that will raise the original error when run.

*New in version 3.5.*

**TestLoader** objects have the following methods:

**loadTestsFromTestCase**(testCaseClass)
Return a suite of all test cases contained in the **TestCase**-derived testCaseClass.

A test case instance is created for each method named by **getTestCaseNames()**. By default these are the method names beginning with test. If **getTestCaseNames()** returns no methods, but the runTest() method is implemented, a single test case is created for that method instead.

**loadTestsFromModule**(module, pattern=None)
Return a suite of all test cases contained in the given module. This method searches **module** for classes derived from **TestCase** and creates an instance of the class for each test method defined for the class.

**Note:** While using a hierarchy of **TestCase**-derived classes
can be convenient in sharing fixtures and helper functions, defining test methods on base classes that are not intended to be instantiated directly does not play well with this method. Doing so, however, can be useful when the fixtures are different and defined in subclasses.

If a module provides a `load_tests` function it will be called to load the tests. This allows modules to customize test loading. This is the `load_tests` protocol. The `pattern` argument is passed as the third argument to `load_tests`.

*Changed in version 3.2:* Support for `load_tests` added.

*Changed in version 3.5:* The undocumented and unofficial `use_load_tests` default argument is deprecated and ignored, although it is still accepted for backward compatibility. The method also now accepts a keyword-only argument `pattern` which is passed to `load_tests` as the third argument.

### `loadTestsFromName(name, module=None)`

Return a suite of all test cases given a string specifier.

The specifier `name` is a “dotted name” that may resolve either to a module, a test case class, a test method within a test case class, a `TestSuite` instance, or a callable object which returns a `TestCase` or `TestSuite` instance. These checks are applied in the order listed here; that is, a method on a possible test case class will be picked up as “a test method within a test case class”, rather than “a callable object”.

For example, if you have a module `SampleTests` containing a `TestCase`-derived class `SampleTestCase` with three test methods (`test_one()`, `test_two()`, and `test_three()`)
the specifier `SampleTests.SampleTestCase` would cause this method to return a suite which will run all three test methods. Using the specifier `SampleTests.SampleTestCase.test_two` would cause it to return a test suite which will run only the test_two() test method. The specifier can refer to modules and packages which have not been imported; they will be imported as a side-effect.

The method optionally resolves *name* relative to the given *module*.

*Changed in version 3.5:* If an ImportError or AttributeError occurs while traversing *name* then a synthetic test that raises that error when run will be returned. These errors are included in the errors accumulated by self.errors.

**loadTestsFromNames**(*names, module=None*)

Similar to loadTestsFromName(), but takes a sequence of names rather than a single name. The return value is a test suite which supports all the tests defined for each name.

**getTestCaseNames**(*testCaseClass*)

Return a sorted sequence of method names found within *testCaseClass*; this should be a subclass of **TestCase**.

**discover**(*start_dir, pattern='test*.py', top_level_dir=None*)

Find all the test modules by recursing into subdirectories from the specified start directory, and return a TestSuite object containing them. Only test files that match *pattern* will be loaded. (Using shell style pattern matching.) Only module
names that are importable (i.e. are valid Python identifiers) will be loaded.

All test modules must be importable from the top level of the project. If the start directory is not the top level directory then the top level directory must be specified separately.

If importing a module fails, for example due to a syntax error, then this will be recorded as a single error and discovery will continue. If the import failure is due to `SkipTest` being raised, it will be recorded as a skip instead of an error.

If a package (a directory containing a file named `__init__.py`) is found, the package will be checked for a `load_tests` function. If this exists then it will be called `package.load_tests(loader, tests, pattern)`. Test discovery takes care to ensure that a package is only checked for tests once during an invocation, even if the `load_tests` function itself calls `loader.discover`.

If `load_tests` exists then discovery does not recurse into the package, `load_tests` is responsible for loading all tests in the package.

The pattern is deliberately not stored as a loader attribute so that packages can continue discovery themselves. `top_level_dir` is stored so `load_tests` does not need to pass this argument in to `loader.discover()`.

`start_dir` can be a dotted module name as well as a directory.

*New in version 3.2.*
Changed in version 3.4: Modules that raise `SkipTest` on import are recorded as skips, not errors. Discovery works for namespace packages. Paths are sorted before being imported so that execution order is the same even if the underlying file system’s ordering is not dependent on file name.

Changed in version 3.5: Found packages are now checked for `load_tests` regardless of whether their path matches `pattern`, because it is impossible for a package name to match the default pattern.

The following attributes of a `TestLoader` can be configured either by subclassing or assignment on an instance:

**testMethodPrefix**

String giving the prefix of method names which will be interpreted as test methods. The default value is `'test'`.

This affects `getTestCaseNames()` and all the `loadTestsFrom*()` methods.

**sortTestMethodsUsing**

Function to be used to compare method names when sorting them in `getTestCaseNames()` and all the `loadTestsFrom*()` methods.

**suiteClass**

Callable object that constructs a test suite from a list of tests. No methods on the resulting object are needed. The default value is the `TestSuite` class.

This affects all the `loadTestsFrom*()` methods.
testNamePatterns

List of Unix shell-style wildcard test name patterns that test methods have to match to be included in test suites (see -v option).

If this attribute is not None (the default), all test methods to be included in test suites must match one of the patterns in this list. Note that matches are always performed using fnmatch.fnmatchcase(), so unlike patterns passed to the -v option, simple substring patterns will have to be converted using * wildcards.

This affects all the loadTestsFrom*() methods.

New in version 3.7.

class unittest. TestResult

This class is used to compile information about which tests have succeeded and which have failed.

A TestResult object stores the results of a set of tests. The TestCase and TestSuite classes ensure that results are properly recorded; test authors do not need to worry about recording the outcome of tests.

Testing frameworks built on top of unittest may want access to the TestResult object generated by running a set of tests for reporting purposes; a TestResult instance is returned by the TestRunner.run() method for this purpose.

TestResult instances have the following attributes that will be of interest when inspecting the results of running a set of tests:
**errors**
A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents a test which raised an unexpected exception.

**failures**
A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents a test where a failure was explicitly signalled using the `TestCase.assert*()` methods.

**skipped**
A list containing 2-tuples of `TestCase` instances and strings holding the reason for skipping the test.

*New in version 3.1.*

**expectedFailures**
A list containing 2-tuples of `TestCase` instances and strings holding formatted tracebacks. Each tuple represents an expected failure of the test case.

**unexpectedSuccesses**
A list containing `TestCase` instances that were marked as expected failures, but succeeded.

**shouldStop**
Set to `True` when the execution of tests should stop by `stop()`.

**testsRun**
The total number of tests run so far.
buffer
If set to true, `sys.stdout` and `sys.stderr` will be buffered in between `startTest()` and `stopTest()` being called. Collected output will only be echoed onto the real `sys.stdout` and `sys.stderr` if the test fails or errors. Any output is also attached to the failure / error message.

*New in version 3.2.*

failfast
If set to true `stop()` will be called on the first failure or error, halting the test run.

*New in version 3.2.*

tb_locals
If set to true then local variables will be shown in tracebacks.

*New in version 3.5.*

wasSuccessful()
Return `True` if all tests run so far have passed, otherwise returns `False`.

*Changed in version 3.4:* Returns `False` if there were any `unexpectedSuccesses` from tests marked with the `expectedFailure()` decorator.

stop()
This method can be called to signal that the set of tests being run should be aborted by setting the `shouldStop` attribute to `True`. TestRunner objects should respect this flag and return without running any additional tests.
For example, this feature is used by the `TextTestRunner` class to stop the test framework when the user signals an interrupt from the keyboard. Interactive tools which provide `TestRunner` implementations can use this in a similar manner.

The following methods of the `TestResult` class are used to maintain the internal data structures, and may be extended in subclasses to support additional reporting requirements. This is particularly useful in building tools which support interactive reporting while tests are being run.

`startTest(test)`
Called when the test case `test` is about to be run.

`stopTest(test)`
Called after the test case `test` has been executed, regardless of the outcome.

`startTestRun()`
Called once before any tests are executed.

*New in version 3.1.*

`stopTestRun()`
Called once after all tests are executed.

*New in version 3.1.*

`addError(test, err)`
Called when the test case `test` raises an unexpected exception. `err` is a tuple of the form returned by `sys.exc_info()`:
```
(type, value, traceback).
```
The default implementation appends a tuple `(test, formatted_err)` to the instance's `errors` attribute, where `formatted_err` is a formatted traceback derived from `err`.

**addFailure**(test, err)
Called when the test case `test` signals a failure. `err` is a tuple of the form returned by `sys.exc_info()`: `(type, value, traceback)`.

The default implementation appends a tuple `(test, formatted_err)` to the instance's `failures` attribute, where `formatted_err` is a formatted traceback derived from `err`.

**addSuccess**(test)
Called when the test case `test` succeeds.

The default implementation does nothing.

**addSkip**(test, reason)
Called when the test case `test` is skipped. `reason` is the reason the test gave for skipping.

The default implementation appends a tuple `(test, reason)` to the instance's `skipped` attribute.

**addExpectedFailure**(test, err)
Called when the test case `test` fails, but was marked with the `expectedFailure()` decorator.

The default implementation appends a tuple `(test, formatted_err)` to the instance's `expectedFailures` attribute, where `formatted_err` is a formatted traceback derived from `err`. 
addUnexpectedSuccess\((test)\)
Called when the test case test was marked with the expectedFailure() decorator, but succeeded.

The default implementation appends the test to the instance's unexpectedSuccesses attribute.

addSubTest\((test, subtest, outcome)\)
Called when a subtest finishes. test is the test case corresponding to the test method. subtest is a custom TestCase instance describing the subtest.

If outcome is None, the subtest succeeded. Otherwise, it failed with an exception where outcome is a tuple of the form returned by sys.exc_info(): (type, value, traceback).

The default implementation does nothing when the outcome is a success, and records subtest failures as normal failures.

New in version 3.4.

class unittest.TextTestResult\((stream, descriptions, verbosity)\)
A concrete implementation of TestResult used by the TextTestRunner.

New in version 3.2: This class was previously named _TextTestResult. The old name still exists as an alias but is deprecated.

unittest.defaultTestLoader
Instance of the TestLoader class intended to be shared. If no customization of the TestLoader is needed, this instance can be
used instead of repeatedly creating new instances.

class unittest.TextTestRunner(stream=None, descriptions=True, verbosity=1, failfast=False, buffer=False, resultclass=None, warnings=None, *, tb_locals=False)

A basic test runner implementation that outputs results to a stream. If stream is None, the default, sys.stderr is used as the output stream. This class has a few configurable parameters, but is essentially very simple. Graphical applications which run test suites should provide alternate implementations. Such implementations should accept **kwargs as the interface to construct runners changes when features are added to unittest.

By default this runner shows DeprecationWarning, PendingDeprecationWarning, ResourceWarning and ImportWarning even if they are ignored by default. Deprecation warnings caused by deprecated unittest methods are also special-cased and, when the warning filters are 'default' or 'always', they will appear only once per-module, in order to avoid too many warning messages. This behavior can be overridden using Python's -Wd or -Wa options (see Warning control) and leaving warnings to None.

*Changed in version 3.2:* Added the warnings argument.

*Changed in version 3.2:* The default stream is set to sys.stderr at instantiation time rather than import time.

*Changed in version 3.5:* Added the tb_locals parameter.

_makeResult()

This method returns the instance of TestResult used by
run(). It is not intended to be called directly, but can be overridden in subclasses to provide a custom TestResult.

_makeResult() instantiates the class or callable passed in the TextTestRunner constructor as the resultclass argument. It defaults to TextTestResult if no resultclass is provided. The result class is instantiated with the following arguments:

stream, descriptions, verbosity

run(test)
This method is the main public interface to the TextTestRunner. This method takes a TestSuite or TestCase instance. A TestResult is created by calling _makeResult() and the test(s) are run and the results printed to stdout.

unittest.main(module='__main__', defaultTest=None, argv=None, testRunner=None, testLoader=unittest.defaultTestLoader, exit=True, verbosity=1, failfast=None, catchbreak=None, buffer=None, warnings=None)

A command-line program that loads a set of tests from module and runs them; this is primarily for making test modules conveniently executable. The simplest use for this function is to include the following line at the end of a test script:

if __name__ == '__main__':
    unittest.main()

You can run tests with more detailed information by passing in the verbosity argument:

if __name__ == '__main__':

unittest.main(verbosity=2)

The `defaultTest` argument is either the name of a single test or an iterable of test names to run if no test names are specified via `argv`. If not specified or `None` and no test names are provided via `argv`, all tests found in `module` are run.

The `argv` argument can be a list of options passed to the program, with the first element being the program name. If not specified or `None`, the values of `sys.argv` are used.

The `testRunner` argument can either be a test runner class or an already created instance of it. By default `main` calls `sys.exit()` with an exit code indicating success or failure of the tests run.

The `testLoader` argument has to be a `TestLoader` instance, and defaults to `defaultTestLoader`.

`main` supports being used from the interactive interpreter by passing in the argument `exit=False`. This displays the result on standard output without calling `sys.exit()`:

```python
>>> from unittest import main
>>> main(module='test_module', exit=False)
```

The `failfast`, `catchbreak` and `buffer` parameters have the same effect as the same-name command-line options.

The `warnings` argument specifies the `warning filter` that should be used while running the tests. If it's not specified, it will remain `None` if a `-W` option is passed to `python` (see `Warning control`), otherwise it will be set to `'default'`.
Calling `main` actually returns an instance of the `TestProgram` class. This stores the result of the tests run as the `result` attribute.

*Changed in version 3.1:* The `exit` parameter was added.

*Changed in version 3.2:* The `verbosity`, `failfast`, `catchbreak`, `buffer` and `warnings` parameters were added.

*Changed in version 3.4:* The `defaultTest` parameter was changed to also accept an iterable of test names.

### 26.4.8.3.1. load_tests Protocol

*New in version 3.2.*

Modules or packages can customize how tests are loaded from them during normal test runs or test discovery by implementing a function called `load_tests`.

If a test module defines `load_tests` it will be called by `TestLoader.loadTestsFromModule()` with the following arguments:

```python
load_tests(loader, standard_tests, pattern)
```

where `pattern` is passed straight through from `loadTestsFromModule`. It defaults to `None`.

It should return a `TestSuite`.

`loader` is the instance of `TestLoader` doing the loading. `standard_tests` are the tests that would be loaded by default from the
module. It is common for test modules to only want to add or remove tests from the standard set of tests. The third argument is used when loading packages as part of test discovery.

A typical `load_tests` function that loads tests from a specific set of `TestCase` classes may look like:

```python
test_cases = (TestCase1, TestCase2, TestCase3)

def load_tests(loader, tests, pattern):
    suite = TestSuite()
    for test_class in test_cases:
        tests = loader.loadTestsFromTestCase(test_class)
        suite.addTests(tests)
    return suite
```

If discovery is started in a directory containing a package, either from the command line or by calling `TestLoader.discover()`, then the package `__init__.py` will be checked for `load_tests`. If that function does not exist, discovery will recurse into the package as though it were just another directory. Otherwise, discovery of the package’s tests will be left up to `load_tests` which is called with the following arguments:

```python
load_tests(loader, standard_tests, pattern)
```

This should return a `TestSuite` representing all the tests from the package. (`standard_tests` will only contain tests collected from `__init__.py`.)

Because the pattern is passed into `load_tests` the package is free to continue (and potentially modify) test discovery. A ‘do nothing’ `load_tests` function for a test package would look like:
def load_tests(loader, standard_tests, pattern):
    # top level directory cached on loader instance
    this_dir = os.path.dirname(__file__)
    package_tests = loader.discover(start_dir=this_dir)
    standard_tests.addTests(package_tests)
    return standard_tests

Changed in version 3.5: Discovery no longer checks package names for matching pattern due to the impossibility of package names matching the default pattern.
26.4.9. Class and Module Fixtures

Class and module level fixtures are implemented in `TestSuite`. When the test suite encounters a test from a new class then `tearDownClass()` from the previous class (if there is one) is called, followed by `setUpClass()` from the new class.

Similarly if a test is from a different module from the previous test then `tearDownModule` from the previous module is run, followed by `setUpModule` from the new module.

After all the tests have run the final `tearDownClass` and `tearDownModule` are run.

Note that shared fixtures do not play well with [potential] features like test parallelization and they break test isolation. They should be used with care.

The default ordering of tests created by the unittest test loaders is to group all tests from the same modules and classes together. This will lead to `setUpClass` / `setUpModule` (etc) being called exactly once per class and module. If you randomize the order, so that tests from different modules and classes are adjacent to each other, then these shared fixture functions may be called multiple times in a single test run.

Shared fixtures are not intended to work with suites with non-standard ordering. A `BaseTestSuite` still exists for frameworks that don’t want to support shared fixtures.

If there are any exceptions raised during one of the shared fixture functions the test is reported as an error. Because there is no
corresponding test instance an `_ErrorHolder` object (that has the same interface as a `TestCase`) is created to represent the error. If you are just using the standard unittest test runner then this detail doesn’t matter, but if you are a framework author it may be relevant.

26.4.9.1. setUpClass and tearDownClass

These must be implemented as class methods:

```python
import unittest

class Test(unittest.TestCase):
    @classmethod
    def setUpClass(cls):
        cls._connection = createExpensiveConnectionObject

    @classmethod
    def tearDownClass(cls):
        cls._connection.destroy()
```

If you want the `setUpClass` and `tearDownClass` on base classes called then you must call up to them yourself. The implementations in `TestCase` are empty.

If an exception is raised during a `setUpClass` then the tests in the class are not run and the `tearDownClass` is not run. Skipped classes will not have `setUpClass` or `tearDownClass` run. If the exception is a `SkipTest` exception then the class will be reported as having been skipped instead of as an error.

26.4.9.2. setUpModule and tearDownModule
These should be implemented as functions:

```python
def setUpModule():
    createConnection()

def tearDownModule():
    closeConnection()
```

If an exception is raised in a `setUpModule` then none of the tests in the module will be run and the `tearDownModule` will not be run. If the exception is a `SkipTest` exception then the module will be reported as having been skipped instead of as an error.
26.4.10. Signal Handling

New in version 3.2.

The -c/--catch command-line option to unittest, along with the catchbreak parameter to unittest.main(), provide more friendly handling of control-C during a test run. With catch break behavior enabled control-C will allow the currently running test to complete, and the test run will then end and report all the results so far. A second control-c will raise a KeyboardInterrupt in the usual way.

The control-c handling signal handler attempts to remain compatible with code or tests that install their own signal.SIGINT handler. If the unittest handler is called but isn’t the installed signal.SIGINT handler, i.e. it has been replaced by the system under test and delegated to, then it calls the default handler. This will normally be the expected behavior by code that replaces an installed handler and delegates to it. For individual tests that need unittest control-c handling disabled the removeHandler() decorator can be used.

There are a few utility functions for framework authors to enable control-c handling functionality within test frameworks.

unittest.installHandler()

Install the control-c handler. When a signal.SIGINT is received (usually in response to the user pressing control-c) all registered results have stop() called.

unittest.registerResult(result)
Register a `TestResult` object for control-c handling. Registering a result stores a weak reference to it, so it doesn't prevent the result from being garbage collected.

Registering a `TestResult` object has no side-effects if control-c handling is not enabled, so test frameworks can unconditionally register all results they create independently of whether or not handling is enabled.

`unittest.removeResult(result)`
Remove a registered result. Once a result has been removed then `stop()` will no longer be called on that result object in response to a control-c.

`unittest.removeHandler(function=None)`
When called without arguments this function removes the control-c handler if it has been installed. This function can also be used as a test decorator to temporarily remove the handler whilst the test is being executed:

```python
@unittest.removeHandler
def test_signal_handling(self):
    ...
```

```
26.5. unittest.mock — mock object library

New in version 3.3.

Source code: Lib/unittest/mock.py

unittest.mock is a library for testing in Python. It allows you to replace parts of your system under test with mock objects and make assertions about how they have been used.

unittest.mock provides a core Mock class removing the need to create a host of stubs throughout your test suite. After performing an action, you can make assertions about which methods / attributes were used and arguments they were called with. You can also specify return values and set needed attributes in the normal way.

Additionally, mock provides a patch() decorator that handles patching module and class level attributes within the scope of a test, along with sentinel for creating unique objects. See the quick guide for some examples of how to use Mock, MagicMock and patch().

Mock is very easy to use and is designed for use with unittest. Mock is based on the ‘action -> assertion’ pattern instead of ‘record -> replay’ used by many mocking frameworks.

There is a backport of unittest.mock for earlier versions of Python, available as mock on PyPI.
26.5.1. Quick Guide

Mock and MagicMock objects create all attributes and methods as you access them and store details of how they have been used. You can configure them, to specify return values or limit what attributes are available, and then make assertions about how they have been used:

```python
>>> from unittest.mock import MagicMock
>>> thing = ProductionClass()
>>> thing.method = MagicMock(return_value=3)
>>> thing.method(3, 4, 5, key='value')
3
>>> thing.method.assert_called_with(3, 4, 5, key='value')
```

side_effect allows you to perform side effects, including raising an exception when a mock is called:

```python
>>> mock = Mock(side_effect=KeyError('foo'))
>>> mock()
Traceback (most recent call last):
...  KeyError: 'foo'
```

```python
>>> values = {'a': 1, 'b': 2, 'c': 3}
>>> def side_effect(arg):
...    return values[arg]
...
>>> mock.side_effect = side_effect
>>> mock('a'), mock('b'), mock('c')
(1, 2, 3)
>>> mock.side_effect = [5, 4, 3, 2, 1]
>>> mock(), mock(), mock()
(5, 4, 3)
```
Mock has many other ways you can configure it and control its behaviour. For example the *spec* argument configures the mock to take its specification from another object. Attempting to access attributes or methods on the mock that don’t exist on the spec will fail with an *AttributeError*.

The *patch()* decorator / context manager makes it easy to mock classes or objects in a module under test. The object you specify will be replaced with a mock (or other object) during the test and restored when the test ends:

```python
>>> from unittest.mock import patch
>>> @patch('module.ClassName2')
... @patch('module.ClassName1')
... def test(MockClass1, MockClass2):
...     module.ClassName1()
...     module.ClassName2()
...     assert MockClass1 is module.ClassName1
...     assert MockClass2 is module.ClassName2
...     assert MockClass1.called
...     assert MockClass2.called
... >>> test()
```

**Note:** When you nest patch decorators the mocks are passed in to the decorated function in the same order they applied (the normal *python* order that decorators are applied). This means from the bottom up, so in the example above the mock for *module.ClassName1* is passed in first.

With *patch()* it matters that you patch objects in the namespace where they are looked up. This is normally straightforward, but for a quick guide read *where to patch*. 
As well as a decorator `patch()` can be used as a context manager in a `with` statement:

```python
>>> with patch.object(ProductionClass, 'method', return_value='thing'):
...     thing = ProductionClass()
...     thing.method(1, 2, 3)
... >>> mock_method.assert_called_once_with(1, 2, 3)
```

There is also `patch.dict()` for setting values in a dictionary just during a scope and restoring the dictionary to its original state when the test ends:

```python
>>> foo = {'key': 'value'}
>>> original = foo.copy()
>>> with patch.dict(foo, {'newkey': 'newvalue'}, clear=True):
...     assert foo == {'newkey': 'newvalue'}
... >>> assert foo == original
```

Mock supports the mocking of Python `magic methods`. The easiest way of using magic methods is with the `MagicMock` class. It allows you to do things like:

```python
>>> mock = MagicMock()
>>> mock.__str__.return_value = 'foobaz'  
>>> str(mock)
'foobaz'  
>>> mock.__str__.assert_called_with()
```

Mock allows you to assign functions (or other Mock instances) to magic methods and they will be called appropriately. The `MagicMock` class is just a Mock variant that has all of the magic methods pre-
created for you (well, all the useful ones anyway).

The following is an example of using magic methods with the ordinary Mock class:

```python
>>> mock = Mock()
>>> mock.__str__ = Mock(return_value='wheeeeee')
>>> str(mock)
'wheeeeee'
```

For ensuring that the mock objects in your tests have the same api as the objects they are replacing, you can use auto-speccing. Auto-speccing can be done through the autospec argument to patch, or the create_autospec() function. Auto-speccing creates mock objects that have the same attributes and methods as the objects they are replacing, and any functions and methods (including constructors) have the same call signature as the real object.

This ensures that your mocks will fail in the same way as your production code if they are used incorrectly:

```python
>>> from unittest.mock import create_autospec
>>> def function(a, b, c):
...    pass
...
>>> mock_function = create_autospec(function, return_value='fishy')
>>> mock_function(1, 2, 3)
'fishy'
>>> mock_function.assert_called_once_with(1, 2, 3)
>>> mock_function(['wrong arguments'])
Traceback (most recent call last):
...  TypeError: <lambda>() takes exactly 3 arguments (1 given)
```
create_autospec() can also be used on classes, where it copies the signature of the \_\_init\_\_ method, and on callable objects where it copies the signature of the \_\_call\_\_ method.
26.5.2. The Mock Class

Mock is a flexible mock object intended to replace the use of stubs and test doubles throughout your code.Mocks are callable and create attributes as new mocks when you access them [1]. Accessing the same attribute will always return the same mock.Mocks record how you use them, allowing you to make assertions about what your code has done to them.

MagicMock is a subclass of Mock with all the magic methods pre-created and ready to use. There are also non-callable variants, useful when you are mocking out objects that aren’t callable: NonCallableMock and NonCallableMagicMock

The patch() decorators makes it easy to temporarily replace classes in a particular module with a Mock object. By default patch() will create a MagicMock for you. You can specify an alternative class of Mock using the new_callable argument to patch().

class unittest.mock.Mock(spec=None, side_effect=None, return_value=DEFAULT, wraps=None, name=None, spec_set=None, unsafe=False, **kwargs)

Create a new Mock object. Mock takes several optional arguments that specify the behaviour of the Mock object:

- spec: This can be either a list of strings or an existing object (a class or instance) that acts as the specification for the mock object. If you pass in an object then a list of strings is formed by calling dir on the object (excluding unsupported magic attributes and methods). Accessing any attribute not in this list will raise an AttributeError.
If `spec` is an object (rather than a list of strings) then `__class__` returns the class of the spec object. This allows mocks to pass `isinstance()` tests.

- `spec_set`: A stricter variant of `spec`. If used, attempting to set or get an attribute on the mock that isn't on the object passed as `spec_set` will raise an `AttributeError`.

- `side_effect`: A function to be called whenever the Mock is called. See the `side_effect` attribute. Useful for raising exceptions or dynamically changing return values. The function is called with the same arguments as the mock, and unless it returns `DEFAULT`, the return value of this function is used as the return value.

  Alternatively `side_effect` can be an exception class or instance. In this case the exception will be raised when the mock is called.

  If `side_effect` is an iterable then each call to the mock will return the next value from the iterable.

  A `side_effect` can be cleared by setting it to `None`.

- `return_value`: The value returned when the mock is called. By default this is a new Mock (created on first access). See the `return_value` attribute.

- `unsafe`: By default if any attribute starts with `assert` or `assret` will raise an `AttributeError`. Passing `unsafe=True` will allow access to these attributes.

  New in version 3.5.
• *wraps*: Item for the mock object to wrap. If *wraps* is not None then calling the Mock will pass the call through to the wrapped object (returning the real result). Attribute access on the mock will return a Mock object that wraps the corresponding attribute of the wrapped object (so attempting to access an attribute that doesn’t exist will raise an *AttributeError*).

If the mock has an explicit *return_value* set then calls are not passed to the wrapped object and the *return_value* is returned instead.

• *name*: If the mock has a name then it will be used in the repr of the mock. This can be useful for debugging. The name is propagated to child mocks.

Mocks can also be called with arbitrary keyword arguments. These will be used to set attributes on the mock after it is created. See the *configure_mock()* method for details.

**assert_called(***args, **kwargs)**

Assert that the mock was called at least once.

```python
>>> mock = Mock()
>>> mock.method()
<Mock name='mock.method()' id='...'>
>>> mock.method.assert_called()
```

*New in version 3.6.*

**assert_called_once(***args, **kwargs)**

Assert that the mock was called exactly once.

```python
>>> mock = Mock()
>>> mock.method()
```
mock.method.assert_called_once()

```
>>> mock.method()
