The level of debug output to use. This may be set from 0 (the default, no output) to 3 (the most output). Debugging information is written to `sys.stdout`.

**ZipFile.** `comment`

The comment text associated with the ZIP file. If assigning a comment to a `ZipFile` instance created with mode ‘a’ or ‘w’, this should be a string no longer than 65535 bytes. Comments longer than this will be truncated in the written archive when `ZipFile.close()` is called.
12.4.2. PyZipFile Objects

The `PyZipFile` constructor takes the same parameters as the `ZipFile` constructor. Instances have one method in addition to those of `ZipFile` objects.

```
PyZipFile.writepy(pathname[, basename])
```

Search for files `*.py` and add the corresponding file to the archive. The corresponding file is a `*.pyo` file if available, else a `*.pyc` file, compiling if necessary. If the pathname is a file, the filename must end with `.py`, and just the (corresponding `*.py[co]`) file is added at the top level (no path information). If the pathname is a file that does not end with `.py`, a `RuntimeError` will be raised. If it is a directory, and the directory is not a package directory, then all the files `*.py[co]` are added at the top level. If the directory is a package directory, then all `*.py[co]` are added under the package name as a file path, and if any subdirectories are package directories, all of these are added recursively. `basename` is intended for internal use only. The `writepy()` method makes archives with file names like this:

```
string.pyc # Top level name
test/__init__.pyc # Package director
  # Module test
test/test_support.pyc # Subpackage direc
test/bogus/__init__.pyc # Submodule test.b
test/bogus/myfile.pyc
```

12.4.3. ZipInfo Objects

Instances of the `ZipInfo` class are returned by the `getinfo()` and `infolist()` methods of `ZipFile` objects. Each object stores information about a single member of the ZIP archive.

Instances have the following attributes:

**ZipInfo.** `filename`
Name of the file in the archive.

**ZipInfo.** `date_time`
The time and date of the last modification to the archive member. This is a tuple of six values:

<table>
<thead>
<tr>
<th>Index</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Year</td>
</tr>
<tr>
<td>1</td>
<td>Month (one-based)</td>
</tr>
<tr>
<td>2</td>
<td>Day of month (one-based)</td>
</tr>
<tr>
<td>3</td>
<td>Hours (zero-based)</td>
</tr>
<tr>
<td>4</td>
<td>Minutes (zero-based)</td>
</tr>
<tr>
<td>5</td>
<td>Seconds (zero-based)</td>
</tr>
</tbody>
</table>

**ZipInfo.** `compress_type`
Type of compression for the archive member.

**ZipInfo.** `comment`
Comment for the individual archive member.

**ZipInfo.** `extra`
Expansion field data. The PKZIP Application Note contains some comments on the internal structure of the data contained in this string.
ZipInfo. `create_system`
System which created ZIP archive.

ZipInfo. `create_version`
PKZIP version which created ZIP archive.

ZipInfo. `extract_version`
PKZIP version needed to extract archive.

ZipInfo. `reserved`
Must be zero.

ZipInfo. `flag_bits`
ZIP flag bits.

ZipInfo. `volume`
Volume number of file header.

ZipInfo. `internal_attr`
Internal attributes.

ZipInfo. `external_attr`
External file attributes.

ZipInfo. `header_offset`
Byte offset to the file header.

ZipInfo. `CRC`
CRC-32 of the uncompressed file.

ZipInfo. `compress_size`
Size of the compressed data.

ZipInfo. `file_size`
Size of the uncompressed file.
12.5. tarfile — Read and write tar archive files

New in version 2.3.

The `tarfile` module makes it possible to read and write tar archives, including those using gzip or bz2 compression. (.zip files can be read and written using the `zipfile` module.)

Some facts and figures:

- reads and writes `gzip` and `bz2` compressed archives.
- read/write support for the POSIX.1-1988 (ustar) format.
- read/write support for the GNU tar format including `longname` and `longlink` extensions, read-only support for the `sparse` extension.
- read/write support for the POSIX.1-2001 (pax) format.

New in version 2.6.

- handles directories, regular files, hardlinks, symbolic links, fifos, character devices and block devices and is able to acquire and restore file information like timestamp, access permissions and owner.

tarfile. `open(name=None, mode='r', fileobj=None, bufsize=10240, **kwargs)`

Return a `TarFile` object for the pathname `name`. For detailed information on `TarFile` objects and the keyword arguments that are allowed, see `TarFile Objects`. 
mode has to be a string of the form 'filemode[:compression]', it defaults to 'r'. Here is a full list of mode combinations:

<table>
<thead>
<tr>
<th>mode</th>
<th>action</th>
</tr>
</thead>
<tbody>
<tr>
<td>'r' or 'r:*'</td>
<td>Open for reading with transparent compression (recommended).</td>
</tr>
<tr>
<td>'r:'</td>
<td>Open for reading exclusively without compression.</td>
</tr>
<tr>
<td>'r:gz'</td>
<td>Open for reading with gzip compression.</td>
</tr>
<tr>
<td>'r:bz2'</td>
<td>Open for reading with bzip2 compression.</td>
</tr>
<tr>
<td>'a' or 'a:'</td>
<td>Open for appending with no compression. The file is created if it does not exist.</td>
</tr>
<tr>
<td>'w' or 'w:'</td>
<td>Open for uncompressed writing.</td>
</tr>
<tr>
<td>'w:gz'</td>
<td>Open for gzip compressed writing.</td>
</tr>
<tr>
<td>'w:bz2'</td>
<td>Open for bzip2 compressed writing.</td>
</tr>
</tbody>
</table>

Note that 'a:gz' or 'a:bz2' is not possible. If mode is not suitable to open a certain (compressed) file for reading, ReadError is raised. Use mode 'r' to avoid this. If a compression method is not supported, CompressionError is raised.

If fileobj is specified, it is used as an alternative to a file object opened for name. It is supposed to be at position 0.

For special purposes, there is a second format for mode: 'filemode[compression]'. tarfile.open() will return a TarFile object that processes its data as a stream of blocks. No random seeking will be done on the file. If given, fileobj may be any object that has a read() or write() method (depending on the mode). bufsize specifies the blocksize and defaults to 20 * 512 bytes. Use this variant in combination with e.g. sys.stdin, a socket file object or a tape device. However, such a TarFile object is limited in that it does not allow to be accessed randomly, see Examples. The currently possible modes:
<table>
<thead>
<tr>
<th>Mode</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>'r</td>
<td>*'</td>
</tr>
<tr>
<td>'r'</td>
<td></td>
</tr>
<tr>
<td>'r</td>
<td>gz'</td>
</tr>
<tr>
<td>'r</td>
<td>bz2'</td>
</tr>
<tr>
<td>'w'</td>
<td></td>
</tr>
<tr>
<td>'w</td>
<td>gz'</td>
</tr>
<tr>
<td>'w</td>
<td>bz2'</td>
</tr>
</tbody>
</table>

**class tarfile.TarFile**

Class for reading and writing tar archives. Do not use this class directly, better use `tarfile.open()` instead. See [TarFile Objects](#).

tarfile.is_tarfile(name)

Return True if name is a tar archive file, that the tarfile module can read.

class tarfile.TarFileCompat(filename, mode='r', compression=TAR_PLAIN)

Class for limited access to tar archives with a zipfile-like interface. Please consult the documentation of the zipfile module for more details. compression must be one of the following constants:

**TAR_PLAIN**

Constant for an uncompressed tar archive.

**TAR_GZIPPED**

Constant for a gzip compressed tar archive.

*Deprecated since version 2.6:* The TarFileCompat class has been deprecated for removal in Python 3.0.
exception `tarfile.TarError`  
Base class for all `tarfile` exceptions.

exception `tarfile.ReadError`  
Is raised when a tar archive is opened, that either cannot be handled by the `tarfile` module or is somehow invalid.

exception `tarfile.CompressionError`  
Is raised when a compression method is not supported or when the data cannot be decoded properly.

exception `tarfile.StreamError`  
Is raised for the limitations that are typical for stream-like `TarFile` objects.

exception `tarfile.ExtractError`  
Is raised for non-fatal errors when using `TarFile.extract()`, but only if `TarFile.errorlevel==2`.

exception `tarfile.HeaderError`  
Is raised by `TarInfo.frombuf()` if the buffer it gets is invalid.

*New in version 2.6.*

Each of the following constants defines a tar archive format that the `tarfile` module is able to create. See section `Supported tar formats` for details.

`tarfile.USTAR_FORMAT`  
POSIX.1-1988 (ustar) format.

`tarfile.GNU_FORMAT`  
GNU tar format.

`tarfile.PAX_FORMAT`  
POSIX.1-2001 (pax) format.
tarfile. **DEFAULT_FORMAT**

The default format for creating archives. This is currently **GNU_FORMAT**.

The following variables are available on module level:

**tarfile. ENCODING**

The default character encoding i.e. the value from either `sys.getfilesystemencoding()` or `sys.getdefaultencoding()`.

---

**See also:**

**Module zipfile**

Documentation of the `zipfile` standard module.

**GNU tar manual, Basic Tar Format**

Documentation for tar archive files, including GNU tar extensions.
12.5.1. TarFile Objects

The `TarFile` object provides an interface to a tar archive. A tar archive is a sequence of blocks. An archive member (a stored file) is made up of a header block followed by data blocks. It is possible to store a file in a tar archive several times. Each archive member is represented by a `TarInfo` object, see `TarInfo Objects` for details.

A `TarFile` object can be used as a context manager in a `with` statement. It will automatically be closed when the block is completed. Please note that in the event of an exception an archive opened for writing will not be finalized; only the internally used file object will be closed. See the `Examples` section for a use case.

*New in version 2.7:* Added support for the context manager protocol.

```python
class tarfile. TarFile(name=None, mode='r', fileobj=None, format=DEFAULT_FORMAT, tarinfo=TarInfo, dereference=False, ignore_zeros=False, encoding=ENCODING, errors=None, pax_headers=None, debug=0, errorlevel=0)
```

All following arguments are optional and can be accessed as instance attributes as well.

- `name` is the pathname of the archive. It can be omitted if `fileobj` is given. In this case, the file object’s `name` attribute is used if it exists.

- `mode` is either `'r'` to read from an existing archive, `'a'` to append data to an existing file or `'w'` to create a new file overwriting an existing one.

If `fileobj` is given, it is used for reading or writing data. If it can be determined, `mode` is overridden by `fileobj`’s mode. `fileobj` will be used from position 0.
Note: fileobj is not closed, when TarFile is closed.

format controls the archive format. It must be one of the constants USTAR_FORMAT, GNU_FORMAT or PAX_FORMAT that are defined at module level.

New in version 2.6.

The tarinfo argument can be used to replace the default TarInfo class with a different one.

New in version 2.6.

If dereference is False, add symbolic and hard links to the archive. If it is True, add the content of the target files to the archive. This has no effect on systems that do not support symbolic links.

If ignore_zeros is False, treat an empty block as the end of the archive. If it is True, skip empty (and invalid) blocks and try to get as many members as possible. This is only useful for reading concatenated or damaged archives.

debug can be set from 0 (no debug messages) up to 3 (all debug messages). The messages are written to sys.stderr.

If errorlevel is 0, all errors are ignored when using TarFile.extract(). Nevertheless, they appear as error messages in the debug output, when debugging is enabled. If 1, all fatal errors are raised as OSError or IOError exceptions. If 2, all non-fatal errors are raised as TarError exceptions as well.

The encoding and errors arguments control the way strings are converted to unicode objects and vice versa. The default settings
will work for most users. See section *Unicode issues* for in-depth information.

*New in version 2.6.*

The *pax_headers* argument is an optional dictionary of unicode strings which will be added as a pax global header if *format* is *PAX_FORMAT*.

*New in version 2.6.*

**TarFile.open(...)**

Alternative constructor. The *tarfile.open()* function is actually a shortcut to this classmethod.

**TarFile.getmember(name)**

Return a *TarInfo* object for member *name*. If *name* can not be found in the archive, *KeyError* is raised.

**Note:** If a member occurs more than once in the archive, its last occurrence is assumed to be the most up-to-date version.

**TarFile.getmembers()**

Return the members of the archive as a list of *TarInfo* objects. The list has the same order as the members in the archive.

**TarFile.getnames()**

Return the members as a list of their names. It has the same order as the list returned by *getmembers()*.

**TarFile.list(VERBOSE=TRUE)**

Print a table of contents to *sys.stdout*. If *VERBOSE* is *False*, only the names of the members are printed. If it is *True*, output similar to that of *ls -l* is produced.
**TarFile.next()**

Return the next member of the archive as a `TarInfo` object, when `TarFile` is opened for reading. Return `None` if there is no more available.

**TarFile.extractall(path=".", members=None)**

Extract all members from the archive to the current working directory or directory `path`. If optional `members` is given, it must be a subset of the list returned by `getmembers()`. Directory information like owner, modification time and permissions are set after all members have been extracted. This is done to work around two problems: A directory's modification time is reset each time a file is created in it. And, if a directory's permissions do not allow writing, extracting files to it will fail.

**Warning:** Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of `path`, e.g. members that have absolute filenames starting with `/` or filenames with two dots `".."`.

*New in version 2.5.*

**TarFile.extract(member, path="")**

Extract a member from the archive to the current working directory, using its full name. Its file information is extracted as accurately as possible. `member` may be a filename or a `TarInfo` object. You can specify a different directory using `path`.

**Note:** The `extract()` method does not take care of several extraction issues. In most cases you should consider using the `extractall()` method.

**Warning:** See the warning for `extractall()`.
**TarFile.extractfile(member)**

Extract a member from the archive as a file object. *member* may be a filename or a [TarInfo](#) object. If *member* is a regular file, a file-like object is returned. If *member* is a link, a file-like object is constructed from the link's target. If *member* is none of the above, **None** is returned.

**Note:** The file-like object is read-only. It provides the methods `read()`, `readline()`, `readlines()`, `seek()`, `tell()`, and `close()`, and also supports iteration over its lines.

**TarFile.add(name, arcname=None, recursive=True, exclude=None, filter=None)**

Add the file *name* to the archive. *name* may be any type of file (directory, fifo, symbolic link, etc.). If given, *arcname* specifies an alternative name for the file in the archive. Directories are added recursively by default. This can be avoided by setting *recursive* to **False**. If *exclude* is given it must be a function that takes one filename argument and returns a boolean value. Depending on this value the respective file is either excluded (**True**) or added (**False**). If *filter* is specified it must be a function that takes a [TarInfo](#) object argument and returns the changed [TarInfo](#) object. If it instead returns **None** the [TarInfo](#) object will be excluded from the archive. See **Examples** for an example.

*Changed in version 2.6:* Added the *exclude* parameter.

*Changed in version 2.7:* Added the *filter* parameter.

**Deprecated since version 2.7:** The *exclude* parameter is deprecated, please use the *filter* parameter instead. For maximum portability, *filter* should be used as a keyword argument rather than as a positional argument so that code
won’t be affected when `exclude` is ultimately removed.

**TarFile.** `.addfile(tarinfo, fileobj=None)`

Add the `TarInfo` object `tarinfo` to the archive. If `fileobj` is given, `tarinfo.size` bytes are read from it and added to the archive. You can create `TarInfo` objects using `.gettarinfo()`.

**Note:** On Windows platforms, `fileobj` should always be opened with mode `'rb'` to avoid irritation about the file size.

**TarFile.** `.gettarinfo(name=None, arcname=None, fileobj=None)`

Create a `TarInfo` object for either the file `name` or the file object `fileobj` (using `os.fstat()` on its file descriptor). You can modify some of the `TarInfo`’s attributes before you add it using `.addfile()`. If given, `arcname` specifies an alternative name for the file in the archive.

**TarFile.** `.close()`

Close the `TarFile`. In write mode, two finishing zero blocks are appended to the archive.

**TarFile.** `.posix`

Setting this to `True` is equivalent to setting the `format` attribute to `USTAR_FORMAT`, `False` is equivalent to `GNU_FORMAT`.

*Changed in version 2.4:* `posix` defaults to `False`.

*Deprecated since version 2.6:* Use the `format` attribute instead.

**TarFile.** `.pax_headers`

A dictionary containing key-value pairs of pax global headers.

*New in version 2.6.*
12.5.2. TarInfo Objects

A TarInfo object represents one member in a TarFile. Aside from storing all required attributes of a file (like file type, size, time, permissions, owner etc.), it provides some useful methods to determine its type. It does not contain the file’s data itself.

TarInfo objects are returned by TarFile’s methods getmember(), getmembers() and gettarinfo().

class tarfile.TarInfo(name="")
    Create a TarInfo object.

TarInfo.frombuf(buf)
    Create and return a TarInfo object from string buffer buf.

    New in version 2.6: Raises HeaderError if the buffer is invalid..

TarInfo.fromtarfile(tarfile)
    Read the next member from the TarFile object tarfile and return it as a TarInfo object.

    New in version 2.6.

TarInfo.tobuf(format=DEFAULT_FORMAT, encoding=ENCODING, errors='strict')
    Create a string buffer from a TarInfo object. For information on the arguments see the constructor of the TarFile class.

    Changed in version 2.6: The arguments were added.

A TarInfo object has the following public data attributes:
TarInfo.name
   Name of the archive member.

TarInfo.size
   Size in bytes.

TarInfo.mtime
   Time of last modification.

TarInfo.mode
   Permission bits.

TarInfo.type
   File type. type is usually one of these constants: REGTYPE, AREGTYPE, LNKTYPE, SYMTYPE, DIRTYPE, FIFOTYPE, CONTTYPE, CHRTYPE, BLKTYPE, GNUTYPE_SPARSE. To determine the type of a TarInfo object more conveniently, use the is_*() methods below.

TarInfo.linkname
   Name of the target file name, which is only present in TarInfo objects of type LNKTYPE and SYMTYPE.

TarInfo.uid
   User ID of the user who originally stored this member.

TarInfo.gid
   Group ID of the user who originally stored this member.

TarInfo.uname
   User name.

TarInfo.gname
   Group name.

TarInfo.pax_headers
   A dictionary containing key-value pairs of an associated pax
extended header.

New in version 2.6.

A TarInfo object also provides some convenient query methods:

TarInfo. **isfile**()
    Return True if the Tarinfo object is a regular file.

TarInfo. **isreg**()
    Same as isfile().

TarInfo. **isdir**()
    Return True if it is a directory.

TarInfo. **issym**()
    Return True if it is a symbolic link.

TarInfo. **islnk**()
    Return True if it is a hard link.

TarInfo. **ischr**()
    Return True if it is a character device.

TarInfo. **isblk**()
    Return True if it is a block device.

TarInfo. **isfifo**()
    Return True if it is a FIFO.

TarInfo. **isdev**()
    Return True if it is one of character device, block device or FIFO.
12.5.3. Examples

How to extract an entire tar archive to the current working directory:

```python
import tarfile
tar = tarfile.open("sample.tar.gz")
tar.extractall()
tar.close()
```

How to extract a subset of a tar archive with `TarFile.extractall()` using a generator function instead of a list:

```python
import os
import tarfile
def py_files(members):
    for tarinfo in members:
        if os.path.splitext(tarinfo.name)[1] == ".py":
            yield tarinfo
tar = tarfile.open("sample.tar.gz")
tar.extractall(members=py_files(tar))
tar.close()
```

How to create an uncompressed tar archive from a list of filenames:

```python
import tarfile
tar = tarfile.open("sample.tar", "w")
for name in ["foo", "bar", "quux"]:    
    tar.add(name)
tar.close()
```

The same example using the `with` statement:

```python
import tarfile
with tarfile.open("sample.tar", "w") as tar:
    for name in ["foo", "bar", "quux"]:    
        tar.add(name)
```
How to read a gzip compressed tar archive and display some member information:

```python
import tarfile
tar = tarfile.open("sample.tar.gz", "r:gz")
for tarinfo in tar:
    print tarinfo.name, "is", tarinfo.size, "bytes in size and"
    if tarinfo.isreg():
        print "a regular file."
    elif tarinfo.isdir():
        print "a directory."
    else:
        print "something else."
tar.close()
```

How to create an archive and reset the user information using the `filter` parameter in `TarFile.add()`:

```python
import tarfile
def reset(tarinfo):
    tarinfo.uid = tarinfo.gid = 0
    tarinfo.uname = tarinfo.gname = "root"
    return tarinfo
tar = tarfile.open("sample.tar.gz", "w:gz")
tar.add("foo", filter=reset)
tar.close()
```
There are three tar formats that can be created with the `tarfile` module:

- The POSIX.1-1988 ustar format (**USTAR_FORMAT**). It supports filenames up to a length of at best 256 characters and linknames up to 100 characters. The maximum file size is 8 gigabytes. This is an old and limited but widely supported format.

- The GNU tar format (**GNU_FORMAT**). It supports long filenames and linknames, files bigger than 8 gigabytes and sparse files. It is the de facto standard on GNU/Linux systems. `tarfile` fully supports the GNU tar extensions for long names, sparse file support is read-only.

- The POSIX.1-2001 pax format (**PAX_FORMAT**). It is the most flexible format with virtually no limits. It supports long filenames and linknames, large files and stores pathnames in a portable way. However, not all tar implementations today are able to handle pax archives properly.

The pax format is an extension to the existing ustar format. It uses extra headers for information that cannot be stored otherwise. There are two flavours of pax headers: Extended headers only affect the subsequent file header, global headers are valid for the complete archive and affect all following files. All the data in a pax header is encoded in **UTF-8** for portability reasons.

There are some more variants of the tar format which can be read, but not created:
• The ancient V7 format. This is the first tar format from Unix Seventh Edition, storing only regular files and directories. Names must not be longer than 100 characters, there is no user/group name information. Some archives have miscalculated header checksums in case of fields with non-ASCII characters.

• The SunOS tar extended format. This format is a variant of the POSIX.1-2001 pax format, but is not compatible.
The tar format was originally conceived to make backups on tape drives with the main focus on preserving file system information. Nowadays tar archives are commonly used for file distribution and exchanging archives over networks. One problem of the original format (that all other formats are merely variants of) is that there is no concept of supporting different character encodings. For example, an ordinary tar archive created on a UTF-8 system cannot be read correctly on a Latin-1 system if it contains non-ASCII characters. Names (i.e. filenames, linknames, user/group names) containing these characters will appear damaged. Unfortunately, there is no way to autodetect the encoding of an archive.

The pax format was designed to solve this problem. It stores non-ASCII names using the universal character encoding UTF-8. When a pax archive is read, these UTF-8 names are converted to the encoding of the local file system.

The details of unicode conversion are controlled by the encoding and errors keyword arguments of the TarFile class.

The default value for encoding is the local character encoding. It is deduced from sys.getfilesystemencoding() and sys.getdefaultencoding(). In read mode, encoding is used exclusively to convert unicode names from a pax archive to strings in the local character encoding. In write mode, the use of encoding depends on the chosen archive format. In case of PAX_FORMAT, input names that contain non-ASCII characters need to be decoded before being stored as UTF-8 strings. The other formats do not make use of encoding unless unicode objects are used as input names. These are converted to 8-bit character strings before they are added to the archive.
The *errors* argument defines how characters are treated that cannot be converted to or from *encoding*. Possible values are listed in section *Codec Base Classes*. In read mode, there is an additional scheme "utf-8" which means that bad characters are replaced by their *UTF-8* representation. This is the default scheme. In write mode the default value for *errors* is "strict" to ensure that name information is not altered unnoticed.
13. File Formats

The modules described in this chapter parse various miscellaneous file formats that aren’t markup languages or are related to e-mail.

- **13.1. csv — CSV File Reading and Writing**
  - 13.1.1. Module Contents
  - 13.1.2. Dialects and Formatting Parameters
  - 13.1.3. Reader Objects
  - 13.1.4. Writer Objects
  - 13.1.5. Examples
- **13.2. ConfigParser — Configuration file parser**
  - 13.2.1. RawConfigParser Objects
  - 13.2.2. ConfigParser Objects
  - 13.2.3. SafeConfigParser Objects
  - 13.2.4. Examples
- **13.3. robotparser — Parser for robots.txt**
- **13.4. netrc — netrc file processing**
  - 13.4.1. netrc Objects
- **13.5. xdrlib — Encode and decode XDR data**
  - 13.5.1. Packer Objects
  - 13.5.2. Unpacker Objects
  - 13.5.3. Exceptions
- **13.6. plistlib — Generate and parse Mac OS X .plist files**
  - 13.6.1. Examples
13.1. csv — CSV File Reading and Writing

New in version 2.3.

The so-called CSV (Comma Separated Values) format is the most common import and export format for spreadsheets and databases. There is no “CSV standard”, so the format is operationally defined by the many applications which read and write it. The lack of a standard means that subtle differences often exist in the data produced and consumed by different applications. These differences can make it annoying to process CSV files from multiple sources. Still, while the delimiters and quoting characters vary, the overall format is similar enough that it is possible to write a single module which can efficiently manipulate such data, hiding the details of reading and writing the data from the programmer.

The csv module implements classes to read and write tabular data in CSV format. It allows programmers to say, “write this data in the format preferred by Excel,” or “read data from this file which was generated by Excel,” without knowing the precise details of the CSV format used by Excel. Programmers can also describe the CSV formats understood by other applications or define their own special-purpose CSV formats.

The csv module’s reader and writer objects read and write sequences. Programmers can also read and write data in dictionary form using the DictReader and DictWriter classes.

Note: This version of the csv module doesn’t support Unicode input. Also, there are currently some issues regarding ASCII NUL characters. Accordingly, all input should be UTF-8 or printable ASCII to be safe; see the examples in section Examples. These
restrictions will be removed in the future.

See also:

**PEP 305 - CSV File API**

The Python Enhancement Proposal which proposed this addition to Python.
The `csv` module defines the following functions:

```python
csv.reader(csvfile[, dialect='excel'][, fmtparam])
```

Return a reader object which will iterate over lines in the given `csvfile`. `csvfile` can be any object which supports the `iterator` protocol and returns a string each time its `next()` method is called — file objects and list objects are both suitable. If `csvfile` is a file object, it must be opened with the ‘b’ flag on platforms where that makes a difference. An optional `dialect` parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the `Dialect` class or one of the strings returned by the `list_dialects()` function. The other optional `fmtparam` keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about the dialect and formatting parameters, see section *Dialects and Formatting Parameters*.

Each row read from the csv file is returned as a list of strings. No automatic data type conversion is performed.

A short usage example:

```python
>>> import csv
>>> spamReader = csv.reader(open('eggs.csv', 'rb'), delimiter=',
...   for row in spamReader:
...     print ', '.join(row)
Spam, Spam, Spam, Spam, Spam, Baked Beans
Spam, Lovely Spam, Wonderful Spam
```

*Changed in version 2.5:* The parser is now stricter with respect to multi-line quoted fields. Previously, if a line ended within a quoted
field without a terminating newline character, a newline would be inserted into the returned field. This behavior caused problems when reading files which contained carriage return characters within fields. The behavior was changed to return the field without inserting newlines. As a consequence, if newlines embedded within fields are important, the input should be split into lines in a manner which preserves the newline characters.

```
csv.writer(csvfile[, dialect='excel'][, fmtparam])
```

Return a writer object responsible for converting the user's data into delimited strings on the given file-like object. `csvfile` can be any object with a `write()` method. If `csvfile` is a file object, it must be opened with the ‘b’ flag on platforms where that makes a difference. An optional `dialect` parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the `Dialect` class or one of the strings returned by the `list_dialects()` function. The other optional `fmtparam` keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about the dialect and formatting parameters, see section `Dialects and Formatting Parameters`. To make it as easy as possible to interface with modules which implement the DB API, the value `None` is written as the empty string. While this isn’t a reversible transformation, it makes it easier to dump SQL NULL data values to CSV files without preprocessing the data returned from a `cursor.fetch*` call. All other non-string data are stringified with `str()` before being written.

A short usage example:

```python
>>> import csv

>>> spamWriter = csv.writer(open('eggs.csv', 'wb'), delimiter=' ', quotechar='|', quoting=csv.QUOTE_MINIMAL)

>>> spamWriter.writerow(['Spam'] * 5 + ['Baked Beans'])

>>> spamWriter.writerow(['Spam', 'Lovely Spam', 'Wonderful Spam'])
```
**csv.** `register_dialect(name[, dialect][, fmtparam])`

Associate `dialect` with `name`. `name` must be a string or Unicode object. The dialect can be specified either by passing a sub-class of `Dialect`, or by `fmtparam` keyword arguments, or both, with keyword arguments overriding parameters of the dialect. For full details about the dialect and formatting parameters, see section *Dialects and Formatting Parameters*.

**csv.** `unregister_dialect(name)`

Delete the dialect associated with `name` from the dialect registry. An **Error** is raised if `name` is not a registered dialect name.

**csv.** `get_dialect(name)`

Return the dialect associated with `name`. An **Error** is raised if `name` is not a registered dialect name.

* Changed in version 2.5: This function now returns an immutable `Dialect`. Previously an instance of the requested dialect was returned. Users could modify the underlying class, changing the behavior of active readers and writers.

**csv.** `list_dialects()`

Return the names of all registered dialects.

**csv.** `field_size_limit([new_limit])`

Returns the current maximum field size allowed by the parser. If `new_limit` is given, this becomes the new limit.

* New in version 2.5.

The **csv** module defines the following classes:

```python
class csv.DictReader(csvfile[, fieldnames=None[, restkey=None[, restval=None[, encoding=None[, dialect=Dialect]]]]]])
```
Create an object which operates like a regular reader but maps the information read into a dict whose keys are given by the optional fieldnames parameter. If the fieldnames parameter is omitted, the values in the first row of the csvfile will be used as the fieldnames. If the row read has more fields than the fieldnames sequence, the remaining data is added as a sequence keyed by the value of restkey. If the row read has fewer fields than the fieldnames sequence, the remaining keys take the value of the optional restval parameter. Any other optional or keyword arguments are passed to the underlying reader instance.

Create an object which operates like a regular writer but maps dictionaries onto output rows. The fieldnames parameter identifies the order in which values in the dictionary passed to the writerow() method are written to the csvfile. The optional restval parameter specifies the value to be written if the dictionary is missing a key in fieldnames. If the dictionary passed to the writerow() method contains a key not found in fieldnames, the optional extrasaction parameter indicates what action to take. If it is set to 'raise' a ValueError is raised. If it is set to 'ignore', extra values in the dictionary are ignored. Any other optional or keyword arguments are passed to the underlying writer instance.

Note that unlike the DictReader class, the fieldnames parameter of the DictWriter is not optional. Since Python’s dict objects are not ordered, there is not enough information available to deduce the order in which the row should be written to the csvfile.
class csv.Dialect
    The Dialect class is a container class relied on primarily for its attributes, which are used to define the parameters for a specific reader or writer instance.

class csv.excel
    The excel class defines the usual properties of an Excel-generated CSV file. It is registered with the dialect name 'excel'.

class csv.excel_tab
    The excel_tab class defines the usual properties of an Excel-generated TAB-delimited file. It is registered with the dialect name 'excel-tab'.

class csv.Sniffer
    The Sniffer class is used to deduce the format of a CSV file.

    The Sniffer class provides two methods:

    sniff(sample[, delimiters=None])
        Analyze the given sample and return a Dialect subclass reflecting the parameters found. If the optional delimiters parameter is given, it is interpreted as a string containing possible valid delimiter characters.

    has_header(sample)
        Analyze the sample text (presumed to be in CSV format) and return True if the first row appears to be a series of column headers.

An example for Sniffer use:

```python
csvfile = open("example.csv", "rb")
dialect = csv.Sniffer().sniff(csvfile.read(1024))
csvfile.seek(0)
```
reader = csv.reader(csvfile, dialect)
# ... process CSV file contents here ...

The `csv` module defines the following constants:

**`csv.QUOTE_ALL`**
Instructs `writer` objects to quote all fields.

**`csv.QUOTE_MINIMAL`**
Instructs `writer` objects to only quote those fields which contain special characters such as `delimiter`, `quotechar` or any of the characters in `lineterminator`.

**`csv.QUOTE_NONNUMERIC`**
Instructs `writer` objects to quote all non-numeric fields.

Instructs the reader to convert all non-quoted fields to type `float`.

**`csv.QUOTE_NONE`**
Instructs `writer` objects to never quote fields. When the current `delimiter` occurs in output data it is preceded by the current `escapechar` character. If `escapechar` is not set, the writer will raise `Error` if any characters that require escaping are encountered.

Instructs `reader` to perform no special processing of quote characters.

The `csv` module defines the following exception:

`exception csv.Error`
Raised by any of the functions when an error is detected.
13.1.2. Dialects and Formatting Parameters

To make it easier to specify the format of input and output records, specific formatting parameters are grouped together into dialects. A dialect is a subclass of the `Dialect` class having a set of specific methods and a single `validate()` method. When creating `reader` or `writer` objects, the programmer can specify a string or a subclass of the `Dialect` class as the dialect parameter. In addition to, or instead of, the `dialect` parameter, the programmer can also specify individual formatting parameters, which have the same names as the attributes defined below for the `Dialect` class.

Dialects support the following attributes:

**Dialect.** `delimiter`  
A one-character string used to separate fields. It defaults to `'','`.

**Dialect.** `doublequote`  
Controls how instances of `quotechar` appearing inside a field should be themselves be quoted. When `True`, the character is doubled. When `False`, the `escapechar` is used as a prefix to the `quotechar`. It defaults to `True`.

On output, if `doublequote` is `False` and no `escapechar` is set, `Error` is raised if a `quotechar` is found in a field.

**Dialect.** `escapechar`  
A one-character string used by the writer to escape the `delimiter` if `quoting` is set to `QUOTE_NONE` and the `quotechar` if `doublequote` is `False`. On reading, the `escapechar` removes any special meaning from the following character. It defaults to `None`, which disables escaping.
Dialect. **lineterminator**
The string used to terminate lines produced by the **writer**. It defaults to `\r\n`.

**Note:** The **reader** is hard-coded to recognise either `\r` or `\n` as end-of-line, and ignores **lineterminator**. This behavior may change in the future.

Dialect. **quotechar**
A one-character string used to quote fields containing special characters, such as the **delimiter** or **quotechar**, or which contain new-line characters. It defaults to `"`.

Dialect. **quoting**
Controls when quotes should be generated by the writer and recognised by the reader. It can take on any of the **QUOTE_** constants (see section Module Contents) and defaults to **QUOTE_MINIMAL**.

Dialect. **skipinitialspace**
When **True**, whitespace immediately following the **delimiter** is ignored. The default is **False**.
13.1.3. Reader Objects

Reader objects (DictReader instances and objects returned by the reader() function) have the following public methods:

csvreader.next()

Return the next row of the reader’s iterable object as a list, parsed according to the current dialect.

Reader objects have the following public attributes:

csvreader.dialect

A read-only description of the dialect in use by the parser.

csvreader.line_num

The number of lines read from the source iterator. This is not the same as the number of records returned, as records can span multiple lines.

New in version 2.5.

DictReader objects have the following public attribute:

csvreader.fieldnames

If not passed as a parameter when creating the object, this attribute is initialized upon first access or when the first record is read from the file.

Changed in version 2.6.
13.1.4. Writer Objects

Writer objects (DictWriter instances and objects returned by the writer() function) have the following public methods. A row must be a sequence of strings or numbers for Writer objects and a dictionary mapping fieldnames to strings or numbers (by passing them through str() first) for DictWriter objects. Note that complex numbers are written out surrounded by parens. This may cause some problems for other programs which read CSV files (assuming they support complex numbers at all).

**csvwriter.writerow(row)**
Write the row parameter to the writer’s file object, formatted according to the current dialect.

**csvwriter.writerows(rows)**
Write all the rows parameters (a list of row objects as described above) to the writer's file object, formatted according to the current dialect.

Writer objects have the following public attribute:

**csvwriter.dialect**
A read-only description of the dialect in use by the writer.

DictWriter objects have the following public method:

**DictWriter.writeheader()**
Write a row with the field names (as specified in the constructor).

New in version 2.7.
13.1.5. Examples

The simplest example of reading a CSV file:

```python
import csv
with open('some.csv', 'rb') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

Reading a file with an alternate format:

```python
import csv
with open('passwd', 'rb') as f:
    reader = csv.reader(f, delimiter=':', quoting=csv.QUOTE_NONE)
    for row in reader:
        print(row)
```

The corresponding simplest possible writing example is:

```python
import csv
with open('some.csv', 'wb') as f:
    writer = csv.writer(f)
    writer.writerows(someiterable)
```

Registering a new dialect:

```python
import csv
csv.register_dialect('unixpwd', delimiter=':', quoting=csv.QUOTE_NONE)
with open('passwd', 'rb') as f:
    reader = csv.reader(f, 'unixpwd')
```

A slightly more advanced use of the reader — catching and reporting errors:

```python
import csv, sys
filename = 'some.csv'
```
And while the module doesn’t directly support parsing strings, it can easily be done:

```python
import csv
for row in csv.reader(['one,two,three']):
    print row
```

The `csv` module doesn’t directly support reading and writing Unicode, but it is 8-bit-clean save for some problems with ASCII NUL characters. So you can write functions or classes that handle the encoding and decoding for you as long as you avoid encodings like UTF-16 that use NULs. UTF-8 is recommended.

`unicode_csv_reader()` below is a `generator` that wraps `csv.reader` to handle Unicode CSV data (a list of Unicode strings). `utf_8_encoder()` is a `generator` that encodes the Unicode strings as UTF-8, one string (or row) at a time. The encoded strings are parsed by the CSV reader, and `unicode_csv_reader()` decodes the UTF-8-encoded cells back into Unicode:

```python
import csv

def unicode_csv_reader(unicode_csv_data, dialect=csv.excel, **kwds):
    # csv.py doesn't do Unicode; encode temporarily as UTF-8:
    csv_reader = csv.reader(utf_8_encoder(unicode_csv_data),
                            dialect=dialect, **kwds)
    for row in csv_reader:
        # decode UTF-8 back to Unicode, cell by cell:
        yield [unicode(cell, 'utf-8') for cell in row]

def utf_8_encoder(unicode_csv_data):
```
for line in unicode_csv_data:
    yield line.encode('utf-8')

For all other encodings the following `UnicodeReader` and `UnicodeWriter` classes can be used. They take an additional `encoding` parameter in their constructor and make sure that the data passes the real reader or writer encoded as UTF-8:

```python
import csv, codecs, cStringIO

class UTF8Recoder:
    """
    Iterator that reads an encoded stream and reencodes the input
    to UTF-8.
    """
    def __init__(self, f, encoding):
        self.reader = codecs.getreader(encoding)(f)

    def __iter__(self):
        return self

    def next(self):
        return self.reader.next().encode("utf-8")

class UnicodeReader:
    """
    A CSV reader which will iterate over lines in the CSV file
    which is encoded in the given encoding.
    """
    def __init__(self, f, dialect=csv.excel, encoding="utf-8",
                 **kwds):
        f = UTF8Recoder(f, encoding)
        self.reader = csv.reader(f, dialect=dialect, **kwds)

    def next(self):
        row = self.reader.next()
        return [unicode(s, "utf-8") for s in row]

    def __iter__(self):
        return self

class UnicodeWriter:
    """
    A CSV writer which will write rows to CSV file "f",
    which is encoded in the given encoding.
    """
```
def __init__(self, f, dialect=csv.excel, encoding="utf-8",
            # Redirect output to a queue
            self.queue = cStringIO.StringIO()
            self.writer = csv.writer(self.queue, dialect=dialect, *
            self.stream = f
            self.encoder = codecs.getincrementalencoder(encoding)()

    def writerow(self, row):
        self.writer.writerow([s.encode("utf-8") for s in row])
            # Fetch UTF-8 output from the queue ... 
            data = self.queue.getvalue()
            data = data.decode("utf-8")
            # ... and reencode it into the target encoding
            data = self.encoder.encode(data)
            # write to the target stream
            self.stream.write(data)
            # empty queue
            self.queue.truncate(0)

    def writerows(self, rows):
        for row in rows:
            self.writerow(row)
The Python Standard Library » 13. File Formats »
13.2. ConfigParser — Configuration file parser

**Note:** The `ConfigParser` module has been renamed to `configparser` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

This module defines the class `ConfigParser`. The `ConfigParser` class implements a basic configuration file parser language which provides a structure similar to what you would find on Microsoft Windows INI files. You can use this to write Python programs which can be customized by end users easily.

**Note:** This library does not interpret or write the value-type prefixes used in the Windows Registry extended version of INI syntax.

**See also:**

**Module** `shlex`

Support for creating Unix shell-like mini-languages which can be used as an alternate format for application configuration files.

**Module** `json`

The json module implements a subset of JavaScript syntax which can also be used for this purpose.

The configuration file consists of sections, led by a `[section]` header and followed by `name: value` entries, with continuations in the style of RFC 822 (see section 3.1.1, “LONG HEADER FIELDS”); `name=value` is also accepted. Note that leading whitespace is
removed from values. The optional values can contain format strings which refer to other values in the same section, or values in a special **DEFAULT** section. Additional defaults can be provided on initialization and retrieval. Lines beginning with '#' or ';' are ignored and may be used to provide comments.

Configuration files may include comments, prefixed by specific characters (# and ;). Comments may appear on their own in an otherwise empty line, or may be entered in lines holding values or section names. In the latter case, they need to be preceded by a whitespace character to be recognized as a comment. (For backwards compatibility, only ; starts an inline comment, while # does not.)

On top of the core functionality, **SafeConfigParser** supports interpolation. This means values can contain format strings which refer to other values in the same section, or values in a special **DEFAULT** section. Additional defaults can be provided on initialization.

For example:

```ini
[My Section]
foodir: %(dir)s/whatever
dir=frob
long: this value continues
     in the next line
```

would resolve the %(dir)s to the value of dir (frob in this case). All reference expansions are done on demand.

Default values can be specified by passing them into the **ConfigParser** constructor as a dictionary. Additional defaults may be passed into the `get()` method which will override all others.

Sections are normally stored in a built-in dictionary. An alternative
dictionary type can be passed to the `ConfigParser` constructor. For example, if a dictionary type is passed that sorts its keys, the sections will be sorted on write-back, as will be the keys within each section.

```python
class ConfigParser.RawConfigParser([defaults[, dict_type[, allow_no_value]]])
```

The basic configuration object. When `defaults` is given, it is initialized into the dictionary of intrinsic defaults. When `dict_type` is given, it will be used to create the dictionary objects for the list of sections, for the options within a section, and for the default values. When `allow_no_value` is true (default: False), options without values are accepted; the value presented for these is None.

This class does not support the magical interpolation behavior.

All option names are passed through the `optionxform()` method. Its default implementation converts option names to lower case.

*New in version 2.3.*

*Changed in version 2.6:* `dict_type` was added.

*Changed in version 2.7:* The default `dict_type` is `collections.OrderedDict`. `allow_no_value` was added.

```python
class ConfigParser.ConfigParser([defaults[, dict_type[, allow_no_value]]])
```

Derived class of `RawConfigParser` that implements the magical interpolation feature and adds optional arguments to the `get()` and `items()` methods. The values in `defaults` must be appropriate for the `%()`s string interpolation. Note that `__name__` is an
intrinsic default; its value is the section name, and will override any value provided in defaults.

All option names used in interpolation will be passed through the optionxform() method just like any other option name reference. Using the default implementation of optionxform(), the values foo %(bar)s and foo %(BAR)s are equivalent.

New in version 2.3.

Changed in version 2.6: dict_type was added.

Changed in version 2.7: The default dict_type is collections.OrderedDict. allow_no_value was added.

class ConfigParser.SafeConfigParser([defaults[, dict_type[, allow_no_value]]])

Derived class of ConfigParser that implements a more-sane variant of the magical interpolation feature. This implementation is more predictable as well. New applications should prefer this version if they don’t need to be compatible with older versions of Python.

New in version 2.3.

Changed in version 2.6: dict_type was added.

Changed in version 2.7: The default dict_type is collections.OrderedDict. allow_no_value was added.

exception ConfigParser.Error
Base class for all other configparser exceptions.

exception ConfigParser.NoSectionError
Exception raised when a specified section is not found.
exception ConfigParser.DuplicateSectionError
Exception raised if add_section() is called with the name of a section that is already present.

exception ConfigParser.NoOptionError
Exception raised when a specified option is not found in the specified section.

exception ConfigParser.InterpolationError
Base class for exceptions raised when problems occur performing string interpolation.

exception ConfigParser.InterpolationDepthError
Exception raised when string interpolation cannot be completed because the number of iterations exceeds MAX_INTERPOLATION_DEPTH. Subclass of InterpolationError.

exception ConfigParser.InterpolationMissingOptionError
Exception raised when an option referenced from a value does not exist. Subclass of InterpolationError.

New in version 2.3.

exception ConfigParser.InterpolationSyntaxError
Exception raised when the source text into which substitutions are made does not conform to the required syntax. Subclass of InterpolationError.

New in version 2.3.

exception ConfigParser.MissingSectionHeaderError
Exception raised when attempting to parse a file which has no section headers.

exception ConfigParser.ParsingError
Exception raised when errors occur attempting to parse a file.

ConfigParser. **MAX_INTERPOLATION_DEPTH**

The maximum depth for recursive interpolation for `get()` when the `raw` parameter is false. This is relevant only for the `ConfigParser` class.

See also:

**Module shlex**

Support for a creating Unix shell-like mini-languages which can be used as an alternate format for application configuration files.
13.2.1. RawConfigParser Objects

RawConfigParser instances have the following methods:

RawConfigParser.defaults()
    Return a dictionary containing the instance-wide defaults.

RawConfigParser.sections()
    Return a list of the sections available; DEFAULT is not included in the list.

RawConfigParser.add_section(section)
    Add a section named section to the instance. If a section by the given name already exists, DuplicateSectionError is raised. If the name DEFAULT (or any of it’s case-insensitive variants) is passed, ValueError is raised.

RawConfigParser.has_section(section)
    Indicates whether the named section is present in the configuration. The DEFAULT section is not acknowledged.

RawConfigParser.options(section)
    Returns a list of options available in the specified section.

RawConfigParser.has_option(section, option)
    If the given section exists, and contains the given option, return True; otherwise return False.

    New in version 1.6.

RawConfigParser.read(filenames)
    Attempt to read and parse a list of filenames, returning a list of filenames which were successfully parsed. If filenames is a string
or Unicode string, it is treated as a single filename. If a file named in filenames cannot be opened, that file will be ignored. This is designed so that you can specify a list of potential configuration file locations (for example, the current directory, the user’s home directory, and some system-wide directory), and all existing configuration files in the list will be read. If none of the named files exist, the ConfigParser instance will contain an empty dataset. An application which requires initial values to be loaded from a file should load the required file or files using readfp() before calling read() for any optional files:

```
import ConfigParser, os

config = ConfigParser.ConfigParser()
config.readfp(open('defaults.cfg'))
config.read(['site.cfg', os.path.expanduser('~/myapp.cfg')])
```

*Changed in version 2.4:* Returns list of successfully parsed filenames.

**RawConfigParser.**

*readfp(fp[, filename]*)

Read and parse configuration data from the file or file-like object in fp (only the readline() method is used). If filename is omitted and fp has a name attribute, that is used for filename; the default is «???».

**RawConfigParser.**

*get(section, option)*

Get an option value for the named section.

**RawConfigParser.**

*getint(section, option)*

A convenience method which coerces the option in the specified section to an integer.

**RawConfigParser.**

*getfloat(section, option)*
A convenience method which coerces the *option* in the specified *section* to a floating point number.

**RawConfigParser**. getboolean(*section*, *option*)

A convenience method which coerces the *option* in the specified *section* to a Boolean value. Note that the accepted values for the option are "1", "yes", "true", and "on", which cause this method to return `True`, and "0", "no", "false", and "off", which cause it to return `False`. These string values are checked in a case-insensitive manner. Any other value will cause it to raise `ValueError`.

**RawConfigParser**. items(*section*)

Return a list of `(name, value)` pairs for each option in the given *section*.

**RawConfigParser**. set(*section*, *option*, *value*)

If the given section exists, set the given option to the specified value; otherwise raise `NoSectionError`. While it is possible to use `RawConfigParser` (or `ConfigParser` with `raw` parameters set to `true`) for *internal* storage of non-string values, full functionality (including interpolation and output to files) can only be achieved using string values.

*New in version 1.6.*

**RawConfigParser**. write(*fileobject*)

Write a representation of the configuration to the specified file object. This representation can be parsed by a future `read()` call.

*New in version 1.6.*

**RawConfigParser**. remove_option(*section*, *option*)

Remove the specified *option* from the specified *section*. If the
section does not exist, raise `NoSectionError`. If the option existed to be removed, return `True`; otherwise return `False`.

*New in version 1.6.*

```
RawConfigParser.remove_section(section)
```

Remove the specified section from the configuration. If the section in fact existed, return `True`. Otherwise return `False`.

```
RawConfigParser.optionxform(option)
```

Transforms the option name `option` as found in an input file or as passed in by client code to the form that should be used in the internal structures. The default implementation returns a lower-case version of `option`; subclasses may override this or client code can set an attribute of this name on instances to affect this behavior.

You don’t necessarily need to subclass a ConfigParser to use this method, you can also re-set it on an instance, to a function that takes a string argument. Setting it to `str`, for example, would make option names case sensitive:

```
cfgparser = ConfigParser()
...
cfgparser.optionxform = str
```

Note that when reading configuration files, whitespace around the option names are stripped before `optionxform()` is called.
13.2.2. ConfigParser Objects

The `ConfigParser` class extends some methods of the `RawConfigParser` interface, adding some optional arguments.

`ConfigParser.get(section, option[, raw[, vars]])`

Get an `option` value for the named `section`. If `vars` is provided, it must be a dictionary. The `option` is looked up in `vars` (if provided), `section`, and in `defaults` in that order.

All the `'%'` interpolations are expanded in the return values, unless the `raw` argument is true. Values for interpolation keys are looked up in the same manner as the option.

`ConfigParser.items(section[, raw[, vars]])`

Return a list of `(name, value)` pairs for each option in the given `section`. Optional arguments have the same meaning as for the `get()` method.

*New in version 2.3.*
13.2.3. SafeConfigParser Objects

The SafeConfigParser class implements the same extended interface as ConfigParser, with the following addition:

SafeConfigParser.set(section, option, value)

If the given section exists, set the given option to the specified value; otherwise raise NoSectionError. value must be a string (str or unicode); if not, TypeError is raised.

New in version 2.4.
13.2.4. Examples

An example of writing to a configuration file:

```python
import ConfigParser

config = ConfigParser.RawConfigParser()

# When adding sections or items, add them in the reverse order
# how you want them to be displayed in the actual file.
# In addition, please note that using RawConfigParser's and the
# mode of ConfigParser's respective set functions, you can assi
# non-string values to keys internally, but will receive an err
# when attempting to write to a file or when you get it in non-
# mode. SafeConfigParser does not allow such assignments to take
config.add_section('Section1')
config.set('Section1', 'int', '15')
config.set('Section1', 'bool', 'true')
config.set('Section1', 'float', '3.1415')
config.set('Section1', 'baz', 'fun')
config.set('Section1', 'bar', 'Python')
config.set('Section1', 'foo', '%(bar)s is %(baz)s!')

# Writing our configuration file to 'example.cfg'
with open('example.cfg', 'wb') as configfile:
    config.write(configfile)
```

An example of reading the configuration file again:

```python
import ConfigParser

config = ConfigParser.RawConfigParser()
config.read('example.cfg')

# getfloat() raises an exception if the value is not a float
# getint() and getboolean() also do this for their respective t
float = config.getfloat('Section1', 'float')
int = config.getint('Section1', 'int')
print float + int

# Notice that the next output does not interpolate '%(bar)s' or
# This is because we are using a RawConfigParser().
```
if config.getboolean('Section1', 'bool'):
    print config.get('Section1', 'foo')

To get interpolation, you will need to use a ConfigParser or SafeConfigParser:

```python
import ConfigParser
config = ConfigParser.ConfigParser()
config.read('example.cfg')

# Set the third, optional argument of get to 1 if you wish to use interpolation.
print config.get('Section1', 'foo', 0) # -> "Python is fun!"
print config.get('Section1', 'foo', 1) # -> "%(bar)s is %(baz)s"

# The optional fourth argument is a dict with members that will take precedence in interpolation.
print config.get('Section1', 'foo', 0, {'bar': 'Documentation', 'baz': 'evil'})
```

Defaults are available in all three types of ConfigParsers. They are used in interpolation if an option used is not defined elsewhere.

```python
import ConfigParser

# New instance with 'bar' and 'baz' defaulting to 'Life' and 'hard'.
config = ConfigParser.SafeConfigParser({'bar': 'Life', 'baz': 'hard'})
config.read('example.cfg')

print config.get('Section1', 'foo') # -> "Python is fun!"
config.remove_option('Section1', 'bar')
config.remove_option('Section1', 'baz')
print config.get('Section1', 'foo') # -> "Life is hard!"
```

The function `opt_move` below can be used to move options between sections:

```python
def opt_move(config, section1, section2, option):
    try:
```
Some configuration files are known to include settings without values, but which otherwise conform to the syntax supported by `ConfigParser`. The `allow_no_value` parameter to the constructor can be used to indicate that such values should be accepted:

```python
>>> import ConfigParser
>>> import io

>>> sample_config = """
... [mysqld]
... user = mysql
... pid-file = /var/run/mysqld/mysqld.pid
... skip-external-locking
... old_passwords = 1
... skip-bdb
... skip-innodb
... """

>>> config = ConfigParser.RawConfigParser(allow_no_value=True)
>>> config.readfp(io.BytesIO(sample_config))

>>> # Settings with values are treated as before:
>>> config.get("mysqld", "user")
'mysql'

>>> # Settings without values provide None:
>>> config.get("mysqld", "skip-bdb")

>>> # Settings which aren't specified still raise an error:
>>> config.get("mysqld", "does-not-exist")
Traceback (most recent call last):
...
ConfigParser.NoOptionError: No option 'does-not-exist' in section
```
13.3. robotparser — Parser for robots.txt

**Note:** The robotparser module has been renamed urllib.robotparser in Python 3.0. The 2to3 tool will automatically adapt imports when converting your sources to 3.0.

This module provides a single class, RobotFileParser, which answers questions about whether or not a particular user agent can fetch a URL on the Web site that published the robots.txt file. For more details on the structure of robots.txt files, see http://www.robotstxt.org/orig.html.

```python
class robotparser.RobotFileParser

    This class provides a set of methods to read, parse and answer questions about a single robots.txt file.

    set_url(url)
        Sets the URL referring to a robots.txt file.

    read()
        Reads the robots.txt URL and feeds it to the parser.

    parse(lines)
        Parses the lines argument.

    can_fetch(useragent, url)
        Returns True if the useragent is allowed to fetch the url according to the rules contained in the parsed robots.txt file.

    mtime()
        Returns the time the robots.txt file was last fetched. This is
useful for long-running web spiders that need to check for new robots.txt files periodically.

modified()
Sets the time the robots.txt file was last fetched to the current time.

The following example demonstrates basic use of the RobotFileParser class.

```python
>>> import robotparser
>>> rp = robotparser.RobotFileParser()
>>> rp.set_url("http://www.musi-cal.com/robots.txt")
>>> rp.read()
>>> rp.can_fetch("*", "http://www.musi-cal.com/cgi-bin/search?city=San+Francisco")
False
>>> rp.can_fetch("*", "http://www.musi-cal.com/")
True
```
13. File Formats
13.4. netrc — netrc file processing

New in version 1.5.2.

The netrc class parses and encapsulates the netrc file format used by the Unix ftp program and other FTP clients.

```python
class netrc(netrc([file]))
```

A netrc instance or subclass instance encapsulates data from a netrc file. The initialization argument, if present, specifies the file to parse. If no argument is given, the file .netrc in the user's home directory will be read. Parse errors will raise NetrcParseError with diagnostic information including the file name, line number, and terminating token.

```python
exception netrc.NetrcParseError
```

Exception raised by the netrc class when syntactical errors are encountered in source text. Instances of this exception provide three interesting attributes: msg is a textual explanation of the error, filename is the name of the source file, and lineno gives the line number on which the error was found.
13.4.1. netrc Objects

A netrc instance has the following methods:

```python
netrc.authenticators(host)
```
Return a 3-tuple `(login, account, password)` of authenticators for `host`. If the netrc file did not contain an entry for the given host, return the tuple associated with the ‘default’ entry. If neither matching host nor default entry is available, return `None`.

```python
netrc.__repr__()
```
Dump the class data as a string in the format of a netrc file. (This discards comments and may reorder the entries.)

Instances of netrc have public instance variables:

```python
netrc.hosts
```
Dictionary mapping host names to `(login, account, password)` tuples. The ‘default’ entry, if any, is represented as a pseudo-host by that name.

```python
netrc.macros
```
Dictionary mapping macro names to string lists.

**Note:** Passwords are limited to a subset of the ASCII character set. Versions of this module prior to 2.3 were extremely limited. Starting with 2.3, all ASCII punctuation is allowed in passwords. However, note that whitespace and non-printable characters are not allowed in passwords. This is a limitation of the way the .netrc file is parsed and may be removed in the future.
13.5. xdrlib — Encode and decode XDR data

The *xdrlib* module supports the External Data Representation Standard as described in RFC 1014, written by Sun Microsystems, Inc. June 1987. It supports most of the data types described in the RFC.

The *xdrlib* module defines two classes, one for packing variables into XDR representation, and another for unpacking from XDR representation. There are also two exception classes.

*class xdrlib.Packer*

    *Packer* is the class for packing data into XDR representation. The *Packer* class is instantiated with no arguments.

*class xdrlib.Unpacker*(data)*

    *Unpacker* is the complementary class which unpacks XDR data values from a string buffer. The input buffer is given as *data*.

**See also:**

RFC 1014 - XDR: External Data Representation Standard

This RFC defined the encoding of data which was XDR at the time this module was originally written. It has apparently been obsoleted by RFC 1832.

RFC 1832 - XDR: External Data Representation Standard

Newer RFC that provides a revised definition of XDR.
Packer instances have the following methods:

- **Packer.get_buffer()**

  Returns the current pack buffer as a string.

- **Packer.reset()**

  Resets the pack buffer to the empty string.

In general, you can pack any of the most common XDR data types by calling the appropriate `pack_type()` method. Each method takes a single argument, the value to pack. The following simple data type packing methods are supported: `pack_uint()`, `pack_int()`, `pack_enum()`, `pack_bool()`, `pack_uhyper()`, and `pack_hyper()`.

- **Packer.pack_float(value)**

  Packs the single-precision floating point number `value`.

- **Packer.pack_double(value)**

  Packs the double-precision floating point number `value`.

The following methods support packing strings, bytes, and opaque data:

- **Packer.pack_fstring(n, s)**

  Packs a fixed length string, `s`. `n` is the length of the string but it is *not* packed into the data buffer. The string is padded with null bytes if necessary to guaranteed 4 byte alignment.

- **Packer.pack_fopaque(n, data)**

  Packs a fixed length opaque data stream, similarly to `pack_fstring()`.
Packer. **pack_string**(*s*)

Packs a variable length string, *s*. The length of the string is first packed as an unsigned integer, then the string data is packed with `pack_fstring()`.

Packer. **pack_opaque**(*data*)

Packs a variable length opaque data string, similarly to `pack_string()`.

Packer. **pack_bytes**(*bytes*)

Packs a variable length byte stream, similarly to `pack_string()`.

The following methods support packing arrays and lists:

Packer. **pack_list**(*list, pack_item*)

Packs a *list* of homogeneous items. This method is useful for lists with an indeterminate size; i.e. the size is not available until the entire list has been walked. For each item in the list, an unsigned integer 1 is packed first, followed by the data value from the list. `pack_item` is the function that is called to pack the individual item. At the end of the list, an unsigned integer 0 is packed.

For example, to pack a list of integers, the code might appear like this:

```python
import xdrlib
p = xdrlib.Packer()
p.pack_list([1, 2, 3], p.pack_int)
```

Packer. **pack_farray**(*n, array, pack_item*)

Packs a fixed length list (*array*) of homogeneous items. *n* is the length of the list; it is not packed into the buffer, but a `ValueError` exception is raised if `len(array)` is not equal to *n*. As above, `pack_item` is the function used to pack each element.
Packer. **pack_array**(*list, pack_item*)

Packs a variable length *list* of homogeneous items. First, the length of the list is packed as an unsigned integer, then each element is packed as in **pack_farray()** above.
13.5.2. Unpacker Objects

The `Unpacker` class offers the following methods:

**Unpacker.** `.reset(data)`

Resets the string buffer with the given `data`.

**Unpacker.** `.get_position()`

Returns the current unpack position in the data buffer.

**Unpacker.** `.set_position(position)`

Sets the data buffer unpack position to `position`. You should be careful about using `get_position()` and `set_position()`.

**Unpacker.** `.get_buffer()`

Returns the current unpack data buffer as a string.

**Unpacker.** `.done()`

Indicates unpack completion. Raises an `Error` exception if all of the data has not been unpacked.

In addition, every data type that can be packed with a `Packer`, can be unpacked with an `Unpacker`. Unpacking methods are of the form `unpack_type()`, and take no arguments. They return the unpacked object.

**Unpacker.** `.unpack_float()`

Unpacks a single-precision floating point number.

**Unpacker.** `.unpack_double()`

Unpacks a double-precision floating point number, similarly to `unpack_float()`.
In addition, the following methods unpack strings, bytes, and opaque data:

**Unpacker.** `unpack_fstring(n)`  
Unpacks and returns a fixed length string. *n* is the number of characters expected. Padding with null bytes to guaranteed 4 byte alignment is assumed.

**Unpacker.** `unpack_fopaque(n)`  
Unpacks and returns a fixed length opaque data stream, similarly to `unpack_fstring()`.

**Unpacker.** `unpack_string()`  
Unpacks and returns a variable length string. The length of the string is first unpacked as an unsigned integer, then the string data is unpacked with `unpack_fstring()`.

**Unpacker.** `unpack_opaque()`  
Unpacks and returns a variable length opaque data string, similarly to `unpack_string()`.

**Unpacker.** `unpack_bytes()`  
Unpacks and returns a variable length byte stream, similarly to `unpack_string()`.

The following methods support unpacking arrays and lists:

**Unpacker.** `unpack_list(unpack_item)`  
Unpacks and returns a list of homogeneous items. The list is unpacked one element at a time by first unpacking an unsigned integer flag. If the flag is `1`, then the item is unpacked and appended to the list. A flag of `0` indicates the end of the list. `unpack_item` is the function that is called to unpack the items.
Unpacker. **unpack_farray**(*n*, *unpack_item*)

Unpacks and returns (as a list) a fixed length array of homogeneous items. *n* is number of list elements to expect in the buffer. As above, *unpack_item* is the function used to unpack each element.

Unpacker. **unpack_array**(*unpack_item*)

Unpacks and returns a variable length list of homogeneous items. First, the length of the list is unpacked as an unsigned integer, then each element is unpacked as in **unpack_farray()** above.
13.5.3. Exceptions

Exceptions in this module are coded as class instances:

```python
exception xdrlib.Error
    The base exception class. Error has a single public data member
    msg containing the description of the error.

exception xdrlib.ConversionError
    Class derived from Error. Contains no additional instance
    variables.
```

Here is an example of how you would catch one of these exceptions:

```python
import xdrlib
p = xdrlib.Packer()
try:
    p.pack_double(8.01)
except xdrlib.ConversionError, instance:
    print 'packing the double failed:', instance.msg
```
13.6. `plistlib` — Generate and parse Mac OS X `.plist` files

Changed in version 2.6: This module was previously only available in the Mac-specific library, it is now available for all platforms.

This module provides an interface for reading and writing the “property list” XML files used mainly by Mac OS X.

The property list (.plist) file format is a simple XML pickle supporting basic object types, like dictionaries, lists, numbers and strings. Usually the top level object is a dictionary.

Values can be strings, integers, floats, booleans, tuples, lists, dictionaries (but only with string keys), `Data` or `datetime.datetime` objects. String values (including dictionary keys) may be unicode strings – they will be written out as UTF-8.

The `<data>` plist type is supported through the `Data` class. This is a thin wrapper around a Python string. Use `Data` if your strings contain control characters.

See also:

**PList manual page**

Apple’s documentation of the file format.

This module defines the following functions:

`plistlib.readPlist(pathOrFile)`

Read a plist file. `pathOrFile` may either be a file name or a (readable) file object. Return the unpacked root object (which usually is a dictionary).
The XML data is parsed using the Expat parser from `xml.parsers.expat` – see its documentation for possible exceptions on ill-formed XML. Unknown elements will simply be ignored by the plist parser.

```python
plistlib.writePlist(rootObject, pathOrFile)
```
Write `rootObject` to a plist file. `pathOrFile` may either be a file name or a (writable) file object.

A `TypeError` will be raised if the object is of an unsupported type or a container that contains objects of unsupported types.

```python
plistlib.readPlistFromString(data)
```
Read a plist from a string. Return the root object.

```python
plistlib.writePlistToString(rootObject)
```
Return `rootObject` as a plist-formatted string.

```python
plistlib.readPlistFromResource(path[, restype='plst'[, resid=0]])
```
Read a plist from the resource with type `restype` from the resource fork of `path`. Availability: Mac OS X.

**Note:** In Python 3.x, this function has been removed.

```python
plistlib.writePlistToResource(rootObject, path[, restype='plst'[, resid=0]])
```
Write `rootObject` as a resource with type `restype` to the resource fork of `path`. Availability: Mac OS X.

**Note:** In Python 3.x, this function has been removed.

The following class is available:
class plistlib.Data(data)

Return a “data” wrapper object around the string data. This is used in functions converting from/to plists to represent the <data> type available in plists.

It has one attribute, data, that can be used to retrieve the Python string stored in it.
13.6.1. Examples

Generating a plist:

```python
pl = dict(
    aString="Doodah",
    aList=['A', 'B', 12, 32.1, [1, 2, 3]],
    aFloat = 0.1,
    anInt = 728,
    aDict=dict(
        anotherString="<hello & hi there!>",
        aUnicodeValue=u'M\xe4ssig, Ma\xdf',
        aTrueValue=True,
        aFalseValue=False,
    ),
    someData = Data("<binary gunk>"),
    someMoreData = Data("<lots of binary gunk>" * 10),
    aDate = datetime.datetime.fromtimestamp(time.mktime(time.gmtime(0))
)
# unicode keys are possible, but a little awkward to use:
pl[u'\xc5benraa'] = "That was a unicode key."
writePlist(pl, fileName)
```

Parsing a plist:

```python
pl = readPlist(pathOrFile)
print pl["aKey"]
```
14. Cryptographic Services

The modules described in this chapter implement various algorithms of a cryptographic nature. They are available at the discretion of the installation. Here’s an overview:

- **14.1. hashlib** — Secure hashes and message digests
- **14.2. hmac** — Keyed-Hashing for Message Authentication
- **14.3. md5** — MD5 message digest algorithm
- **14.4. sha** — SHA-1 message digest algorithm

Hardcore cypherpunks will probably find the cryptographic modules written by A.M. Kuchling of further interest; the package contains modules for various encryption algorithms, most notably AES. These modules are not distributed with Python but available separately. See the URL [http://www.amk.ca/python/code/crypto.html](http://www.amk.ca/python/code/crypto.html) for more information.
14.1. hashlib — Secure hashes and message digests

*New in version 2.5.*

This module implements a common interface to many different secure hash and message digest algorithms. Included are the FIPS secure hash algorithms SHA1, SHA224, SHA256, SHA384, and SHA512 (defined in FIPS 180-2) as well as RSA's MD5 algorithm (defined in Internet RFC 1321). The terms secure hash and message digest are interchangeable. Older algorithms were called message digests. The modern term is secure hash.

**Note:** If you want the adler32 or crc32 hash functions they are available in the zlib module.

**Warning:** Some algorithms have known hash collision weaknesses, see the FAQ at the end.

There is one constructor method named for each type of hash. All return a hash object with the same simple interface. For example: use `sha1()` to create a SHA1 hash object. You can now feed this object with arbitrary strings using the `update()` method. At any point you can ask it for the *digest* of the concatenation of the strings fed to it so far using the `digest()` or `hexdigest()` methods.

Constructors for hash algorithms that are always present in this module are `md5()`, `sha1()`, `sha224()`, `sha256()`, `sha384()`, and `sha512()`. Additional algorithms may also be available depending upon the OpenSSL library that Python uses on your platform.

For example, to obtain the digest of the string 'Nobody inspects the
import hashlib
m = hashlib.md5()
m.update("Nobody inspects")
m.update(" the spammish repetition")
m.digest()  # 'xbbd\x9c\x83\xdd\xe1\x8d\xf0\xff\xe9'
m.digest_size  # 16
m.block_size  # 64

More condensed:

hashlib.sha224("Nobody inspects the spammish repetition").hexdigest()  # 'a4337bc45a8fc544c03f52dc550cd6e1e87021bc896588bd79e901e2'

A generic new() constructor that takes the string name of the desired algorithm as its first parameter also exists to allow access to the above listed hashes as well as any other algorithms that your OpenSSL library may offer. The named constructors are much faster than new() and should be preferred.

Using new() with an algorithm provided by OpenSSL:

h = hashlib.new('ripemd160')
h.update("Nobody inspects the spammish repetition")
h.hexdigest()  # 'cc4a5ce1b3df48aec5d22d1f16b894a0b894ecc'

This module provides the following constant attribute:

    hashlib.algorithms

    A tuple providing the names of the hash algorithms guaranteed to be supported by this module.

    New in version 2.7.
The following values are provided as constant attributes of the hash objects returned by the constructors:

`hash.digest_size`

The size of the resulting hash in bytes.

`hash.block_size`

The internal block size of the hash algorithm in bytes.

A hash object has the following methods:

`hash.update(arg)`

Update the hash object with the string `arg`. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a+b)`.

*Changed in version 2.7.*

`hash.digest()`

Return the digest of the strings passed to the `update()` method so far. This is a string of `digest_size` bytes which may contain non-ASCII characters, including null bytes.

`hash.hexdigest()`

Like `digest()` except the digest is returned as a string of double length, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

`hash.copy()`

Return a copy ("clone") of the hash object. This can be used to efficiently compute the digests of strings that share a common initial substring.
See also:

**Module `hmac`**
A module to generate message authentication codes using hashes.

**Module `base64`**
Another way to encode binary hashes for non-binary environments.

The FIPS 180-2 publication on Secure Hash Algorithms.

http://en.wikipedia.org/wiki/Cryptographic_hash_function#Cryptographic_hash_functions
Wikipedia article with information on which algorithms have known issues and what that means regarding their use.
14.2. hmac — Keyed-Hashing for Message Authentication

New in version 2.2.

This module implements the HMAC algorithm as described by RFC 2104.

```python
hmac.new(key[, msg[, digestmod]])
```

Return a new hmac object. If msg is present, the method call `update(msg)` is made. digestmod is the digest constructor or module for the HMAC object to use. It defaults to the `hashlib.md5()` constructor.

An HMAC object has the following methods:

```python
hmac.update(msg)
```

Update the hmac object with the string msg. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a + b)`.

```python
hmac.digest()
```

Return the digest of the strings passed to the `update()` method so far. This string will be the same length as the digest_size of the digest given to the constructor. It may contain non-ASCII characters, including NUL bytes.

```python
hmac.hexdigest()
```

Like `digest()` except the digest is returned as a string twice the length containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary
environments.

hmac.copy()

Return a copy ("clone") of the hmac object. This can be used to efficiently compute the digests of strings that share a common initial substring.

See also:

Module hashlib

The Python module providing secure hash functions.
14.3. md5 — MD5 message digest algorithm

Deprecated since version 2.5: Use the hashlib module instead.

This module implements the interface to RSA's MD5 message digest algorithm (see also Internet RFC 1321). Its use is quite straightforward: use new() to create an md5 object. You can now feed this object with arbitrary strings using the update() method, and at any point you can ask it for the digest (a strong kind of 128-bit checksum, a.k.a. “fingerprint”) of the concatenation of the strings fed to it so far using the digest() method.

For example, to obtain the digest of the string 'Nobody inspects the spammish repetition':

```python
>>> import md5
>>> m = md5.new()
>>> m.update("Nobody inspects")
>>> m.update(" the spammish repetition")
>>> m.digest()
'\xbbd\x9c\x83\xdd\xa5\xc9\xd9\xde\xc9\xa1\x8d\xf0\xff\xe9'
```

More condensed:

```python
>>> md5.new("Nobody inspects the spammish repetition").digest()
'\xbbd\x9c\x83\xdd\x1e\xa5\xc9\xd9\xde\xc9\xa1\x8d\xf0\xff\xe9'
```

The following values are provided as constants in the module and as attributes of the md5 objects returned by new():

md5.digest_size

The size of the resulting digest in bytes. This is always 16.
The md5 module provides the following functions:

**md5.\texttt{new}(\texttt{[arg]})**

Return a new md5 object. If \texttt{arg} is present, the method call \texttt{update(arg)} is made.

**md5.\texttt{md5}(\texttt{[arg]})**

For backward compatibility reasons, this is an alternative name for the \texttt{new()} function.

An md5 object has the following methods:

**md5.\texttt{update}(\texttt{arg})**

Update the md5 object with the string \texttt{arg}. Repeated calls are equivalent to a single call with the concatenation of all the arguments: \texttt{m.update(a); m.update(b)} is equivalent to \texttt{m.update(a+b)}.

**md5.\texttt{digest}()**

Return the digest of the strings passed to the \texttt{update()} method so far. This is a 16-byte string which may contain non-ASCII characters, including null bytes.

**md5.\texttt{hexdigest}()**

Like \texttt{digest()} except the digest is returned as a string of length 32, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

**md5.\texttt{copy}()**

Return a copy ("clone") of the md5 object. This can be used to efficiently compute the digests of strings that share a common initial substring.
See also:

Module sha

Similar module implementing the Secure Hash Algorithm (SHA). The SHA algorithm is considered a more secure hash.
14.4. sha — SHA-1 message digest algorithm

Deprecated since version 2.5: Use the hashlib module instead.

This module implements the interface to NIST's secure hash algorithm, known as SHA-1. SHA-1 is an improved version of the original SHA hash algorithm. It is used in the same way as the md5 module: use new() to create an sha object, then feed this object with arbitrary strings using the update() method, and at any point you can ask it for the digest of the concatenation of the strings fed to it so far. SHA-1 digests are 160 bits instead of MD5's 128 bits.

sha.new([string])

Return a new sha object. If string is present, the method call update(string) is made.

The following values are provided as constants in the module and as attributes of the sha objects returned by new():

sha.blocksize

Size of the blocks fed into the hash function; this is always 1. This size is used to allow an arbitrary string to be hashed.

sha.digest_size

The size of the resulting digest in bytes. This is always 20.

An sha object has the same methods as md5 objects:

sha.update(arg)

Update the sha object with the string arg. Repeated calls are equivalent to a single call with the concatenation of all the
arguments:  \texttt{m.update(a); m.update(b)} is equivalent to \texttt{m.update(a+b)}.

\texttt{sha.digest()}  
Return the digest of the strings passed to the \texttt{update()} method so far. This is a 20-byte string which may contain non-ASCII characters, including null bytes.

\texttt{sha.hexdigest()}  
Like \texttt{digest()} except the digest is returned as a string of length 40, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

\texttt{sha.copy()}  
Return a copy ("clone") of the \texttt{sha} object. This can be used to efficiently compute the digests of strings that share a common initial substring.

15. Generic Operating System Services

The modules described in this chapter provide interfaces to operating system features that are available on (almost) all operating systems, such as files and a clock. The interfaces are generally modeled after the Unix or C interfaces, but they are available on most other systems as well. Here’s an overview:

- **15.1. os — Miscellaneous operating system interfaces**
  - 15.1.1. Process Parameters
  - 15.1.2. File Object Creation
  - 15.1.3. File Descriptor Operations
    - 15.1.3.1. `open()` flag constants
  - 15.1.4. Files and Directories
  - 15.1.5. Process Management
  - 15.1.6. Miscellaneous System Information
  - 15.1.7. Miscellaneous Functions

- **15.2. io — Core tools for working with streams**
  - 15.2.1. Module Interface
  - 15.2.2. I/O Base Classes
  - 15.2.3. Raw File I/O
  - 15.2.4. Buffered Streams
  - 15.2.5. Text I/O
  - 15.2.6. Advanced topics
    - 15.2.6.1. Performance
      - 15.2.6.1.1. Binary I/O
      - 15.2.6.1.2. Text I/O
    - 15.2.6.2. Multi-threading
    - 15.2.6.3. Reentrancy

- **15.3. time — Time access and conversions**

- **15.4. argparse — Parser for command-line options, arguments**
and sub-commands

- **15.4.1. Example**
  - 15.4.1.1. Creating a parser
  - 15.4.1.2. Adding arguments
  - 15.4.1.3. Parsing arguments

- **15.4.2. ArgumentParser objects**
  - 15.4.2.1. description
  - 15.4.2.2. epilog
  - 15.4.2.3. add_help
  - 15.4.2.4. prefix_chars
  - 15.4.2.5. fromfile_prefix_chars
  - 15.4.2.6. argument_default
  - 15.4.2.7. parents
  - 15.4.2.8. formatter_class
  - 15.4.2.9. conflict_handler
  - 15.4.2.10. prog
  - 15.4.2.11. usage

- **15.4.3. The add_argument() method**
  - 15.4.3.1. name or flags
  - 15.4.3.2. action
  - 15.4.3.3. nargs
  - 15.4.3.4. const
  - 15.4.3.5. default
  - 15.4.3.6. type
  - 15.4.3.7. choices
  - 15.4.3.8. required
  - 15.4.3.9. help
  - 15.4.3.10. metavar
  - 15.4.3.11. dest

- **15.4.4. The parse_args() method**
  - 15.4.4.1. Option value syntax
  - 15.4.4.2. Invalid arguments
  - 15.4.4.3. Arguments containing "- -"
  - 15.4.4.4. Argument abbreviations
- 15.4.4.5. Beyond `sys.argv`
- 15.4.4.6. The Namespace object

- 15.4.5. Other utilities
  - 15.4.5.1. Sub-commands
  - 15.4.5.2. FileType objects
  - 15.4.5.3. Argument groups
  - 15.4.5.4. Mutual exclusion
  - 15.4.5.5. Parser defaults
  - 15.4.5.6. Printing help
  - 15.4.5.7. Partial parsing
  - 15.4.5.8. Customizing file parsing
  - 15.4.5.9. Exiting methods

- 15.4.6. Upgrading `optparse` code

- 15.5. `optparse` — Parser for command line options
  - 15.5.1. Background
    - 15.5.1.1. Terminology
    - 15.5.1.2. What are options for?
    - 15.5.1.3. What are positional arguments for?
  - 15.5.2. Tutorial
    - 15.5.2.1. Understanding option actions
    - 15.5.2.2. The store action
    - 15.5.2.3. Handling boolean (flag) options
    - 15.5.2.4. Other actions
    - 15.5.2.5. Default values
    - 15.5.2.6. Generating help
      - 15.5.2.6.1. Grouping Options
    - 15.5.2.7. Printing a version string
    - 15.5.2.8. How `optparse` handles errors
    - 15.5.2.9. Putting it all together
  - 15.5.3. Reference Guide
    - 15.5.3.1. Creating the parser
    - 15.5.3.2. Populating the parser
    - 15.5.3.3. Defining options
    - 15.5.3.4. Option attributes
- 15.5.3.5. Standard option actions
- 15.5.3.6. Standard option types
- 15.5.3.7. Parsing arguments
- 15.5.3.8. Querying and manipulating your option parser
- 15.5.3.9. Conflicts between options
- 15.5.3.10. Cleanup
- 15.5.3.11. Other methods

- 15.5.4. Option Callbacks
  - 15.5.4.1. Defining a callback option
  - 15.5.4.2. How callbacks are called
  - 15.5.4.3. Raising errors in a callback
  - 15.5.4.4. Callback example 1: trivial callback
  - 15.5.4.5. Callback example 2: check option order
  - 15.5.4.6. Callback example 3: check option order (generalized)
  - 15.5.4.7. Callback example 4: check arbitrary condition
  - 15.5.4.8. Callback example 5: fixed arguments
  - 15.5.4.9. Callback example 6: variable arguments

- 15.5.5. Extending optparse
  - 15.5.5.1. Adding new types
  - 15.5.5.2. Adding new actions

- 15.6. getopt — C-style parser for command line options

- 15.7. logging — Logging facility for Python
  - 15.7.1. Logger Objects
  - 15.7.2. Handler Objects
  - 15.7.3. Formatter Objects
  - 15.7.4. Filter Objects
  - 15.7.5. LogRecord Objects
  - 15.7.6. LogRecord attributes
  - 15.7.7. LoggerAdapter Objects
  - 15.7.8. Thread Safety
  - 15.7.9. Module-Level Functions
  - 15.7.10. Integration with the warnings module

- 15.8. logging.config — Logging configuration
15.8.1. Configuration functions
15.8.2. Configuration dictionary schema
  ▪ 15.8.2.1. Dictionary Schema Details
  ▪ 15.8.2.2. Incremental Configuration
  ▪ 15.8.2.3. Object connections
  ▪ 15.8.2.4. User-defined objects
  ▪ 15.8.2.5. Access to external objects
  ▪ 15.8.2.6. Access to internal objects
15.8.3. Configuration file format
15.9. `logging.handlers` — Logging handlers
  ▪ 15.9.1. StreamHandler
  ▪ 15.9.2. FileHandler
  ▪ 15.9.3. NullHandler
  ▪ 15.9.4. WatchedFileHandler
  ▪ 15.9.5. RotatingFileHandler
  ▪ 15.9.6. TimedRotatingFileHandler
  ▪ 15.9.7. SocketHandler
  ▪ 15.9.8. DatagramHandler
  ▪ 15.9.9. SysLogHandler
  ▪ 15.9.10. NTEventLogHandler
  ▪ 15.9.11. SMTPHandler
  ▪ 15.9.12. MemoryHandler
  ▪ 15.9.13. HTTPHandler
15.10. `getpass` — Portable password input
15.11. `curses` — Terminal handling for character-cell displays
  ▪ 15.11.1. Functions
  ▪ 15.11.2. Window Objects
  ▪ 15.11.3. Constants
15.12. `curses.textpad` — Text input widget for curses programs
  ▪ 15.12.1. Textbox objects
15.13. `curses.wrapper` — Terminal handler for curses programs
15.14. `curses.ascii` — Utilities for ASCII characters
15.15. `curses.panel` — A panel stack extension for curses
• 15.15.1. Functions
• 15.15.2. Panel Objects

• 15.16. platform — Access to underlying platform's identifying data
  • 15.16.1. Cross Platform
  • 15.16.2. Java Platform
  • 15.16.3. Windows Platform
    ■ 15.16.3.1. Win95/98 specific
  • 15.16.4. Mac OS Platform
  • 15.16.5. Unix Platforms

• 15.17. errno — Standard errno system symbols

• 15.18. ctypes — A foreign function library for Python
  • 15.18.1. ctypes tutorial
    ■ 15.18.1.1. Loading dynamic link libraries
    ■ 15.18.1.2. Accessing functions from loaded dlls

  - 15.18.2.8. Structured data types
  - 15.18.2.9. Arrays and pointers
This module provides a portable way of using operating system dependent functionality. If you just want to read or write a file see `open()`, if you want to manipulate paths, see the `os.path` module, and if you want to read all the lines in all the files on the command line see the `fileinput` module. For creating temporary files and directories see the `tempfile` module, and for high-level file and directory handling see the `shutil` module.

Notes on the availability of these functions:

- The design of all built-in operating system dependent modules of Python is such that as long as the same functionality is available, it uses the same interface; for example, the function `os.stat(path)` returns stat information about `path` in the same format (which happens to have originated with the POSIX interface).
- Extensions peculiar to a particular operating system are also available through the `os` module, but using them is of course a threat to portability.
- An “Availability: Unix” note means that this function is commonly found on Unix systems. It does not make any claims about its existence on a specific operating system.
- If not separately noted, all functions that claim “Availability: Unix” are supported on Mac OS X, which builds on a Unix core.

**Note:** All functions in this module raise `OSError` in the case of invalid or inaccessible file names and paths, or other arguments that have the correct type, but are not accepted by the operating system.
exception os.error
   An alias for the built-in OSError exception.

os.name
   The name of the operating system dependent module imported.
   The following names have currently been registered: 'posix',
   'nt', 'os2', 'ce', 'java', 'riscos'.
15.1.1. Process Parameters

These functions and data items provide information and operate on the current process and user.

**os.environ**

A mapping object representing the string environment. For example, `environ['HOME']` is the pathname of your home directory (on some platforms), and is equivalent to `getenv("HOME")` in C.

This mapping is captured the first time the `os` module is imported, typically during Python startup as part of processing `site.py`. Changes to the environment made after this time are not reflected in `os.environ`, except for changes made by modifying `os.environ` directly.

If the platform supports the `putenv()` function, this mapping may be used to modify the environment as well as query the environment. `putenv()` will be called automatically when the mapping is modified.

**Note:** Calling `putenv()` directly does not change `os.environ`, so it's better to modify `os.environ`.

**Note:** On some platforms, including FreeBSD and Mac OS X, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv()`.

If `putenv()` is not provided, a modified copy of this mapping may be passed to the appropriate process-creation functions to cause child processes to use a modified environment.
If the platform supports the `unsetenv()` function, you can delete items in this mapping to unset environment variables. `unsetenv()` will be called automatically when an item is deleted from `os.environ`, and when one of the `pop()` or `clear()` methods is called.

*Changed in version 2.6:* Also unset environment variables when calling `os.environ.clear()` and `os.environ.pop()`.

**os.chdir(path)**
**os.fchdir(fd)**
**os.getcwd()**

These functions are described in *Files and Directories*.

**os.ctermid()**
Return the filename corresponding to the controlling terminal of the process.

*Availability: Unix.*

**os.getegid()**
Return the effective group id of the current process. This corresponds to the “set id” bit on the file being executed in the current process.

*Availability: Unix.*

**os.geteuid()**
Return the current process's effective user id.

*Availability: Unix.*

**os.getgid()**
Return the real group id of the current process.
Availability: Unix.

```python
os.getgroups()
```
Return list of supplemental group ids associated with the current process.

Availability: Unix.

```python
os.initgroups(username, gid)
```
Call the system `initgroups()` to initialize the group access list with all of the groups of which the specified username is a member, plus the specified group id.

Availability: Unix.

*New in version 2.7.*

```python
os.getlogin()
```
Return the name of the user logged in on the controlling terminal of the process. For most purposes, it is more useful to use the environment variable `LOGNAME` to find out who the user is, or `pwd.getpwuid(os.getuid())[0]` to get the login name of the currently effective user id.

Availability: Unix.

```python
os.getpgid(pid)
```
Return the process group id of the process with process id `pid`. If `pid` is 0, the process group id of the current process is returned.

Availability: Unix.

*New in version 2.3.*

```python
os.getpgrp()
```
Return the id of the current process group.
Availability: Unix.

```
import os

os.getpid()
```
Return the current process id.

Availability: Unix, Windows.

```
import os

os.getppid()
```
Return the parent's process id.

Availability: Unix.

```
import os

os.getresuid()
```
Return a tuple (ruid, euid, suid) denoting the current process’s real, effective, and saved user ids.

Availability: Unix.

*New in version 2.7.*

```
import os

os.getresgid()
```
Return a tuple (rgid, egid, sgid) denoting the current process’s real, effective, and saved group ids.

Availability: Unix.

*New in version 2.7.*

```
import os

os.getuid()
```
Return the current process’s user id.

Availability: Unix.

```
import os

os.getenv(varname[, value])
```
Return the value of the environment variable *varname* if it exists, or *value* if it doesn’t. *value* defaults to *None*. 
Availability: most flavors of Unix, Windows.

**os.putenv**(varname, value)
Set the environment variable named varname to the string value. Such changes to the environment affect subprocesses started with os.system(), popen() or fork() and execv().

Availability: most flavors of Unix, Windows.

**Note:** On some platforms, including FreeBSD and Mac OS X, setting environ may cause memory leaks. Refer to the system documentation for putenv.

When putenv() is supported, assignments to items in os.environ are automatically translated into corresponding calls to putenv(); however, calls to putenv() don’t update os.environ, so it is actually preferable to assign to items of os.environ.

**os.setegid**(egid)
Set the current process’s effective group id.

Availability: Unix.

**os.seteuid**(euid)
Set the current process’s effective user id.

Availability: Unix.

**os.setgid**(gid)
Set the current process’ group id.

Availability: Unix.

**os.setgroups**(groups)
Set the list of supplemental group ids associated with the current
process to groups. groups must be a sequence, and each element must be an integer identifying a group. This operation is typically available only to the superuser.

Availability: Unix.

New in version 2.2.

os. setpgrp()
Call the system call setpgrp() or setpgrp(0, 0)() depending on which version is implemented (if any). See the Unix manual for the semantics.

Availability: Unix.

os. setpgid(pid, pgrp)
Call the system call setpgid() to set the process group id of the process with id pid to the process group with id pgrp. See the Unix manual for the semantics.

Availability: Unix.

os. setregid(rgid, egid)
Set the current process's real and effective group ids.

Availability: Unix.

os. setresgid(rgid, egid, sgid)
Set the current process's real, effective, and saved group ids.

Availability: Unix.

New in version 2.7.

os. setresuid(ruid, euid, suid)
Set the current process's real, effective, and saved user ids.
Availability: Unix.

*New in version 2.7.*

**os.setreuid(ruid, euid)**
Set the current process's real and effective user ids.

Availability: Unix.

**os.getsid(pid)**
Call the system call `getsid()`. See the Unix manual for the semantics.

Availability: Unix.

*New in version 2.4.*

**os.setsid()**
Call the system call `setsid()`. See the Unix manual for the semantics.

Availability: Unix.

**os.setuid(uid)**
Set the current process's user id.

Availability: Unix.

**os.strerror(code)**
Return the error message corresponding to the error code in *code*. On platforms where `strerror()` returns `NULL` when given an unknown error number, `ValueError` is raised.

Availability: Unix, Windows.

**os.umask(mask)**
Set the current numeric umask and return the previous umask.

**Availability:** Unix, Windows.

```python
os.uname()
```

Return a 5-tuple containing information identifying the current operating system. The tuple contains 5 strings: `(sysname, nodename, release, version, machine)`. Some systems truncate the nodename to 8 characters or to the leading component; a better way to get the hostname is `socket.gethostname()` or even `socket.gethostbyaddr(socket.gethostname())`.

**Availability:** recent flavors of Unix.

```python
os.unsetenv(varname)
```

Unset (delete) the environment variable named `varname`. Such changes to the environment affect subprocesses started with `os.system()`, `popen()` or `fork()` and `execv()`.

When `unsetenv()` is supported, deletion of items in `os.environ` is automatically translated into a corresponding call to `unsetenv()`, however, calls to `unsetenv()` don’t update `os.environ`, so it is actually preferable to delete items of `os.environ`.

**Availability:** most flavors of Unix, Windows.
15.1.2. File Object Creation

These functions create new file objects. (See also open().)

**os. fdopen(fd[, mode[, bufsize]])**

Return an open file object connected to the file descriptor *fd*. The *mode* and *bufsize* arguments have the same meaning as the corresponding arguments to the built-in open() function.

Availability: Unix, Windows.

*Changed in version* 2.3: When specified, the *mode* argument must now start with one of the letters 'r', 'w', or 'a', otherwise a ValueError is raised.

*Changed in version* 2.5: On Unix, when the *mode* argument starts with 'a', the O_APPEND flag is set on the file descriptor (which the fdopen() implementation already does on most platforms).

**os. popen(command[, mode[, bufsize]])**

Open a pipe to or from *command*. The return value is an open file object connected to the pipe, which can be read or written depending on whether *mode* is 'r' (default) or 'w'. The *bufsize* argument has the same meaning as the corresponding argument to the built-in open() function. The exit status of the command (encoded in the format specified for wait()) is available as the return value of the close() method of the file object, except that when the exit status is zero (termination without errors), None is returned.

Availability: Unix, Windows.
**Deprecated since version 2.6:** This function is obsolete. Use the `subprocess` module. Check especially the *Replacing Older Functions with the subprocess Module* section.

**Changed in version 2.0:** This function worked unreliably under Windows in earlier versions of Python. This was due to the use of the `_popen()` function from the libraries provided with Windows. Newer versions of Python do not use the broken implementation from the Windows libraries.

```python
os.tmpfile()
```

Return a new file object opened in update mode \((w+b)\). The file has no directory entries associated with it and will be automatically deleted once there are no file descriptors for the file.

**Availability:** Unix, Windows.

There are a number of different `popen*()` functions that provide slightly different ways to create subprocesses.

**Deprecated since version 2.6:** All of the `popen*()` functions are obsolete. Use the `subprocess` module.

For each of the `popen*()` variants, if `bufsize` is specified, it specifies the buffer size for the I/O pipes. `mode`, if provided, should be the string `'b'` or `'t'`; on Windows this is needed to determine whether the file objects should be opened in binary or text mode. The default value for `mode` is `'t'`.

Also, for each of these variants, on Unix, `cmd` may be a sequence, in which case arguments will be passed directly to the program without shell intervention (as with `os.spawnv()`). If `cmd` is a string it will be
passed to the shell (as with `os.system()`).

These methods do not make it possible to retrieve the exit status from the child processes. The only way to control the input and output streams and also retrieve the return codes is to use the `subprocess` module; these are only available on Unix.

For a discussion of possible deadlock conditions related to the use of these functions, see *Flow Control Issues*.

```python
os.popen2(cmd[, mode[, bufsize]])
```
Execute `cmd` as a sub-process and return the file objects `child_stdin, child_stdout`.

*Deprecated since version 2.6:* This function is obsolete. Use the `subprocess` module. Check especially the *Replacing Older Functions with the subprocess Module* section.

Availability: Unix, Windows.

*New in version 2.0.*

```python
os.popen3(cmd[, mode[, bufsize]])
```
Execute `cmd` as a sub-process and return the file objects `child_stdin, child_stdout, child_stderr`.

*Deprecated since version 2.6:* This function is obsolete. Use the `subprocess` module. Check especially the *Replacing Older Functions with the subprocess Module* section.

Availability: Unix, Windows.

*New in version 2.0.*
os.popen4(cmd[, mode[, bufsize]])

Execute cmd as a sub-process and return the file objects (child_stdin, child_stdout_and_stderr).

*Deprecated since version 2.6:* This function is obsolete. Use the subprocess module. Check especially the Replacing Older Functions with the subprocess Module section.

Availability: Unix, Windows.

*New in version 2.0.*

(Note that child_stdin, child_stdout, and child_stderr are named from the point of view of the child process, so child_stdin is the child’s standard input.)

This functionality is also available in the popen2 module using functions of the same names, but the return values of those functions have a different order.
15.1.3. File Descriptor Operations

These functions operate on I/O streams referenced using file descriptors.

File descriptors are small integers corresponding to a file that has been opened by the current process. For example, standard input is usually file descriptor 0, standard output is 1, and standard error is 2. Further files opened by a process will then be assigned 3, 4, 5, and so forth. The name “file descriptor” is slightly deceptive; on Unix platforms, sockets and pipes are also referenced by file descriptors.

The `fileno()` method can be used to obtain the file descriptor associated with a file object when required. Note that using the file descriptor directly will bypass the file object methods, ignoring aspects such as internal buffering of data.

```python
os.close(fd)
```

Close file descriptor `fd`.

Availability: Unix, Windows.

**Note:** This function is intended for low-level I/O and must be applied to a file descriptor as returned by `os.open()` or `pipe()`. To close a “file object” returned by the built-in function `open()` or by `popen()` or `fdopen()`, use its `close()` method.

```python
os.closerange(fd_low, fd_high)
```

Close all file descriptors from `fd_low` (inclusive) to `fd_high` (exclusive), ignoring errors. Equivalent to:

```python
for fd in xrange(fd_low, fd_high):
    try:
        os.close(fd)
```
except OSError:
    pass

Availability: Unix, Windows.

New in version 2.6.

`os.dup(fd)`
Return a duplicate of file descriptor `fd`.

Availability: Unix, Windows.

`os.dup2(fd, fd2)`
Duplicate file descriptor `fd` to `fd2`, closing the latter first if necessary.

Availability: Unix, Windows.

`os.fchmod(fd, mode)`
Change the mode of the file given by `fd` to the numeric `mode`. See the docs for `chmod()` for possible values of `mode`.

Availability: Unix.

New in version 2.6.

`os.fchown(fd, uid, gid)`
Change the owner and group id of the file given by `fd` to the numeric `uid` and `gid`. To leave one of the ids unchanged, set it to -1.

Availability: Unix.

New in version 2.6.

`os.fdatasync(fd)`
Force write of file with filedescriptor `fd` to disk. Does not force
update of metadata.

Availability: Unix.

**Note:** This function is not available on MacOS.

```python
os.fpathconf(fd, name)
```
Return system configuration information relevant to an open file. `name` specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for `name` is also accepted.

If `name` is a string and is not known, `ValueError` is raised. If a specific value for `name` is not supported by the host system, even if it is included in `pathconf_names`, an `OSError` is raised with `errno.EINVAL` for the error number.

Availability: Unix.

```python
os.fstat(fd)
```
Return status for file descriptor `fd`, like `stat()`.

Availability: Unix, Windows.

```python
os.fstatvfs(fd)
```
Return information about the filesystem containing the file associated with file descriptor `fd`, like `statvfs()`.

Availability: Unix.
**os.fsync(fd)**
Force write of file with filedescriptor `fd` to disk. On Unix, this calls the native `fsync()` function; on Windows, the MS _commit() function.

If you're starting with a Python file object `f`, first do `f.flush()`, and then do `os.fsync(f.fileno())`, to ensure that all internal buffers associated with `f` are written to disk.

Availability: Unix, and Windows starting in 2.2.3.

**os.ftruncate(fd, length)**
Truncate the file corresponding to file descriptor `fd`, so that it is at most `length` bytes in size.

Availability: Unix.

**os.isatty(fd)**
Return `True` if the file descriptor `fd` is open and connected to a tty(-like) device, else `False`.

Availability: Unix.

**os.lseek(fd, pos, how)**
Set the current position of file descriptor `fd` to position `pos`, modified by `how`: `SEEK_SET` or 0 to set the position relative to the beginning of the file; `SEEK_CUR` or 1 to set it relative to the current position; `os.SEEK_END` or 2 to set it relative to the end of the file.

Availability: Unix, Windows.

**os.SEEK_SET**
**os.SEEK_CUR**
**os.SEEK_END**
Parameters to the `lseek()` function. Their values are 0, 1, and 2,
respectively.

Availability: Windows, Unix.

*New in version 2.5.*

**os.open**(file, flags[, mode])
Open the file *file* and set various flags according to *flags* and possibly its mode according to *mode*. The default *mode* is `0777` (octal), and the current umask value is first masked out. Return the file descriptor for the newly opened file.

For a description of the flag and mode values, see the C run-time documentation; flag constants (like `O_RDONLY` and `O_WRONLY`) are defined in this module too (see *open()* flag constants). In particular, on Windows adding `O_BINARY` is needed to open files in binary mode.

Availability: Unix, Windows.

---

**Note:** This function is intended for low-level I/O. For normal usage, use the built-in function `open()`, which returns a “file object” with `read()` and `write()` methods (and many more). To wrap a file descriptor in a “file object”, use `fdopen()`.

**os.openpty()**
Open a new pseudo-terminal pair. Return a pair of file descriptors (master, slave) for the pty and the tty, respectively. For a (slightly) more portable approach, use the `pty` module.

Availability: some flavors of Unix.

**os.pipe()**
Create a pipe. Return a pair of file descriptors (r, w) usable for
reading and writing, respectively.

Availability: Unix, Windows.

**os.read**(fd, n)
Read at most n bytes from file descriptor fd. Return a string containing the bytes read. If the end of the file referred to by fd has been reached, an empty string is returned.

Availability: Unix, Windows.

---

**Note:** This function is intended for low-level I/O and must be applied to a file descriptor as returned by os.open() or pipe(). To read a “file object” returned by the built-in function open() or by popen() or fdopen(), or sys.stdin, use its read() or readline() methods.

**os.tcgetpgrp**(fd)
Return the process group associated with the terminal given by fd (an open file descriptor as returned by os.open()).

Availability: Unix.

**os.tcsetpgrp**(fd, pg)
Set the process group associated with the terminal given by fd (an open file descriptor as returned by os.open()) to pg.

Availability: Unix.

**os.ttyname**(fd)
Return a string which specifies the terminal device associated with file descriptor fd. If fd is not associated with a terminal device, an exception is raised.

Availability: Unix.
os.write(fd, str)

Write the string str to file descriptor fd. Return the number of bytes actually written.

Availability: Unix, Windows.

**Note:** This function is intended for low-level I/O and must be applied to a file descriptor as returned by os.open() or pipe(). To write a “file object” returned by the built-in function open() or by popen() or fdopen(), or sys.stdout or sys.stderr, use its write() method.

### 15.1.3.1. open() flag constants

The following constants are options for the flags parameter to the open() function. They can be combined using the bitwise OR operator |. Some of them are not available on all platforms. For descriptions of their availability and use, consult the open(2) manual page on Unix or the MSDN on Windows.

- os.O_RDONLY
- os.O_WRONLY
- os.O_RDWR
- os.O_APPEND
- os.O_CREAT
- os.O_EXCL
- os.O_TRUNC

These constants are available on Unix and Windows.

- os.O_DSYNC
- os.O_RSYNC
- os.O_SYNC
- os.O_NDELAY
- os.O_NONBLOCK
- os.O_NOCTTY
os. **O_SHLOCK**
*O_EXLOCK*

These constants are only available on Unix.

*O_BINARY*
*O_NOINHERIT*
*O_SHORT_LIVED*
*O_TEMPORARY*
*O_RANDOM*
*O_SEQUENTIAL*
*O_TEXT*

These constants are only available on Windows.

*O_ASYNC*
*O_DIRECT*
*O_DIRECTORY*
*O_NOFOLLOW*
*O_NOATIME*

These constants are GNU extensions and not present if they are not defined by the C library.
15.1.4. Files and Directories

**os.access**(*path, mode*)

Use the real uid/gid to test for access to *path*. Note that most operations will use the effective uid/gid, therefore this routine can be used in a suid/sgid environment to test if the invoking user has the specified access to *path*. *mode* should be **F_OK** to test the existence of *path*, or it can be the inclusive OR of one or more of **R_OK**, **W_OK**, and **X_OK** to test permissions. Return **True** if access is allowed, **False** if not. See the Unix man page *access*(2) for more information.

Availability: Unix, Windows.

**Note:** Using *access()* to check if a user is authorized to e.g. open a file before actually doing so using *open()* creates a security hole, because the user might exploit the short time interval between checking and opening the file to manipulate it. It's preferable to use **EAFP** techniques. For example:

```python
if os.access("myfile", os.R_OK):
    with open("myfile") as fp:
        return fp.read()
return "some default data"
```

is better written as:

```python
try:
    fp = open("myfile")
except IOError as e:
    if e.errno == errno.EACCESS:
        return "some default data"
    # Not a permission error.
    raise
else:
    with fp:
        return fp.read()
```
**Note:** I/O operations may fail even when `access()` indicates that they would succeed, particularly for operations on network filesystems which may have permissions semantics beyond the usual POSIX permission-bit model.

```python
os.F_OK
Value to pass as the *mode* parameter of `access()` to test the existence of *path*.
```

```python
os.R_OK
Value to include in the *mode* parameter of `access()` to test the readability of *path*.
```

```python
os.W_OK
Value to include in the *mode* parameter of `access()` to test the writability of *path*.
```

```python
os.X_OK
Value to include in the *mode* parameter of `access()` to determine if *path* can be executed.
```

```python
os.chdir(*path*)
Change the current working directory to *path*.

Availability: Unix, Windows.
```

```python
os.fchdir(*fd*)
Change the current working directory to the directory represented by the file descriptor *fd*. The descriptor must refer to an opened directory, not an open file.

Availability: Unix.

*New in version 2.3.*
**os.getcwd()**

Return a string representing the current working directory.

*Availability: Unix, Windows.*

**os.getcwdu()**

Return a Unicode object representing the current working directory.

*Availability: Unix, Windows.*

*New in version 2.3.*

**os.chflags(path, flags)**

Set the flags of *path* to the numeric *flags*. *flags* may take a combination (bitwise OR) of the following values (as defined in the *stat* module):

- `stat.UF_NODUMP`
- `stat.UF_IMMUTABLE`
- `stat.UF_APPEND`
- `stat.UF_OPAQUE`
- `stat.UF_NOUNLINK`
- `stat.SF_ARCHIVED`
- `stat.SF_IMMUTABLE`
- `stat.SF_APPEND`
- `stat.SF_NOUNLINK`
- `stat.SF_SNAPSHOT`

*Availability: Unix.*

*New in version 2.6.*

**os.chroot(path)**

Change the root directory of the current process to *path*.
Availability: Unix.

*New in version 2.2.*

```python
os.chmod(path, mode)
```

Change the mode of `path` to the numeric `mode`. `mode` may take one of the following values (as defined in the `stat` module) or bitwise ORed combinations of them:

- `stat.S_ISUID`
- `stat.S_ISGID`
- `stat.S_ENFMT`
- `stat.S_ISVTX`
- `stat.S_IWRITE`
- `stat.S_IEXEC`
- `stat.S_IRWXU`
- `stat.S_IRUSR`
- `stat.S_IWUSR`
- `stat.S_IXUSR`
- `stat.S_IRWXG`
- `stat.S_IRGRP`
- `stat.S_IWGRP`
- `stat.S_IXGRP`
- `stat.S_IRWXO`
- `stat.S_IROTH`
- `stat.S_IWOTH`
- `stat.S_IXOTH`

Availability: Unix, Windows.

**Note:** Although Windows supports `chmod()`, you can only set the file's read-only flag with it (via the `stat.S_IWRITE` and
The `stat.S_IREAD` constants or a corresponding integer value). All other bits are ignored.

**os.chown(path, uid, gid)**
Change the owner and group id of `path` to the numeric `uid` and `gid`. To leave one of the ids unchanged, set it to -1.

Availability: Unix.

**os.lchflags(path, flags)**
Set the flags of `path` to the numeric `flags`, like `chflags()`, but do not follow symbolic links.

Availability: Unix.

*New in version 2.6.*

**os.lchmod(path, mode)**
Change the mode of `path` to the numeric `mode`. If `path` is a symlink, this affects the symlink rather than the target. See the docs for `chmod()` for possible values of `mode`.

Availability: Unix.

*New in version 2.6.*

**os.lchown(path, uid, gid)**
Change the owner and group id of `path` to the numeric `uid` and `gid`. This function will not follow symbolic links.

Availability: Unix.

*New in version 2.3.*

**os.link(source, link_name)**
Create a hard link pointing to source named link_name.

Availability: Unix.

**os.listdir(path)**

Return a list containing the names of the entries in the directory given by path. The list is in arbitrary order. It does not include the special entries ‘.’ and ‘..’ even if they are present in the directory.

Availability: Unix, Windows.

*Changed in version 2.3:* On Windows NT/2k/XP and Unix, if path is a Unicode object, the result will be a list of Unicode objects. Undecodable filenames will still be returned as string objects.

**os.lstat(path)**

Perform the equivalent of an lstat() system call on the given path. Similar to stat(), but does not follow symbolic links. On platforms that do not support symbolic links, this is an alias for stat().

**os.mkfifo(path[, mode])**

Create a FIFO (a named pipe) named path with numeric mode mode. The default mode is 0666 (octal). The current umask value is first masked out from the mode.

Availability: Unix.

FIFOs are pipes that can be accessed like regular files. FIFOs exist until they are deleted (for example with os.unlink()). Generally, FIFOs are used as rendezvous between “client” and “server” type processes: the server opens the FIFO for reading, and the client opens it for writing. Note that mkfifo() doesn’t
open the FIFO — it just creates the rendezvous point.

```python
os.mknod(filename[, mode=0600, device])
```
Create a filesystem node (file, device special file or named pipe) named `filename`. `mode` specifies both the permissions to use and the type of node to be created, being combined (bitwise OR) with one of `stat.S_IFREG`, `stat.S_IFCHR`, `stat.S_IFBLK`, and `stat.S_IFIFO` (those constants are available in `stat`). For `stat.S_IFCHR` and `stat.S_IFBLK`, `device` defines the newly created device special file (probably using `os.makedev()`), otherwise it is ignored.

*New in version 2.3.*

```python
os.major(device)
```
Extract the device major number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

*New in version 2.3.*

```python
os.minor(device)
```
Extract the device minor number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

*New in version 2.3.*

```python
os.makedev(major, minor)
```
Compose a raw device number from the major and minor device numbers.

*New in version 2.3.*

```python
os.mkdir(path[, mode])
```
Create a directory named `path` with numeric mode `mode`. The
default mode is 0777 (octal). On some systems, mode is ignored. Where it is used, the current umask value is first masked out. If the directory already exists, OSError is raised.

It is also possible to create temporary directories; see the tempfile module’s tempfile.mkdtemp() function.

Availability: Unix, Windows.

```
import os

os.makedirs(path[, mode])
```

Recursive directory creation function. Like mkdir(), but makes all intermediate-level directories needed to contain the leaf directory. Raises an error exception if the leaf directory already exists or cannot be created. The default mode is 0777 (octal). On some systems, mode is ignored. Where it is used, the current umask value is first masked out.

**Note:** makedirs() will become confused if the path elements to create include os.pardir.

*New in version 1.5.2.*

*Changed in version 2.3:* This function now handles UNC paths correctly.

```
import os

os.pathconf(path, name)
```

Return system configuration information relevant to a named file. name specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the pathconf_names dictionary. For configuration variables not included in that mapping, passing an integer for name is also
accepted.

If name is a string and is not known, ValueError is raised. If a specific value for name is not supported by the host system, even if it is included in pathconf_names, an OSError is raised with errno.EINVAL for the error number.

Availability: Unix.

os.pathconf_names
Dictionary mapping names accepted by pathconf() and fpathconf() to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system. Availability: Unix.

os.readlink(path)
Return a string representing the path to which the symbolic link points. The result may be either an absolute or relative pathname; if it is relative, it may be converted to an absolute pathname using os.path.join(os.path.dirname(path), result).

Changed in version 2.6: If the path is a Unicode object the result will also be a Unicode object.

Availability: Unix.

os.remove(path)
Remove (delete) the file path. If path is a directory, OSError is raised; see rmdir() below to remove a directory. This is identical to the unlink() function documented below. On Windows, attempting to remove a file that is in use causes an exception to be raised; on Unix, the directory entry is removed but the storage allocated to the file is not made available until the original file is no longer in use.
Availability: Unix, Windows.

**os.removedirs(path)**
Remove directories recursively. Works like `rmdir()` except that, if the leaf directory is successfully removed, `removedirs()` tries to successively remove every parent directory mentioned in `path` until an error is raised (which is ignored, because it generally means that a parent directory is not empty). For example, `os.removedirs('foo/bar/baz')` will first remove the directory 'foo/bar/baz', and then remove 'foo/bar' and 'foo' if they are empty. Raises `OSError` if the leaf directory could not be successfully removed.

*New in version 1.5.2.*

**os.rename(src, dst)**
Rename the file or directory `src` to `dst`. If `dst` is a directory, `OSError` will be raised. On Unix, if `dst` exists and is a file, it will be replaced silently if the user has permission. The operation may fail on some Unix flavors if `src` and `dst` are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement). On Windows, if `dst` already exists, `OSError` will be raised even if it is a file; there may be no way to implement an atomic rename when `dst` names an existing file.

Availability: Unix, Windows.

**os.renames(old, new)**
Recursive directory or file renaming function. Works like `rename()`, except creation of any intermediate directories needed to make the new pathname good is attempted first. After the rename, directories corresponding to rightmost path segments of the old name will be pruned away using `removedirs()`. 
New in version 1.5.2.

**Note:** This function can fail with the new directory structure made if you lack permissions needed to remove the leaf directory or file.

```
import os

os.rmdir(path)
```

Remove (delete) the directory `path`. Only works when the directory is empty, otherwise, `OSError` is raised. In order to remove whole directory trees, `shutil.rmtree()` can be used.

Availability: Unix, Windows.

```
import os

os.stat(path)
```

Perform the equivalent of a `stat()` system call on the given path. (This function follows symlinks; to stat a symlink use `lstat()`.)

The return value is an object whose attributes correspond to the members of the `stat` structure, namely:

- `st_mode` - protection bits,
- `st_ino` - inode number,
- `st_dev` - device,
- `st_nlink` - number of hard links,
- `st_uid` - user id of owner,
- `st_gid` - group id of owner,
- `st_size` - size of file, in bytes,
- `st_atime` - time of most recent access,
- `st_mtime` - time of most recent content modification,
- `st_ctime` - platform dependent; time of most recent metadata change on Unix, or the time of creation on Windows)

*Changed in version 2.3:* If `stat_float_times()` returns `True`, the
time values are floats, measuring seconds. Fractions of a second may be reported if the system supports that. On Mac OS, the times are always floats. See `stat_float_times()` for further discussion.

On some Unix systems (such as Linux), the following attributes may also be available:

- `st_blocks` - number of blocks allocated for file
- `st_blksize` - filesystem blocksize
- `st_rdev` - type of device if an inode device
- `st_flags` - user defined flags for file

On other Unix systems (such as FreeBSD), the following attributes may be available (but may be only filled out if root tries to use them):

- `st_gen` - file generation number
- `st_birthtime` - time of file creation

On Mac OS systems, the following attributes may also be available:

- `st_rsize`
- `st_creator`
- `st_type`

On RISCOS systems, the following attributes are also available:

- `st_ftype` (file type)
- `st_attrrs` (attributes)
- `st_obtype` (object type).

**Note:** The exact meaning and resolution of the `st_atime`, `st_mtime`, and `st_ctime` members depends on the operating system and the file system. For example, on Windows systems
using the FAT or FAT32 file systems, \texttt{st_mtime} has 2-second resolution, and \texttt{st_atime} has only 1-day resolution. See your operating system documentation for details.

For backward compatibility, the return value of \texttt{stat()} is also accessible as a tuple of at least 10 integers giving the most important (and portable) members of the \texttt{stat} structure, in the order \texttt{st_mode, st_ino, st_dev, st_nlink, st_uid, st_gid, st_size, st_atime, st_mtime, st_ctime}. More items may be added at the end by some implementations.

The standard module \texttt{stat} defines functions and constants that are useful for extracting information from a \texttt{stat} structure. (On Windows, some items are filled with dummy values.)

Example:

```
>>> import os
>>> statinfo = os.stat('somefile.txt')
>>> statinfo
(33188, 422511, 769, 1, 1032, 100, 926, 1105022698, 1105022732,
926
```

Availability: Unix, Windows.

\textit{Changed in version 2.2}: Added access to values as attributes of the returned object.

\textit{Changed in version 2.5}: Added \texttt{st_gen} and \texttt{st_birthtime}.

\texttt{os.stat_float_times([newvalue])}

Determine whether \texttt{stat_result} represents time stamps as float objects. If \texttt{newvalue} is \texttt{True}, future calls to \texttt{stat()} return floats, if it is \texttt{False}, future calls return ints. If \texttt{newvalue} is omitted, return
the current setting.

For compatibility with older Python versions, accessing `stat_result` as a tuple always returns integers.

*Changed in version 2.5:* Python now returns float values by default. Applications which do not work correctly with floating point time stamps can use this function to restore the old behaviour.

The resolution of the timestamps (that is the smallest possible fraction) depends on the system. Some systems only support second resolution; on these systems, the fraction will always be zero.

It is recommended that this setting is only changed at program startup time in the `__main__` module; libraries should never change this setting. If an application uses a library that works incorrectly if floating point time stamps are processed, this application should turn the feature off until the library has been corrected.

```python
os.statvfs(path)
```

Perform a `statvfs()` system call on the given path. The return value is an object whose attributes describe the filesystem on the given path, and correspond to the members of the `statvfs` structure, namely: `f_bsize`, `f_frsize`, `f_blocks`, `f_bfree`, `f_bavail`, `f_files`, `f_ffree`, `f_favail`, `f_flag`, `f_namemax`.

For backward compatibility, the return value is also accessible as a tuple whose values correspond to the attributes, in the order given above. The standard module `statvfs` defines constants that are useful for extracting information from a `statvfs` structure when accessing it as a sequence; this remains useful when writing code that needs to work with versions of Python that don’t
support accessing the fields as attributes.

Availability: Unix.

*Changed in version 2.2:* Added access to values as attributes of the returned object.

**os.symlink**(source, link_name)

Create a symbolic link pointing to `source` named `link_name`.

Availability: Unix.

**os.tempnam**([dir[, prefix]])

Return a unique path name that is reasonable for creating a temporary file. This will be an absolute path that names a potential directory entry in the directory `dir` or a common location for temporary files if `dir` is omitted or `None`. If given and not `None`, `prefix` is used to provide a short prefix to the filename. Applications are responsible for properly creating and managing files created using paths returned by `tempnam()`; no automatic cleanup is provided. On Unix, the environment variable `TMPDIR` overrides `dir`, while on Windows `TMP` is used. The specific behavior of this function depends on the C library implementation; some aspects are underspecified in system documentation.

**Warning:** Use of `tempnam()` is vulnerable to symlink attacks; consider using `tmpfile()` (section *File Object Creation*) instead.

Availability: Unix, Windows.

**os.tmpnam**()

Return a unique path name that is reasonable for creating a temporary file. This will be an absolute path that names a potential directory entry in a common location for temporary files.
Applications are responsible for properly creating and managing files created using paths returned by `tmpnam()`; no automatic cleanup is provided.

**Warning:** Use of `tmpnam()` is vulnerable to symlink attacks; consider using `tmpfile()` (section *File Object Creation*) instead.

Availability: Unix, Windows. This function probably shouldn’t be used on Windows, though: Microsoft’s implementation of `tmpnam()` always creates a name in the root directory of the current drive, and that’s generally a poor location for a temp file (depending on privileges, you may not even be able to open a file using this name).

**os.** `TMP_MAX`

The maximum number of unique names that `tmpnam()` will generate before reusing names.

**os.** `unlink(path)`

Remove (delete) the file `path`. This is the same function as `remove()`; the `unlink()` name is its traditional Unix name.

Availability: Unix, Windows.

**os.** `utime(path, times)`

Set the access and modified times of the file specified by `path`. If `times` is `None`, then the file’s access and modified times are set to the current time. (The effect is similar to running the Unix program `touch` on the path.) Otherwise, `times` must be a 2-tuple of numbers, of the form `(atime, mtime)` which is used to set the access and modified times, respectively. Whether a directory can be given for `path` depends on whether the operating system implements directories as files (for example, Windows does not). Note that the exact times you set here may not be returned by a
subsequent `stat()` call, depending on the resolution with which your operating system records access and modification times; see `stat()`.

Changed in version 2.0: Added support for `None` for `times`.

Availability: Unix, Windows.

```python
os.walk(top[, topdown=True[, onerror=None[, followlinks=False]]]])
```

Generate the file names in a directory tree by walking the tree either top-down or bottom-up. For each directory in the tree rooted at directory `top` (including `top` itself), it yields a 3-tuple `(dirpath, dirnames, filenames)`.

`dirpath` is a string, the path to the directory. `dirnames` is a list of the names of the subdirectories in `dirpath` (excluding `'.` and ` '..'`). `filenames` is a list of the names of the non-directory files in `dirpath`. Note that the names in the lists contain no path components. To get a full path (which begins with `top`) to a file or directory in `dirpath`, do `os.path.join(dirpath, name)`.

If optional argument `topdown` is `True` or not specified, the triple for a directory is generated before the triples for any of its subdirectories (directories are generated top-down). If `topdown` is `False`, the triple for a directory is generated after the triples for all of its subdirectories (directories are generated bottom-up).

When `topdown` is `True`, the caller can modify the `dirnames` list in-place (perhaps using `del` or slice assignment), and `walk()` will only recurse into the subdirectories whose names remain in `dirnames`; this can be used to prune the search, impose a specific order of visiting, or even to inform `walk()` about directories the caller creates or renames before it resumes `walk()` again. Modifying `dirnames` when `topdown` is `False` is
ineffective, because in bottom-up mode the directories in
\texttt{dirnames} are generated before \texttt{dirpath} itself is generated.

By default errors from the \texttt{listdir()} call are ignored. If optional
argument \texttt{onerror} is specified, it should be a function; it will be
called with one argument, an \texttt{OSError} instance. It can report the
error to continue with the walk, or raise the exception to abort the
walk. Note that the filename is available as the \texttt{filename} attribute
of the exception object.

By default, \texttt{walk()} will not walk down into symbolic links that
resolve to directories. Set \texttt{followlinks} to \texttt{True} to visit directories
pointed to by symlinks, on systems that support them.

\textit{New in version 2.6:} The \texttt{followlinks} parameter.

\begin{verbatim}
Note: Be aware that setting \texttt{followlinks} to \texttt{True} can lead to
infinite recursion if a link points to a parent directory of itself.
\texttt{walk()} does not keep track of the directories it visited already.

Note: If you pass a relative pathname, don't change the
current working directory between resumptions of \texttt{walk()}.
\texttt{walk()} never changes the current directory, and assumes that
its caller doesn't either.
\end{verbatim}

This example displays the number of bytes taken by non-
directory files in each directory under the starting directory,
except that it doesn't look under any CVS subdirectory:

\begin{verbatim}
import os
from os.path import join, getsize
for root, dirs, files in os.walk('python/Lib/email'):
    print root, "consumes",
    print sum(getsize(join(root, name)) for name in files),
    print "bytes in", len(files), "non-directory files"
if 'CVS' in dirs:
\end{verbatim}
dirs.remove('CVS')  # don't visit CVS directories

In the next example, walking the tree bottom-up is essential: `rmdir()` doesn't allow deleting a directory before the directory is empty:

```python
# Delete everything reachable from the directory named in "t
# assuming there are no symbolic links.
# CAUTION: This is dangerous! For example, if top == '/',
# could delete all your disk files.
import os
for root, dirs, files in os.walk(top, topdown=False):
    for name in files:
        os.remove(os.path.join(root, name))
    for name in dirs:
        os.rmdir(os.path.join(root, name))
```

*New in version 2.3.*
15.1.5. Process Management

These functions may be used to create and manage processes.

The various `exec*()` functions take a list of arguments for the new program loaded into the process. In each case, the first of these arguments is passed to the new program as its own name rather than as an argument a user may have typed on a command line. For the C programmer, this is the `argv[0]` passed to a program’s `main()`. For example, `os.execv('/bin/echo', ['foo', 'bar'])` will only print `bar` on standard output; `foo` will seem to be ignored.

`os.abort()`
Generate a `SIGABRT` signal to the current process. On Unix, the default behavior is to produce a core dump; on Windows, the process immediately returns an exit code of 3. Be aware that programs which use `signal.signal()` to register a handler for `SIGABRT` will behave differently.

Availability: Unix, Windows.

`os.exec1(path, arg0, arg1, ...)`
`os.execle(path, arg0, arg1, ..., env)`
`os.exec1p(file, arg0, arg1, ...)`
`os.exec1pe(file, arg0, arg1, ..., env)`
`os.execv(path, args)`
`os.execve(path, args, env)`
`os.execvp(file, args)`
`os.execvpe(file, args, env)`

These functions all execute a new program, replacing the current process; they do not return. On Unix, the new executable is loaded into the current process, and will have the same process
id as the caller. Errors will be reported as OSError exceptions.

The current process is replaced immediately. Open file objects and descriptors are not flushed, so if there may be data buffered on these open files, you should flush them using sys.stdout.flush() or os.fsync() before calling an exec*() function.

The “l” and “v” variants of the exec*() functions differ in how command-line arguments are passed. The “l” variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the exec1*() functions. The “v” variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the args parameter. In either case, the arguments to the child process should start with the name of the command being run, but this is not enforced.

The variants which include a “p” near the end (exec1p(), exec1pe(), execvp(), and execvpe()) will use the PATH environment variable to locate the program file. When the environment is being replaced (using one of the exec*e() variants, discussed in the next paragraph), the new environment is used as the source of the PATH variable. The other variants, exec1(), execle(), execv(), and execve(), will not use the PATH variable to locate the executable; path must contain an appropriate absolute or relative path.

For execle(), exec1pe(), execve(), and execvpe() (note that these all end in “e”), the env parameter must be a mapping which is used to define the environment variables for the new process (these are used instead of the current process’ environment); the functions exec1(), exec1p(), execv(), and execvp() all cause the
new process to inherit the environment of the current process.

Availability: Unix, Windows.

os._exit(n)
Exit the process with status \( n \), without calling cleanup handlers, flushing stdio buffers, etc.

Availability: Unix, Windows.

**Note:** The standard way to exit is `sys.exit(n)`. `_exit()` should normally only be used in the child process after a `fork()`.

The following exit codes are defined and can be used with `_exit()`, although they are not required. These are typically used for system programs written in Python, such as a mail server’s external command delivery program.

**Note:** Some of these may not be available on all Unix platforms, since there is some variation. These constants are defined where they are defined by the underlying platform.

os.EX_OK
Exit code that means no error occurred.

Availability: Unix.

*New in version 2.3.*

os.EX_USAGE
Exit code that means the command was used incorrectly, such as when the wrong number of arguments are given.

Availability: Unix.
New in version 2.3.

**os. EX_DATAERR**
Exit code that means the input data was incorrect.

Availability: Unix.

New in version 2.3.

**os. EX_NOINPUT**
Exit code that means an input file did not exist or was not readable.

Availability: Unix.

New in version 2.3.

**os. EX_NOUSER**
Exit code that means a specified user did not exist.

Availability: Unix.

New in version 2.3.

**os. EX_NOHOST**
Exit code that means a specified host did not exist.

Availability: Unix.

New in version 2.3.

**os. EX_UNAVAILABLE**
Exit code that means that a required service is unavailable.

Availability: Unix.

New in version 2.3.
os. **EXSOFTWARE**
Exit code that means an internal software error was detected.

Availability: Unix.

*New in version 2.3.*

os. **EXOSERR**
Exit code that means an operating system error was detected, such as the inability to fork or create a pipe.

Availability: Unix.

*New in version 2.3.*

os. **EXOSFILE**
Exit code that means some system file did not exist, could not be opened, or had some other kind of error.

Availability: Unix.

*New in version 2.3.*

os. **EX_CANTCREATE**
Exit code that means a user specified output file could not be created.

Availability: Unix.

*New in version 2.3.*

os. **EX_IOERR**
Exit code that means that an error occurred while doing I/O on some file.

Availability: Unix.

*New in version 2.3.*
os. **EX_TEMPFAIL**
Exit code that means a temporary failure occurred. This indicates something that may not really be an error, such as a network connection that couldn’t be made during a retryable operation.

Availability: Unix.

*New in version 2.3.*

os. **EX_PROTOCOL**
Exit code that means that a protocol exchange was illegal, invalid, or not understood.

Availability: Unix.

*New in version 2.3.*

os. **EX_NOPERM**
Exit code that means that there were insufficient permissions to perform the operation (but not intended for file system problems).

Availability: Unix.

*New in version 2.3.*

os. **EX_CONFIG**
Exit code that means that some kind of configuration error occurred.

Availability: Unix.

*New in version 2.3.*

os. **EX_NOTFOUND**
Exit code that means something like “an entry was not found”.

Availability: Unix.
New in version 2.3.

**os.fork()**
Fork a child process. Return 0 in the child and the child's process id in the parent. If an error occurs OSError is raised.

Note that some platforms including FreeBSD <= 6.3, Cygwin and OS/2 EMX have known issues when using fork() from a thread.

Availability: Unix.

**os.forkpty()**
Fork a child process, using a new pseudo-terminal as the child's controlling terminal. Return a pair of (pid, fd), where pid is 0 in the child, the new child's process id in the parent, and fd is the file descriptor of the master end of the pseudo-terminal. For a more portable approach, use the pty module. If an error occurs OSError is raised.

Availability: some flavors of Unix.

**os.kill(pid, sig)**
Send signal sig to the process pid. Constants for the specific signals available on the host platform are defined in the signal module.

Windows: The signal.CTRL_C_EVENT and signal.CTRL_BREAK_EVENT signals are special signals which can only be sent to console processes which share a common console window, e.g., some subprocesses. Any other value for sig will cause the process to be unconditionally killed by the TerminateProcess API, and the exit code will be set to sig. The Windows version of kill() additionally takes process handles to be killed.
New in version 2.7: Windows support

\texttt{os.killpg(pgid, sig)}

Send the signal \textit{sig} to the process group \textit{pgid}.

Availability: Unix.

\textit{New in version 2.3.}

\texttt{os.nice(increment)}

Add \textit{increment} to the process’s “niceness”. Return the new niceness.

Availability: Unix.

\texttt{os.plock(op)}

Lock program segments into memory. The value of \textit{op} (defined in <sys/lock.h>) determines which segments are locked.

Availability: Unix.

\texttt{os.popen(...)}
\texttt{os.popen2(...)}
\texttt{os.popen3(...)}
\texttt{os.popen4(...)}

Run child processes, returning opened pipes for communications. These functions are described in section \textit{File Object Creation}.

\texttt{os.spawnl(mode, path, ...)}
\texttt{os.spawnle(mode, path, ..., env)}
\texttt{os.spawnlp(mode, file, ...)}
\texttt{os.spawnlpe(mode, file, ..., env)}
\texttt{os.spawnv(mode, path, args)}
\texttt{os.spawnve(mode, path, args, env)}
\texttt{os.spawnvp(mode, file, args)}
os. \texttt{spawnvpe}(\textit{mode}, \textit{file}, \textit{args}, \textit{env})

Execute the program \textit{path} in a new process.

(Note that the \texttt{subprocess} module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using these functions. Check especially the \textit{Replacing Older Functions with the subprocess Module} section.)

If \textit{mode} is \texttt{P\_NOWAIT}, this function returns the process id of the new process; if \textit{mode} is \texttt{P\_WAIT}, returns the process's exit code if it exits normally, or \texttt{-signal}, where \textit{signal} is the signal that killed the process. On Windows, the process id will actually be the process handle, so can be used with the \texttt{waitpid()} function.

The “l” and “v” variants of the \texttt{spawn*()} functions differ in how command-line arguments are passed. The “l” variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the \texttt{spawnl*()} functions. The “v” variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the \textit{args} parameter. In either case, the arguments to the child process must start with the name of the command being run.

The variants which include a second “p” near the end (\texttt{spawnlp()}, \texttt{spawnlpe()}, \texttt{spawnvp()}, and \texttt{spawnvpe()}) will use the \texttt{PATH} environment variable to locate the program \textit{file}. When the environment is being replaced (using one of the \texttt{spawn*e()} variants, discussed in the next paragraph), the new environment is used as the source of the \texttt{PATH} variable. The other variants, \texttt{spawnl()}, \texttt{spawnle()}, \texttt{spawnv()}, and \texttt{spawnve()}, will not use the \texttt{PATH} variable to locate the executable; \textit{path} must contain an appropriate absolute or relative path.
For `spawnle()`, `spawnlpe()`, `spawnve()`, and `spawnvpe()` (note that these all end in “e”), the `env` parameter must be a mapping which is used to define the environment variables for the new process (they are used instead of the current process' environment); the functions `spawnl()`, `spawnlp()`, `spawnv()`, and `spawnvp()` all cause the new process to inherit the environment of the current process. Note that keys and values in the `env` dictionary must be strings; invalid keys or values will cause the function to fail, with a return value of 127.

As an example, the following calls to `spawnlp()` and `spawnvpe()` are equivalent:

```python
import os
os.spawnlp(os.P_WAIT, 'cp', 'cp', 'index.html', '/dev/null')

L = ['cp', 'index.html', '/dev/null']
os.spawnvpe(os.P_WAIT, 'cp', L, os.environ)
```

Availability: Unix, Windows. `spawnlp()`, `spawnlpe()`, `spawnvp()` and `spawnvpe()` are not available on Windows.

*New in version 1.6.*

`os.P_NOWAIT`

`os.P_NOWAITO`

Possible values for the `mode` parameter to the `spawn*()` family of functions. If either of these values is given, the `spawn*()` functions will return as soon as the new process has been created, with the process id as the return value.

Availability: Unix, Windows.

*New in version 1.6.*

`os.P_WAIT`
Possible value for the `mode` parameter to the `spawn*()` family of functions. If this is given as `mode`, the `spawn*()` functions will not return until the new process has run to completion and will return the exit code of the process the run is successful, or `-signal` if a signal kills the process.

Availability: Unix, Windows.

*New in version 1.6.*

**os.** `P_DETACH`

**os.** `P_OVERLAY`

Possible values for the `mode` parameter to the `spawn*()` family of functions. These are less portable than those listed above. `P_DETACH` is similar to `P_NOWAIT`, but the new process is detached from the console of the calling process. If `P_OVERLAY` is used, the current process will be replaced; the `spawn*()` function will not return.

Availability: Windows.

*New in version 1.6.*

**os.** `startfile(path[, operation])`

Start a file with its associated application.

When `operation` is not specified or `'open'`, this acts like double-clicking the file in Windows Explorer, or giving the file name as an argument to the `start` command from the interactive command shell: the file is opened with whatever application (if any) its extension is associated.

When another `operation` is given, it must be a “command verb” that specifies what should be done with the file. Common verbs documented by Microsoft are `'print'` and `'edit'` (to be used on
files) as well as 'explore' and 'find' (to be used on directories).

`startfile()` returns as soon as the associated application is launched. There is no option to wait for the application to close, and no way to retrieve the application's exit status. The path parameter is relative to the current directory. If you want to use an absolute path, make sure the first character is not a slash ('/'); the underlying Win32 `ShellExecute()` function doesn’t work if it is. Use the `os.path.normpath()` function to ensure that the path is properly encoded for Win32.

Availability: Windows.

*New in version 2.0.*

*New in version 2.5:* The operation parameter.

`os.system(command)`

Execute the command (a string) in a subshell. This is implemented by calling the Standard C function `system()`, and has the same limitations. Changes to `sys.stdin`, etc. are not reflected in the environment of the executed command.

On Unix, the return value is the exit status of the process encoded in the format specified for `wait()`. Note that POSIX does not specify the meaning of the return value of the C `system()` function, so the return value of the Python function is system-dependent.

On Windows, the return value is that returned by the system shell after running `command`, given by the Windows environment variable `COMSPEC`: on `command.com` systems (Windows 95, 98 and ME) this is always 0; on `cmd.exe` systems (Windows NT, 2000 and XP) this is the exit status of the command run; on systems using a non-native shell, consult your shell
The `subprocess` module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using this function. See the *Replacing Older Functions with the subprocess Module* section in the `subprocess` documentation for some helpful recipes.

Availability: Unix, Windows.

`os.times()`
Return a 5-tuple of floating point numbers indicating accumulated (processor or other) times, in seconds. The items are: user time, system time, children's user time, children's system time, and elapsed real time since a fixed point in the past, in that order. See the Unix manual page `times(2)` or the corresponding Windows Platform API documentation. On Windows, only the first two items are filled, the others are zero.

Availability: Unix, Windows

`os.wait()`
Wait for completion of a child process, and return a tuple containing its pid and exit status indication: a 16-bit number, whose low byte is the signal number that killed the process, and whose high byte is the exit status (if the signal number is zero); the high bit of the low byte is set if a core file was produced.

Availability: Unix.

`os.waitpid(pid, options)`
The details of this function differ on Unix and Windows.

On Unix: Wait for completion of a child process given by process id `pid`, and return a tuple containing its process id and exit status
indication (encoded as for \texttt{wait()}). The semantics of the call are affected by the value of the integer \texttt{options}, which should be \texttt{0} for normal operation.

If \texttt{pid} is greater than \texttt{0}, \texttt{waitpid()} requests status information for that specific process. If \texttt{pid} is \texttt{0}, the request is for the status of any child in the process group of the current process. If \texttt{pid} is \texttt{-1}, the request pertains to any child of the current process. If \texttt{pid} is less than \texttt{-1}, status is requested for any process in the process group \texttt{-pid} (the absolute value of \texttt{pid}).

An \texttt{OSError} is raised with the value of \texttt{errno} when the syscall returns \texttt{-1}.

On Windows: Wait for completion of a process given by process handle \texttt{pid}, and return a tuple containing \texttt{pid}, and its exit status shifted left by 8 bits (shifting makes cross-platform use of the function easier). A \texttt{pid} less than or equal to \texttt{0} has no special meaning on Windows, and raises an exception. The value of integer \texttt{options} has no effect. \texttt{pid} can refer to any process whose id is known, not necessarily a child process. The \texttt{spawn()} functions called with \texttt{P_NOWAIT} return suitable process handles.

\texttt{os.wait3([\texttt{options}])}

Similar to \texttt{waitpid()}, except no process id argument is given and a 3-element tuple containing the child’s process id, exit status indication, and resource usage information is returned. Refer to \texttt{resource.getrusage()} for details on resource usage information. The option argument is the same as that provided to \texttt{waitpid()} and \texttt{wait4()}.

Availability: Unix.
New in version 2.5.

`os.wait4(pid, options)`

Similar to `waitpid()`, except a 3-element tuple, containing the child’s process id, exit status indication, and resource usage information is returned. Refer to `resource.getrusage()` for details on resource usage information. The arguments to `wait4()` are the same as those provided to `waitpid()`.

Availability: Unix.

New in version 2.5.

`os.WNOHANG`

The option for `waitpid()` to return immediately if no child process status is available immediately. The function returns `(0, 0)` in this case.

Availability: Unix.

`os.WCONTINUED`

This option causes child processes to be reported if they have been continued from a job control stop since their status was last reported.

Availability: Some Unix systems.

New in version 2.3.

`os.WUNTRACED`

This option causes child processes to be reported if they have been stopped but their current state has not been reported since they were stopped.

Availability: Unix.
New in version 2.3.

The following functions take a process status code as returned by `system()`, `wait()`, or `waitpid()` as a parameter. They may be used to determine the disposition of a process.

```python
os.WCOREDUMP(status)
```
Return `True` if a core dump was generated for the process, otherwise return `False`.

Availability: Unix.

New in version 2.3.

```python
os.WIFCONTINUED(status)
```
Return `True` if the process has been continued from a job control stop, otherwise return `False`.

Availability: Unix.

New in version 2.3.

```python
os.WIFSTOPPED(status)
```
Return `True` if the process has been stopped, otherwise return `False`.

Availability: Unix.

```python
os.WIFSIGNALED(status)
```
Return `True` if the process exited due to a signal, otherwise return `False`.

Availability: Unix.

```python
os.WIFEXITED(status)
```
Return True if the process exited using the exit(2) system call, otherwise return False.

Availability: Unix.

```
os.WEXITSTATUS(status)
```

If WIFEXITED(status) is true, return the integer parameter to the exit(2) system call. Otherwise, the return value is meaningless.

Availability: Unix.

```
os.WSTOPSIG(status)
```

Return the signal which caused the process to stop.

Availability: Unix.

```
os.WTERMSIG(status)
```

Return the signal which caused the process to exit.

Availability: Unix.
15.1.6. Miscellaneous System Information

**os.confstr(name)**

Return string-valued system configuration values. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given as the keys of the `confstr_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If the configuration value specified by *name* isn’t defined, `None` is returned.

If *name* is a string and is not known, `ValueError` is raised. If a specific value for *name* is not supported by the host system, even if it is included in `confstr_names`, an `OSError` is raised with `errno.EINVAL` for the error number.

Availability: Unix

**os.confstr_names**

Dictionary mapping names accepted by `confstr()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

**os.getloadavg()**

Return the number of processes in the system run queue averaged over the last 1, 5, and 15 minutes or raises `OSError` if
the load average was unobtainable.

Availability: Unix.

*New in version 2.3.*

**os. sysconf(name)**

Return integer-valued system configuration values. If the configuration value specified by name isn't defined, -1 is returned. The comments regarding the name parameter for `confstr()` apply here as well; the dictionary that provides information on the known names is given by `sysconf_names`.

Availability: Unix.

**os. sysconf_names**

Dictionary mapping names accepted by `sysconf()` to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

The following data values are used to support path manipulation operations. These are defined for all platforms.

Higher-level operations on pathnames are defined in the `os.path` module.

**os. curdir**

The constant string used by the operating system to refer to the current directory. This is '.*' for Windows and POSIX. Also available via `os.path`.

**os. pardir**

The constant string used by the operating system to refer to the
parent directory. This is '..' for Windows and POSIX. Also available via os.path.

**os.sep**
The character used by the operating system to separate pathname components. This is '/' for POSIX and '\\' for Windows. Note that knowing this is not sufficient to be able to parse or concatenate pathnames — use os.path.split() and os.path.join() — but it is occasionally useful. Also available via os.path.

**os.altsep**
An alternative character used by the operating system to separate pathname components, or None if only one separator character exists. This is set to '/' on Windows systems where `sep` is a backslash. Also available via os.path.

**os.extsep**
The character which separates the base filename from the extension; for example, the '.' in os.py. Also available via os.path.

*New in version 2.2.*

**os.pathsep**
The character conventionally used by the operating system to separate search path components (as in PATH), such as ':' for POSIX or ';' for Windows. Also available via os.path.

**os.defpath**
The default search path used by exec*p*() and spawn*p*() if the environment doesn’t have a 'PATH' key. Also available via os.path.
**os.linesep**

The string used to separate (or, rather, terminate) lines on the current platform. This may be a single character, such as ' \n ' for POSIX, or multiple characters, for example, ' \r \n ' for Windows. Do not use `os.linesep` as a line terminator when writing files opened in text mode (the default); use a single ' \n ' instead, on all platforms.

**os.devnull**

The file path of the null device. For example: `/dev/null` for POSIX, `\nul` for Windows. Also available via `os.path`.

*New in version 2.4.*
15.1.7. Miscellaneous Functions

os.urandom(n)

Return a string of \( n \) random bytes suitable for cryptographic use.

This function returns random bytes from an OS-specific randomness source. The returned data should be unpredictable enough for cryptographic applications, though its exact quality depends on the OS implementation. On a UNIX-like system this will query /dev/urandom, and on Windows it will use CryptGenRandom. If a randomness source is not found, \texttt{NotImplementedError} will be raised.

\textit{New in version 2.4.}
15.2. \textit{io} — Core tools for working with streams

\textit{New in version 2.6.}

The \textit{io} module provides the Python interfaces to stream handling. Under Python 2.x, this is proposed as an alternative to the built-in \textit{file} object, but in Python 3.x it is the default interface to access files and streams.

\textbf{Note:} Since this module has been designed primarily for Python 3.x, you have to be aware that all uses of “bytes” in this document refer to the \texttt{str} type (of which \texttt{bytes} is an alias), and all uses of “text” refer to the \texttt{unicode} type. Furthermore, those two types are not interchangeable in the \textit{io} APIs.

At the top of the I/O hierarchy is the abstract base class \texttt{IOBase}. It defines the basic interface to a stream. Note, however, that there is no separation between reading and writing to streams; implementations are allowed to raise an \texttt{IOError} if they do not support a given operation.

Extending \texttt{IOBase} is \texttt{RawIOBase} which deals simply with the reading and writing of raw bytes to a stream. \texttt{FileIO} subclasses \texttt{RawIOBase} to provide an interface to files in the machine’s file system.

\texttt{BufferedIOBase} deals with buffering on a raw byte stream (\texttt{RawIOBase}). Its subclasses, \texttt{BufferedWriter}, \texttt{BufferedReader}, and \texttt{BufferedRWPair} buffer streams that are readable, writable, and both readable and writable. \texttt{BufferedRandom} provides a buffered interface to random access streams. \texttt{BytesIO} is a simple stream of in-memory
Another `IOBase` subclass, `TextIOBase`, deals with streams whose bytes represent text, and handles encoding and decoding from and to `unicode` strings. `TextIOWrapper`, which extends it, is a buffered text interface to a buffered raw stream (`BufferedIOBase`). Finally, `StringIO` is an in-memory stream for `unicode` text.

Argument names are not part of the specification, and only the arguments of `open()` are intended to be used as keyword arguments.
15.2.1. Module Interface

io.DEFAULT_BUFFER_SIZE
An int containing the default buffer size used by the module’s buffered I/O classes. open() uses the file’s blksize (as obtained by os.stat()) if possible.

io.open(file, mode='r', buffering=-1, encoding=None, errors=None, newline=None, closefd=True)
Open file and return a corresponding stream. If the file cannot be opened, an IOError is raised.

file is either a string giving the pathname (absolute or relative to the current working directory) of the file to be opened or an integer file descriptor of the file to be wrapped. (If a file descriptor is given, it is closed when the returned I/O object is closed, unless closefd is set to False.)

mode is an optional string that specifies the mode in which the file is opened. It defaults to 'r' which means open for reading in text mode. Other common values are 'w' for writing (truncating the file if it already exists), and 'a' for appending (which on some Unix systems, means that all writes append to the end of the file regardless of the current seek position). In text mode, if encoding is not specified the encoding used is platform dependent. (For reading and writing raw bytes use binary mode and leave encoding unspecified.) The available modes are:

<table>
<thead>
<tr>
<th>Character</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'r'</td>
<td>open for reading (default)</td>
</tr>
<tr>
<td>'w'</td>
<td>open for writing, truncating the file first</td>
</tr>
<tr>
<td>'a'</td>
<td>open for writing, appending to the end of the file if it exists</td>
</tr>
</tbody>
</table>
The default mode is 'rt' (open for reading text). For binary random access, the mode 'w+b' opens and truncates the file to 0 bytes, while 'r+b' opens the file without truncation.

Python distinguishes between files opened in binary and text modes, even when the underlying operating system doesn’t. Files opened in binary mode (including 'b' in the mode argument) return contents as bytes objects without any decoding. In text mode (the default, or when 't' is included in the mode argument), the contents of the file are returned as unicode strings, the bytes having been first decoded using a platform-dependent encoding or using the specified encoding if given.

buffering is an optional integer used to set the buffering policy. Pass 0 to switch buffering off (only allowed in binary mode), 1 to select line buffering (only usable in text mode), and an integer > 1 to indicate the size of a fixed-size chunk buffer. When no buffering argument is given, the default buffering policy works as follows:

- Binary files are buffered in fixed-size chunks; the size of the buffer is chosen using a heuristic trying to determine the underlying device’s “block size” and falling back on DEFAULT_BUFFER_SIZE. On many systems, the buffer will typically be 4096 or 8192 bytes long.
- “Interactive” text files (files for which isatty() returns True) use line buffering. Other text files use the policy described above for binary files.
**encoding** is the name of the encoding used to decode or encode the file. This should only be used in text mode. The default encoding is platform dependent (whatever `locale.getpreferredencoding()` returns), but any encoding supported by Python can be used. See the `codecs` module for the list of supported encodings.

**errors** is an optional string that specifies how encoding and decoding errors are to be handled—this cannot be used in binary mode. Pass `'strict'` to raise a `ValueError` exception if there is an encoding error (the default of `None` has the same effect), or pass `'ignore'` to ignore errors. (Note that ignoring encoding errors can lead to data loss.) `'replace'` causes a replacement marker (such as `'?') to be inserted where there is malformed data. When writing, `'xmlcharrefreplace'` (replace with the appropriate XML character reference) or `'backslashreplace'` (replace with backslashed escape sequences) can be used. Any other error handling name that has been registered with `codecs.register_error()` is also valid.

**newline** controls how universal newlines works (it only applies to text mode). It can be `None`, `' '`, `'\n'`, `'\r'`, and `'\r\n'`. It works as follows:

- On input, if **newline** is `None`, universal newlines mode is enabled. Lines in the input can end in `'\n'`, `'\r'`, or `'\r\n'`, and these are translated into `'\n'` before being returned to the caller. If it is `' '`, universal newline mode is enabled, but line endings are returned to the caller untranslated. If it has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- On output, if **newline** is `None`, any `'\n'` characters written are
translated to the system default line separator, \texttt{os.linesep}. If \texttt{newline} is 
'', no translation takes place. If \texttt{newline} is any of
the other legal values, any \
\n\texttt{characters} written are
translated to the given string.

If \texttt{closefd} is \texttt{False} and a file descriptor rather than a filename was
given, the underlying file descriptor will be kept open when the
file is closed. If a filename is given \texttt{closefd} has no effect and must
be \texttt{True} (the default).

The type of file object returned by the \texttt{open()} function depends
on the mode. When \texttt{open()} is used to open a file in a text mode
(\texttt{'w'}, \texttt{'r'}, \texttt{'wt'}, \texttt{'rt'}, etc.), it returns a subclass of \texttt{TextIOWrapper}
specifically \texttt{TextIOWrapper}. When used to open a file in a binary
mode with buffering, the returned class is a subclass of
\texttt{BufferedIOBase}. The exact class varies: in read binary mode, it
returns a \texttt{BufferedReader}; in write binary and append binary
modes, it returns a \texttt{BufferedWriter}, and in read/write mode, it
returns a \texttt{BufferedRandom}. When buffering is disabled, the raw
stream, a subclass of \texttt{RawIOBase, FileIO}, is returned.

It is also possible to use an \texttt{unicode} or \texttt{bytes} string as a file for
both reading and writing. For \texttt{unicode} strings \texttt{StringIO}
can be
used like a file opened in text mode, and for \texttt{bytes} a \texttt{BytesIO}
can be used like a file opened in a binary mode.

\texttt{exception \texttt{i0.BlockingIOError}}

Error raised when blocking would occur on a non-blocking
stream. It inherits \texttt{IOError}.

In addition to those of \texttt{IOError}, \texttt{BlockingIOError} has one
attribute:

\texttt{characters_written}
An integer containing the number of characters written to the stream before it blocked.

```python
exception io.UnsupportedOperation
An exception inheriting IOError and ValueError that is raised when an unsupported operation is called on a stream.
```
15.2.2. I/O Base Classes

class io.IOBase

The abstract base class for all I/O classes, acting on streams of bytes. There is no public constructor.

This class provides empty abstract implementations for many methods that derived classes can override selectively; the default implementations represent a file that cannot be read, written or sought.

Even though IOBase does not declare read(), readinto(), or write() because their signatures will vary, implementations and clients should consider those methods part of the interface. Also, implementations may raise a IOError when operations they do not support are called.

The basic type used for binary data read from or written to a file is bytes (also known as str). bytearrays are accepted too, and in some cases (such as readinto) required. Text I/O classes work with unicode data.

Note that calling any method (even inquiries) on a closed stream is undefined. Implementations may raise IOError in this case.

IOBase (and its subclasses) support the iterator protocol, meaning that an IOBase object can be iterated over yielding the lines in a stream. Lines are defined slightly differently depending on whether the stream is a binary stream (yielding bytes), or a text stream (yielding unicode strings). See readline() below.

IOBase is also a context manager and therefore supports the with statement. In this example, file is closed after the with
statement’s suite is finished—even if an exception occurs:

```python
with io.open('spam.txt', 'w') as file:
    file.write(u'Spam and eggs!')
```

**IOBase** provides these data attributes and methods:

**close()**
Flush and close this stream. This method has no effect if the file is already closed. Once the file is closed, any operation on the file (e.g. reading or writing) will raise a `ValueError`.

As a convenience, it is allowed to call this method more than once; only the first call, however, will have an effect.

**closed**
True if the stream is closed.

**fileno()**
Return the underlying file descriptor (an integer) of the stream if it exists. An **IOError** is raised if the IO object does not use a file descriptor.

**flush()**
Flush the write buffers of the stream if applicable. This does nothing for read-only and non-blocking streams.

**isatty()**
Return **True** if the stream is interactive (i.e., connected to a terminal/tty device).

**readable()**
Return **True** if the stream can be read from. If False, `read()` will raise **IOError**.

**readline(limit=-1)**
Read and return one line from the stream. If *limit* is specified, at most *limit* bytes will be read.

The line terminator is always `b'\n'` for binary files; for text files, the *newlines* argument to *open()* can be used to select the line terminator(s) recognized.

**readlines**(*hint=-1*)

Read and return a list of lines from the stream. *hint* can be specified to control the number of lines read: no more lines will be read if the total size (in bytes/characters) of all lines so far exceeds *hint*.

**seek**(offset, whence=SEEK_SET)

Change the stream position to the given byte *offset*. *offset* is interpreted relative to the position indicated by *whence*. Values for *whence* are:

- **SEEK_SET** or 0 – start of the stream (the default); *offset* should be zero or positive
- **SEEK_CUR** or 1 – current stream position; *offset* may be negative
- **SEEK_END** or 2 – end of the stream; *offset* is usually negative

Return the new absolute position.

*New in version 2.7*: The SEEK_* constants

**seekable()**

Return True if the stream supports random access. If False, *seek()*, *tell()* and *truncate()* will raise IOError.

**tell()**

Return the current stream position.
**truncate(size=None)**
Resize the stream to the given size in bytes (or the current position if size is not specified). The current stream position isn’t changed. This resizing can extend or reduce the current file size. In case of extension, the contents of the new file area depend on the platform (on most systems, additional bytes are zero-filled, on Windows they’re undetermined). The new file size is returned.

**writable()**
Return True if the stream supports writing. If False, write() and truncate() will raise IOError.

**writelines(lines)**
Write a list of lines to the stream. Line separators are not added, so it is usual for each of the lines provided to have a line separator at the end.

---

**class io.RawIOBase**
Base class for raw binary I/O. It inherits IOBase. There is no public constructor.

Raw binary I/O typically provides low-level access to an underlying OS device or API, and does not try to encapsulate it in high-level primitives (this is left to Buffered I/O and Text I/O, described later in this page).

In addition to the attributes and methods from IOBase, RawIOBase provides the following methods:

**read(n=-1)**
Read up to n bytes from the object and return them. As a convenience, if n is unspecified or -1, readall() is called. Otherwise, only one system call is ever made. Fewer than n bytes may be returned if the operating system call returns
fewer than \( n \) bytes.

If 0 bytes are returned, and \( n \) was not 0, this indicates end of file. If the object is in non-blocking mode and no bytes are available, \texttt{None} is returned.

\texttt{readall()} \\
Read and return all the bytes from the stream until EOF, using multiple calls to the stream if necessary.

\texttt{readinto(b)} \\
Read up to \( \text{len}(b) \) bytes into bytearray \( b \) and return the number of bytes read. If the object is in non-blocking mode and no bytes are available, \texttt{None} is returned.

\texttt{write(b)} \\
Write the given bytes or bytearray object, \( b \), to the underlying raw stream and return the number of bytes written. This can be less than \( \text{len}(b) \), depending on specifics of the underlying raw stream, and especially if it is in non-blocking mode. \texttt{None} is returned if the raw stream is set not to block and no single byte could be readily written to it.

class \texttt{io.BufferedIOBase} \\
Base class for binary streams that support some kind of buffering. It inherits \texttt{IOBase}. There is no public constructor.

The main difference with \texttt{RawIOBase} is that methods \texttt{read()}, \texttt{readinto()} and \texttt{write()} will try (respectively) to read as much input as requested or to consume all given output, at the expense of making perhaps more than one system call.

In addition, those methods can raise \texttt{BlockingIOError} if the underlying raw stream is in non-blocking mode and cannot take or give enough data; unlike their \texttt{RawIOBase} counterparts, they will
never return `None`.

Besides, the `read()` method does not have a default implementation that defers to `readinto()`.

A typical `BufferedIOBase` implementation should not inherit from a `RawIOBase` implementation, but wrap one, like `BufferedWriter` and `BufferedReader` do.

`BufferedIOBase` provides or overrides these members in addition to those from `IOBase`:

- **raw**
  The underlying raw stream (a `RawIOBase` instance) that `BufferedIOBase` deals with. This is not part of the `BufferedIOBase` API and may not exist on some implementations.

- **detach()**
  Separate the underlying raw stream from the buffer and return it.

  After the raw stream has been detached, the buffer is in an unusable state.

  Some buffers, like `BytesIO`, do not have the concept of a single raw stream to return from this method. They raise `UnsupportedOperation`.

  *New in version 2.7.*

- **read**(\(n=-1\))
  Read and return up to \(n\) bytes. If the argument is omitted, `None`, or negative, data is read and returned until EOF is reached. An empty bytes object is returned if the stream is
already at EOF.

If the argument is positive, and the underlying raw stream is not interactive, multiple raw reads may be issued to satisfy the byte count (unless EOF is reached first). But for interactive raw streams, at most one raw read will be issued, and a short result does not imply that EOF is imminent.

A `BlockingIOError` is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

**read1**(n=-1)

Read and return up to n bytes, with at most one call to the underlying raw stream’s `read()` method. This can be useful if you are implementing your own buffering on top of a `BufferedIOBase` object.

**readinto**(b)

Read up to len(b) bytes into bytearray b and return the number of bytes read.

Like `read()`, multiple reads may be issued to the underlying raw stream, unless the latter is ‘interactive’.

A `BlockingIOError` is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

**write**(b)

Write the given bytes or bytearray object, b and return the number of bytes written (never less than `len(b)`, since if the write fails an `IOError` will be raised). Depending on the actual implementation, these bytes may be readily written to the underlying stream, or held in a buffer for performance and latency reasons.
When in non-blocking mode, a **BlockingIOError** is raised if the data needed to be written to the raw stream but it couldn’t accept all the data without blocking.
15.2.3. Raw File I/O

```python
class io.FileIO(name, mode='r', closefd=True)
```

FileIO represents an OS-level file containing bytes data. It implements the RawIOBase interface (and therefore the IOBase interface, too).

The name can be one of two things:

- a string representing the path to the file which will be opened;
- an integer representing the number of an existing OS-level file descriptor to which the resulting FileIO object will give access.

The mode can be 'r', 'w' or 'a' for reading (default), writing, or appending. The file will be created if it doesn’t exist when opened for writing or appending; it will be truncated when opened for writing. Add a '+' to the mode to allow simultaneous reading and writing.

The read() (when called with a positive argument), readinto() and write() methods on this class will only make one system call.

In addition to the attributes and methods from IOBase and RawIOBase, FileIO provides the following data attributes and methods:

- **mode**
  - The mode as given in the constructor.

- **name**
  - The file name. This is the file descriptor of the file when no
name is given in the constructor.
15.2.4. Buffered Streams

Buffered I/O streams provide a higher-level interface to an I/O device than raw I/O does.

```python
class io.BytesIO([initial_bytes])

A stream implementation using an in-memory bytes buffer. It inherits BufferedIOBase.
```

The argument `initial_bytes` is an optional initial `bytes`.

`BytesIO` provides or overrides these methods in addition to those from BufferedIOBase and IOBase:

```python
getvalue()
    Return `bytes` containing the entire contents of the buffer.

read1()
    In `BytesIO`, this is the same as `read()`.
```

```python
class io.BufferedReader(raw, buffer_size=DEFAULT_BUFFER_SIZE)

A buffer providing higher-level access to a readable, sequential RawIOBase object. It inherits BufferedIOBase. When reading data from this object, a larger amount of data may be requested from the underlying raw stream, and kept in an internal buffer. The buffered data can then be returned directly on subsequent reads.

The constructor creates a BufferedReader for the given readable raw stream and buffer_size. If buffer_size is omitted, DEFAULT_BUFFER_SIZE is used.
```

BufferedReader provides or overrides these methods in addition
to those from `BufferedIOBase` and `IOBase`:

**peek([n])**

Return bytes from the stream without advancing the position. At most one single read on the raw stream is done to satisfy the call. The number of bytes returned may be less or more than requested.

**read([n])**

Read and return n bytes, or if n is not given or negative, until EOF or if the read call would block in non-blocking mode.

**read1(n)**

Read and return up to n bytes with only one call on the raw stream. If at least one byte is buffered, only buffered bytes are returned. Otherwise, one raw stream read call is made.

class io.BufferedWriter(raw,
buffer_size=DEFAULT_BUFFER_SIZE)

A buffer providing higher-level access to a writeable, sequential `RawIOBase` object. It inherits `BufferedIOBase`. When writing to this object, data is normally held into an internal buffer. The buffer will be written out to the underlying `RawIOBase` object under various conditions, including:

- when the buffer gets too small for all pending data;
- when `flush()` is called;
- when a `seek()` is requested (for `BufferedRandom` objects);
- when the `BufferedWriter` object is closed or destroyed.

The constructor creates a `BufferedWriter` for the given writeable `raw` stream. If the `buffer_size` is not given, it defaults to `DEFAULT_BUFFER_SIZE`. 
A third argument, *max_buffer_size*, is supported, but unused and deprecated.

`BufferedWriter` provides or overrides these methods in addition to those from `BufferedIOBase` and `IOBase`:

**flush()**

Force bytes held in the buffer into the raw stream. A `BlockingIOError` should be raised if the raw stream blocks.

**write(b)**

Write the bytes or bytearray object, `b` and return the number of bytes written. When in non-blocking mode, a `BlockingIOError` is raised if the buffer needs to be written out but the raw stream blocks.

```python
class io.BufferedRWPair(reader, writer,  
buffer_size=DEFAULT_BUFFER_SIZE)
```

A buffered I/O object giving a combined, higher-level access to two sequential `RawIOBase` objects: one readable, the other writeable. It is useful for pairs of unidirectional communication channels (pipes, for instance). It inherits `BufferedIOBase`.

*reader* and *writer* are `RawIOBase` objects that are readable and writeable respectively. If the *buffer_size* is omitted it defaults to `DEFAULT_BUFFER_SIZE`.

A fourth argument, *max_buffer_size*, is supported, but unused and deprecated.

`BufferedRWPair` implements all of `BufferedIOBase`'s methods except for `detach()`, which raises `UnsupportedOperation`.

```python
class io.BufferedRandom(raw,
```
buffer_size=DEFAULT_BUFFER_SIZE)
A buffered interface to random access streams. It inherits BufferedReader and BufferedWriter, and further supports seek() and tell() functionality.

The constructor creates a reader and writer for a seekable raw stream, given in the first argument. If the buffer_size is omitted it defaults to DEFAULT_BUFFER_SIZE.

A third argument, max_buffer_size, is supported, but unused and deprecated.

BufferedRandom is capable of anything BufferedReader or BufferedWriter can do.
15.2.5. Text I/O

class io.TextIOBase

Base class for text streams. This class provides an unicode character and line based interface to stream I/O. There is no readinto() method because Python’s unicode strings are immutable. It inherits IOBase. There is no public constructor.

TextIOBase provides or overrides these data attributes and methods in addition to those from IOBase:

encoding
The name of the encoding used to decode the stream’s bytes into strings, and to encode strings into bytes.

errors
The error setting of the decoder or encoder.

newlines
A string, a tuple of strings, or None, indicating the newlines translated so far. Depending on the implementation and the initial constructor flags, this may not be available.

buffer
The underlying binary buffer (a BufferedIOBase instance) that TextIOBase deals with. This is not part of the TextIOBase API and may not exist on some implementations.

detach()
Separate the underlying binary buffer from the TextIOBase and return it.

After the underlying buffer has been detached, the TextIOBase is in an unusable state.
Some `TextIOBase` implementations, like `StringIO`, may not have the concept of an underlying buffer and calling this method will raise `UnsupportedOperation`.

*New in version 2.7.*

**read**(n)

Read and return at most n characters from the stream as a single `unicode`. If n is negative or `None`, reads until EOF.

**readline()**

Read until newline or EOF and return a single `unicode`. If the stream is already at EOF, an empty string is returned.

**write**(s)

Write the `unicode` string s to the stream and return the number of characters written.

```python
class io.TextIOWrapper(buffer=None, encoding=None, errors=None,
                        newline=None, line_buffering=False)
```

A buffered text stream over a `BufferedIOBase` binary stream. It inherits `TextIOBase`.

*encoding* gives the name of the encoding that the stream will be decoded or encoded with. It defaults to `locale.getpreferredencoding()`.

*errors* is an optional string that specifies how encoding and decoding errors are to be handled. Pass `'strict'` to raise a `ValueError` exception if there is an encoding error (the default of `None` has the same effect), or pass `'ignore'` to ignore errors. (Note that ignoring encoding errors can lead to data loss.) `'replace'` causes a replacement marker (such as `'?') to be inserted where there is malformed data. When writing,
'xmlcharrefreplace' (replace with the appropriate XML character reference) or 'backslashreplace' (replace with backslashed escape sequences) can be used. Any other error handling name that has been registered with `codecs.register_error()` is also valid.

`newline` can be `None`, `'`, '\n', '\r', or '\r\n'. It controls the handling of line endings. If it is `None`, universal newlines is enabled. With this enabled, on input, the lines endings '\n', '\r', or '\r\n' are translated to '\n' before being returned to the caller. Conversely, on output, '\n' is translated to the system default line separator, `os.linesep`. If `newline` is any other of its legal values, that newline becomes the newline when the file is read and it is returned untranslated. On output, '\n' is converted to the `newline`.

If `line_buffering` is `True`, `flush()` is implied when a call to `write` contains a newline character.

`TextIOWrapper` provides one attribute in addition to those of `TextIOBase` and its parents:

- **line_buffering**
  Whether line buffering is enabled.

```python
class io.StringIO(initial_value=u'', newline=None)
An in-memory stream for unicode text. It inherits `TextIOWrapper`.
```

The initial value of the buffer (an empty unicode string by default) can be set by providing `initial_value`. The `newline` argument works like that of `TextIOWrapper`. The default is to do no newline translation.

`StringIO` provides this method in addition to those from
TextIOWrapper and its parents:

getvalue()

Return a unicode containing the entire contents of the buffer at any time before the StringIO object's close() method is called.

Example usage:

```python
import io
output = io.StringIO()
output.write(u'First line.
')
output.write(u'Second line.
')

# Retrieve file contents -- this will be
# u'First line.
Second line.'
contents = output.getvalue()

# Close object and discard memory buffer --
# ..getvalue() will now raise an exception.
output.close()
```

class io.IncrementalNewlineDecoder

A helper codec that decodes newlines for universal newlines mode. It inherits codecs.IncrementalDecoder.
15.2.6. Advanced topics

Here we will discuss several advanced topics pertaining to the concrete I/O implementations described above.

15.2.6.1. Performance

15.2.6.1.1. Binary I/O

By reading and writing only large chunks of data even when the user asks for a single byte, buffered I/O is designed to hide any inefficiency in calling and executing the operating system’s unbuffered I/O routines. The gain will vary very much depending on the OS and the kind of I/O which is performed (for example, on some contemporary OSes such as Linux, unbuffered disk I/O can be as fast as buffered I/O). The bottom line, however, is that buffered I/O will offer you predictable performance regardless of the platform and the backing device. Therefore, it is most always preferable to use buffered I/O rather than unbuffered I/O.

15.2.6.1.2. Text I/O

Text I/O over a binary storage (such as a file) is significantly slower than binary I/O over the same storage, because it implies conversions from unicode to binary data using a character codec. This can become noticeable if you handle huge amounts of text data (for example very large log files). Also, TextIOWrapper.tell() and TextIOWrapper.seek() are both quite slow due to the reconstruction algorithm used.

 StringIO, however, is a native in-memory unicode container and will exhibit similar speed to BytesIO.
15.2.6.2. Multi-threading

FileIO objects are thread-safe to the extent that the operating system calls (such as `read(2)` under Unix) they are wrapping are thread-safe too.

Binary buffered objects (instances of `BufferedReader`, `BufferedWriter`, `BufferedRandom` and `BufferedRWPair`) protect their internal structures using a lock; it is therefore safe to call them from multiple threads at once.

TextIOWrapper objects are not thread-safe.

15.2.6.3. Reentrancy

Binary buffered objects (instances of `BufferedReader`, `BufferedWriter`, `BufferedRandom` and `BufferedRWPair`) are not reentrant. While reentrant calls will not happen in normal situations, they can arise if you are doing I/O in a `signal` handler. If it is attempted to enter a buffered object again while already being accessed from the same thread, then a `RuntimeError` is raised.

The above implicitly extends to text files, since the `open()` function will wrap a buffered object inside a `TextIOWrapper`. This includes standard streams and therefore affects the built-in function `print()` as well.
15.3. time — Time access and conversions

This module provides various time-related functions. For related functionality, see also the `datetime` and `calendar` modules.

Although this module is always available, not all functions are available on all platforms. Most of the functions defined in this module call platform C library functions with the same name. It may sometimes be helpful to consult the platform documentation, because the semantics of these functions varies among platforms.

An explanation of some terminology and conventions is in order.

- The *epoch* is the point where the time starts. On January 1st of that year, at 0 hours, the “time since the epoch” is zero. For Unix, the epoch is 1970. To find out what the epoch is, look at `gmtime(0)`.

- The functions in this module do not handle dates and times before the epoch or far in the future. The cut-off point in the future is determined by the C library; for Unix, it is typically in 2038.

- **Year 2000 (Y2K) issues**: Python depends on the platform’s C library, which generally doesn’t have year 2000 issues, since all dates and times are represented internally as seconds since the epoch. Functions accepting a `struct_time` (see below) generally require a 4-digit year. For backward compatibility, 2-digit years are supported if the module variable `accept2dyear` is a non-zero integer; this variable is initialized to 1 unless the environment variable `PYTHONY2K` is set to a non-empty string, in which case it is initialized to 0. Thus, you can set `PYTHONY2K` to a
non-empty string in the environment to require 4-digit years for all year input. When 2-digit years are accepted, they are converted according to the POSIX or X/Open standard: values 69-99 are mapped to 1969-1999, and values 0–68 are mapped to 2000–2068. Values 100–1899 are always illegal. Note that this is new as of Python 1.5.2(a2); earlier versions, up to Python 1.5.1 and 1.5.2a1, would add 1900 to year values below 1900.

- **UTC** is Coordinated Universal Time (formerly known as Greenwich Mean Time, or GMT). The acronym UTC is not a mistake but a compromise between English and French.

- **DST** is Daylight Saving Time, an adjustment of the timezone by (usually) one hour during part of the year. DST rules are magic (determined by local law) and can change from year to year. The C library has a table containing the local rules (often it is read from a system file for flexibility) and is the only source of True Wisdom in this respect.

- The precision of the various real-time functions may be less than suggested by the units in which their value or argument is expressed. E.g. on most Unix systems, the clock “ticks” only 50 or 100 times a second.

- On the other hand, the precision of `time()` and `sleep()` is better than their Unix equivalents: times are expressed as floating point numbers, `time()` returns the most accurate time available (using Unix `gettimeofday()` where available), and `sleep()` will accept a time with a nonzero fraction (Unix `select()` is used to implement this, where available).

- The time value as returned by `gmtime()`, `localtime()`, and `strptime()`, and accepted by `asctime()`, `mktime()` and `strftime()`, may be considered as a sequence of 9 integers.
The return values of \texttt{gmtime()}, \texttt{localtime()}, and \texttt{strptime()} also offer attribute names for individual fields.

See \texttt{struct
time} for a description of these objects.

\textit{Changed in version 2.2:} The time value sequence was changed from a tuple to a \texttt{struct
time}, with the addition of attribute names for the fields.

- Use the following functions to convert between time representations:

<table>
<thead>
<tr>
<th>From</th>
<th>To</th>
<th>Use</th>
</tr>
</thead>
</table>
| seconds since the epoch     | \texttt{struct
time} in UTC    | \texttt{gmtime()} |
| seconds since the epoch     | \texttt{struct
time} in local time | \texttt{localtime()} |
| \texttt{struct
time} in UTC | seconds since the epoch          | \texttt{calendar.timegm()} |
| \texttt{struct
time} in local time | seconds since the epoch       | \texttt{mktime()} |

The module defines the following functions and data items:

\texttt{time.accept2dyear}

Boolean value indicating whether two-digit year values will be accepted. This is true by default, but will be set to false if the environment variable \texttt{PYTHONY2K} has been set to a non-empty string. It may also be modified at run time.

\texttt{time.altzone}

The offset of the local DST timezone, in seconds west of UTC, if one is defined. This is negative if the local DST timezone is east of UTC (as in Western Europe, including the UK). Only use this if
daylight is nonzero.

time.asctime([t])
Convert a tuple or struct_time representing a time as returned by gmtime() or localtime() to a 24-character string of the following form: 'Sun Jun 20 23:21:05 1993'. If t is not provided, the current time as returned by localtime() is used. Locale information is not used by asctime().

**Note:** Unlike the C function of the same name, there is no trailing newline.

*Changed in version 2.1:* Allowed t to be omitted.

time.clock()
On Unix, return the current processor time as a floating point number expressed in seconds. The precision, and in fact the very definition of the meaning of “processor time”, depends on that of the C function of the same name, but in any case, this is the function to use for benchmarking Python or timing algorithms.

On Windows, this function returns wall-clock seconds elapsed since the first call to this function, as a floating point number, based on the Win32 function QueryPerformanceCounter(). The resolution is typically better than one microsecond.

time.ctime([secs])
Convert a time expressed in seconds since the epoch to a string representing local time. If secs is not provided or None, the current time as returned by time() is used. ctime(secs) is equivalent to asctime(localtime(secs)). Locale information is not used by ctime().
Changed in version 2.1: Allowed secs to be omitted.

Changed in version 2.4: If secs is None, the current time is used.

time.daylight
Nonzero if a DST timezone is defined.

time.gmtime([secs])
Convert a time expressed in seconds since the epoch to a struct_time in UTC in which the dst flag is always zero. If secs is not provided or None, the current time as returned by time() is used. Fractions of a second are ignored. See above for a description of the struct_time object. See calendar.timegm() for the inverse of this function.

Changed in version 2.1: Allowed secs to be omitted.

Changed in version 2.4: If secs is None, the current time is used.

time.localtime([secs])
Like gmtime() but converts to local time. If secs is not provided or None, the current time as returned by time() is used. The dst flag is set to 1 when DST applies to the given time.

Changed in version 2.1: Allowed secs to be omitted.

Changed in version 2.4: If secs is None, the current time is used.

time.mktime(t)
This is the inverse function of localtime(). Its argument is the struct_time or full 9-tuple (since the dst flag is needed; use -1 as the dst flag if it is unknown) which expresses the time in local time, not UTC. It returns a floating point number, for compatibility with time(). If the input value cannot be represented as a valid
time, either `OverflowError` or `ValueError` will be raised (which depends on whether the invalid value is caught by Python or the underlying C libraries). The earliest date for which it can generate a time is platform-dependent.

**time.sleep(secs)**

Suspend execution for the given number of seconds. The argument may be a floating point number to indicate a more precise sleep time. The actual suspension time may be less than that requested because any caught signal will terminate the `sleep()` following execution of that signal's catching routine. Also, the suspension time may be longer than requested by an arbitrary amount because of the scheduling of other activity in the system.

**time.strftime(format[, t])**

Convert a tuple or `struct_time` representing a time as returned by `gmtime()` or `localtime()` to a string as specified by the `format` argument. If `t` is not provided, the current time as returned by `localtime()` is used. `format` must be a string. `ValueError` is raised if any field in `t` is outside of the allowed range.

*Changed in version 2.1:* Allowed `t` to be omitted.

*Changed in version 2.4:* `ValueError` raised if a field in `t` is out of range.

*Changed in version 2.5:* 0 is now a legal argument for any position in the time tuple; if it is normally illegal the value is forced to a correct one.

The following directives can be embedded in the `format` string. They are shown without the optional field width and precision specification, and are replaced by the indicated characters in the
### strftime() result:

<table>
<thead>
<tr>
<th>Directive</th>
<th>Meaning</th>
<th>Notes</th>
</tr>

<tr>
<td>%%</td>
<td>A literal '%' character.</td>
<td></td>
</tr>
</tbody>
</table>

Notes:

1. When used with the `strptime()` function, the `%p` directive only affects the output hour field if the `%I` directive is used to parse the hour.
2. The range really is 0 to 61; this accounts for leap seconds and the (very rare) double leap seconds.
3. When used with the `strptime()` function, `%u` and `%w` are only used in calculations when the day of the week and the year are specified.

Here is an example, a format for dates compatible with that specified in the RFC 2822 Internet email standard. [1]

```python
>>> from time import gmtime, strftime
>>> strftime("%a, %d %b %Y %H:%M:%S %z", gmtime())
'Thu, 28 Jun 2001 14:17:15 +0000'
```

Additional directives may be supported on certain platforms, but only the ones listed here have a meaning standardized by ANSI C.

On some platforms, an optional field width and precision specification can immediately follow the initial '%' of a directive in the following order; this is also not portable. The field width is normally 2 except for %j where it is 3.
time.strptime\(\text{string}[\text{, format}]\)\)

Parse a string representing a time according to a format. The return value is a \texttt{struct\_time} as returned by \texttt{gmtime()} or \texttt{localtime()}.

The \texttt{format} parameter uses the same directives as those used by \texttt{strftime()}; it defaults to "\texttt{%a %b %d %H:%M:%S %Y}" which matches the formatting returned by \texttt{ctime()}. If \texttt{string} cannot be parsed according to \texttt{format}, or if it has excess data after parsing, \texttt{ValueError} is raised. The default values used to fill in any missing data when more accurate values cannot be inferred are \texttt{(1900, 1, 1, 0, 0, 0, 0, 1, -1)}.

For example:

```python
>>> import time
>>> time.strptime("30 Nov 00", "%d %b %Y")  # doctest: +NORMALIZE_WHITESPACE
time.struct_time(tm_year=2000, tm_mon=11, tm_mday=30, tm_hour=0, tm_min=0, tm_sec=0, tm_wday=3, tm_yday=335, tm_isdst=-1)
```

Support for the \texttt{%z} directive is based on the values contained in \texttt{tzname} and whether \texttt{daylight} is true. Because of this, it is platform-specific except for recognizing UTC and GMT which are always known (and are considered to be non-daylight savings timezones).

Only the directives specified in the documentation are supported. Because \texttt{strftime()} is implemented per platform it can sometimes offer more directives than those listed. But \texttt{strptime()} is independent of any platform and thus does not necessarily support all directives available that are not documented as supported.

\texttt{class time.struct\_time}
The type of the time value sequence returned by `gmtime()`, `localtime()`, and `strptime()`. It is an object with a named tuple interface: values can be accessed by index and by attribute name. The following values are present:

<table>
<thead>
<tr>
<th>Index</th>
<th>Attribute</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><code>tm_year</code></td>
<td>(for example, 1993)</td>
</tr>
<tr>
<td>1</td>
<td><code>tm_mon</code></td>
<td>range [1, 12]</td>
</tr>
<tr>
<td>2</td>
<td><code>tm_mday</code></td>
<td>range [1, 31]</td>
</tr>
<tr>
<td>3</td>
<td><code>tm_hour</code></td>
<td>range [0, 23]</td>
</tr>
<tr>
<td>4</td>
<td><code>tm_min</code></td>
<td>range [0, 59]</td>
</tr>
<tr>
<td>5</td>
<td><code>tm_sec</code></td>
<td>range [0, 61]; see (1) in <code>strftime()</code> description</td>
</tr>
<tr>
<td>6</td>
<td><code>tm_wday</code></td>
<td>range [0, 6], Monday is 0</td>
</tr>
<tr>
<td>7</td>
<td><code>tm_yday</code></td>
<td>range [1, 366]</td>
</tr>
<tr>
<td>8</td>
<td><code>tm_isdst</code></td>
<td>0, 1 or -1; see below</td>
</tr>
</tbody>
</table>

*New in version 2.2.*

Note that unlike the C structure, the month value is a range of [1, 12], not [0, 11]. A year value will be handled as described under *Year 2000 (Y2K) issues* above. A `-1` argument as the daylight savings flag, passed to `mktime()` will usually result in the correct daylight savings state to be filled in.

When a tuple with an incorrect length is passed to a function expecting a `struct_time`, or having elements of the wrong type, a `TypeError` is raised.

`time.time()`  
Return the time as a floating point number expressed in seconds since the epoch, in UTC. Note that even though the time is always returned as a floating point number, not all systems provide time with a better precision than 1 second. While this
function normally returns non-decreasing values, it can return a lower value than a previous call if the system clock has been set back between the two calls.

**time.timezone**

The offset of the local (non-DST) timezone, in seconds west of UTC (negative in most of Western Europe, positive in the US, zero in the UK).

**time.tzname**

A tuple of two strings: the first is the name of the local non-DST timezone, the second is the name of the local DST timezone. If no DST timezone is defined, the second string should not be used.

**time.tzset()**

Resets the time conversion rules used by the library routines. The environment variable **TZ** specifies how this is done.

*New in version 2.3.*

Availability: Unix.

**Note:** Although in many cases, changing the **TZ** environment variable may affect the output of functions like `localtime()` without calling `tzset()`, this behavior should not be relied on. The **TZ** environment variable should contain no whitespace.

The standard format of the **TZ** environment variable is (whitespace added for clarity):

```
std offset [dst [offset [,start[/time], end[/time]]]]
```

Where the components are:

```
std and dst
```
Three or more alphanumerics giving the timezone abbreviations. These will be propagated into time.tzname

offset

The offset has the form: \( \pm \text{hh}[:\text{mm}[:\text{ss}]] \). This indicates the value added the local time to arrive at UTC. If preceded by a ‘-‘, the timezone is east of the Prime Meridian; otherwise, it is west. If no offset follows dst, summer time is assumed to be one hour ahead of standard time.

start[/time], end[/time]

Indicates when to change to and back from DST. The format of the start and end dates are one of the following:

\( Jn \)

The Julian day \( n \) (1 \( \leq \) \( n \) \( \leq \) 365). Leap days are not counted, so in all years February 28 is day 59 and March 1 is day 60.

\( n \)

The zero-based Julian day (0 \( \leq \) \( n \) \( \leq \) 365). Leap days are counted, and it is possible to refer to February 29.

\( Mm.n.d \)

The \( d \)’th day (0 \( \leq \) \( d \) \( \leq \) 6) or week \( n \) of month \( m \) of the year (1 \( \leq \) \( n \) \( \leq \) 5, 1 \( \leq \) \( m \) \( \leq \) 12, where week 5 means “the last \( d \) day in month \( m \)” which may occur in either the fourth or the fifth week). Week 1 is the first week in which the \( d \)’th day occurs. Day zero is Sunday.

time has the same format as offset except that no leading sign (‘-‘ or ‘+’) is allowed. The default, if time is not given, is 02:00:00.

```python
>>> os.environ[\'TZ\'] = \'EST+05EDT,M4.1.0,M10.5.0\'
>>> time.tzset()
>>> time.strftime(\'%X %x %Z\')
'02:07:36 05/08/03 EDT'
```
On many Unix systems (including *BSD, Linux, Solaris, and Darwin), it is more convenient to use the system’s zoneinfo (tzfile(5)) database to specify the timezone rules. To do this, set the TZ environment variable to the path of the required timezone datafile, relative to the root of the systems ‘zoneinfo’ timezone database, usually located at /usr/share/zoneinfo. For example, ‘US/Eastern’, ‘Australia/Melbourne', 'Egypt' or 'Europe/Amsterdam'.

See also:

**Module datetime**

More object-oriented interface to dates and times.

**Module locale**

Internationalization services. The locale settings can affect the return values for some of the functions in the time module.

**Module calendar**

General calendar-related functions. timegm() is the inverse of gmtime() from this module.
The use of %z is now deprecated, but the %z escape that expands to the preferred hour/minute offset is not supported by all ANSI C libraries. Also, a strict reading of the original 1982 RFC 822 standard calls for a two-digit year (%y rather than %Y), but practice moved to 4-digit years long before the year 2000. The 4-digit year has been mandated by RFC 2822, which obsoletes RFC 822.

[1] RFC 822 standard calls for a two-digit year (%y rather than %Y), but practice moved to 4-digit years long before the year 2000. The 4-digit year has been mandated by RFC 2822, which obsoletes RFC 822.
15.4. argparse — Parser for command-line options, arguments and sub-commands

New in version 2.7.

The argparse module makes it easy to write user-friendly command-line interfaces. The program defines what arguments it requires, and argparse will figure out how to parse those out of sys.argv. The argparse module also automatically generates help and usage messages and issues errors when users give the program invalid arguments.
15.4.1. Example

The following code is a Python program that takes a list of integers and produces either the sum or the max:

```python
import argparse

parser = argparse.ArgumentParser(description='Process some integers.

parser.add_argument("integers", metavar='N', type=int, nargs='+
    help='an integer for the accumulator')
parser.add_argument("--sum", dest='accumulate', action='store_const'
    const=sum, default=max,
    help='sum the integers (default: find the max)

args = parser.parse_args()
print(args.accumulate(args.integers))
```

Assuming the Python code above is saved into a file called `prog.py`, it can be run at the command line and provides useful help messages:

```
$ prog.py -h
usage: prog.py [-h] [--sum] N [N ...]

Process some integers.

positional arguments:
  N                  an integer for the accumulator

optional arguments:
  -h, --help         show this help message and exit
  --sum              sum the integers (default: find the max)
```

When run with the appropriate arguments, it prints either the sum or the max of the command-line integers:

```
$ prog.py 1 2 3 4
4
```
If invalid arguments are passed in, it will issue an error:

$ prog.py a b c
usage: prog.py [-h] [--sum] N [N ...]
prog.py: error: argument N: invalid int value: 'a'

The following sections walk you through this example.

## 15.4.1.1. Creating a parser

The first step in using the `argparse` is creating an `ArgumentParser` object:

```python
>>> parser = argparse.ArgumentParser(description='Process some integers.')
...```

The `ArgumentParser` object will hold all the information necessary to parse the command line into Python data types.

## 15.4.1.2. Adding arguments

Filling an `ArgumentParser` with information about program arguments is done by making calls to the `add_argument()` method. Generally, these calls tell the `ArgumentParser` how to take the strings on the command line and turn them into objects. This information is stored and used when `parse_args()` is called. For example:

```python
>>> parser.add_argument('integers', metavar='N', type=int, nargs='...',
                     help='an integer for the accumulator')
>>> parser.add_argument('--sum', dest='accumulate', action='store_const',
                     const=sum, default=max,
                     help='sum the integers (default: find the max)')
...```
Later, calling `parse_args()` will return an object with two attributes, `integers` and `accumulate`. The `integers` attribute will be a list of one or more ints, and the `accumulate` attribute will be either the `sum()` function, if `--sum` was specified at the command line, or the `max()` function if it was not.

### 15.4.1.3. Parsing arguments

`ArgumentParser` parses args through the `parse_args()` method. This will inspect the command line, convert each arg to the appropriate type and then invoke the appropriate action. In most cases, this means a simple namespace object will be built up from attributes parsed out of the command line:

```python
>>> parser.parse_args(['--sum', '7', '-1', '42'])
Namespace(accumulate=<built-in function sum>, integers=[7, -1, 42])
```

In a script, `parse_args()` will typically be called with no arguments, and the `ArgumentParser` will automatically determine the command-line args from `sys.argv`.
class argparse.ArgumentParser([description[, epilog[, prog][, usage][, add_help][, argument_default][, parents][, prefix_chars][, conflict_handler][, formatter_class]])

Create a new ArgumentParser object. Each parameter has its own more detailed description below, but in short they are:

- **description** - Text to display before the argument help.
- **epilog** - Text to display after the argument help.
- **add_help** - Add a -h/–help option to the parser. (default: True)
- **argument_default** - Set the global default value for arguments. (default: None)
- **parents** - A list of ArgumentParser objects whose arguments should also be included.
- **prefix_chars** - The set of characters that prefix optional arguments. (default: ‘-‘)
- **fromfile_prefix_chars** - The set of characters that prefix files from which additional arguments should be read. (default: None)
- **formatter_class** - A class for customizing the help output.
- **conflict_handler** - Usually unnecessary, defines strategy for resolving conflicting optionals.
- **prog** - The name of the program (default: sys.argv[0])
- **usage** - The string describing the program usage (default: generated)

The following sections describe how each of these are used.

15.4.2.1. description
Most calls to the `ArgumentParser` constructor will use the `description=` keyword argument. This argument gives a brief description of what the program does and how it works. In help messages, the description is displayed between the command-line usage string and the help messages for the various arguments:

```python
>>> parser = argparse.ArgumentParser(description='A foo that bars
usage: argparse.py [-h]

A foo that bars

optional arguments:
   -h, --help    show this help message and exit
```

By default, the description will be line-wrapped so that it fits within the given space. To change this behavior, see the `formatter_class` argument.

### 15.4.2.2. epilog

Some programs like to display additional description of the program after the description of the arguments. Such text can be specified using the `epilog=` argument to `ArgumentParser`:

```python
>>> parser = argparse.ArgumentParser(
...   description='A foo that bars',
...   epilog='And that's how you'd foo a bar')
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

optional arguments:
   -h, --help    show this help message and exit

And that's how you'd foo a bar
```
As with the description argument, the epilog= text is by default line-wrapped, but this behavior can be adjusted with the formatter_class argument to ArgumentParser.

15.4.2.3. add_help

By default, ArgumentParser objects add an option which simply displays the parser’s help message. For example, consider a file named myprogram.py containing the following code:

```python
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

If -h or --help is supplied at the command line, the ArgumentParser help will be printed:

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]
optional arguments:
  -h, --help    show this help message and exit
  --foo FOO     foo help
```

Occasionally, it may be useful to disable the addition of this help option. This can be achieved by passing False as the add_help= argument to ArgumentParser:

```python
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> parser.add_argument('--foo', help='foo help')
>>> parser.print_help()
usage: PROG [--foo FOO]
optional arguments:
  --foo FOO     foo help
```
The help option is typically `-h/--help`. The exception to this is if the `prefix_chars` is specified and does not include `'-'`, in which case `-h` and `--help` are not valid options. In this case, the first character in `prefix_chars` is used to prefix the help options:

```python
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='-+/
>>> parser.print_help()
usage: PROG [+h]
optional arguments:
  +h, ++help  show this help message and exit
```

### 15.4.2.4. prefix_chars

Most command-line options will use `'-'` as the prefix, e.g. `-f/--foo`. Parsers that need to support different or additional prefix characters, e.g. for options like `+f` or `/foo`, may specify them using the `prefix_chars` argument to the `ArgumentParser` constructor:

```python
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='-+/
>>> parser.add_argument('+f')
>>> parser.add_argument('++bar')
>>> parser.parse_args('+f X ++bar Y'.split())
Namespace(bar='Y', f='X')
```

The `prefix_chars` argument defaults to `'-'`. Supplying a set of characters that does not include `'-'` will cause `-f/--foo` options to be disallowed.

### 15.4.2.5. fromfile_prefix_chars

Sometimes, for example when dealing with a particularly long argument lists, it may make sense to keep the list of arguments in a file rather than typing it out at the command line. If the
The `fromfile_prefix_chars=` argument is given to the `ArgumentParser` constructor, then arguments that start with any of the specified characters will be treated as files, and will be replaced by the arguments they contain. For example:

```python
>>> with open('args.txt', 'w') as fp:
...     fp.write('-f
bar')
>>> parser = argparse.ArgumentParser(fromfile_prefix_chars='@')
>>> parser.add_argument('-f')
>>> parser.parse_args(['-f', 'foo', '@args.txt'])
Namespace(f='bar')
```

Arguments read from a file must by default be one per line (but see also `convert_arg_line_to_args()`) and are treated as if they were in the same place as the original file referencing argument on the command line. So in the example above, the expression `['-f', 'foo', '@args.txt']` is considered equivalent to the expression `['-f', 'foo', '-f', 'bar']`.

The `fromfile_prefix_chars=` argument defaults to `None`, meaning that arguments will never be treated as file references.

### 15.4.2.6. argument_default

Generally, argument defaults are specified either by passing a default to `add_argument()` or by calling the `set_defaults()` methods with a specific set of name-value pairs. Sometimes however, it may be useful to specify a single parser-wide default for arguments. This can be accomplished by passing the `argument_default=` keyword argument to `ArgumentParser`. For example, to globally suppress attribute creation on `parse_args()` calls, we supply `argument_default=argparse.SUPPRESS`:

```python
>>> parser = argparse.ArgumentParser(argument_default=argparse.SUPPRESS)
>>> parser.add_argument('--foo')
```
15.4.2.7. parents

Sometimes, several parsers share a common set of arguments. Rather than repeating the definitions of these arguments, a single parser with all the shared arguments and passed to `parents=` argument to `ArgumentParser` can be used. The `parents=` argument takes a list of `ArgumentParser` objects, collects all the positional and optional actions from them, and adds these actions to the `ArgumentParser` object being constructed:

```
>>> parent_parser = argparse.ArgumentParser(add_help=False)
>>> parent_parser.add_argument('--parent', type=int)

>>> foo_parser = argparse.ArgumentParser(parents=[parent_parser
>>> foo_parser.add_argument('foo')
>>> foo_parser.parse_args(['foo', 'bar', 'YYY']
Namespace(bar='YYY', parent=None)
```

Note that most parent parsers will specify `add_help=False`. Otherwise, the `ArgumentParser` will see two `-h/--help` options (one in the parent and one in the child) and raise an error.

**Note:** You must fully initialize the parsers before passing them via `parents=`. If you change the parent parsers after the child parser, those changes will not be reflected in the child.
15.4.2.8. formatter_class

ArgumentParser objects allow the help formatting to be customized by specifying an alternate formatting class. Currently, there are three such classes:

class argparse.RawDescriptionHelpFormatter
class argparse.RawTextHelpFormatter
class argparse.ArgumentDefaultsHelpFormatter

The first two allow more control over how textual descriptions are displayed, while the last automatically adds information about argument default values.

By default, ArgumentParser objects line-wrap the description and epilog texts in command-line help messages:

```python
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     description='''this description was indented weird
...     but that is okay''',
...     epilog='''
...     likewise for this epilog whose whitespace will be cleaned up and whose words will be wrapped across a couple lines''')
>>> parser.print_help()
usage: PROG [-h]

this description was indented weird but that is okay

optional arguments:
-h, --help   show this help message and exit

likewise for this epilog whose whitespace will be cleaned up and whose words will be wrapped across a couple lines
```

Passing RawDescriptionHelpFormatter as formatter_class= indicates that description and epilog are already correctly formatted and
should not be line-wrapped:

```python
>>> parser = argparse.ArgumentParser(
...    prog='PROG',
...    formatter_class=argparse.RawDescriptionHelpFormatter,
...    description=textwrap.dedent('''
...    Please do not mess up this text!
...    --------------------------------
...    I have indented it
...    exactly the way
...    I want it
...    '''))
>>> parser.print_help()
usage: PROG [-h]

Please do not mess up this text!
--------------------------------
    I have indented it
    exactly the way
    I want it

optional arguments:
    -h, --help    show this help message and exit

RawTextHelpFormatter maintains whitespace for all sorts of help text including argument descriptions.

The other formatter class available, ArgumentDefaultsHelpFormatter, will add information about the default value of each of the arguments:

```
15.4.2.9. **conflict_handler**

*ArgumentParser* objects do not allow two actions with the same option string. By default, *ArgumentParser* objects raises an exception if an attempt is made to create an argument with an option string that is already in use:

```bash
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
Traceback (most recent call last):
  ...
ArgumentError: argument --foo: conflicting option string(s): --foo
```

Sometimes (e.g. when using *parents*) it may be useful to simply override any older arguments with the same option string. To get this behavior, the value `'resolve'` can be supplied to the `conflict_handler=` argument of *ArgumentParser*:

```bash
>>> parser = argparse.ArgumentParser(prog='PROG', conflict_handler='resolve')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
>>> parser.print_help()
usage: PROG [-h] [-f FOO] [--foo FOO]

optional arguments:
  -h, --help    show this help message and exit
  -f FOO        old foo help
  --foo FOO     new foo help
```

Note that *ArgumentParser* objects only remove an action if all of its option strings are overridden. So, in the example above, the old `-f/-foo` action is retained as the `-f` action, because only the `--foo`
option string was overridden.

## 15.4.2.10. prog

By default, `ArgumentParser` objects uses `sys.argv[0]` to determine how to display the name of the program in help messages. This default is almost always desirable because it will make the help messages match how the program was invoked on the command line. For example, consider a file named `myprogram.py` with the following code:

```python
import argparse
parser = argparse.ArgumentParser()
parsed = parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

The help for this program will display `myprogram.py` as the program name (regardless of where the program was invoked from):

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

optional arguments:
  -h, --help    show this help message and exit
  --foo FOO    foo help
$ cd ..
$ python subdir\myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

optional arguments:
  -h, --help    show this help message and exit
  --foo FOO    foo help
```

To change this default behavior, another value can be supplied using the `prog=` argument to `ArgumentParser`:

```python
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.print_help()
usage: myprogram [-h]
```
optional arguments:
-h, --help    show this help message and exit

Note that the program name, whether determined from `sys.argv[0]` or from the `prog=` argument, is available to help messages using the `%(prog)s` format specifier.

```python
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.add_argument('--foo', help='foo of the %(prog)s program')
>>> parser.print_help()
usage: myprogram [-h] [--foo FOO]
optional arguments:
-h, --help    show this help message and exit
--foo FOO    foo of the myprogram program
```

**15.4.2.11. usage**

By default, *ArgumentParser* calculates the usage message from the arguments it contains:

```python
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [-h] [--foo [FOO]] bar [bar ...]
positional arguments:
bar          bar help
optional arguments:
-h, --help    show this help message and exit
--foo [FOO]   foo help
```

The default message can be overridden with the `usage=` keyword argument:

```python
>>> parser = argparse.ArgumentParser(prog='PROG', usage='%(prog)s [options]')
```
>>> parser.add_argument('--foo', nargs='?', help='foo help')

>>> parser.add_argument('bar', nargs='+', help='bar help')

>>> parser.print_help()

usage: PROG [options]

positional arguments:
    bar              bar help

optional arguments:
    -h, --help      show this help message and exit
    --foo [FOO]    foo help

The %(prog)s format specifier is available to fill in the program name in your usage messages.
15.4.3. The add_argument() method

```python
ArgumentParser.add_argument(name or flags..., action[, nargs[, const[, default[, type[, choices[, required[, help[, metavar[, dest]]]]]]]]])
```

Define how a single command-line argument should be parsed. Each parameter has its own more detailed description below, but in short they are:

- **name or flags** - Either a name or a list of option strings, e.g. `foo` or `-f, --foo`.
- **action** - The basic type of action to be taken when this argument is encountered at the command line.
- **nargs** - The number of command-line arguments that should be consumed.
- **const** - A constant value required by some `action` and `nargs` selections.
- **default** - The value produced if the argument is absent from the command line.
- **type** - The type to which the command-line argument should be converted.
- **choices** - A container of the allowable values for the argument.
- **required** - Whether or not the command-line option may be omitted (optionals only).
- **help** - A brief description of what the argument does.
- **metavar** - A name for the argument in usage messages.
- **dest** - The name of the attribute to be added to the object returned by `parse_args()`.

The following sections describe how each of these are used.
15.4.3.1. name or flags

The `add_argument()` method must know whether an optional argument, like `-f` or `--foo`, or a positional argument, like a list of filenames, is expected. The first arguments passed to `add_argument()` must therefore be either a series of flags, or a simple argument name. For example, an optional argument could be created like:

```python
>>> parser.add_argument('-f', '--foo')
```

while a positional argument could be created like:

```python
>>> parser.add_argument('bar')
```

When `parse_args()` is called, optional arguments will be identified by the `-` prefix, and the remaining arguments will be assumed to be positional:

```python
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args(['BAR'])
Namespace(bar='BAR', foo=None)
>>> parser.parse_args(['BAR', '--foo', 'FOO'])
Namespace(bar='BAR', foo='FOO')
>>> parser.parse_args(['--foo', 'FOO'])
usage: PROG [-h] [-f FOO] bar
PROG: error: too few arguments
```

15.4.3.2. action

`ArgumentParser` objects associate command-line args with actions. These actions can do just about anything with the command-line args associated with them, though most actions simply add an attribute to the object returned by `parse_args()`. The `action` keyword
argument specifies how the command-line args should be handled. The supported actions are:

- **'store'** - This just stores the argument's value. This is the default action. For example:

  ```python
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo')
  >>> parser.parse_args('--foo 1'.split())
  Namespace(foo='1')
  ```

- **'store_const'** - This stores the value specified by the `const` keyword argument. (Note that the `const` keyword argument defaults to the rather unhelpful `None`.) The 'store_const' action is most commonly used with optional arguments that specify some sort of flag. For example:

  ```python
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo', action='store_const', const=42)
  >>> parser.parse_args('--foo'.split())
  Namespace(foo=42)
  ```

- **'store_true'** and **'store_false'** - These store the values `True` and `False` respectively. These are special cases of 'store_const'. For example:

  ```python
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo', action='store_true')
  >>> parser.add_argument('--bar', action='store_false')
  >>> parser.parse_args('--foo --bar'.split())
  Namespace(bar=False, foo=True)
  ```

- **'append'** - This stores a list, and appends each argument value to the list. This is useful to allow an option to be specified multiple times. Example usage:

  ```python
  >>> parser = argparse.ArgumentParser()
  ```
>>> parser.add_argument('--foo', action='append')
>>> parser.parse_args('--foo 1 --foo 2'.split())
Namespace(foo=['1', '2'])

- **'append_const'** - This stores a list, and appends the value specified by the `const` keyword argument to the list. (Note that the `const` keyword argument defaults to `None`.) The 'append_const' action is typically useful when multiple arguments need to store constants to the same list. For example:

```python
>>> parser.add_argument('--str', dest='types', action='append_const')
>>> parser.add_argument('--int', dest='types', action='append_const')
>>> parser.parse_args('--str --int'.split())
Namespace(types=[<type 'str'>, <type 'int'>])
```

- **'version'** - This expects a `version` keyword argument in the `add_argument()` call, and prints version information and exits when invoked.

```python
>>> import argparse
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--version', action='version', version='PROG 2.0')
```

You can also specify an arbitrary action by passing an object that implements the Action API. The easiest way to do this is to extend `argparse.Action`, supplying an appropriate `__call__` method. The `__call__` method should accept four parameters:

- **parser** - The ArgumentParser object which contains this action.
- **namespace** - The namespace object that will be returned by `parse_args()`. Most actions add an attribute to this object.
- **values** - The associated command-line args, with any type-
conversions applied. (Type-conversions are specified with the `type` keyword argument to `add_argument()`.

- `option_string` - The option string that was used to invoke this action. The `option_string` argument is optional, and will be absent if the action is associated with a positional argument.

An example of a custom action:

```python
>>> class FooAction(argparse.Action):
...     def __call__(self, parser, namespace, values, option_string=None):
...         print '%r %r' % (namespace, values, option_string)
...         setattr(namespace, self.dest, values)
...      
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=FooAction)
>>> parser.add_argument('bar', action=FooAction)
>>> args = parser.parse_args('1 --foo a b'.split())
Namespace(bar='1', foo='2')
```

15.4.3.3. nargs

ArgumentParser objects usually associate a single command-line argument with a single action to be taken. The `nargs` keyword argument associates a different number of command-line arguments with a single action. The supported values are:

- N (an integer). N args from the command line will be gathered together into a list. For example:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs=2)
>>> parser.add_argument('bar', nargs=1)
>>> parser.parse_args('c --foo a b'.split())
Namespace(bar=['c'], foo=['a', 'b'])
```
Note that nargs=1 produces a list of one item. This is different from the default, in which the item is produced by itself.

- '?'. One arg will be consumed from the command line if possible, and produced as a single item. If no command-line arg is present, the value from default will be produced. Note that for optional arguments, there is an additional case - the option string is present but not followed by a command-line arg. In this case the value from const will be produced. Some examples to illustrate this:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='?', const='c', default='d')
>>> parser.parser.parse_args('XX --foo YY'.split())
Namespace(bar='XX', foo='YY')
>>> parser.parser.parse_args('XX --foo'.split())
Namespace(bar='XX', foo='c')
>>> parser.parser.parse_args(''.split())
Namespace(bar='d', foo='d')
```

One of the more common uses of nargs='?' is to allow optional input and output files:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', nargs='?', type=argparse.FileType(), default=sys.stdin)
>>> parser.add_argument('outfile', nargs='?', type=argparse.FileType(), default=sys.stdout)
>>> parser.parser.parse_args(['input.txt', 'output.txt'])
Namespace(infile=<open file 'input.txt', mode 'r' at 0x...>,
          outfile=<open file 'output.txt', mode 'w' at 0x...>)
>>> parser.parser.parse_args([])
Namespace(infile=<open file '<stdin>', mode 'r' at 0x...>,
          outfile=<open file '<stdout>', mode 'w' at 0x...>)
```

- '*'. All command-line args present are gathered into a list. Note that it generally doesn't make much sense to have more than
one positional argument with \texttt{nargs='*'}, but multiple optional arguments with \texttt{nargs='*'} is possible. For example:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='*')
>>> parser.add_argument('--bar', nargs='*')
>>> parser.add_argument('baz', nargs='*')
>>> parser.parse_args('a b --foo x y --bar 1 2'.split())
Namespace(bar=['1', '2'], baz=['a', 'b'], foo=['x', 'y'])
```

- `'+'`. Just like `'*'`, all command-line args present are gathered into a list. Additionally, an error message will be generated if there wasn’t at least one command-line arg present. For example:

```python
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', nargs='+')
>>> parser.parse_args('a b'.split())
Namespace(foo=['a', 'b'])
>>> parser.parse_args('').split())
usage: PROG [-h] foo [foo ...]
PROG: error: too few arguments
```

If the \texttt{nargs} keyword argument is not provided, the number of args consumed is determined by the \texttt{action}. Generally this means a single command-line arg will be consumed and a single item (not a list) will be produced.

### 15.4.3.4. const

The \texttt{const} argument of \texttt{add_argument()} is used to hold constant values that are not read from the command line but are required for the various \texttt{ArgumentParser} actions. The two most common uses of it are:

- When \texttt{add_argument()} is called with \texttt{action='store_const'} or \texttt{action='append_const'}. These actions add the \texttt{const} value to
one of the attributes of the object returned by `parse_args()`. See the action description for examples.

- When `add_argument()` is called with option strings (like `-f` or `--foo`) and `nargs='?'`. This creates an optional argument that can be followed by zero or one command-line args. When parsing the command line, if the option string is encountered with no command-line arg following it, the value of `const` will be assumed instead. See the `nargs` description for examples.

The `const` keyword argument defaults to `None`.

### 15.4.3.5. default

All optional arguments and some positional arguments may be omitted at the command line. The `default` keyword argument of `add_argument()`, whose value defaults to `None`, specifies what value should be used if the command-line arg is not present. For optional arguments, the `default` value is used when the option string was not present at the command line:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args('--foo 2'.split())
Namespace(foo='2')
>>> parser.parse_args('').split())
Namespace(foo=42)
```

For positional arguments with `nargs = '?` or `'*', the `default` value is used when no command-line arg was present:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', nargs='?', default=42)
>>> parser.parse_args('a'.split())
Namespace(foo='a')
>>> parser.parse_args('').split())
Namespace(foo=42)
```
Providing default=argparse.SUPPRESS causes no attribute to be added if the command-line argument was not present:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=argparse.SUPPRESS)
>>> parser.parse_args([])
Namespace()
>>> parser.parse_args(['--foo', '1'])
Namespace(foo='1')
```

### 15.4.3.6. type

By default, ArgumentParser objects read command-line args in as simple strings. However, quite often the command-line string should instead be interpreted as another type, like a float, int or file. The `type` keyword argument of `add_argument()` allows any necessary type-checking and type-conversions to be performed. Many common built-in types can be used directly as the value of the `type` argument:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.add_argument('bar', type=argparse.FileType('w'))
>>> parser.parse_args(['2', 'temp.txt'].split())
Namespace(bar=<open file 'temp.txt', mode 'r' at 0x...>, foo=2)
```

To ease the use of various types of files, the argparse module provides the factory `FileType` which takes the `mode=` and `bufsize=` arguments of the `file` object. For example, `FileType('w')` can be used to create a writable file:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar', type=argparse.FileType('w'))
>>> parser.parse_args(['out.txt'])
Namespace(bar=<open file 'out.txt', mode 'w' at 0x...>)
```

type= can take any callable that takes a single string argument and
returns the type-converted value:

```python
def perfect_square(string):
    value = int(string)
    sqrt = math.sqrt(value)
    if sqrt != int(sqrt):
        msg = "%r is not a perfect square" % string
        raise argparse.ArgumentTypeError(msg)
    return value
```

```python
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', type=perfect_square)
>>> parser.parse_args('9'.split())
Namespace(foo=9)
```

```python
>>> parser.parse_args('7'.split())
usage: PROG [-h] foo
PROG: error: argument foo: '7' is not a perfect square
```

The `choices` keyword argument may be more convenient for type checkers that simply check against a range of values:

```python
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', type=int, choices=xrange(5, 10))
>>> parser.parse_args('7'.split())
Namespace(foo=7)
```

```python
>>> parser.parse_args('11'.split())
usage: PROG [-h] {5,6,7,8,9}
PROG: error: argument foo: invalid choice: 11 (choose from 5, 6
```

See the `choices` section for more details.

### 15.4.3.7. choices

Some command-line args should be selected from a restricted set of values. These can be handled by passing a container object as the `choices` keyword argument to `add_argument()`. When the command line is parsed, arg values will be checked, and an error message will be displayed if the arg was not one of the acceptable values:

```python
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', choices=range(5, 10))
```
Note that inclusion in the `choices` container is checked after any `type` conversions have been performed, so the type of the objects in the `choices` container should match the `type` specified:

```python
>>> parser.add_argument('foo', choices='abc')
Namespace(foo='c')
>>> parser.parse_args('c'.split())
usage: PROG [-h] {a,b,c}
PROG: error: argument foo: invalid choice: 'X' (choose from 'a', 'b', 'c')
```

Any object that supports the `in` operator can be passed as the `choices` value, so `dict` objects, `set` objects, custom containers, etc. are all supported.

### 15.4.3.8. required

In general, the `argparse` module assumes that flags like `-f` and `--bar` indicate `optional` arguments, which can always be omitted at the command line. To make an option `required`, `True` can be specified for the `required=` keyword argument to `add_argument()`:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', required=True)
>>> parser.parse_args(['--foo', 'BAR'])
Namespace(foo='BAR')
>>> parser.parse_args([])
usage: argparse.py [-h] [--foo FOO]
argparse.py: error: option --foo is required
```
As the example shows, if an option is marked as required, parse_args() will report an error if that option is not present at the command line.

**Note:** Required options are generally considered bad form because users expect options to be optional, and thus they should be avoided when possible.

### 15.4.3.9. help

The help value is a string containing a brief description of the argument. When a user requests help (usually by using -h or --help at the command line), these help descriptions will be displayed with each argument:

```python
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', action='store_true',
... help='foo the bars before frobbling')
>>> parser.add_argument('bar', nargs='+',
... help='one of the bars to be frobbled')
>>> parser.parse_args('-h'.split())
usage: frobble [-h] [--foo] bar [bar ...]

positional arguments:
  bar    one of the bars to be frobbled

optional arguments:
  -h, --help  show this help message and exit
  --foo      foo the bars before frobbling
```

The help strings can include various format specifiers to avoid repetition of things like the program name or the argument default. The available specifiers include the program name, %prog, and most keyword arguments to add_argument(), e.g. %default, %type, etc.:

```python
>>> parser = argparse.ArgumentParser(prog='frobble')
```
15.4.3.10. metavar

When `ArgumentParser` generates help messages, it need some way to refer to each expected argument. By default, `ArgumentParser` objects use the `dest` value as the “name” of each object. By default, for positional argument actions, the `dest` value is used directly, and for optional argument actions, the `dest` value is uppercased. So, a single positional argument with `dest='bar'` will that argument will be referred to as `bar`. A single optional argument `--foo` that should be followed by a single command-line arg will be referred to as `foo`. An example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage: [-h] [--foo FOO] bar

positional arguments:
  bar

optional arguments:
  -h, --help    show this help message and exit
  --foo FOO
```

An alternative name can be specified with `metavar`:
Note that `metavar` only changes the *displayed* name - the name of the attribute on the `parse_args()` object is still determined by the `dest` value.

Different values of `nargs` may cause the metavar to be used multiple times. Providing a tuple to `metavar` specifies a different display for each of the arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', nargs=2)
>>> parser.add_argument('--foo', nargs=2, metavar=('bar', 'baz'))
>>> parser.print_help()
usage: PROG [-h] [-x X X] [--foo bar baz]
optional arguments:
  -h, --help        show this help message and exit
  -x X X
  --foo bar baz
```
positional argument actions, dest is normally supplied as the first argument to add_argument():

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar')
>>> parser.parse_args('XXX'.split())
Namespace(bar='XXX')
```

For optional argument actions, the value of dest is normally inferred from the option strings. ArgumentParser generates the value of dest by taking the first long option string and stripping away the initial '--' string. If no long option strings were supplied, dest will be derived from the first short option string by stripping the initial '-' character. Any internal '-' characters will be converted to '_' characters to make sure the string is a valid attribute name. The examples below illustrate this behavior:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('-f', '--foo-bar', '--foo')
>>> parser.add_argument('-x', '-y')
>>> parser.parse_args('-f 1 -x 2'.split())
Namespace(foo_bar='1', x='2')
>>> parser.parse_args('--foo 1 -y 2'.split())
Namespace(foo_bar='1', x='2')
```

dest allows a custom attribute name to be provided:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', dest='bar')
>>> parser.parse_args('--foo XXX'.split())
Namespace(bar='XXX')
```
15.4.4. The parse_args() method

ArgumentParser.parse_args(args=None, namespace=None)

Convert argument strings to objects and assign them as attributes of the namespace. Return the populated namespace.

Previous calls to add_argument() determine exactly what objects are created and how they are assigned. See the documentation for add_argument() for details.

By default, the arg strings are taken from sys.argv, and a new empty Namespace object is created for the attributes.

15.4.4.1. Option value syntax

The parse_args() method supports several ways of specifying the value of an option (if it takes one). In the simplest case, the option and its value are passed as two separate arguments:

```python
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('--foo')
>>> parser.parse_args ['-x X'.split())
Namespace(foo=None, x='X')
>>> parser.parse_args('--foo=FOO'.split())
Namespace(foo='FOO', x=None)
```

For long options (options with names longer than a single character), the option and value can also be passed as a single command-line argument, using = to separate them:

```python
>>> parser.parse_args('--foo=FOO'.split())
Namespace(foo='FOO', x=None)
```

For short options (options only one character long), the option and its
**value** can be concatenated:

```
>>> parser.parse_args('-xx'.split())
Namespace(foo=None, x='X')
```

Several short options can be joined together, using only a single `-` prefix, as long as only the last option (or none of them) requires a value:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', action='store_true')
>>> parser.add_argument('-y', action='store_true')
>>> parser.add_argument('-z')
>>> parser.parse_args('-xyzZ'.split())
Namespace(x=True, y=True, z='Z')
```

### 15.4.4.2. Invalid arguments

While parsing the command line, **parse_args()** checks for a variety of errors, including ambiguous options, invalid types, invalid options, wrong number of positional arguments, etc. When it encounters such an error, it exits and prints the error along with a usage message:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', nargs='?')

>>> # invalid type
>>> parser.parse_args(['--foo', 'spam'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: argument --foo: invalid int value: 'spam'

>>> # invalid option
>>> parser.parse_args(['--bar'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: no such option: --bar

>>> # wrong number of arguments
>>> parser.parse_args(['spam', 'badger'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: extra arguments found: badger
```
The `parse_args()` method attempts to give errors whenever the user has clearly made a mistake, but some situations are inherently ambiguous. For example, the command-line arg `-1` could either be an attempt to specify an option or an attempt to provide a positional argument. The `parse_args()` method is cautious here: positional arguments may only begin with `-` if they look like negative numbers and there are no options in the parser that look like negative numbers:

```python
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('foo', nargs='?')

>>> # no negative number options, so -1 is a positional argument
>>> parser.parse_args(['-x', '-1'])
Namespace(foo=None, x='-1')

>>> # no negative number options, so -1 and -5 are positional arguments
>>> parser.parse_args(['-x', '-1', '-5'])
Namespace(foo='-5', x='-1')

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-1', dest='one')
>>> parser.add_argument('foo', nargs='?')

>>> # negative number options present, so -1 is an option
>>> parser.parse_args(['-1', 'X'])
Namespace(foo=None, one='X')

>>> # negative number options present, so -2 is an option
>>> parser.parse_args(['-2'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: no such option: -2

>>> # negative number options present, so both -1s are options
>>> parser.parse_args(['-1', '-1'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: argument -1: expected one argument
If you have positional arguments that must begin with '--' and don't look like negative numbers, you can insert the pseudo-argument '--' which tells `parse_args()` that everything after that is a positional argument:

```python
>>> parser.parse_args(['--', '-f'])
Namespace(foo='-f', one=None)
```

### 15.4.4.4. Argument abbreviations

The `parse_args()` method allows long options to be abbreviated if the abbreviation is unambiguous:

```python
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-bacon')
>>> parser.add_argument('-badger')
>>> parser.parse_args('-bac MMM'.split())
Namespace(bacon='MMM', badger=None)
>>> parser.parse_args('-bad WOOD'.split())
Namespace(bacon=None, badger='WOOD')
```

An error is produced for arguments that could produce more than one options.

### 15.4.4.5. Beyond `sys.argv`

Sometimes it may be useful to have an ArgumentParser parse args other than those of `sys.argv`. This can be accomplished by passing a list of strings to `parse_args()`. This is useful for testing at the interactive prompt:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument(
```
15.4.4.6. The Namespace object

By default, `parse_args()` will return a new object of type `Namespace` where the necessary attributes have been set. This class is deliberately simple, just an `object` subclass with a readable string representation. If you prefer to have dict-like view of the attributes, you can use the standard Python idiom via `vars()`:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> args = parser.parse_args(['--foo', 'BAR'])
>>> vars(args)
{'foo': 'BAR'}
```

It may also be useful to have an `ArgumentParser` assign attributes to an already existing object, rather than a new `Namespace` object. This can be achieved by specifying the `namespace=` keyword argument:

```python
>>> class C(object):
...     pass
... >>> c = C()
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args(args=['--foo', 'BAR'], namespace=c)
>>> c.foo
'BAR'
```
15.4.5. Other utilities

15.4.5.1. Sub-commands

ArgumentParser.add_subparsers()

Many programs split up their functionality into a number of sub-commands, for example, the svn program can invoke sub-commands like svn checkout, svn update, and svn commit. Splitting up functionality this way can be a particularly good idea when a program performs several different functions which require different kinds of command-line arguments. ArgumentParser supports the creation of such sub-commands with the add_subparsers() method. The add_subparsers() method is normally called with no arguments and returns an special action object. This object has a single method, add_parser(), which takes a command name and any ArgumentParser constructor arguments, and returns an ArgumentParser object that can be modified as usual.

Some example usage:

```python
code
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', action='store_true', help='foo help')
>>> subparsers = parser.add_subparsers(help='sub-command help')
>>> # create the parser for the "a" command
>>> parser_a = subparsers.add_parser('a', help='a help')
>>> parser_a.add_argument('bar', type=int, help='bar help')
>>> # create the parser for the "b" command
>>> parser_b = subparsers.add_parser('b', help='b help')
>>> parser_b.add_argument('--baz', choices='XYZ', help='baz')
>>> # parse some arg lists
>>> parser.parse_args(['a', '12'])
```
Note that the object returned by `parse_args()` will only contain attributes for the main parser and the subparser that was selected by the command line (and not any other subparsers). So in the example above, when the "a" command is specified, only the `foo` and `bar` attributes are present, and when the "b" command is specified, only the `foo` and `baz` attributes are present.

Similarly, when a help message is requested from a subparser, only the help for that particular parser will be printed. The help message will not include parent parser or sibling parser messages. (A help message for each subparser command, however, can be given by supplying the `help` argument to `add_parser()` as above.)
```python
>>> parser.parse_args(['b', '--help'])
usage: PROG b [-h] [--baz {X,Y,Z}]

optional arguments:
    -h, --help    show this help message and exit
    --baz {X,Y,Z} baz help

The `add_subparsers()` method also supports `title` and `description` keyword arguments. When either is present, the subparser’s commands will appear in their own group in the help output. For example:

```python
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(title='subcommands',
...                                       description='valid subcommands',
...                                       help='additional help')
>>> subparsers.add_parser('foo')
>>> subparsers.add_parser('bar')
>>> parser.parse_args(['-h'])

optional arguments:
    -h, --help    show this help message and exit

subcommands:
    valid subcommands
        {foo,bar} additional help
```

One particularly effective way of handling sub-commands is to combine the use of the `add_subparsers()` method with calls to `set_defaults()` so that each subparser knows which Python function it should execute. For example:

```python
>>> # sub-command functions
>>> def foo(args):
...    print args.x * args.y
...>>> def bar(args):
...    print '(%s)' % args.z
...```
This way, you can let `parse_args()` do the job of calling the appropriate function after argument parsing is complete. Associating functions with actions like this is typically the easiest way to handle the different actions for each of your subparsers. However, if it is necessary to check the name of the subparser that was invoked, the dest keyword argument to the add_subparsers() call will work:
15.4.5.2. FileType objects

```
class argparse.FileType(mode='r', bufsize=None)
```

The `FileType` factory creates objects that can be passed to the type argument of `ArgumentParser.add_argument()`. Arguments that have `FileType` objects as their type will open command-line args as files with the requested modes and buffer sizes:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--output', type=argparse.FileType('wb'))
>>> parser.parse_args(['--output', 'out'])
Namespace(output=<open file 'out', mode 'wb' at 0x...>)
```

FileType objects understand the pseudo-argument `-` and automatically convert this into `sys.stdin` for readable `FileType` objects and `sys.stdout` for writable `FileType` objects:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', type=argparse.FileType('r'))
>>> parser.parse_args(['-'])
Namespace(infile=<open file '<stdin>', mode 'r' at 0x...>)
```

15.4.5.3. Argument groups

```
ArgumentParser.add_argument_group(title=None, description=None)
```

By default, `ArgumentParser` groups command-line arguments into “positional arguments” and “optional arguments” when displaying help messages. When there is a better conceptual grouping of arguments than this default one, appropriate groups can be created using the `add_argument_group()` method:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group = parser.add_argument_group('group')
```
The `add_argument_group()` method returns an argument group object which has an `add_argument()` method just like a regular `ArgumentParser`. When an argument is added to the group, the parser treats it just like a normal argument, but displays the argument in a separate group for help messages. The `add_argument_group()` method accepts `title` and `description` arguments which can be used to customize this display:

```python
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group1 = parser.add_argument_group('group1', 'group1 description')
>>> group1.add_argument('foo', help='foo help')
>>> group2 = parser.add_argument_group('group2', 'group2 description')
>>> group2.add_argument('--bar', help='bar help')
>>> parser.print_help()
usage: PROG [-h] [--bar BAR] foo

group1:
    group1 description
    foo  foo help

group2:
    group2 description
    --bar BAR  bar help
```

Note that any arguments not your user defined groups will end up back in the usual “positional arguments” and “optional arguments” sections.
15.4.5.4. Mutual exclusion

**argparse.add_mutually_exclusive_group**(required=False)

Create a mutually exclusive group. *argparse* will make sure that only one of the arguments in the mutually exclusive group was present on the command line:

```python
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group()
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args(['--foo'])
Namespace(bar=True, foo=True)
>>> parser.parse_args(['--bar'])
Namespace(bar=False, foo=False)
>>> parser.parse_args(['--foo', '--bar'])
usage: PROG [-h] [--foo | --bar]
PROG: error: argument --bar: not allowed with argument --foo
```

The *add_mutually_exclusive_group()* method also accepts a *required* argument, to indicate that at least one of the mutually exclusive arguments is required:

```python
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group(required=True)
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args([])
usage: PROG [-h] (--foo | --bar)
PROG: error: one of the arguments --foo --bar is required
```

Note that currently mutually exclusive argument groups do not support the *title* and *description* arguments of *add_argument_group()*.

15.4.5.5. Parser defaults
ArgumentParser.set_defaults(**kwargs)

Most of the time, the attributes of the object returned by parse_args() will be fully determined by inspecting the command-line args and the argument actions. set_defaults() allows some additional attributes that are determined without any inspection of the command line to be added:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.set_defaults(bar=42, baz='badger')
>>> parser.parse_args(['736'])
Namespace(bar=42, baz='badger', foo=736)
```

Note that parser-level defaults always override argument-level defaults:

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='bar')
>>> parser.set_defaults(foo='spam')
>>> parser.parse_args([])
Namespace(foo='spam')
```

Parser-level defaults can be particularly useful when working with multiple parsers. See the add_subparsers() method for an example of this type.

ArgumentParser.get_default(dest)

Get the default value for a namespace attribute, as set by either add_argument() or by set_defaults():

```python
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='badger')
>>> parser.get_default('foo')
'badger'
```
In most typical applications, `parse_args()` will take care of formatting and printing any usage or error messages. However, several formatting methods are available:

`ArgumentParser.print_usage(file=None)`

Print a brief description of how the `ArgumentParser` should be invoked on the command line. If `file` is `None`, `sys.stdout` is assumed.

`ArgumentParser.print_help(file=None)`

Print a help message, including the program usage and information about the arguments registered with the `ArgumentParser`. If `file` is `None`, `sys.stdout` is assumed.

There are also variants of these methods that simply return a string instead of printing it:

`ArgumentParser.format_usage()`

Return a string containing a brief description of how the `ArgumentParser` should be invoked on the command line.

`ArgumentParser.format_help()`

Return a string containing a help message, including the program usage and information about the arguments registered with the `ArgumentParser`.

### 15.4.5.7. Partial parsing

`ArgumentParser.parse_known_args(args=None, namespace=None)`

Sometimes a script may only parse a few of the command-line arguments, passing the remaining arguments on to another script or program. In these cases, the `parse_known_args()` method can be useful. It works much like `parse_args()` except that it does not
produce an error when extra arguments are present. Instead, it returns a two item tuple containing the populated namespace and the list of remaining argument strings.

```python
def parser = argparse.ArgumentParser()
parser.add_argument('--foo', action='store_true')
parser.add_argument('bar')
parser.parse_known_args(['--foo', '--badger', 'BAR', 'spam'])
```

15.4.5.8. Customizing file parsing

ArgumentParser.

```
convert_arg_line_to_args(arg_line)
```
Arguments that are read from a file (see the fromfile_prefix_chars keyword argument to the ArgumentParser constructor) are read one argument per line. convert_arg_line_to_args() can be overriden for fancier reading.

This method takes a single argument `arg_line` which is a string read from the argument file. It returns a list of arguments parsed from this string. The method is called once per line read from the argument file, in order.

A useful override of this method is one that treats each space-separated word as an argument:

```python
def convert_arg_line_to_args(self, arg_line):
   for arg in arg_line.split():
      if not arg.strip():
         continue
      yield arg
```

15.4.5.9. Exiting methods

ArgumentParser.

```
exit(status=0, message=None)
```
This method terminates the program, exiting with the specified
status and, if given, it prints a message before that.

ArgumentParser.error(message)

This method prints a usage message including the message to the standard output and terminates the program with a status code of 2.
15.4.6. Upgrading optparse code

Originally, the argparse module had attempted to maintain compatibility with optparse. However, optparse was difficult to extend transparently, particularly with the changes required to support the new nargs= specifiers and better usage messages. When most everything in optparse had either been copy-pasted over or monkey-patched, it no longer seemed practical to try to maintain the backwards compatibility.

A partial upgrade path from optparse to argparse:

- Replace all optparse.OptionParser.add_option() calls with ArgumentParser.add_argument() calls.
- Replace options, args = parser.parse_args() with args = parser.parse_args() and add additional ArgumentParser.add_argument() calls for the positional arguments.
- Replace callback actions and the callback_* keyword arguments with type or action arguments.
- Replace string names for type keyword arguments with the corresponding type objects (e.g. int, float, complex, etc).
- Replace strings with implicit arguments such as %default or %prog with the standard Python syntax to use dictionaries to format strings, that is, %(default)s and %(prog)s.
- Replace the OptionParser constructor version argument with a call to parser.add_argument('--version', action='version', version='<the version>')
15.5. optparse — Parser for command line options

*Deprecated since version 2.7:* The `optparse` module is deprecated and will not be developed further; development will continue with the `argparse` module.

*New in version 2.3.*

`optparse` is a more convenient, flexible, and powerful library for parsing command-line options than the old `getopt` module. `optparse` uses a more declarative style of command-line parsing: you create an instance of `OptionParser`, populate it with options, and parse the command line. `optparse` allows users to specify options in the conventional GNU/POSIX syntax, and additionally generates usage and help messages for you.

Here's an example of using `optparse` in a simple script:

```python
from optparse import OptionParser
...
parser = OptionParser()
parser.add_option("-f", "--file", dest="filename",
                 help="write report to FILE", metavar="FILE")
parser.add_option("-q", "--quiet",
                 action="store_false", dest="verbose",
                 default=True,
                 help="don't print status messages to stdout")

(options, args) = parser.parse_args()
```

With these few lines of code, users of your script can now do the "usual thing" on the command-line, for example:

```bash
<yourscript> --file=outfile -q
```
As it parses the command line, `optparse` sets attributes of the `options` object returned by `parse_args()` based on user-supplied command-line values. When `parse_args()` returns from parsing this command line, `options.filename` will be "outfile" and `options.verbose` will be `False`. `optparse` supports both long and short options, allows short options to be merged together, and allows options to be associated with their arguments in a variety of ways. Thus, the following command lines are all equivalent to the above example:

```plaintext
<yourscript> -f outfile --quiet
<yourscript> --quiet --file outfile
<yourscript> -q -outfile
<yourscript> -qfoutfile
```

Additionally, users can run one of

```plaintext
<yourscript> -h
<yourscript> --help
```

and `optparse` will print out a brief summary of your script's options:

```
Usage: <yourscript> [options]

Options:
  -h, --help                      show this help message and exit
  -f FILE, --file=FILE            write report to FILE
  -q, --quiet                     don't print status messages to stdout
```

where the value of `yourscript` is determined at runtime (normally from `sys.argv[0]`).
15.5.1. Background

optparse was explicitly designed to encourage the creation of programs with straightforward, conventional command-line interfaces. To that end, it supports only the most common command-line syntax and semantics conventionally used under Unix. If you are unfamiliar with these conventions, read this section to acquaint yourself with them.

15.5.1.1. Terminology

argument

a string entered on the command-line, and passed by the shell to `exec()` or `execv()`. In Python, arguments are elements of `sys.argv[1:]` (`sys.argv[0]` is the name of the program being executed). Unix shells also use the term “word”.

It is occasionally desirable to substitute an argument list other than `sys.argv[1:]`, so you should read “argument” as “an element of `sys.argv[1:]`, or of some other list provided as a substitute for `sys.argv[1:]`“.

option

an argument used to supply extra information to guide or customize the execution of a program. There are many different syntaxes for options; the traditional Unix syntax is a hyphen (“-“) followed by a single letter, e.g. `-x` or `-F`. Also, traditional Unix syntax allows multiple options to be merged into a single argument, e.g. `-x -F` is equivalent to `-xF`. The GNU project introduced `--` followed by a series of hyphen-separated words, e.g. `--file` or `--dry-run`. These are the only two option syntaxes provided by optparse.
Some other option syntaxes that the world has seen include:

- a hyphen followed by a few letters, e.g. `-pf` (this is not the same as multiple options merged into a single argument)
- a hyphen followed by a whole word, e.g. `-file` (this is technically equivalent to the previous syntax, but they aren’t usually seen in the same program)
- a plus sign followed by a single letter, or a few letters, or a word, e.g. `+f`, `+rgb`
- a slash followed by a letter, or a few letters, or a word, e.g. `/f`, `/file`

These option syntaxes are not supported by `optparse`, and they never will be. This is deliberate: the first three are non-standard on any environment, and the last only makes sense if you’re exclusively targeting VMS, MS-DOS, and/or Windows.

**option argument**

an argument that follows an option, is closely associated with that option, and is consumed from the argument list when that option is. With `optparse`, option arguments may either be in a separate argument from their option:

```
-f foo
--file foo
```

or included in the same argument:

```
-foo
--file=foo
```

Typically, a given option either takes an argument or it doesn’t. Lots of people want an “optional option arguments” feature, meaning that some options will take an argument if they see it, and won’t if they don’t. This is somewhat controversial, because it makes parsing ambiguous: if `-a` takes an optional argument and
-b is another option entirely, how do we interpret -ab? Because of this ambiguity, optparse does not support this feature.

positional argument
something leftover in the argument list after options have been parsed, i.e. after options and their arguments have been parsed and removed from the argument list.

required option
an option that must be supplied on the command-line; note that the phrase “required option” is self-contradictory in English. optparse doesn’t prevent you from implementing required options, but doesn’t give you much help at it either.

For example, consider this hypothetical command-line:

```bash
prog -v --report /tmp/report.txt foo bar
```

-v and --report are both options. Assuming that --report takes one argument, /tmp/report.txt is an option argument. foo and bar are positional arguments.

### 15.5.1.2. What are options for?

Options are used to provide extra information to tune or customize the execution of a program. In case it wasn’t clear, options are usually *optional*. A program should be able to run just fine with no options whatsoever. (Pick a random program from the Unix or GNU toolsets. Can it run without any options at all and still make sense? The main exceptions are *find*, *tar*, and *dd*—all of which are mutant oddballs that have been rightly criticized for their non-standard syntax and confusing interfaces.)

Lots of people want their programs to have “required options”. Think about it. If it’s required, then it’s *not optional*! If there is a piece of
information that your program absolutely requires in order to run successfully, that’s what positional arguments are for.

As an example of good command-line interface design, consider the humble `cp` utility, for copying files. It doesn’t make much sense to try to copy files without supplying a destination and at least one source. Hence, `cp` fails if you run it with no arguments. However, it has a flexible, useful syntax that does not require any options at all:

```
cp SOURCE DEST
cp SOURCE ... DEST-DIR
```

You can get pretty far with just that. Most `cp` implementations provide a bunch of options to tweak exactly how the files are copied: you can preserve mode and modification time, avoid following symlinks, ask before clobbering existing files, etc. But none of this distracts from the core mission of `cp`, which is to copy either one file to another, or several files to another directory.

### 15.5.1.3. What are positional arguments for?

Positional arguments are for those pieces of information that your program absolutely, positively requires to run.

A good user interface should have as few absolute requirements as possible. If your program requires 17 distinct pieces of information in order to run successfully, it doesn’t much matter *how* you get that information from the user—most people will give up and walk away before they successfully run the program. This applies whether the user interface is a command-line, a configuration file, or a GUI: if you make that many demands on your users, most of them will simply give up.

In short, try to minimize the amount of information that users are absolutely required to supply—use sensible defaults whenever
possible. Of course, you also want to make your programs reasonably flexible. That’s what options are for. Again, it doesn’t matter if they are entries in a config file, widgets in the “Preferences” dialog of a GUI, or command-line options—the more options you implement, the more flexible your program is, and the more complicated its implementation becomes. Too much flexibility has drawbacks as well, of course; too many options can overwhelm users and make your code much harder to maintain.
15.5.2. Tutorial

While **optparse** is quite flexible and powerful, it’s also straightforward to use in most cases. This section covers the code patterns that are common to any **optparse**-based program.

First, you need to import the OptionParser class; then, early in the main program, create an OptionParser instance:

```python
from optparse import OptionParser
...
parser = OptionParser()
```

Then you can start defining options. The basic syntax is:

```python
parser.add_option(opt_str, ..., attr=value, ...)
```

Each option has one or more option strings, such as `--file`, and several option attributes that tell **optparse** what to expect and what to do when it encounters that option on the command line.

Typically, each option will have one short option string and one long option string, e.g.:

```python
parser.add_option("-f", "--file", ...)
```

You’re free to define as many short option strings and as many long option strings as you like (including zero), as long as there is at least one option string overall.

The option strings passed to **add_option()** are effectively labels for the option defined by that call. For brevity, we will frequently refer to encountering an option on the command line; in reality, **optparse**
encounters *option strings* and looks up options from them.

Once all of your options are defined, instruct **optparse** to parse your program’s command line:

```python
(options, args) = parser.parse_args()
```

(If you like, you can pass a custom argument list to `parse_args()`, but that's rarely necessary: by default it uses `sys.argv[1:]`.)

`parse_args()` returns two values:

- **options**, an object containing values for all of your options—e.g. if `--file` takes a single string argument, then `options.file` will be the filename supplied by the user, or `None` if the user did not supply that option
- **args**, the list of positional arguments leftover after parsing options

This tutorial section only covers the four most important option attributes: **action**, **type**, **dest** (destination), and **help**. Of these, **action** is the most fundamental.

### 15.5.2.1. Understanding option actions

Actions tell **optparse** what to do when it encounters an option on the command line. There is a fixed set of actions hard-coded into **optparse**; adding new actions is an advanced topic covered in section *Extending optparse*. Most actions tell **optparse** to store a value in some variable—for example, take a string from the command line and store it in an attribute of **options**.

If you don’t specify an option action, **optparse** defaults to **store**.
15.5.2.2. The store action

The most common option action is `store`, which tells `optparse` to take the next argument (or the remainder of the current argument), ensure that it is of the correct type, and store it to your chosen destination.

For example:

```python
parser.add_option("-f", "--file", action="store", type="string", dest="filename")
```

Now let's make up a fake command line and ask `optparse` to parse it:

```python
args = ["-f", "foo.txt"]
(options, args) = parser.parse_args(args)
```

When `optparse` sees the option string `-f`, it consumes the next argument, `foo.txt`, and stores it in `options.filename`. So, after this call to `parse_args()`, `options.filename` is "foo.txt".

Some other option types supported by `optparse` are `int` and `float`. Here's an option that expects an integer argument:

```python
parser.add_option("-n", type="int", dest="num")
```

Note that this option has no long option string, which is perfectly acceptable. Also, there's no explicit action, since the default is `store`.

Let's parse another fake command-line. This time, we'll jam the option argument right up against the option: since `-n42` (one argument) is equivalent to `-n 42` (two arguments), the code
(options, args) = parser.parse_args(['-n42'])
print options.num

will print 42.

If you don't specify a type, `optparse` assumes `string`. Combined with the fact that the default action is `store`, that means our first example can be a lot shorter:

```python
parser.add_option("-f", "--file", dest="filename")
```

If you don't supply a destination, `optparse` figures out a sensible default from the option strings: if the first long option string is `--foo-bar`, then the default destination is `foo_bar`. If there are no long option strings, `optparse` looks at the first short option string: the default destination for `-f` is `f`.

`optparse` also includes built-in `long` and `complex` types. Adding types is covered in section `Extending optparse`.

### 15.5.2.3. Handling boolean (flag) options

Flag options—set a variable to true or false when a particular option is seen—are quite common. `optparse` supports them with two separate actions, `store_true` and `store_false`. For example, you might have a `verbose` flag that is turned on with `-v` and off with `-q`:

```python
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose")
```

Here we have two different options with the same destination, which is perfectly OK. (It just means you have to be a bit careful when setting default values—see below.)
When `optparse` encounters `-v` on the command line, it sets `options.verbose` to `True`; when it encounters `-q`, `options.verbose` is set to `False`.

### 15.5.2.4. Other actions

Some other actions supported by `optparse` are:

- **"store_const"**
  store a constant value
- **"append"**
  append this option's argument to a list
- **"count"**
  increment a counter by one
- **"callback"**
  call a specified function

These are covered in section *Reference Guide*, Reference Guide and section *Option Callbacks*.

### 15.5.2.5. Default values

All of the above examples involve setting some variable (the “destination”) when certain command-line options are seen. What happens if those options are never seen? Since we didn’t supply any defaults, they are all set to `None`. This is usually fine, but sometimes you want more control. `optparse` lets you supply a default value for each destination, which is assigned before the command line is parsed.

First, consider the `verbose/quiet` example. If we want `optparse` to set `verbose` to `True` unless `-q` is seen, then we can do this:

```python
parser.add_option("-v", action="store_true", dest="verbose", de"
Since default values apply to the destination rather than to any particular option, and these two options happen to have the same destination, this is exactly equivalent:

```python
parser.add_option("-q", action="store_false", dest="verbose")
parser.add_option("-v", action="store_true", dest="verbose")
```

Consider this:

```python
parser.add_option("-v", action="store_true", dest="verbose")
parser.add_option("-q", action="store_false", dest="verbose", default=True)
```

Again, the default value for verbose will be True: the last default value supplied for any particular destination is the one that counts.

A clearer way to specify default values is the set_defaults() method of OptionParser, which you can call at any time before calling parse_args():

```python
parser.set_defaults(verbos=True)
parser.add_option(...)
(options, args) = parser.parse_args()
```

As before, the last value specified for a given option destination is the one that counts. For clarity, try to use one method or the other of setting default values, not both.

### 15.5.2.6. Generating help

Optparse's ability to generate help and usage text automatically is useful for creating user-friendly command-line interfaces. All you have to do is supply a help value for each option, and optionally a
short usage message for your whole program. Here's an OptionParser populated with user-friendly (documented) options:

```python
usage = "usage: %prog [options] arg1 arg2"
parser = OptionParser(usage=usage)
parser.add_option("-v", "--verbose",
                action="store_true", dest="verbose", default="make lots of noise [default]"
parser.add_option("-q", "--quiet",
                action="store_false", dest="verbose",
                help="be vewwy quiet (I'm hunting wabbits)"
parser.add_option("-f", "--filename",
                metavar="FILE", help="write output to FILE"
parser.add_option("-m", "--mode",
                default="intermediate",
                help="interaction mode: novice, intermediate, expert [default: intermediate"
```

If `optparse` encounters either `-h` or `--help` on the command-line, or if you just call `parser.print_help()`, it prints the following to standard output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help          show this help message and exit
  -v, --verbose       make lots of noise [default]
  -q, --quiet         be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE
      write output to FILE
  -m MODE, --mode=MODE interaction mode: novice, intermediate, expert [default: intermediate
```

(If the help output is triggered by a help option, `optparse` exits after printing the help text.)

There's a lot going on here to help `optparse` generate the best possible help message:
• the script defines its own usage message:

```python
usage = "usage: %prog [options] arg1 arg2"
```

`optparse` expands `%prog` in the usage string to the name of the current program, i.e. `os.path.basename(sys.argv[0])`. The expanded string is then printed before the detailed option help.

If you don’t supply a usage string, `optparse` uses a bland but sensible default: "Usage: %prog [options]", which is fine if your script doesn’t take any positional arguments.

• every option defines a help string, and doesn’t worry about line-wrapping—`optparse` takes care of wrapping lines and making the help output look good.

• options that take a value indicate this fact in their automatically-generated help message, e.g. for the “mode” option:

```bash
-m MODE, --mode=MODE
```

Here, “MODE” is called the meta-variable: it stands for the argument that the user is expected to supply to `-m/--mode`. By default, `optparse` converts the destination variable name to uppercase and uses that for the meta-variable. Sometimes, that’s not what you want—for example, the `--filename` option explicitly sets `metavar="FILE"`, resulting in this automatically-generated option description:

```bash
-f FILE, --filename=FILE
```

This is important for more than just saving space, though: the manually written help text uses the meta-variable `FILE` to clue the user in that there’s a connection between the semi-formal
syntax `-f FILE` and the informal semantic description “write output to FILE”. This is a simple but effective way to make your help text a lot clearer and more useful for end users.

*New in version 2.4:* Options that have a default value can include `%default` in the help string—`optparse` will replace it with `str()` of the option’s default value. If an option has no default value (or the default value is `None`), `%default` expands to `none`.

### 15.5.2.6.1. Grouping Options

When dealing with many options, it is convenient to group these options for better help output. An `OptionParser` can contain several option groups, each of which can contain several options.

An option group is obtained using the class `OptionGroup`:

```python
class optparse.OptionGroup(parser, title, description=None)
```

where

- parser is the `OptionParser` instance the group will be inserted into
- title is the group title
- description, optional, is a long description of the group

`OptionGroup` inherits from `OptionContainer` (like `OptionParser`) and so the `add_option()` method can be used to add an option to the group.

Once all the options are declared, using the `OptionParser` method `add_option_group()` the group is added to the previously defined parser.

Continuing with the parser defined in the previous section, adding an
**OptionGroup** to a parser is easy:

```python
group = OptionGroup(parser, "Dangerous Options",
    "Caution: use these options at your own risk
    "It is believed that some of them bite.")
group.add_option("-g", action="store_true", help="Group option.
parser.add_option_group(group)
```

This would result in the following help output:

```
Usage: <yourscript> [options] arg1 arg2
Options:
  -h, --help                      show this help message and exit
  -v, --verbose                  make lots of noise [default]
  -q, --quiet                    be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE       write output to FILE
  -m MODE, --mode=MODE           interaction mode: novice, intermediate, expert [default: intermediate]

Dangerous Options:
  Caution: use these options at your own risk. It is believed
  of them bite.
  
  -g                            Group option.
```

A bit more complete example might invoke using more than one

```python
group = OptionGroup(parser, "Dangerous Options",
    "Caution: use these options at your own risk
    "It is believed that some of them bite.")
group.add_option("-g", action="store_true", help="Group option.
parser.add_option_group(group)
```

```python
group = OptionGroup(parser, "Debug Options")
group.add_option("-d", "--debug", action="store_true",
    help="Print debug information")
group.add_option("-s", "--sql", action="store_true",
    help="Print all SQL statements executed")
group.add_option("-e", action="store_true", help="Print every a
```
that results in the following output:

```
Usage: <yourscript> [options] arg1 arg2

Options:
  -h, --help            show this help message and exit
  -v, --verbose         make lots of noise [default]
  -q, --quiet           be vewwy quiet (I'm hunting wabbits)
  -f FILE, --filename=FILE write output to FILE
  -m MODE, --mode=MODE  interaction mode: novice, intermediate, [default: intermediate]

Dangerous Options:
  Caution: use these options at your own risk. It is believe of them bite.

  -g                      Group option.

Debug Options:
  -d, --debug             Print debug information
  -s, --sql               Print all SQL statements executed
  -e                      Print every action done
```

Another interesting method, in particular when working programmatically with option groups is:

```
OptionParser.get_option_group(opt_str)
```

Return, if defined, the `OptionGroup` that has the title or the long description equals to `opt_str`

### 15.5.2.7. Printing a version string

Similar to the brief usage string, `optparse` can also print a version string for your program. You have to supply the string as the `version` argument to OptionParser:
parser = OptionParser(usage="%prog [-f] [-q]", version="%prog 1.0")

%prog is expanded just like it is in usage. Apart from that, version can contain anything you like. When you supply it, optparse automatically adds a --version option to your parser. If it encounters this option on the command line, it expands your version string (by replacing %prog), prints it to stdout, and exits.

For example, if your script is called /usr/bin/foo:

```
$ /usr/bin/foo --version
foo 1.0
```

The following two methods can be used to print and get the version string:

OptionParser.print_version(file=None)

Print the version message for the current program (self.version) to file (default stdout). As with print_usage(), any occurrence of %prog in self.version is replaced with the name of the current program. Does nothing if self.version is empty or undefined.

OptionParser.get_version()

Same as print_version() but returns the version string instead of printing it.

15.5.2.8. How optparse handles errors

There are two broad classes of errors that optparse has to worry about: programmer errors and user errors. Programmer errors are usually erroneous calls to OptionParser.add_option(), e.g. invalid option strings, unknown option attributes, missing option attributes, etc. These are dealt with in the usual way: raise an exception (either
optparse.OptionError or TypeError) and let the program crash.

Handling user errors is much more important, since they are guaranteed to happen no matter how stable your code is. optparse can automatically detect some user errors, such as bad option arguments (passing \texttt{-n 4x} where \texttt{-n} takes an integer argument), missing arguments (\texttt{-n} at the end of the command line, where \texttt{-n} takes an argument of any type). Also, you can call \texttt{OptionParser.error()} to signal an application-defined error condition:

\begin{verbatim}
(options, args) = parser.parse_args()
[...]
if options.a and options.b:
    parser.error("options -a and -b are mutually exclusive")
\end{verbatim}

In either case, \texttt{optparse} handles the error the same way: it prints the program’s usage message and an error message to standard error and exits with error status 2.

Consider the first example above, where the user passes \texttt{4x} to an option that takes an integer:

\begin{verbatim}
$ /usr/bin/foo -n 4x
Usage: foo [options]
foo: error: option -n: invalid integer value: '4x'
\end{verbatim}

Or, where the user fails to pass a value at all:

\begin{verbatim}
$ /usr/bin/foo -n
Usage: foo [options]
foo: error: -n option requires an argument
\end{verbatim}

\texttt{optparse}-generated error messages take care always to mention the option involved in the error; be sure to do the same when calling
OptionParser.error() from your application code.

If optparse's default error-handling behaviour does not suit your needs, you'll need to subclass OptionParser and override its exit() and/or error() methods.

15.5.2.9. Putting it all together

Here's what optparse-based scripts usually look like:

```python
from optparse import OptionParser

def main():
    usage = "usage: %prog [options] arg"
    parser = OptionParser(usage)
    parser.add_option("-f", "--file", dest="filename",
                      help="read data from FILENAME")
    parser.add_option("-v", "--verbose",
                      action="store_true", dest="verbose")
    parser.add_option("-q", "--quiet",
                      action="store_false", dest="verbose")

    (options, args) = parser.parse_args()
    if len(args) != 1:
        parser.error("incorrect number of arguments")
    if options.verbose:
        print "reading %s..." % options.filename

if __name__ == "__main__":
    main()
```
The first step in using `optparse` is to create an `OptionParser` instance.

```python
class optparse.OptionParser(...)
```

The `OptionParser` constructor has no required arguments, but a number of optional keyword arguments. You should always pass them as keyword arguments, i.e. do not rely on the order in which the arguments are declared.

**usage** (default: "%prog [options]"

The usage summary to print when your program is run incorrectly or with a help option. When `optparse` prints the usage string, it expands `%prog` to `os.path.basename(sys.argv[0])` (or to `prog` if you passed that keyword argument). To suppress a usage message, pass the special value `optparse.SUPPRESS_USAGE`.

**option_list** (default: [])

A list of `Option` objects to populate the parser with. The options in `option_list` are added after any options in `standard_option_list` (a class attribute that may be set by `OptionParser` subclasses), but before any version or help options. Deprecated; use `add_option()` after creating the parser instead.

**option_class** (default: `optparse.Option`)

Class to use when adding options to the parser in `add_option()`.
version (default: None)

A version string to print when the user supplies a version option. If you supply a true value for version, optparse automatically adds a version option with the single option string --version. The substring %prog is expanded the same as for usage.

conflict_handler (default: "error")

Specifies what to do when options with conflicting option strings are added to the parser; see section Conflicts between options.

description (default: None)

A paragraph of text giving a brief overview of your program. optparse reformats this paragraph to fit the current terminal width and prints it when the user requests help (after usage, but before the list of options).

formatter (default: a new IndentedHelpFormatter)

An instance of optparse.HelpFormatter that will be used for printing help text. optparse provides two concrete classes for this purpose: IndentedHelpFormatter and TitledHelpFormatter.

add_help_option (default: True)

If true, optparse will add a help option (with option strings -h and --help) to the parser.

prog

The string to use when expanding %prog in usage and version instead of os.path.basename(sys.argv[0]).

epilog (default: None)

A paragraph of help text to print after the option help.
15.5.3.2. Populating the parser

There are several ways to populate the parser with options. The preferred way is by using `OptionParser.add_option()`, as shown in section Tutorial. `add_option()` can be called in one of two ways:

- pass it an Option instance (as returned by `make_option()`)
- pass it any combination of positional and keyword arguments that are acceptable to `make_option()` (i.e., to the Option constructor), and it will create the Option instance for you

The other alternative is to pass a list of pre-constructed Option instances to the OptionParser constructor, as in:

```python
option_list = [
    make_option("-f", "--filename",
        action="store", type="string", dest="filename"),
    make_option("-q", "--quiet",
        action="store_false", dest="verbose"),
]
parser = OptionParser(option_list=option_list)
```

(`make_option()` is a factory function for creating Option instances; currently it is an alias for the Option constructor. A future version of `optparse` may split Option into several classes, and `make_option()` will pick the right class to instantiate. Do not instantiate Option directly.)

15.5.3.3. Defining options

Each Option instance represents a set of synonymous command-line option strings, e.g. `-f` and `--file`. You can specify any number of short or long option strings, but you must specify at least one overall option string.
The canonical way to create an Option instance is with the `add_option()` method of `OptionParser`.

```
OptionParser.add_option(opt_str[, ...], attr=value, ...)
```

To define an option with only a short option string:

```
parser.add_option("-f", attr=value, ...)
```

And to define an option with only a long option string:

```
parser.add_option("--foo", attr=value, ...)
```

The keyword arguments define attributes of the new Option object. The most important option attribute is `action`, and it largely determines which other attributes are relevant or required. If you pass irrelevant option attributes, or fail to pass required ones, `optparse` raises an `OptionError` exception explaining your mistake.

An option's `action` determines what `optparse` does when it encounters this option on the command-line. The standard option actions hard-coded into `optparse` are:

- "store"
  - store this option's argument (default)
- "store_const"
  - store a constant value
- "store_true"
  - store a true value
- "store_false"
  - store a false value
- "append"
append this option’s argument to a list
"append_const"
append a constant value to a list
"count"
increment a counter by one
"callback"
call a specified function
"help"
print a usage message including all options and the documentation for them

(If you don’t supply an action, the default is "store". For this action, you may also supply type and dest option attributes; see Standard option actions.)

As you can see, most actions involve storing or updating a value somewhere. optparse always creates a special object for this, conventionally called options (it happens to be an instance of optparse.Values). Option arguments (and various other values) are stored as attributes of this object, according to the dest (destination) option attribute.

For example, when you call

```python
caller.parse_args()
```

one of the first things optparse does is create the options object:

```python
options = Values()
```

If one of the options in this parser is defined with

```python
caller.add_option("-f", "--file", action="store", type="string"
```

...
and the command-line being parsed includes any of the following:

```
-f foo
-f foo
--file=foo
--file foo
```

then `optparse`, on seeing this option, will do the equivalent of

```
options.filename = "foo"
```

The `type` and `dest` option attributes are almost as important as `action`, but `action` is the only one that makes sense for all options.

### 15.5.3.4. Option attributes

The following option attributes may be passed as keyword arguments to `OptionParser.add_option()`. If you pass an option attribute that is not relevant to a particular option, or fail to pass a required option attribute, `optparse` raises `OptionError`.

**Option. action**

(default: "store")

Determines `optparse`'s behaviour when this option is seen on the command line; the available options are documented `here`.

**Option. type**

(default: "string")

The argument type expected by this option (e.g., "string" or "int"); the available option types are documented `here`.

**Option. dest**

(default: derived from option strings)
If the option’s action implies writing or modifying a value somewhere, this tells optparse where to write it: `dest` names an attribute of the `options` object that optparse builds as it parses the command line.

**Option. default**

The value to use for this option’s destination if the option is not seen on the command line. See also `OptionParser.set_defaults()`.

**Option. nargs**

(default: 1)

How many arguments of type `type` should be consumed when this option is seen. If > 1, optparse will store a tuple of values to `dest`.

**Option. const**

For actions that store a constant value, the constant value to store.

**Option. choices**

For options of type "choice", the list of strings the user may choose from.

**Option. callback**

For options with action "callback", the callable to call when this option is seen. See section `Option Callbacks` for detail on the arguments passed to the callable.

**Option. callback_args**

**Option. callback_kwargs**

Additional positional and keyword arguments to pass to `callback` after the four standard callback arguments.
Option. **help**

Help text to print for this option when listing all available options after the user supplies a `help` option (such as `--help`). If no help text is supplied, the option will be listed without help text. To hide this option, use the special value `optparse.SUPPRESS_HELP`.

Option. **metavar**

(default: derived from option strings)

Stand-in for the option argument(s) to use when printing help text. See section *Tutorial* for an example.

### 15.5.3.5. Standard option actions

The various option actions all have slightly different requirements and effects. Most actions have several relevant option attributes which you may specify to guide *optparse*‘s behaviour; a few have required attributes, which you must specify for any option using that action.

- **"store"** [relevant: `type`, `dest`, `nargs`, `choices`]

  The option must be followed by an argument, which is converted to a value according to `type` and stored in `dest`. If `nargs > 1`, multiple arguments will be consumed from the command line; all will be converted according to `type` and stored to `dest` as a tuple. See the *Standard option types* section.

  If `choices` is supplied (a list or tuple of strings), the type defaults to "choice".

  If `type` is not supplied, it defaults to "string".

  If `dest` is not supplied, *optparse* derives a destination from the first long option string (e.g., `--foo-bar` implies `foo_bar`). If there
are no long option strings, **optparse** derives a destination from the first short option string (e.g., `-f` implies `f`).

Example:

```python
parser.add_option("-f")
p_info.add_option("-p", type="float", nargs=3, dest="point")
```

As it parses the command line

```bash
-f foo.txt -p 1 -3.5 4 -fbar.txt
```

**optparse** will set

```python
options.f = "foo.txt"
options.point = (1.0, -3.5, 4.0)
options.f = "bar.txt"
```

- **"store_const"** [required: `const`; relevant: `dest`]

  The value `const` is stored in `dest`.

  Example:

```python
parser.add_option("-q", "--quiet",
    action="store_const", const=0, dest="verb")
parser.add_option("-v", "--verbose",
    action="store_const", const=1, dest="verb")
parser.add_option("--noisy",
    action="store_const", const=2, dest="verb")
```

  If `--noisy` is seen, **optparse** will set

  ```python
  options.verbos = 2
  ```

- **"store_true"** [relevant: `dest`]

A special case of "store_const" that stores a true value to \texttt{dest}.

- \texttt{"store_false" \ [relevant: \texttt{dest}]}

  Like \texttt{"store_true"}, but stores a false value.

Example:

```python
parser.add_option("--clobber", action="store_true", dest="clobber")
parser.add_option("--no-clobber", action="store_false", dest="append")
```

- \texttt{"append" \ [relevant: \texttt{type, dest, nargs, choices}]}

  The option must be followed by an argument, which is appended to the list in \texttt{dest}. If no default value for \texttt{dest} is supplied, an empty list is automatically created when \texttt{optparse} first encounters this option on the command-line. If \texttt{nargs} $> 1$, multiple arguments are consumed, and a tuple of length \texttt{nargs} is appended to \texttt{dest}.

  The defaults for \texttt{type} and \texttt{dest} are the same as for the \texttt{"store" action}.

Example:

```python
parser.add_option("-t", "--tracks", action="append", type="int")
```

If \texttt{-t3} is seen on the command-line, \texttt{optparse} does the equivalent of:

```python
options.tracks = []
options.tracks.append(int("3"))
```

If, a little later on, \texttt{--tracks=4} is seen, it does:
options.tracks.append(int("4"))

- **"append_const"** [required: `const`; relevant: `dest`]

  Like **"store_const"**, but the value `const` is appended to `dest`; as with **"append"**, `dest` defaults to `None`, and an empty list is automatically created the first time the option is encountered.

- **"count"** [relevant: `dest`]

  Increment the integer stored at `dest`. If no default value is supplied, `dest` is set to zero before being incremented the first time.

  Example:

  ```python
  parser.add_option("-v", action="count", dest="verbosity")
  ```

  The first time `-v` is seen on the command line, **`optparse`** does the equivalent of:

  ```python
  options.verbosity = 0
  options.verbosity += 1
  ```

  Every subsequent occurrence of `-v` results in

  ```python
  options.verbosity += 1
  ```

- **"callback"** [required: `callback`; relevant: `type`, `nargs`, `callback_args`, `callback_kwargs`]

  Call the function specified by `callback`, which is called as

  ```python
  func(option, opt_str, value, parser, *args, **kwargs)
  ```

  See section **Option Callbacks** for more detail.
"help"

Prints a complete help message for all the options in the current option parser. The help message is constructed from the usage string passed to OptionParser's constructor and the help string passed to every option.

If no help string is supplied for an option, it will still be listed in the help message. To omit an option entirely, use the special value optparse.SUPPRESS_HELP.

optparse automatically adds a help option to all OptionParsers, so you do not normally need to create one.

**Example:**

```python
from optparse import OptionParser, SUPPRESS_HELP

# usually, a help option is added automatically, but that can be suppressed using the add_help_option argument
parser = OptionParser(add_help_option=False)

parser.add_option("-h", "--help", action="help")
parser.add_option("-v", action="store_true", dest="verbose",
                 help="Be moderately verbose")
parser.add_option("--file", dest="filename",
                 help="Input file to read data from")
parser.add_option("--secret", help=SUPPRESS_HELP)
```

If optparse sees either `-h` or `--help` on the command line, it will print something like the following help message to stdout (assuming `sys.argv[0]` is "foo.py"):  

```
Usage: foo.py [options]
Options:
   -h, --help            Show this help message and exit
   -v                    Be moderately verbose
```
After printing the help message, `optparse` terminates your process with `sys.exit(0)`.

- "version"

Prints the version number supplied to the OptionParser to stdout and exits. The version number is actually formatted and printed by the `print_version()` method of OptionParser. Generally only relevant if the `version` argument is supplied to the OptionParser constructor. As with `help` options, you will rarely create `version` options, since `optparse` automatically adds them when needed.

### 15.5.3.6. Standard option types

`optparse` has six built-in option types: "string", "int", "long", "choice", "float" and "complex". If you need to add new option types, see section *Extending optparse*.

Arguments to string options are not checked or converted in any way: the text on the command line is stored in the destination (or passed to the callback) as-is.

Integer arguments (type "int" or "long") are parsed as follows:

- if the number starts with `0x`, it is parsed as a hexadecimal number
- if the number starts with `0`, it is parsed as an octal number
- if the number starts with `0b`, it is parsed as a binary number
- otherwise, the number is parsed as a decimal number

The conversion is done by calling either `int()` or `long()` with the appropriate base (2, 8, 10, or 16). If this fails, so will `optparse`,
although with a more useful error message.

"float" and "complex" option arguments are converted directly with float() and complex(), with similar error-handling.

"choice" options are a subtype of "string" options. The choices option attribute (a sequence of strings) defines the set of allowed option arguments. optparse.check_choice() compares user-supplied option arguments against this master list and raises OptionValueError if an invalid string is given.

15.5.3.7. Parsing arguments

The whole point of creating and populating an OptionParser is to call its parse_args() method:

```python
(options, args) = parser.parse_args(args=None, values=None)
```

where the input parameters are

args
  the list of arguments to process (default: sys.argv[1:])

values
  a optparse.Values object to store option arguments in (default: a new instance of values) – if you give an existing object, the option defaults will not be initialized on it

and the return values are

options
  the same object that was passed in as values, or the optparse.Values instance created by optparse

args
  the leftover positional arguments after all options have been
The most common usage is to supply neither keyword argument. If you supply values, it will be modified with repeated \texttt{setattr()} calls (roughly one for every option argument stored to an option destination) and returned by \texttt{parse_args()}.

If \texttt{parse_args()} encounters any errors in the argument list, it calls the OptionParser's \texttt{error()} method with an appropriate end-user error message. This ultimately terminates your process with an exit status of 2 (the traditional Unix exit status for command-line errors).

15.5.3.8. Querying and manipulating your option parser

The default behavior of the option parser can be customized slightly, and you can also poke around your option parser and see what's there. OptionParser provides several methods to help you out:

\texttt{OptionParser.disable_interspersed_args()} 
Set parsing to stop on the first non-option. For example, if \texttt{-a} and \texttt{-b} are both simple options that take no arguments, optparse normally accepts this syntax:

\begin{verbatim}
prog -a arg1 -b arg2
\end{verbatim}

and treats it as equivalent to

\begin{verbatim}
prog -a -b arg1 arg2
\end{verbatim}

To disable this feature, call \texttt{disable_interspersed_args()}. This restores traditional Unix syntax, where option parsing stops with the first non-option argument.

Use this if you have a command processor which runs another
command which has options of its own and you want to make sure these options don’t get confused. For example, each command might have a different set of options.

OptionParser\texttt{: enable_interspersed_args()}
Set parsing to not stop on the first non-option, allowing interspersing switches with command arguments. This is the default behavior.

OptionParser\texttt{: get\_option(opt\_str)}
Returns the Option instance with the option string \texttt{opt\_str}, or \texttt{None} if no options have that option string.

OptionParser\texttt{: has\_option(opt\_str)}
Return true if the OptionParser has an option with option string \texttt{opt\_str} (e.g., \texttt{-q} or \texttt{--verbose}).

OptionParser\texttt{: remove\_option(opt\_str)}
If the OptionParser has an option corresponding to \texttt{opt\_str}, that option is removed. If that option provided any other option strings, all of those option strings become invalid. If \texttt{opt\_str} does not occur in any option belonging to this OptionParser, raises \texttt{ValueError}.

15.5.3.9. Conflicts between options

If you’re not careful, it’s easy to define options with conflicting option strings:

\begin{verbatim}
parser.add_option("-n", "--dry-run", ...)
[...]
parser.add_option("-n", "--noisy", ...)
\end{verbatim}

(This is particularly true if you’ve defined your own OptionParser subclass with some standard options.)
Every time you add an option, `optparse` checks for conflicts with existing options. If it finds any, it invokes the current conflict-handling mechanism. You can set the conflict-handling mechanism either in the constructor:

```python
parser = OptionParser(..., conflict_handler=handler)
```

or with a separate call:

```python
parser.set_conflict_handler(handler)
```

The available conflict handlers are:

- **"error"** (default)
  
  assume option conflicts are a programming error and raise `OptionConflictError`

- **"resolve"**
  
  resolve option conflicts intelligently (see below)

As an example, let's define an `OptionParser` that resolves conflicts intelligently and add conflicting options to it:

```python
parser = OptionParser(conflict_handler="resolve")
parser.add_option("-n", "--dry-run", ..., help="do no harm")
parser.add_option("-n", "--noisy", ..., help="be noisy")
```

At this point, `optparse` detects that a previously-added option is already using the `-n` option string. Since `conflict_handler` is "resolve", it resolves the situation by removing `-n` from the earlier option's list of option strings. Now `--dry-run` is the only way for the user to activate that option. If the user asks for help, the help message will reflect that:

```text
Options:
    --dry-run       do no harm
    [...]
```
It’s possible to whittle away the option strings for a previously-added option until there are none left, and the user has no way of invoking that option from the command-line. In that case, optparse removes that option completely, so it doesn’t show up in help text or anywhere else. Carrying on with our existing OptionParser:

```
parser.add_option("--dry-run", ..., help="new dry-run option")
```

At this point, the original `-n/-dry-run` option is no longer accessible, so optparse removes it, leaving this help text:

```
Options:
  [...]
  -n, --noisy  be noisy
  --dry-run    new dry-run option
```

### 15.5.3.10. Cleanup

OptionParser instances have several cyclic references. This should not be a problem for Python’s garbage collector, but you may wish to break the cyclic references explicitly by calling `destroy()` on your OptionParser once you are done with it. This is particularly useful in long-running applications where large object graphs are reachable from your OptionParser.

### 15.5.3.11. Other methods

OptionParser supports several other public methods:

```
OptionParser.set_usage(usage)
```

Set the usage string according to the rules described above for the `usage` constructor keyword argument. Passing `None` sets the default usage string; use `optparse.SUPPRESS_USAGE` to suppress a
usage message.

OptionParser. **print_usage**(*file=None*)

Print the usage message for the current program (self.usage) to *file* (default stdout). Any occurrence of the string %prog in self.usage is replaced with the name of the current program. Does nothing if self.usage is empty or not defined.

OptionParser. **get_usage**()

Same as print_usage() but returns the usage string instead of printing it.

OptionParser. **set_defaults**(*dest=value,...*)

Set default values for several option destinations at once. Using set_defaults() is the preferred way to set default values for options, since multiple options can share the same destination. For example, if several “mode” options all set the same destination, any one of them can set the default, and the last one wins:

```python
parser.add_option("--advanced", action="store_const",
                 dest="mode", const="advanced",
                 default="novice")  # overridden below
parser.add_option("--novice", action="store_const",
                 dest="mode", const="novice",
                 default="advanced")  # overrides above set
```

To avoid this confusion, use set_defaults():

```python
parser.set_defaults(mode="advanced")
parser.add_option("--advanced", action="store_const",
                 dest="mode", const="advanced")
parser.add_option("--novice", action="store_const",
                 dest="mode", const="novice")
```
15.5.4. Option Callbacks

When `optparse`'s built-in actions and types aren't quite enough for your needs, you have two choices: extend `optparse` or define a callback option. Extending `optparse` is more general, but overkill for a lot of simple cases. Quite often a simple callback is all you need.

There are two steps to defining a callback option:

- define the option itself using the "callback" action
- write the callback; this is a function (or method) that takes at least four arguments, as described below

15.5.4.1. Defining a callback option

As always, the easiest way to define a callback option is by using the `OptionParser.add_option()` method. Apart from `action`, the only option attribute you must specify is `callback`, the function to call:

```python
parser.add_option("-c", action="callback", callback=my_callback)
```

`callback` is a function (or other callable object), so you must have already defined `my_callback()` when you create this callback option. In this simple case, `optparse` doesn't even know if `-c` takes any arguments, which usually means that the option takes no arguments—the mere presence of `-c` on the command-line is all it needs to know. In some circumstances, though, you might want your callback to consume an arbitrary number of command-line arguments. This is where writing callbacks gets tricky; it’s covered later in this section.

`optparse` always passes four particular arguments to your callback, and it will only pass additional arguments if you specify them via
**callback_args** and **callback_kwargs**. Thus, the minimal callback function signature is:

```python
def my_callback(option, opt, value, parser):
```

The four arguments to a callback are described below.

There are several other option attributes that you can supply when you define a callback option:

- **type**
  has its usual meaning: as with the "store" or "append" actions, it instructs **optparse** to consume one argument and convert it to **type**. Rather than storing the converted value(s) anywhere, though, **optparse** passes it to your callback function.

- **nargs**
  also has its usual meaning: if it is supplied and > 1, **optparse** will consume **nargs** arguments, each of which must be convertible to **type**. It then passes a tuple of converted values to your callback.

- **callback_args**
  a tuple of extra positional arguments to pass to the callback

- **callback_kwargs**
  a dictionary of extra keyword arguments to pass to the callback

### 15.5.4.2. How callbacks are called

All callbacks are called as follows:

```python
func(option, opt_str, value, parser, *args, **kwargs)
```

where

- **option**
  is the Option instance that’s calling the callback
opt_str
is the option string seen on the command-line that's triggering the callback. (If an abbreviated long option was used, opt_str will be the full, canonical option string—e.g. if the user puts --foo on the command-line as an abbreviation for --foobar, then opt_str will be "--foobar".)

value
is the argument to this option seen on the command-line. optparse will only expect an argument if type is set; the type of value will be the type implied by the option's type. If type for this option is None (no argument expected), then value will be None. If nargs > 1, value will be a tuple of values of the appropriate type.

parser
is the OptionParser instance driving the whole thing, mainly useful because you can access some other interesting data through its instance attributes:

parser.largs
the current list of leftover arguments, ie. arguments that have been consumed but are neither options nor option arguments. Feel free to modify parser.largs, e.g. by adding more arguments to it. (This list will become args, the second return value of parse_args().)

parser.rargs
the current list of remaining arguments, ie. with opt_str and value (if applicable) removed, and only the arguments following them still there. Feel free to modify parser.rargs, e.g. by consuming more arguments.

parser.values
the object where option values are by default stored (an instance of optparse.OptionValues). This lets callbacks use
the same mechanism as the rest of optparse for storing option values; you don't need to mess around with globals or closures. You can also access or modify the value(s) of any options already encountered on the command-line.

args

is a tuple of arbitrary positional arguments supplied via the callback_args option attribute.

kwargs

is a dictionary of arbitrary keyword arguments supplied via callback_kwars.

15.5.4.3. Raising errors in a callback

The callback function should raise OptionValueError if there are any problems with the option or its argument(s). optparse catches this and terminates the program, printing the error message you supply to stderr. Your message should be clear, concise, accurate, and mention the option at fault. Otherwise, the user will have a hard time figuring out what he did wrong.

15.5.4.4. Callback example 1: trivial callback

Here's an example of a callback option that takes no arguments, and simply records that the option was seen:

```python
def record_foo_seen(option, opt_str, value, parser):
    parser.values.saw_foo = True
```

Of course, you could do that with the "store_true" action.

15.5.4.5. Callback example 2: check option order
Here's a slightly more interesting example: record the fact that -a is seen, but blow up if it comes after -b in the command-line.

```python
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use -a after -b")
    parser.values.a = 1

parser.add_option("-a", action="callback", callback=check_order)
parser.add_option("-b", action="store_true", dest="b")
```

15.5.4.6. Callback example 3: check option order (generalized)

If you want to re-use this callback for several similar options (set a flag, but blow up if -b has already been seen), it needs a bit of work: the error message and the flag that it sets must be generalized.

```python
def check_order(option, opt_str, value, parser):
    if parser.values.b:
        raise OptionValueError("can't use %s after -b" % opt_str)
    setattr(parser.values, option.dest, 1)

parser.add_option("-a", action="callback", callback=check_order)
parser.add_option("-b", action="store_true", dest="b")
parser.add_option("-c", action="callback", callback=check_order)
```

15.5.4.7. Callback example 4: check arbitrary condition

Of course, you could put any condition in there—you're not limited to checking the values of already-defined options. For example, if you have options that should not be called when the moon is full, all you have to do is this:

```python
def check_moon(option, opt_str, value, parser):
```
if is_moon_full():
    raise OptionValueError("%s option invalid when moon is % opt_str")
    setattr(parser.values, option.dest, 1)

parser.add_option("--foo",
    action="callback", callback=check_moon, dest="foo")

(The definition of is_moon_full() is left as an exercise for the reader.)

15.5.4.8. Callback example 5: fixed arguments

Things get slightly more interesting when you define callback options that take a fixed number of arguments. Specifying that a callback option takes arguments is similar to defining a "store" or "append" option: if you define type, then the option takes one argument that must be convertible to that type; if you further define nargs, then the option takes nargs arguments.

Here's an example that just emulates the standard "store" action:

def store_value(option, opt_str, value, parser):
    setattr(parser.values, option.dest, value)

parser.add_option("--foo",
    action="callback", callback=store_value,
    type="int", nargs=3, dest="foo")

Note that optparse takes care of consuming 3 arguments and converting them to integers for you; all you have to do is store them. (Or whatever; obviously you don’t need a callback for this example.)

15.5.4.9. Callback example 6: variable arguments

Things get hairy when you want an option to take a variable number
of arguments. For this case, you must write a callback, as optparse doesn't provide any built-in capabilities for it. And you have to deal with certain intricacies of conventional Unix command-line parsing that optparse normally handles for you. In particular, callbacks should implement the conventional rules for bare -- and - arguments:

- either -- or - can be option arguments
- bare -- (if not the argument to some option): halt command-line processing and discard the --
- bare - (if not the argument to some option): halt command-line processing but keep the - (append it to parser.largs)

If you want an option that takes a variable number of arguments, there are several subtle, tricky issues to worry about. The exact implementation you choose will be based on which trade-offs you're willing to make for your application (which is why optparse doesn't support this sort of thing directly).

Nevertheless, here's a stab at a callback for an option with variable arguments:

```python
def vararg_callback(option, opt_str, value, parser):
    assert value is None
    value = []

    def floatable(str):
        try:
            float(str)
            return True
        except ValueError:
            return False

    for arg in parser.rargs:
        # stop on --foo like options
        if arg[:2] == "--" and len(arg) > 2:
            break
        # stop on -a, but not on -3 or -3.0
```
if arg[:1] == "-" and len(arg) > 1 and not floatable(a
break
value.append(arg)

del parser.rargs[:len(value)]
setattr(parser.values, option.dest, value)

[...]
parser.add_option("-c", "--callback", dest="vararg_attr",
    action="callback", callback=vararg_callback)
15.5.5. Extending optparse

Since the two major controlling factors in how optparse interprets command-line options are the action and type of each option, the most likely direction of extension is to add new actions and new types.

15.5.5.1. Adding new types

To add new types, you need to define your own subclass of optparse's Option class. This class has a couple of attributes that define optparse's types: TYPES and TYPE_CHECKER.

Option. TYPES
A tuple of type names; in your subclass, simply define a new tuple TYPES that builds on the standard one.

Option. TYPE_CHECKER
A dictionary mapping type names to type-checking functions. A type-checking function has the following signature:

```python
def check_mytype(option, opt, value)
```

where option is an Option instance, opt is an option string (e.g., -f), and value is the string from the command line that must be checked and converted to your desired type. check_mytype() should return an object of the hypothetical type mytype. The value returned by a type-checking function will wind up in the OptionValues instance returned by OptionParser.parse_args(), or be passed to a callback as the value parameter.

Your type-checking function should raise OptionValueError if it encounters any problems. OptionValueError takes a single string
argument, which is passed as-is to OptionParser's error() method, which in turn prepends the program name and the string "error:" and prints everything to stderr before terminating the process.

Here's a silly example that demonstrates adding a "complex" option type to parse Python-style complex numbers on the command line. (This is even sillier than it used to be, because optparse 1.3 added built-in support for complex numbers, but never mind.)

First, the necessary imports:

```python
from copy import copy
from optparse import Option, OptionValueError
```

You need to define your type-checker first, since it's referred to later (in the TYPE_CHECKER class attribute of your Option subclass):

```python
def check_complex(option, opt, value):
    try:
        return complex(value)
    except ValueError:
        raise OptionValueError("option %s: invalid complex value: %r" % (opt, value))
```

Finally, the Option subclass:

```python
class MyOption(Option):
    TYPES = Option.TYPES + ("complex",)
    TYPE_CHECKER = copy(Option.TYPE_CHECKER)
    TYPE_CHECKER["complex"] = check_complex
```

(If we didn't make a copy() of Option.TYPE_CHECKER, we would end up modifying the TYPE_CHECKER attribute of optparse's Option class. This being Python, nothing stops you from doing that except good manners and common sense.)
That’s it! Now you can write a script that uses the new option type just like any other `optparse`-based script, except you have to instruct your OptionParser to use `MyOption` instead of `Option`:

```python
parser = OptionParser(option_class=MyOption)
paper.add_option("-c", type="complex")
```

Alternately, you can build your own option list and pass it to `OptionParser`; if you don’t use `add_option()` in the above way, you don’t need to tell `OptionParser` which option class to use:

```python
option_list = [MyOption("-c", action="store", type="complex", d
parser = OptionParser(option_list=option_list)
```

15.5.5.2. Adding new actions

Adding new actions is a bit trickier, because you have to understand that `optparse` has a couple of classifications for actions:

“store” actions

actions that result in `optparse` storing a value to an attribute of the current OptionValues instance; these options require a `dest` attribute to be supplied to the Option constructor.

“typed” actions

actions that take a value from the command line and expect it to be of a certain type; or rather, a string that can be converted to a certain type. These options require a `type` attribute to the Option constructor.

These are overlapping sets: some default “store” actions are "store", "store_const", "append", and "count", while the default “typed” actions are "store", "append", and "callback".

When you add an action, you need to categorize it by listing it in at
least one of the following class attributes of Option (all are lists of strings):

Option. **ACTIONS**

All actions must be listed in ACTIONS.

Option. **STORE_ACTIONS**

“store” actions are additionally listed here.

Option. **TYPED_ACTIONS**

“typed” actions are additionally listed here.

Option. **ALWAYS_TYPED_ACTIONS**

Actions that always take a type (i.e. whose options always take a value) are additionally listed here. The only effect of this is that `optparse` assigns the default type, "string", to options with no explicit type whose action is listed in **ALWAYS_TYPED_ACTIONS**.

In order to actually implement your new action, you must override Option’s `take_action()` method and add a case that recognizes your action.

For example, let’s add an "extend" action. This is similar to the standard "append" action, but instead of taking a single value from the command-line and appending it to an existing list, "extend" will take multiple values in a single comma-delimited string, and extend an existing list with them. That is, if --names is an "extend" option of type "string", the command line

```
--names=foo,bar --names blah --names ding,dong
```

would result in a list

```
["foo", "bar", "blah", "ding", "dong"]
```
Again we define a subclass of Option:

```python
class MyOption(Option):
    ACTIONS = Option.ACTIONS + ("extend",)
    STORE_ACTIONS = Option.STORE_ACTIONS + ("extend",)
    TYPED_ACTIONS = Option.TYPED_ACTIONS + ("extend",)
    ALWAYS_TYPED_ACTIONS = Option.ALWAYS_TYPED_ACTIONS + ("extend",)

    def take_action(self, action, dest, opt, value, values, parser):
        if action == "extend":
            lvalue = value.split(",")
            values.ensure_value(dest, []).extend(lvalue)
        else:
            Option.take_action(self, action, dest, opt, value, values, parser)
```

Features of note:

- "extend" both expects a value on the command-line and stores that value somewhere, so it goes in both `STORE_ACTIONS` and `TYPED_ACTIONS`.

- To ensure that `optparse` assigns the default type of "string" to "extend" actions, we put the "extend" action in `ALWAYS_TYPED_ACTIONS` as well.

- `MyOption.take_action()` implements just this one new action, and passes control back to `Option.take_action()` for the standard `optparse` actions.

- `values` is an instance of the `optparse_parser.Values` class, which provides the very useful `ensure_value()` method. `ensure_value()` is essentially `getattr()` with a safety valve; it is called as

  ```python
  values.ensure_value(attr, value)
  ```
If the `attr` attribute of `values` doesn’t exist or is `None`, then `ensure_value()` first sets it to `value`, and then returns `value`. This is very handy for actions like `"extend"`, `"append"`, and `"count"`, all of which accumulate data in a variable and expect that variable to be of a certain type (a list for the first two, an integer for the latter). Using `ensure_value()` means that scripts using your action don’t have to worry about setting a default value for the option destinations in question; they can just leave the default as `None` and `ensure_value()` will take care of getting it right when it’s needed.
15.6. getopt — C-style parser for command line options

Note: The getopt module is a parser for command line options whose API is designed to be familiar to users of the C getopt() function. Users who are unfamiliar with the C getopt() function or who would like to write less code and get better help and error messages should consider using the argparse module instead.

This module helps scripts to parse the command line arguments in sys.argv. It supports the same conventions as the Unix getopt() function (including the special meanings of arguments of the form ‘-‘ and ‘--‘). Long options similar to those supported by GNU software may be used as well via an optional third argument.

A more convenient, flexible, and powerful alternative is the optparse module.

This module provides two functions and an exception:

getopt.getopt(args, options[, long_options])

Parses command line options and parameter list. args is the argument list to be parsed, without the leading reference to the running program. Typically, this means sys.argv[1:]. options is the string of option letters that the script wants to recognize, with options that require an argument followed by a colon (':'; i.e., the same format that Unix getopt() uses).

Note: Unlike GNU getopt(), after a non-option argument, all further arguments are considered also non-options. This is similar to the way non-GNU Unix systems work.
long_options, if specified, must be a list of strings with the names of the long options which should be supported. The leading '--' characters should not be included in the option name. Long options which require an argument should be followed by an equal sign ('='). Optional arguments are not supported. To accept only long options, options should be an empty string. Long options on the command line can be recognized so long as they provide a prefix of the option name that matches exactly one of the accepted options. For example, if long_options is ['foo', 'frob'], the option --fo will match as --foo, but --f will not match uniquely, so GetoptError will be raised.

The return value consists of two elements: the first is a list of (option, value) pairs; the second is the list of program arguments left after the option list was stripped (this is a trailing slice of args). Each option-and-value pair returned has the option as its first element, prefixed with a hyphen for short options (e.g., '-x') or two hyphens for long options (e.g., '--long-option'), and the option argument as its second element, or an empty string if the option has no argument. The options occur in the list in the same order in which they were found, thus allowing multiple occurrences. Long and short options may be mixed.

getopt. gnu_getopt(args, options[, long_options])

This function works like getopt(), except that GNU style scanning mode is used by default. This means that option and non-option arguments may be intermixed. The getopt() function stops processing options as soon as a non-option argument is encountered.

If the first character of the option string is '+', or if the environment variable POSIXLY_CORRECT is set, then option processing stops as soon as a non-option argument is
encountered.

New in version 2.3.

exception getopt. **GetoptError**

This is raised when an unrecognized option is found in the argument list or when an option requiring an argument is given none. The argument to the exception is a string indicating the cause of the error. For long options, an argument given to an option which does not require one will also cause this exception to be raised. The attributes `msg` and `opt` give the error message and related option; if there is no specific option to which the exception relates, `opt` is an empty string.

*Changed in version 1.6:* Introduced **GetoptError** as a synonym for **error**.

exception getopt. **error**

Alias for **GetoptError**; for backward compatibility.

An example using only Unix style options:

```python
>>> import getopt
>>> args = '-a -b -cfoo -d bar a1 a2'.split()
>>> args
['-a', '-b', '-cfoo', '-d', 'bar', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'abc:d:')
>>> optlist
[('-a', ''), ('-b', ''), ('-c', 'foo'), ('-d', 'bar')]
>>> args
['a1', 'a2']
```

Using long option names is equally easy:

```python
>>> s = '--condition=foo --testing --output-file abc.def -x a1
>>> args = s.split()
>>> args
['--condition=foo', '--testing', '--output-file', 'abc.def', '-x a1']
```
>>> optlist, args = getopt.getopt(args, 'x', ['condition=', 'output-file=', 'testing'])
>>> optlist
[('--condition', 'foo'), ('--testing', ''), ('--output-file', '')]
>>> args
['a1', 'a2']

In a script, typical usage is something like this:

```python
import getopt, sys

def main():
    try:
        opts, args = getopt.getopt(sys.argv[1:], "ho:v", ["help",
        except getopt.GetoptError, err:
            # print help information and exit:
            print str(err) # will print something like "option -a not recognized"
            usage()
            sys.exit(2)
        output = None
        verbose = False
        for o, a in opts:
            if o == "-v":
                verbose = True
            elif o in ("-h", "--help"):
                usage()
                sys.exit()
            elif o in ("-o", "--output"):
                output = a
            else:
                assert False, "unhandled option"
            # ...
    if __name__ == "__main__":
        main()
```

Note that an equivalent command line interface could be produced with less code and more informative help and error messages by using the argparse module:

```python
import argparse
```
if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument('-o', '--output')
    parser.add_argument('-v', dest='verbose', action='store_true')
    args = parser.parse_args()
    # ... do something with args.output ...
    # ... do something with args.verbose ..

Module argparse

Alternative command line option and argument parsing library.
15.7. logging — Logging facility for Python

New in version 2.3.

This module defines functions and classes which implement a flexible event logging system for applications and libraries.

The key benefit of having the logging API provided by a standard library module is that all Python modules can participate in logging, so your application log can include your own messages integrated with messages from third-party modules.

The module provides a lot of functionality and flexibility. If you are unfamiliar with logging, the best way to get to grips with it is to see the tutorials (see the links on the right).

The basic classes defined by the module, together with their functions, are listed below.

- Loggers expose the interface that application code directly uses.
- Handlers send the log records (created by loggers) to the appropriate destination.
- Filters provide a finer grained facility for determining which log records to output.
- Formatters specify the layout of log records in the final output.
15.7.1. Logger Objects

Loggers have the following attributes and methods. Note that Loggers are never instantiated directly, but always through the module-level function `logging.getLogger(name)`.

```python
class logging.Logger

    Logger.propagate
    If this evaluates to false, logging messages are not passed by this logger or by its child loggers to the handlers of higher level (ancestor) loggers. The constructor sets this attribute to 1.

    Logger.setLevel(lvl)
    Sets the threshold for this logger to `lvl`. Logging messages which are less severe than `lvl` will be ignored. When a logger is created, the level is set to `NOTSET` (which causes all messages to be processed when the logger is the root logger, or delegation to the parent when the logger is a non-root logger). Note that the root logger is created with level `WARNING`.

    The term ‘delegation to the parent’ means that if a logger has a level of NOTSET, its chain of ancestor loggers is traversed until either an ancestor with a level other than NOTSET is found, or the root is reached.

    If an ancestor is found with a level other than NOTSET, then that ancestor’s level is treated as the effective level of the logger where the ancestor search began, and is used to determine how a logging event is handled.

    If the root is reached, and it has a level of NOTSET, then all messages will be processed. Otherwise, the root’s level will be used as the effective level.
```
Logger. **isEnabledFor**(lvl)

Indicates if a message of severity `lvl` would be processed by this logger. This method checks first the module-level level set by `logging.disable(lvl)` and then the logger's effective level as determined by `getEffectiveLevel()`.

Logger. **getEffectiveLevel**()

Indicates the effective level for this logger. If a value other than `NOTSET` has been set using `setLevel()`, it is returned. Otherwise, the hierarchy is traversed towards the root until a value other than `NOTSET` is found, and that value is returned.

Logger. **getChild**(suffix)

Returns a logger which is a descendant to this logger, as determined by the suffix. Thus, `logging.getLogger('abc').getChild('def.ghi')` would return the same logger as would be returned by `logging.getLogger('abc.def.ghi')`. This is a convenience method, useful when the parent logger is named using e.g. `__name__` rather than a literal string.

New in version 2.7.

Logger. **debug**(msg, *args, **kwargs)

Logs a message with level `DEBUG` on this logger. The `msg` is the message format string, and the `args` are the arguments which are merged into `msg` using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.)

There are two keyword arguments in `kwargs` which are inspected: `exc_info` which, if it does not evaluate as false, causes exception information to be added to the logging message. If an exception tuple (in the format returned by `sys.exc_info()`) is
provided, it is used; otherwise, \texttt{sys.exc_info()} is called to get the exception information.

The second keyword argument is \texttt{extra} which can be used to pass a dictionary which is used to populate the \texttt{__dict__} of the \texttt{LogRecord} created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```python
FORMAT = '%(asctime)-15s %(clientip)s %(user)-8s %(message)s
logging.basicConfig(format=FORMAT)
d = { 'clientip' : '192.168.0.1', 'user' : 'fbloggs' }
logger = logging.getLogger('tcpserver')
logger.warning('Protocol problem: %s', 'connection reset', extra=d)
```

would print something like

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs Protocol proble
```

The keys in the dictionary passed in \texttt{extra} should not clash with the keys used by the logging system. (See the \texttt{Formatter} documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the \texttt{Formatter} has been set up with a format string which expects ‘clientip’ and ‘user’ in the attribute dictionary of the \texttt{LogRecord}. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the \texttt{extra} dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where
the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized Formatters would be used with particular Handlers.

Logger. **info**(*msg*, *args*, **kwargs*)
Logs a message with level INFO on this logger. The arguments are interpreted as for debug().

Logger. **warning**(*msg*, *args*, **kwargs*)
Logs a message with level WARNING on this logger. The arguments are interpreted as for debug().

Logger. **error**(*msg*, *args*, **kwargs*)
Logs a message with level ERROR on this logger. The arguments are interpreted as for debug().

Logger. **critical**(*msg*, *args*, **kwargs*)
Logs a message with level CRITICAL on this logger. The arguments are interpreted as for debug().

Logger. **log**(*lvl*, *msg*, *args*, **kwargs*)
Logs a message with integer level lvl on this logger. The other arguments are interpreted as for debug().

Logger. **exception**(*msg*, *args*)
Logs a message with level ERROR on this logger. The arguments are interpreted as for debug(). Exception info is added to the logging message. This method should only be called from an exception handler.

Logger. **addFilter**(*filt*)
Adds the specified filter \textit{filt} to this logger.

Logger. \texttt{removeFilter(filt)}
Removes the specified filter \textit{filt} from this logger.

Logger. \texttt{filter(record)}
Applies this logger's filters to the record and returns a true value if the record is to be processed.

Logger. \texttt{addHandler(hdlr)}
Adds the specified handler \textit{hdlr} to this logger.

Logger. \texttt{removeHandler(hdlr)}
Removes the specified handler \textit{hdlr} from this logger.

Logger. \texttt{findCaller()}
Finds the caller's source filename and line number. Returns the filename, line number and function name as a 3-element tuple.

\textit{Changed in version 2.4:} The function name was added. In earlier versions, the filename and line number were returned as a 2-element tuple.

Logger. \texttt{handle(record)}
Handles a record by passing it to all handlers associated with this logger and its ancestors (until a false value of \textit{propagate} is found). This method is used for unpickled records received from a socket, as well as those created locally. Logger-level filtering is applied using \texttt{filter()}.

Logger. \texttt{makeRecord(name, lvl, fn, lno, msg, args, exc_info, func=None, extra=None)}
This is a factory method which can be overridden in subclasses to create specialized \texttt{LogRecord} instances.
Changed in version 2.5: func and extra were added.
15.7.2. Handler Objects

Handlers have the following attributes and methods. Note that Handler is never instantiated directly; this class acts as a base for more useful subclasses. However, the __init__() method in subclasses needs to call Handler.__init__().

Handler.__init__(level=NOTSET)
Initializes the Handler instance by setting its level, setting the list of filters to the empty list and creating a lock (using createLock()) for serializing access to an I/O mechanism.

Handler.createLock()
Initializes a thread lock which can be used to serialize access to underlying I/O functionality which may not be threadsafe.

Handler.acquire()
Acquires the thread lock created with createLock().

Handler.release()
Releases the thread lock acquired with acquire().

Handler.setLevel(lvl)
Sets the threshold for this handler to lvl. Logging messages which are less severe than lvl will be ignored. When a handler is created, the level is set to NOTSET (which causes all messages to be processed).

Handler.setFormatter(form)
Sets the Formatter for this handler to form.

Handler.addFilter(filt)
Adds the specified filter `filt` to this handler.

**Handler**. `removeFilter(filt)`
Removes the specified filter `filt` from this handler.

**Handler**. `filter(record)`
Applies this handler’s filters to the record and returns a true value if the record is to be processed.

**Handler**. `flush()`
Ensure all logging output has been flushed. This version does nothing and is intended to be implemented by subclasses.

**Handler**. `close()`
Tidy up any resources used by the handler. This version does no output but removes the handler from an internal list of handlers which is closed when `shutdown()` is called. Subclasses should ensure that this gets called from overridden `close()` methods.

**Handler**. `handle(record)`
Conditionally emits the specified logging record, depending on filters which may have been added to the handler. Wraps the actual emission of the record with acquisition/release of the I/O thread lock.

**Handler**. `handleError(record)`
This method should be called from handlers when an exception is encountered during an `emit()` call. By default it does nothing, which means that exceptions get silently ignored. This is what is mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors. You could, however, replace this with a custom handler if you wish. The specified record is the one which was being processed when the exception occurred.
Handler. `format(record)`
Do formatting for a record - if a formatter is set, use it. Otherwise, use the default formatter for the module.

Handler. `emit(record)`
Do whatever it takes to actually log the specified logging record. This version is intended to be implemented by subclasses and so raises a `NotImplementedError`.

For a list of handlers included as standard, see `logging.handlers`. 
15.7.3. Formatter Objects

Formatter objects have the following attributes and methods. They are responsible for converting a LogRecord to (usually) a string which can be interpreted by either a human or an external system. The base Formatter allows a formatting string to be specified. If none is supplied, the default value of '%(message)s' is used.

A Formatter can be initialized with a format string which makes use of knowledge of the LogRecord attributes - such as the default value mentioned above making use of the fact that the user's message and arguments are pre-formatted into a LogRecord's message attribute. This format string contains standard Python %-style mapping keys. See section String Formatting Operations for more information on string formatting.

The useful mapping keys in a LogRecord are given in the section on LogRecord attributes.

class logging.Formatter(fmt=None, datefmt=None)

    Returns a new instance of the Formatter class. The instance is initialized with a format string for the message as a whole, as well as a format string for the date/time portion of a message. If no fmt is specified, '%%(message)s' is used. If no datefmt is specified, the ISO8601 date format is used.

format(record)

    The record's attribute dictionary is used as the operand to a string formatting operation. Returns the resulting string. Before formatting the dictionary, a couple of preparatory steps are carried out. The message attribute of the record is computed using msg % args. If the formatting string contains
'(asctime)', formatTime() is called to format the event time. If there is exception information, it is formatted using formatException() and appended to the message. Note that the formatted exception information is cached in attribute exc_text. This is useful because the exception information can be pickled and sent across the wire, but you should be careful if you have more than one Formatter subclass which customizes the formatting of exception information. In this case, you will have to clear the cached value after a formatter has done its formatting, so that the next formatter to handle the event doesn’t use the cached value but recalculates it afresh.

formatTime(record, datefmt=None)
This method should be called from format() by a formatter which wants to make use of a formatted time. This method can be overridden in formatters to provide for any specific requirement, but the basic behavior is as follows: if datefmt (a string) is specified, it is used with time.strftime() to format the creation time of the record. Otherwise, the ISO8601 format is used. The resulting string is returned.

formatException(exc_info)
Formats the specified exception information (a standard exception tuple as returned by sys.exc_info()) as a string. This default implementation just uses traceback.print_exception(). The resulting string is returned.
15.7.4. Filter Objects

Filters can be used by Handlers and Loggers for more sophisticated filtering than is provided by levels. The base filter class only allows events which are below a certain point in the logger hierarchy. For example, a filter initialized with ‘A.B’ will allow events logged by loggers ‘A.B’, ‘A.B.C’, ‘A.B.C.D’, ‘A.B.D’ etc. but not ‘A.BB’, ‘B.A.B’ etc. If initialized with the empty string, all events are passed.

```python
class logging.Filter(name='')

Returns an instance of the Filter class. If name is specified, it names a logger which, together with its children, will have its events allowed through the filter. If name is the empty string, allows every event.

filter(record)

Is the specified record to be logged? Returns zero for no, nonzero for yes. If deemed appropriate, the record may be modified in-place by this method.
```

Note that filters attached to handlers are consulted whenever an event is emitted by the handler, whereas filters attached to loggers are consulted whenever an event is logged to the handler (using debug(), info(), etc.) This means that events which have been generated by descendant loggers will not be filtered by a logger’s filter setting, unless the filter has also been applied to those descendant loggers.

You don’t actually need to subclass Filter: you can pass any instance which has a filter method with the same semantics.

Although filters are used primarily to filter records based on more sophisticated criteria than levels, they get to see every record which
is processed by the handler or logger they're attached to: this can be useful if you want to do things like counting how many records were processed by a particular logger or handler, or adding, changing or removing attributes in the LogRecord being processed. Obviously changing the LogRecord needs to be done with some care, but it does allow the injection of contextual information into logs (see *Using Filters to impart contextual information*).
15.7.5. LogRecord Objects

LogRecord instances are created automatically by the Logger every time something is logged, and can be created manually via makeLogRecord() (for example, from a pickled event received over the wire).

```
class logging. LogRecord(name, level, pathname, lineno, msg, args, exc_info, func=None)
```

Contains all the information pertinent to the event being logged.

The primary information is passed in msg and args, which are combined using `msg % args` to create the message field of the record.

### Parameters:

- **name** – The name of the logger used to log the event represented by this LogRecord.
- **level** – The numeric level of the logging event (one of DEBUG, INFO etc.)
- **pathname** – The full pathname of the source file where the logging call was made.
- **lineno** – The line number in the source file where the logging call was made.
- **msg** – The event description message, possibly a format string with placeholders for variable data.
- **args** – Variable data to merge into the msg argument to obtain the event description.
- **exc_info** – An exception tuple with the current exception information, or None if no exception information is available.
- **func** – The name of the function or method from which the logging call was invoked.
*Changed in version 2.5: `func` was added.*

**getMessage()**

Returns the message for this `LogRecord` instance after merging any user-supplied arguments with the message. If the user-supplied message argument to the logging call is not a string, `str()` is called on it to convert it to a string. This allows use of user-defined classes as messages, whose `__str__` method can return the actual format string to be used.
15.7.6. LogRecord attributes

The LogRecord has a number of attributes, most of which are derived from the parameters to the constructor. (Note that the names do not always correspond exactly between the LogRecord constructor parameters and the LogRecord attributes.) These attributes can be used to merge data from the record into the format string. The following table lists (in alphabetical order) the attribute names, their meanings and the corresponding placeholder in a %-style format string.

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>args</td>
<td>You shouldn't need to format this yourself.</td>
<td>The tuple of arguments merged into msg to produce message.</td>
</tr>
<tr>
<td>asctime</td>
<td>%(asctime)s</td>
<td>Human-readable time when the LogRecord was created. By default this is of the form ‘2003-07-08 16:49:45,896’ (the numbers after the comma are millisecond portion of the time).</td>
</tr>
<tr>
<td>created</td>
<td>%(created)f</td>
<td>Time when the LogRecord was created (as returned by time.time()).</td>
</tr>
<tr>
<td>exc_info</td>
<td>You shouldn't need to format this yourself.</td>
<td>Exception tuple (à la sys.exc_info) or, if no exception has occurred, None.</td>
</tr>
<tr>
<td>filename</td>
<td>%(filename)s</td>
<td>Filename portion of pathname.</td>
</tr>
<tr>
<td>funcName</td>
<td>%(funcName)s</td>
<td>Name of function containing the logging call.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Text logging level for the</td>
</tr>
<tr>
<td>Field</td>
<td>Format</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>levelname</td>
<td>%(levelname)s</td>
<td>Message ('DEBUG', 'INFO', 'WARNING', 'ERROR', 'CRITICAL').</td>
</tr>
<tr>
<td>levelno</td>
<td>%(levelname)s</td>
<td>Numeric logging level for the message (DEBUG, INFO, WARNING, ERROR, CRITICAL).</td>
</tr>
<tr>
<td>lineno</td>
<td>%(levelname)s</td>
<td>Source line number where the logging call was issued (if available).</td>
</tr>
<tr>
<td>module</td>
<td>%(levelname)s</td>
<td>Module (name portion of filename).</td>
</tr>
<tr>
<td>msecs</td>
<td>%(levelname)s</td>
<td>Millisecond portion of the time when the LogRecord was created.</td>
</tr>
<tr>
<td>message</td>
<td>%(levelname)s</td>
<td>The logged message, computed as msg % args. This is set when Formatter.format() is invoked.</td>
</tr>
<tr>
<td>msg</td>
<td>You shouldn't need to format this yourself.</td>
<td>The format string passed in the original logging call. Merged with args to produce message, or an arbitrary object (see Using arbitrary objects as messages).</td>
</tr>
<tr>
<td>name</td>
<td>%(levelname)s</td>
<td>Name of the logger used to log the call.</td>
</tr>
<tr>
<td>pathname</td>
<td>%(levelname)s</td>
<td>Full pathname of the source file where the logging call was issued (if available).</td>
</tr>
<tr>
<td>process</td>
<td>%(levelname)s</td>
<td>Process ID (if available).</td>
</tr>
<tr>
<td>processName</td>
<td>%(levelname)s</td>
<td>Process name (if available).</td>
</tr>
<tr>
<td>relativeCreated</td>
<td>%(relativeCreated)d</td>
<td>Time in milliseconds when the LogRecord was created, relative to the time the logging module was loaded.</td>
</tr>
<tr>
<td>thread</td>
<td>%(thread)d</td>
<td>Thread ID (if available).</td>
</tr>
<tr>
<td>----------</td>
<td>------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>threadName</td>
<td>%(threadName)s</td>
<td>Thread name (if available).</td>
</tr>
</tbody>
</table>

*Changed in version 2.5: funcName was added.*
15.7.7. LoggerAdapter Objects

LoggerAdapter instances are used to conveniently pass contextual information into logging calls. For a usage example, see the section on adding contextual information to your logging output.

New in version 2.6.

class logging.LoggerAdapter(logger, extra)

Returns an instance of LoggerAdapter initialized with an underlying Logger instance and a dict-like object.

process(msg, kwargs)

Modifies the message and/or keyword arguments passed to a logging call in order to insert contextual information. This implementation takes the object passed as extra to the constructor and adds it to kwargs using key ‘extra’. The return value is a (msg, kwargs) tuple which has the (possibly modified) versions of the arguments passed in.

In addition to the above, LoggerAdapter supports the following methods of Logger, i.e. debug(), info(), warning(), error(), exception(), critical(), log(), isEnabledFor(), getEffectiveLevel(), setLevel(), hasHandlers(). These methods have the same signatures as their counterparts in Logger, so you can use the two types of instances interchangeably.

Changed in version 2.7: The isEnabledFor() method was added to LoggerAdapter. This method delegates to the underlying logger.
15.7.8. Thread Safety

The logging module is intended to be thread-safe without any special work needing to be done by its clients. It achieves this though using threading locks; there is one lock to serialize access to the module’s shared data, and each handler also creates a lock to serialize access to its underlying I/O.

If you are implementing asynchronous signal handlers using the `signal` module, you may not be able to use logging from within such handlers. This is because lock implementations in the `threading` module are not always re-entrant, and so cannot be invoked from such signal handlers.
15.7.9. Module-Level Functions

In addition to the classes described above, there are a number of module-level functions.

logging.getLogger([name])

Return a logger with the specified name or, if no name is specified, return a logger which is the root logger of the hierarchy. If specified, the name is typically a dot-separated hierarchical name like “a”, “a.b” or “a.b.c.d”. Choice of these names is entirely up to the developer who is using logging.

All calls to this function with a given name return the same logger instance. This means that logger instances never need to be passed between different parts of an application.

logging.getLoggerClass()

Return either the standard Logger class, or the last class passed to setLoggerClass(). This function may be called from within a new class definition, to ensure that installing a customised Logger class will not undo customisations already applied by other code. For example:

```python
class MyLogger(logging.getLoggerClass()):
    # ... override behaviour here
```

logging.debug(msg[, args[, **kwargs]])

Logs a message with level DEBUG on the root logger. The msg is the message format string, and the args are the arguments which are merged into msg using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.)
There are two keyword arguments in `kwargs` which are inspected: `exc_info` which, if it does not evaluate as false, causes exception information to be added to the logging message. If an exception tuple (in the format returned by `sys.exc_info()`) is provided, it is used; otherwise, `sys.exc_info()` is called to get the exception information.

The other optional keyword argument is `extra` which can be used to pass a dictionary which is used to populate the `__dict__` of the LogRecord created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```python
FORMAT = "%(asctime)-15s %(clientip)s %(user)-8s %(message)s"
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logging.warning("Protocol problem: %s", "connection reset", extra=d)
```

would print something like:

```plaintext
2006-02-08 22:20:02,165 192.168.0.1 fbloggs  Protocol problem: connection reset
```

The keys in the dictionary passed in `extra` should not clash with the keys used by the logging system. (See the `Formatter` documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the `Formatter` has been set up with a format string which expects ‘clientip’ and ‘user’ in the attribute dictionary of the LogRecord. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the `extra` dictionary with these keys.
While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized Formatters would be used with particular Handlers.

*Changed in version 2.5: extra was added.*

```python
logging.info(msg[, *args[, **kwargs]])
```
Logs a message with level INFO on the root logger. The arguments are interpreted as for `debug()`.

```python
logging.warning(msg[, *args[, **kwargs]])
```
Logs a message with level WARNING on the root logger. The arguments are interpreted as for `debug()`.

```python
logging.error(msg[, *args[, **kwargs]])
```
Logs a message with level ERROR on the root logger. The arguments are interpreted as for `debug()`.

```python
logging.critical(msg[, *args[, **kwargs]])
```
Logs a message with level CRITICAL on the root logger. The arguments are interpreted as for `debug()`.

```python
logging.exception(msg[, *args])
```
Logs a message with level ERROR on the root logger. The arguments are interpreted as for `debug()`. Exception info is added to the logging message. This function should only be called from an exception handler.
logging.log(level, msg[, *args[, **kwargs]])

Logs a message with level *level* on the root logger. The other arguments are interpreted as for `debug()`.

PLEASE NOTE: The above module-level functions which delegate to the root logger should *not* be used in threads, in versions of Python earlier than 2.7.1 and 3.2, unless at least one handler has been added to the root logger *before* the threads are started. These convenience functions call `basicConfig()` to ensure that at least one handler is available; in earlier versions of Python, this can (under rare circumstances) lead to handlers being added multiple times to the root logger, which can in turn lead to multiple messages for the same event.

logging.disable(lvl)

Provides an overriding level *lvl* for all loggers which takes precedence over the logger’s own level. When the need arises to temporarily throttle logging output down across the whole application, this function can be useful. Its effect is to disable all logging calls of severity *lvl* and below, so that if you call it with a value of INFO, then all INFO and DEBUG events would be discarded, whereas those of severity WARNING and above would be processed according to the logger’s effective level.

logging.addLevelName(lvl, levelName)

Associates level *lvl* with text *levelName* in an internal dictionary, which is used to map numeric levels to a textual representation, for example when a `Formatter` formats a message. This function can also be used to define your own levels. The only constraints are that all levels used must be registered using this function, levels should be positive integers and they should increase in increasing order of severity.

NOTE: If you are thinking of defining your own levels, please see
the section on *Custom Levels*.

**logging.getLevelName(lvl)**

Returns the textual representation of logging level `lvl`. If the level is one of the predefined levels `CRITICAL`, `ERROR`, `WARNING`, `INFO` or `DEBUG` then you get the corresponding string. If you have associated levels with names using `addLevelName()` then the name you have associated with `lvl` is returned. If a numeric value corresponding to one of the defined levels is passed in, the corresponding string representation is returned. Otherwise, the string “Level %s” % lvl is returned.

**logging.makeLogRecord(attrdict)**

Creates and returns a new `LogRecord` instance whose attributes are defined by `attrdict`. This function is useful for taking a pickled `LogRecord` attribute dictionary, sent over a socket, and reconstituting it as a `LogRecord` instance at the receiving end.

**logging.basicConfig([**kwargs])**

Does basic configuration for the logging system by creating a `StreamHandler` with a default `Formatter` and adding it to the root logger. The functions `debug()`, `info()`, `warning()`, `error()` and `critical()` will call `basicConfig()` automatically if no handlers are defined for the root logger.

This function does nothing if the root logger already has handlers configured for it.

*Changed in version 2.4:* Formerly, `basicConfig()` did not take any keyword arguments.

PLEASE NOTE: This function should be called from the main thread before other threads are started. In versions of Python prior to 2.7.1 and 3.2, if this function is called from multiple
threads, it is possible (in rare circumstances) that a handler will be added to the root logger more than once, leading to unexpected results such as messages being duplicated in the log.

The following keyword arguments are supported.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename</td>
<td>Specifies that a FileHandler be created, using the specified filename, rather than a StreamHandler.</td>
</tr>
<tr>
<td>filemode</td>
<td>Specifies the mode to open the file, if filename is specified (if filemode is unspecified, it defaults to ‘a’).</td>
</tr>
<tr>
<td>format</td>
<td>Use the specified format string for the handler.</td>
</tr>
<tr>
<td>datefmt</td>
<td>Use the specified date/time format.</td>
</tr>
<tr>
<td>level</td>
<td>Set the root logger level to the specified level.</td>
</tr>
<tr>
<td>stream</td>
<td>Use the specified stream to initialize the StreamHandler. Note that this argument is incompatible with ‘filename’ - if both are present, ‘stream’ is ignored.</td>
</tr>
</tbody>
</table>

logging.shutdown()

Informs the logging system to perform an orderly shutdown by flushing and closing all handlers. This should be called at application exit and no further use of the logging system should be made after this call.

logging.getLoggerClass(klass)

Tells the logging system to use the class klass when instantiating a logger. The class should define __init__() such that only a name argument is required, and the __init__() should call Logger.__init__(). This function is typically called before any loggers are instantiated by applications which need to use custom logger behavior.
The `captureWarnings()` function can be used to integrate logging with the `warnings` module.

```python
logging.captureWarnings(capture)
```

This function is used to turn the capture of warnings by logging on and off.

If `capture` is `True`, warnings issued by the `warnings` module will be redirected to the logging system. Specifically, a warning will be formatted using `warnings.formatwarning()` and the resulting string logged to a logger named ‘py.warnings’ with a severity of `WARNING`.

If `capture` is `False`, the redirection of warnings to the logging system will stop, and warnings will be redirected to their original destinations (i.e. those in effect before `captureWarnings(True)` was called).

- **Original Python logging package**
This is the original source for the `logging` package. The version of the package available from this site is suitable for use with Python 1.5.2, 2.1.x and 2.2.x, which do not include the `logging` package in the standard library.
15.8. logging.config — Logging configuration

This section describes the API for configuring the logging module.

**Important**

This page contains only reference information. For tutorials, please see:

- *Basic Tutorial*
- *Advanced Tutorial*
- *Logging Cookbook*
15.8.1. Configuration functions

The following functions configure the logging module. They are located in the `logging.config` module. Their use is optional — you can configure the logging module using these functions or by making calls to the main API (defined in `logging` itself) and defining handlers which are declared either in `logging` or `logging.handlers`.

`logging.config.dictConfig(config)`

Takes the logging configuration from a dictionary. The contents of this dictionary are described in `Configuration dictionary schema` below.

If an error is encountered during configuration, this function will raise a `ValueError`, `TypeError`, `AttributeError` or `ImportError` with a suitably descriptive message. The following is a (possibly incomplete) list of conditions which will raise an error:

- A `level` which is not a string or which is a string not corresponding to an actual logging level.
- A `propagate` value which is not a boolean.
- An id which does not have a corresponding destination.
- A non-existent handler id found during an incremental call.
- An invalid logger name.
- Inability to resolve to an internal or external object.

Parsing is performed by the `DictConfigurator` class, whose constructor is passed the dictionary used for configuration, and has a `configure()` method. The `logging.config` module has a callable attribute `dictConfigClass` which is initially set
to *DictConfigurator*. You can replace the value of *dictConfigClass* with a suitable implementation of your own.

`dictConfig()` calls *dictConfigClass* passing the specified dictionary, and then calls the *configure()* method on the returned object to put the configuration into effect:

```python
def dictConfig(config):
    dictConfigClass(config).configure()
```

For example, a subclass of *DictConfigurator* could call *DictConfigurator.__init__()* in its own *__init__()*, then set up custom prefixes which would be usable in the subsequent *configure()* call. *dictConfigClass* would be bound to this new subclass, and then *dictConfig()* could be called exactly as in the default, uncustomized state.

*New in version 2.7.*

logging.config.*fileConfig*(fname, defaults=None, disable_existing_loggers=True)

Reads the logging configuration from a *configparser*-format file named *fname*. This function can be called several times from an application, allowing an end user to select from various pre-canned configurations (if the developer provides a mechanism to present the choices and load the chosen configuration).

### Parameters:

- **defaults** – Defaults to be passed to the ConfigParser can be specified in this argument.
- **disable_existing_loggers** – If specified as False, loggers which exist when this call is made are left alone. The default is True because this enables old behaviour in a backward-compatible way. This behaviour is to
disable any existing loggers unless they or their ancestors are explicitly named in the logging configuration.

*Changed in version 2.6:* The `disable_existing_loggers` keyword argument was added. Previously, existing loggers were *always* disabled.

```python
logging.config.listen(port=DEFAULT_LOGGING_CONFIG_PORT)
```

Starts up a socket server on the specified port, and listens for new configurations. If no port is specified, the module's default `DEFAULT_LOGGING_CONFIG_PORT` is used. Logging configurations will be sent as a file suitable for processing by `fileConfig()`. Returns a `Thread` instance on which you can call `start()` to start the server, and which you can `join()` when appropriate. To stop the server, call `stopListening()`.

To send a configuration to the socket, read in the configuration file and send it to the socket as a string of bytes preceded by a four-byte length string packed in binary using `struct.pack('>L', n)`.

```python
logging.config.stopListening()
```

Stops the listening server which was created with a call to `listen()`. This is typically called before calling `join()` on the return value from `listen()`.
15.8.2. Configuration dictionary schema

Describing a logging configuration requires listing the various objects to create and the connections between them; for example, you may create a handler named ‘console’ and then say that the logger named ‘startup’ will send its messages to the ‘console’ handler. These objects aren’t limited to those provided by the `logging` module because you might write your own formatter or handler class. The parameters to these classes may also need to include external objects such as `sys.stderr`. The syntax for describing these objects and connections is defined in *Object connections* below.

15.8.2.1. Dictionary Schema Details

The dictionary passed to `dictConfig()` must contain the following keys:

- `version` - to be set to an integer value representing the schema version. The only valid value at present is 1, but having this key allows the schema to evolve while still preserving backwards compatibility.

All other keys are optional, but if present they will be interpreted as described below. In all cases below where a ‘configuring dict’ is mentioned, it will be checked for the special `'()'` key to see if a custom instantiation is required. If so, the mechanism described in *User-defined objects* below is used to create an instance; otherwise, the context is used to determine what to instantiate.

- `formatters` - the corresponding value will be a dict in which each key is a formatter id and each value is a dict describing how to configure the corresponding Formatter instance.
The configuring dict is searched for keys `format` and `datefmt` (with defaults of `None`) and these are used to construct a `logging.Formatter` instance.

- **filters** - the corresponding value will be a dict in which each key is a filter id and each value is a dict describing how to configure the corresponding Filter instance.

The configuring dict is searched for the key `name` (defaulting to the empty string) and this is used to construct a `logging.Filter` instance.

- **handlers** - the corresponding value will be a dict in which each key is a handler id and each value is a dict describing how to configure the corresponding Handler instance.

The configuring dict is searched for the following keys:

- **class** (mandatory). This is the fully qualified name of the handler class.
- **level** (optional). The level of the handler.
- **formatter** (optional). The id of the formatter for this handler.
- **filters** (optional). A list of ids of the filters for this handler.

All other keys are passed through as keyword arguments to the handler’s constructor. For example, given the snippet:

```python
handlers:
    console:
        class : logging.StreamHandler
        formatter: brief
        level : INFO
        filters: [allow_foo]
        stream : ext://sys.stdout
    file:
        class : logging.handlers.RotatingFileHandler
        formatter: precise
```
the handler with id \texttt{console} is instantiated as a \texttt{logging.StreamHandler}, using \texttt{sys.stdout} as the underlying stream. The handler with id \texttt{file} is instantiated as a \texttt{logging.handlers.RotatingFileHandler} with the keyword arguments \begin{verbatim} filename='logconfig.log', maxBytes=1024, backupCount=3 \end{verbatim}.

- \textit{loggers} - the corresponding value will be a dict in which each key is a logger name and each value is a dict describing how to configure the corresponding \texttt{Logger} instance.

The configuring dict is searched for the following keys:

- \texttt{level} (optional). The level of the logger.
- \texttt{propagate} (optional). The propagation setting of the logger.
- \texttt{filters} (optional). A list of ids of the filters for this logger.
- \texttt{handlers} (optional). A list of ids of the handlers for this logger.

The specified loggers will be configured according to the level, propagation, filters and handlers specified.

- \textit{root} - this will be the configuration for the root logger. Processing of the configuration will be as for any logger, except that the \texttt{propagate} setting will not be applicable.

- \textit{incremental} - whether the configuration is to be interpreted as incremental to the existing configuration. This value defaults to \texttt{False}, which means that the specified configuration replaces the existing configuration with the same semantics as used by the existing \texttt{fileConfig()} API.
If the specified value is **True**, the configuration is processed as described in the section on *Incremental Configuration*.

- `disable_existing_loggers` - whether any existing loggers are to be disabled. This setting mirrors the parameter of the same name in `fileConfig()`. If absent, this parameter defaults to **True**. This value is ignored if `incremental` is **True**.

### 15.8.2.2. Incremental Configuration

It is difficult to provide complete flexibility for incremental configuration. For example, because objects such as filters and formatters are anonymous, once a configuration is set up, it is not possible to refer to such anonymous objects when augmenting a configuration.

Furthermore, there is not a compelling case for arbitrarily altering the object graph of loggers, handlers, filters, formatters at run-time, once a configuration is set up; the verbosity of loggers and handlers can be controlled just by setting levels (and, in the case of loggers, propagation flags). Changing the object graph arbitrarily in a safe way is problematic in a multi-threaded environment; while not impossible, the benefits are not worth the complexity it adds to the implementation.

Thus, when the `incremental` key of a configuration dict is present and is **True**, the system will completely ignore any `formatters` and `filters` entries, and process only the `level` settings in the `handlers` entries, and the `level` and `propagate` settings in the `loggers` and `root` entries.

Using a value in the configuration dict lets configurations to be sent over the wire as pickled dicts to a socket listener. Thus, the logging verbosity of a long-running application can be altered over time with
no need to stop and restart the application.

15.8.2.3. Object connections

The schema describes a set of logging objects - loggers, handlers, formatters, filters - which are connected to each other in an object graph. Thus, the schema needs to represent connections between the objects. For example, say that, once configured, a particular logger has attached to it a particular handler. For the purposes of this discussion, we can say that the logger represents the source, and the handler the destination, of a connection between the two. Of course in the configured objects this is represented by the logger holding a reference to the handler. In the configuration dict, this is done by giving each destination object an id which identifies it unambiguously, and then using the id in the source object's configuration to indicate that a connection exists between the source and the destination object with that id.

So, for example, consider the following YAML snippet:

```yaml
default:
    # configuration for formatter with id 'default' goes here
precise:
    # configuration for formatter with id 'precise' goes here
loggers:
    foo.bar.baz:
        # other configuration for logger 'foo.bar.baz'
        handlers: [h1, h2]
```

(Note: YAML used here because it's a little more readable than the equivalent Python source form for the dictionary.)
The ids for loggers are the logger names which would be used programmatically to obtain a reference to those loggers, e.g. `foo.bar.baz`. The ids for Formatters and Filters can be any string value (such as `brief`, `precise` above) and they are transient, in that they are only meaningful for processing the configuration dictionary and used to determine connections between objects, and are not persisted anywhere when the configuration call is complete.

The above snippet indicates that logger named `foo.bar.baz` should have two handlers attached to it, which are described by the handler ids `h1` and `h2`. The formatter for `h1` is that described by id `brief`, and the formatter for `h2` is that described by id `precise`.

### 15.8.2.4. User-defined objects

The schema supports user-defined objects for handlers, filters and formatters. (Loggers do not need to have different types for different instances, so there is no support in this configuration schema for user-defined logger classes.)

Objects to be configured are described by dictionaries which detail their configuration. In some places, the logging system will be able to infer from the context how an object is to be instantiated, but when a user-defined object is to be instantiated, the system will not know how to do this. In order to provide complete flexibility for user-defined object instantiation, the user needs to provide a ‘factory’ - a callable which is called with a configuration dictionary and which returns the instantiated object. This is signalled by an absolute import path to the factory being made available under the special key `'(())'`. Here’s a concrete example:

```python
formatters:
    brief:
        format: '%(message)s'
    default:
```
The above YAML snippet defines three formatters. The first, with id `brief`, is a standard `logging.Formatter` instance with the specified format string. The second, with id `default`, has a longer format and also defines the time format explicitly, and will result in a `logging.Formatter` initialized with those two format strings. Shown in Python source form, the `brief` and `default` formatters have configuration sub-dictionaries:

```
{
    'format' : '%(message)s'
}
```

and:

```
{
  'format' : '%(asctime)s %(levelname)-8s %(name)-15s %(message)s'
  'datefmt' : '%Y-%m-%d %H:%M:%S'
}
```

respectively, and as these dictionaries do not contain the special key `'()'`, the instantiation is inferred from the context: as a result, standard `logging.Formatter` instances are created. The configuration sub-dictionary for the third formatter, with id `custom`, is:

```
{
    '()' : 'my.package.customFormatterFactory',
    'bar' : 'baz',
    'spam' : 99.9,
    'answer' : 42
}
```
and this contains the special key '()', which means that user-defined instantiation is wanted. In this case, the specified factory callable will be used. If it is an actual callable it will be used directly - otherwise, if you specify a string (as in the example) the actual callable will be located using normal import mechanisms. The callable will be called with the **remaining** items in the configuration sub-dictionary as keyword arguments. In the above example, the formatter with id `custom` will be assumed to be returned by the call:

```python
my.package.customFormatterFactory(bar='baz', spam=99.9, answer=42)
```

The key '()' has been used as the special key because it is not a valid keyword parameter name, and so will not clash with the names of the keyword arguments used in the call. The '()' also serves as a mnemonic that the corresponding value is a callable.

### 15.8.2.5. Access to external objects

There are times where a configuration needs to refer to objects external to the configuration, for example `sys.stderr`. If the configuration dict is constructed using Python code, this is straightforward, but a problem arises when the configuration is provided via a text file (e.g. JSON, YAML). In a text file, there is no standard way to distinguish `sys.stderr` from the literal string 'sys.stderr'. To facilitate this distinction, the configuration system looks for certain special prefixes in string values and treat them specially. For example, if the literal string 'ext://sys.stderr' is provided as a value in the configuration, then the `ext://` will be stripped off and the remainder of the value processed using normal import mechanisms.
The handling of such prefixes is done in a way analogous to protocol handling: there is a generic mechanism to look for prefixes which match the regular expression
\^(?P<prefix>[a-z]+)://(?P<suffix>.*$)\nwhereby, if the prefix is recognised, the suffix is processed in a prefix-dependent manner and the result of the processing replaces the string value. If the prefix is not recognised, then the string value will be left as-is.

15.8.2.6. Access to internal objects

As well as external objects, there is sometimes also a need to refer to objects in the configuration. This will be done implicitly by the configuration system for things that it knows about. For example, the string value 'DEBUG' for a level in a logger or handler will automatically be converted to the value logging.DEBUG, and the handlers, filters and formatter entries will take an object id and resolve to the appropriate destination object.

However, a more generic mechanism is needed for user-defined objects which are not known to the logging module. For example, consider logging.handlers.MemoryHandler, which takes a target argument which is another handler to delegate to. Since the system already knows about this class, then in the configuration, the given target just needs to be the object id of the relevant target handler, and the system will resolve to the handler from the id. If, however, a user defines a my.package.MyHandler which has an alternate handler, the configuration system would not know that the alternate referred to a handler. To cater for this, a generic resolution system allows the user to specify:

```
handlers:
  file:
    # configuration of file handler goes here
```
The literal string 'cfg://handlers.file' will be resolved in an analogous way to strings with the ext:// prefix, but looking in the configuration itself rather than the import namespace. The mechanism allows access by dot or by index, in a similar way to that provided by str.format. Thus, given the following snippet:

```python
custom:
  (): my.package.MyHandler
alternate: cfg://handlers.file
```

in the configuration, the string 'cfg://handlers' would resolve to the dict with key handlers, the string 'cfg://handlers.email' would resolve to the dict with key email in the handlers dict, and so on. The string 'cfg://handlers.email.toaddrs[1]' would resolve to 'dev_team@domain.tld' and the string 'cfg://handlers.email.toaddrs[0]' would resolve to the value 'support_team@domain.tld'. The subject value could be accessed using either 'cfg://handlers.email.subject' or, equivalently, 'cfg://handlers.email[subject]'. The latter form only needs to be used if the key contains spaces or non-alphanumeric characters. If an index value consists only of decimal digits, access will be attempted using the corresponding integer value, falling back to the string value if needed.

Given a string 'cfg://handlers.myhandler.mykey.123', this will resolve to `config_dict['handlers']['myhandler']['mykey']['123']`. If the
string is specified as `cfg://handlers.myhandler.mykey[123]`, the system will attempt to retrieve the value from `config_dict['handlers']['myhandler']['mykey'][123]`, and fall back to `config_dict['handlers']['myhandler']['mykey']['123']` if that fails.
15.8.3. Configuration file format

The configuration file format understood by `fileConfig()` is based on `configparser` functionality. The file must contain sections called `[loggers]`, `[handlers]` and `[formatters]` which identify by name the entities of each type which are defined in the file. For each such entity, there is a separate section which identifies how that entity is configured. Thus, for a logger named `log01` in the `[loggers]` section, the relevant configuration details are held in a section `[logger_log01]`. Similarly, a handler called `hand01` in the `[handlers]` section will have its configuration held in a section called `[handler_hand01]`, while a formatter called `form01` in the `[formatters]` section will have its configuration specified in a section called `[formatter_form01]`. The root logger configuration must be specified in a section called `[logger_root]`.

Examples of these sections in the file are given below.

```ini
[loggers]
keys=root,log02,log03,log04,log05,log06,log07

[handlers]
keys=hand01,hand02,hand03,hand04,hand05,hand06,hand07,hand08

[formatters]
keys=form01/form02/form03/form04/form05/form06/form07/form08/form09
```

The root logger must specify a level and a list of handlers. An example of a root logger section is given below.

```ini
[logger_root]
level=NOTSET
handlers=hand01
```
The `level` entry can be one of DEBUG, INFO, WARNING, ERROR, CRITICAL or NOTSET. For the root logger only, NOTSET means that all messages will be logged. Level values are `eval()`uated in the context of the logging package’s namespace.

The `handlers` entry is a comma-separated list of handler names, which must appear in the `[handlers]` section. These names must appear in the `[handlers]` section and have corresponding sections in the configuration file.

For loggers other than the root logger, some additional information is required. This is illustrated by the following example.

```
[logger_parser]
level=DEBUG
handlers=hand01
propagate=1
qualname=compiler.parser
```

The `level` and `handlers` entries are interpreted as for the root logger, except that if a non-root logger’s level is specified as NOTSET, the system consults loggers higher up the hierarchy to determine the effective level of the logger. The `propagate` entry is set to 1 to indicate that messages must propagate to handlers higher up the logger hierarchy from this logger, or 0 to indicate that messages are not propagated to handlers up the hierarchy. The `qualname` entry is the hierarchical channel name of the logger, that is to say the name used by the application to get the logger.

Sections which specify handler configuration are exemplified by the following.

```
[handler_hand01]
class=StreamHandler
level=NOTSET
formatter=form01
```
The **class** entry indicates the handler’s class (as determined by `eval()` in the **logging** package’s namespace). The **level** is interpreted as for loggers, and **NOTSET** is taken to mean ‘log everything’.

*Changed in version 2.6:* Added support for resolving the handler’s class as a dotted module and class name.

The **formatter** entry indicates the key name of the formatter for this handler. If blank, a default formatter (**logging._defaultFormatter**) is used. If a name is specified, it must appear in the [formatters] section and have a corresponding section in the configuration file.

The **args** entry, when `eval()`uated in the context of the **logging** package’s namespace, is the list of arguments to the constructor for the handler class. Refer to the constructors for the relevant handlers, or to the examples below, to see how typical entries are constructed.

```python
[handler_hand02]
class=FileHandler
level=DEBUG
formatter=form02
args=('python.log', 'w')

[handler_hand03]
class=handlers.SocketHandler
level=INFO
formatter=form03
args=('localhost', handlers.DEFAULT_TCP_LOGGING_PORT)

[handler_hand04]
class=handlers.DatagramHandler
level=WARN
formatter=form04
args=('localhost', handlers.DEFAULT_UDP_LOGGING_PORT)

[handler_hand05]
class=handlers.SysLogHandler
```
Sections which specify formatter configuration are typified by the following.

```
[formatter_form01]
format=F1 %(asctime)s %(levelname)s %(message)s
datefmt=
class=logging.Formatter
```

The `format` entry is the overall format string, and the `datefmt` entry is the `strftime()`-compatible date/time format string. If empty, the package substitutes ISO8601 format date/times, which is almost equivalent to specifying the date format string `'%Y-%m-%d %H:%M:%S'`. The ISO8601 format also specifies milliseconds, which are
appended to the result of using the above format string, with a comma separator. An example time in ISO8601 format is 2003-01-23 00:29:50,411.

The *class* entry is optional. It indicates the name of the formatter’s class (as a dotted module and class name.) This option is useful for instantiating a *Formatter* subclass. Subclasses of *Formatter* can present exception tracebacks in an expanded or condensed format.

**See also:**

**Module** [logging](https://docs.python.org/2.7/library/logging.html)

API reference for the logging module.

**Module** [logging.handlers](https://docs.python.org/2.7/library/logging.handlers.html)

Useful handlers included with the logging module.
The following useful handlers are provided in the package. Note that three of the handlers (StreamHandler, FileHandler and NullHandler) are actually defined in the logging module itself, but have been documented here along with the other handlers.
The `StreamHandler` class, located in the core `logging` package, sends logging output to streams such as `sys.stdout`, `sys.stderr`, or any file-like object (or, more precisely, any object which supports `write()` and `flush()` methods).

```python
class logging.StreamHandler(stream=None)
    Returns a new instance of the StreamHandler class. If stream is specified, the instance will use it for logging output; otherwise, `sys.stderr` will be used.

    emit(record)
        If a formatter is specified, it is used to format the record. The record is then written to the stream with a newline terminator. If exception information is present, it is formatted using `traceback.print_exception()` and appended to the stream.

    flush()
        Flushes the stream by calling its flush() method. Note that the close() method is inherited from Handler and so does no output, so an explicit flush() call may be needed at times.
```
15.9.2. FileHandler

The `FileHandler` class, located in the core `logging` package, sends logging output to a disk file. It inherits the output functionality from `StreamHandler`.

```python
class logging.FileHandler(filename, mode='a', encoding=None, delay=False)
```

Returns a new instance of the `FileHandler` class. The specified file is opened and used as the stream for logging. If `mode` is not specified, 'a' is used. If `encoding` is not `None`, it is used to open the file with that encoding. If `delay` is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely.

*Changed in version 2.6: delay was added.*

```python
close()
```

Closes the file.

```python
emit(record)
```

Outputs the record to the file.
15.9.3. NullHandler

New in version 2.7.

The NullHandler class, located in the core logging package, does not do any formatting or output. It is essentially a ‘no-op’ handler for use by library developers.

```python
class logging.NullHandler
    Returns a new instance of the NullHandler class.

    emit(record)
        This method does nothing.

    handle(record)
        This method does nothing.

    createLock()
        This method returns None for the lock, since there is no underlying I/O to which access needs to be serialized.
```

See Configuring Logging for a Library for more information on how to use NullHandler.
15.9.4. WatchedFileHandler

New in version 2.6.

The `WatchedFileHandler` class, located in the `logging.handlers` module, is a `FileHandler` which watches the file it is logging to. If the file changes, it is closed and reopened using the file name.

A file change can happen because of usage of programs such as `newsyslog` and `logrotate` which perform log file rotation. This handler, intended for use under Unix/Linux, watches the file to see if it has changed since the last emit. (A file is deemed to have changed if its device or inode have changed.) If the file has changed, the old file stream is closed, and the file opened to get a new stream.

This handler is not appropriate for use under Windows, because under Windows open log files cannot be moved or renamed - logging opens the files with exclusive locks - and so there is no need for such a handler. Furthermore, `ST_INO` is not supported under Windows; `stat()` always returns zero for this value.

```python
class logging.handlers.WatchedFileHandler(filename[, mode[, encoding[, delay]]])
```

Returns a new instance of the `WatchedFileHandler` class. The specified file is opened and used as the stream for logging. If `mode` is not specified, 'a' is used. If `encoding` is not `None`, it is used to open the file with that encoding. If `delay` is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely.

```python
emit(record)
```

Outputs the record to the file, but first checks to see if the file
has changed. If it has, the existing stream is flushed and closed and the file opened again, before outputting the record to the file.
The `RotatingFileHandler` class, located in the `logging.handlers` module, supports rotation of disk log files.

```python
class logging.handlers.RotatingFileHandler(filename, mode='a', maxBytes=0, backupCount=0, encoding=None, delay=0)
```

Returns a new instance of the `RotatingFileHandler` class. The specified file is opened and used as the stream for logging. If `mode` is not specified, `'a'` is used. If `encoding` is not `None`, it is used to open the file with that encoding. If `delay` is true, then file opening is deferred until the first call to `emit()`. By default, the file grows indefinitely.

You can use the `maxBytes` and `backupCount` values to allow the file to *rollover* at a predetermined size. When the size is about to be exceeded, the file is closed and a new file is silently opened for output. Rollover occurs whenever the current log file is nearly `maxBytes` in length; if `maxBytes` is zero, rollover never occurs. If `backupCount` is non-zero, the system will save old log files by appending the extensions `.1`, `.2` etc., to the filename. For example, with a `backupCount` of 5 and a base file name of `app.log`, you would get `app.log`, `app.log.1`, `app.log.2`, up to `app.log.5`. The file being written to is always `app.log`. When this file is filled, it is closed and renamed to `app.log.1`, and if files `app.log.1`, `app.log.2`, etc. exist, then they are renamed to `app.log.2`, `app.log.3` etc. respectively.

*Changed in version 2.6: delay was added.*

```python
def doRollover()
    Does a rollover, as described above.
```
**emit**(*record*)

Outputs the record to the file, catering for rollover as described previously.
15.9.6. TimedRotatingFileHandler

The `TimedRotatingFileHandler` class, located in the `logging.handlers` module, supports rotation of disk log files at certain timed intervals.

```python
class logging.handlers.TimedRotatingFileHandler(filename,
    when='h', interval=1, backupCount=0, encoding=None, delay=False,
    utc=False)
```

Returns a new instance of the `TimedRotatingFileHandler` class. The specified file is opened and used as the stream for logging. On rotating it also sets the filename suffix. Rotating happens based on the product of `when` and `interval`.

You can use the `when` to specify the type of `interval`. The list of possible values is below. Note that they are not case sensitive.

<table>
<thead>
<tr>
<th>Value</th>
<th>Type of interval</th>
</tr>
</thead>
<tbody>
<tr>
<td>'S'</td>
<td>Seconds</td>
</tr>
<tr>
<td>'M'</td>
<td>Minutes</td>
</tr>
<tr>
<td>'H'</td>
<td>Hours</td>
</tr>
<tr>
<td>'D'</td>
<td>Days</td>
</tr>
<tr>
<td>'W'</td>
<td>Week day (0=Monday)</td>
</tr>
<tr>
<td>'midnight'</td>
<td>Roll over at midnight</td>
</tr>
</tbody>
</table>

The system will save old log files by appending extensions to the filename. The extensions are date-and-time based, using the `strftime` format `%Y-%m-%d_%H-%M-%S` or a leading portion thereof, depending on the rollover interval.

When computing the next rollover time for the first time (when the handler is created), the last modification time of an existing log
file, or else the current time, is used to compute when the next rotation will occur.

If the utc argument is true, times in UTC will be used; otherwise local time is used.

If backupCount is nonzero, at most backupCount files will be kept, and if more would be created when rollover occurs, the oldest one is deleted. The deletion logic uses the interval to determine which files to delete, so changing the interval may leave old files lying around.

If delay is true, then file opening is deferred until the first call to emit().

*Changed in version 2.6: delay was added.*

*Changed in version 2.7: utc was added.*

**doRollover()**

Does a rollover, as described above.

**emit(record)**

Outputs the record to the file, catering for rollover as described above.
The `SocketHandler` class, located in the `logging.handlers` module, sends logging output to a network socket. The base class uses a TCP socket.

```python
class logging.handlers.SocketHandler(host, port)
```

Returns a new instance of the `SocketHandler` class intended to communicate with a remote machine whose address is given by `host` and `port`.

- `close()`
  Closes the socket.

- `emit()`
  Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. If the connection was previously lost, re-establishes the connection. To unpickle the record at the receiving end into a `LogRecord`, use the `makeLogRecord()` function.

- `handleError()`
  Handles an error which has occurred during `emit()`. The most likely cause is a lost connection. Closes the socket so that we can retry on the next event.

- `makeSocket()`
  This is a factory method which allows subclasses to define the precise type of socket they want. The default implementation creates a TCP socket (`socket.SOCK_STREAM`).

- `makePickle(record)`
Pickles the record’s attribute dictionary in binary format with a length prefix, and returns it ready for transmission across the socket.

Note that pickles aren’t completely secure. If you are concerned about security, you may want to override this method to implement a more secure mechanism. For example, you can sign pickles using HMAC and then verify them on the receiving end, or alternatively you can disable unpickling of global objects on the receiving end.

**send(packet)**

Send a pickled string *packet* to the socket. This function allows for partial sends which can happen when the network is busy.

**createSocket()**

Tries to create a socket; on failure, uses an exponential back-off algorithm. On initial failure, the handler will drop the message it was trying to send. When subsequent messages are handled by the same instance, it will not try connecting until some time has passed. The default parameters are such that the initial delay is one second, and if after that delay the connection still can’t be made, the handler will double the delay each time up to a maximum of 30 seconds.

This behaviour is controlled by the following handler attributes:

- `retryStart` (initial delay, defaulting to 1.0 seconds).
- `retryFactor` (multiplier, defaulting to 2.0).
- `retryMax` (maximum delay, defaulting to 30.0 seconds).

This means that if the remote listener starts up *after* the handler has been used, you could lose messages (since the
handler won’t even attempt a connection until the delay has elapsed, but just silently drop messages during the delay period).
15.9.8. DatagramHandler

The `DatagramHandler` class, located in the `logging.handlers` module, inherits from `SocketHandler` to support sending logging messages over UDP sockets.

```python
class logging.handlers.DatagramHandler(host, port)
```

Returns a new instance of the `DatagramHandler` class intended to communicate with a remote machine whose address is given by `host` and `port`.

```python
emit()
```

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. To unpickle the record at the receiving end into a `LogRecord`, use the `makeLogRecord()` function.

```python
makeSocket()
```

The factory method of `SocketHandler` is here overridden to create a UDP socket (`socket.SOCK_DGRAM`).

```python
send(s)
```

Send a pickled string to a socket.
The `SysLogHandler` class, located in the `logging.handlers` module, supports sending logging messages to a remote or local Unix syslog.

```python
class logging.handlers.SysLogHandler(address=('localhost', SYSLOG_UDP_PORT), facility=LOG_USER, socktype=socket.SOCK_DGRAM)
```

Returns a new instance of the `SysLogHandler` class intended to communicate with a remote Unix machine whose address is given by `address` in the form of a `(host, port)` tuple. If `address` is not specified, `(‘localhost’, 514)` is used. The address is used to open a socket. An alternative to providing a `(host, port)` tuple is providing an address as a string, for example ‘/dev/log’. In this case, a Unix domain socket is used to send the message to the syslog. If `facility` is not specified, `LOG_USER` is used. The type of socket opened depends on the `socktype` argument, which defaults to `socket.SOCK_DGRAM` and thus opens a UDP socket. To open a TCP socket (for use with the newer syslog daemons such as rsyslog), specify a value of `socket.SOCK_STREAM`.

Note that if your server is not listening on UDP port 514, `SysLogHandler` may appear not to work. In that case, check what address you should be using for a domain socket - it’s system dependent. For example, on Linux it’s usually ‘/dev/log’ but on OS/X it’s ‘/var/run/syslog’. You’ll need to check your platform and use the appropriate address (you may need to do this check at runtime if your application needs to run on several platforms). On Windows, you pretty much have to use the UDP option.

*Changed in version 2.7: socktype was added.*

`close()`
Closes the socket to the remote host.

**emit**(record)
The record is formatted, and then sent to the syslog server. If exception information is present, it is *not* sent to the server.

**encodePriority**(facility, priority)
Encodes the facility and priority into an integer. You can pass in strings or integers - if strings are passed, internal mapping dictionaries are used to convert them to integers.

The symbolic LOG_ values are defined in *SysLogHandler* and mirror the values defined in the *sys/syslog.h* header file.

### Priorities

<table>
<thead>
<tr>

<td>local6</td>
<td>LOG_LOCAL6</td>
</tr>
<tr>
<td>local7</td>
<td>LOG_LOCAL7</td>
</tr>
</tbody>
</table>

**mapPriority(levelname)**

Maps a logging level name to a syslog priority name. You may need to override this if you are using custom levels, or if the default algorithm is not suitable for your needs. The default algorithm maps `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL` to the equivalent syslog names, and all other level names to `'warning'`. 
15.9.10. NTEventLogHandler

The **NTEventLogHandler** class, located in the `logging.handlers` module, supports sending logging messages to a local Windows NT, Windows 2000 or Windows XP event log. Before you can use it, you need Mark Hammond's Win32 extensions for Python installed.

```python
class logging.handlers.NTEventLogHandler(appname, dllname=None, logtype='Application')
```

Returns a new instance of the **NTEventLogHandler** class. The `appname` is used to define the application name as it appears in the event log. An appropriate registry entry is created using this name. The `dllname` should give the fully qualified pathname of a .dll or .exe which contains message definitions to hold in the log (if not specified, 'win32service.pyd' is used - this is installed with the Win32 extensions and contains some basic placeholder message definitions. Note that use of these placeholders will make your event logs big, as the entire message source is held in the log. If you want slimmer logs, you have to pass in the name of your own .dll or .exe which contains the message definitions you want to use in the event log). The `logtype` is one of 'Application', 'System' or 'Security', and defaults to 'Application'.

**close()**

At this point, you can remove the application name from the registry as a source of event log entries. However, if you do this, you will not be able to see the events as you intended in the Event Log Viewer - it needs to be able to access the registry to get the .dll name. The current version does not do this.

**emit(record)**
Determines the message ID, event category and event type, and then logs the message in the NT event log.

**getEventCategory(record)**

Returns the event category for the record. Override this if you want to specify your own categories. This version returns 0.

**getEventType(record)**

Returns the event type for the record. Override this if you want to specify your own types. This version does a mapping using the handler’s typemap attribute, which is set up in `__init__()` to a dictionary which contains mappings for `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL`. If you are using your own levels, you will either need to override this method or place a suitable dictionary in the handler’s `typemap` attribute.

**getMessageID(record)**

Returns the message ID for the record. If you are using your own messages, you could do this by having the `msg` passed to the logger being an ID rather than a format string. Then, in here, you could use a dictionary lookup to get the message ID. This version returns 1, which is the base message ID in `win32service.pyd`. 
15.9.11. SMTPHandler

The `SMTPHandler` class, located in the `logging.handlers` module, supports sending logging messages to an email address via SMTP.

```python
class logging.handlers.SMTPHandler(mailhost, fromaddr, toaddrs, subject, credentials=None, secure=None)
```

Returns a new instance of the `SMTPHandler` class. The instance is initialized with the from and to addresses and subject line of the email. The `toaddrs` should be a list of strings. To specify a non-standard SMTP port, use the (host, port) tuple format for the `mailhost` argument. If you use a string, the standard SMTP port is used. If your SMTP server requires authentication, you can specify a (username, password) tuple for the `credentials` argument. If `secure` is True, then the handler will attempt to use TLS for the email transmission.

*Changed in version 2.6:* `credentials` was added.

*Changed in version 2.7:* `secure` was added.

```python
emit(record)
```

Formats the record and sends it to the specified addressees.

```python
getSubject(record)
```

If you want to specify a subject line which is record-dependent, override this method.
15.9.12. MemoryHandler

The MemoryHandler class, located in the logging.handlers module, supports buffering of logging records in memory, periodically flushing them to a target handler. Flushing occurs whenever the buffer is full, or when an event of a certain severity or greater is seen.

MemoryHandler is a subclass of the more general BufferingHandler, which is an abstract class. This buffers logging records in memory. Whenever each record is added to the buffer, a check is made by calling shouldFlush() to see if the buffer should be flushed. If it should, then flush() is expected to do the needful.

class logging.handlers.BufferingHandler(capacity)

    Initializes the handler with a buffer of the specified capacity.

    emit(record)

        Appends the record to the buffer. If shouldFlush() returns true, calls flush() to process the buffer.

    flush()

        You can override this to implement custom flushing behavior. This version just zaps the buffer to empty.

    shouldFlush(record)

        Returns true if the buffer is up to capacity. This method can be overridden to implement custom flushing strategies.

class logging.handlers.MemoryHandler(capacity, flushLevel=ERROR, target=None)

    Returns a new instance of the MemoryHandler class. The instance is initialized with a buffer size of capacity. If flushLevel is not specified, ERROR is used. If no target is specified, the target will
need to be set using `setTarget()` before this handler does anything useful.

**close()**
Calls `flush()`, sets the target to `None` and clears the buffer.

**flush()**
For a `MemoryHandler`, flushing means just sending the buffered records to the target, if there is one. The buffer is also cleared when this happens. Override if you want different behavior.

**setTarget(target)**
*Changed in version 2.6: credentials was added.*

Sets the target handler for this handler.

**shouldFlush(record)**
Checks for buffer full or a record at the `flushLevel` or higher.
15.9.13. HTTPHandler

The **HTTPHandler** class, located in the `logging.handlers` module, supports sending logging messages to a Web server, using either GET or POST semantics.

```python
class logging.handlers.HTTPHandler(host, url, method='GET')
```

Returns a new instance of the **HTTPHandler** class. The `host` can be of the form `host:port`, should you need to use a specific port number. If no `method` is specified, GET is used.

```python
emit(record)
```

Sends the record to the Web server as a percent-encoded dictionary.

**See also:**

**Module** `logging`

API reference for the logging module.

**Module** `logging.config`

Configuration API for the logging module.
15. Generic Operating System Services
The `getpass` module provides two functions:

```python
google.getpass([prompt[, stream]])
```

Prompt the user for a password without echoing. The user is prompted using the string `prompt`, which defaults to `'Password:'`. On Unix, the prompt is written to the file-like object `stream`. `stream` defaults to the controlling terminal (`/dev/tty`) or if that is unavailable to `sys.stderr` (this argument is ignored on Windows).

If echo free input is unavailable `getpass()` falls back to printing a warning message to `stream` and reading from `sys.stdin` and issuing a `GetPassWarning`.

Availability: Macintosh, Unix, Windows.

*Changed in version 2.5:* The `stream` parameter was added.

*Changed in version 2.6:* On Unix it defaults to using `/dev/tty` before falling back to `sys.stdin` and `sys.stderr`.

**Note:** If you call `getpass` from within IDLE, the input may be done in the terminal you launched IDLE from rather than the idle window itself.

**exception** `getpass.GetPassWarning`

A `UserWarning` subclass issued when password input may be echoed.

```python
google.getuser()
```
Return the “login name” of the user. Availability: Unix, Windows.

This function checks the environment variables LOGNAME, USER, LNAME and USERNAME, in order, and returns the value of the first one which is set to a non-empty string. If none are set, the login name from the password database is returned on systems which support the pwd module, otherwise, an exception is raised.
15.11. curses — Terminal handling for character-cell displays

Platforms: Unix

Changed in version 1.6: Added support for the ncurses library and converted to a package.

The curses module provides an interface to the curses library, the de-facto standard for portable advanced terminal handling.

While curses is most widely used in the Unix environment, versions are available for DOS, OS/2, and possibly other systems as well. This extension module is designed to match the API of ncurses, an open-source curses library hosted on Linux and the BSD variants of Unix.

**Note:** Since version 5.4, the ncurses library decides how to interpret non-ASCII data using the nl_langinfo function. That means that you have to call `locale.setlocale()` in the application and encode Unicode strings using one of the system’s available encodings. This example uses the system’s default encoding:

```python
import locale
locale.setlocale(locale.LC_ALL, '')
code = locale.getpreferredencoding()
```

Then use `code` as the encoding for `str.encode()` calls.

Module **curses.ascii**

Utilities for working with ASCII characters, regardless of your
locale settings.

**Module curses.panel**
A panel stack extension that adds depth to curses windows.

**Module curses.textpad**
Editable text widget for curses supporting *Emacs*-like bindings.

**Module curses.wrapper**
Convenience function to ensure proper terminal setup and resetting on application entry and exit.

*Curses Programming with Python*
Tutorial material on using curses with Python, by Andrew Kuchling and Eric Raymond.

The Demo/curses/ directory in the Python source distribution contains some example programs using the curses bindings provided by this module.
15.11.1. Functions

The module `curses` defines the following exception:

```
exception curses.error
```

Exception raised when a curses library function returns an error.

**Note:** Whenever `x` or `y` arguments to a function or a method are optional, they default to the current cursor location. Whenever `attr` is optional, it defaults to `A_NORMAL`.

The module `curses` defines the following functions:

**curses.baudrate()**

Returns the output speed of the terminal in bits per second. On software terminal emulators it will have a fixed high value. Included for historical reasons; in former times, it was used to write output loops for time delays and occasionally to change interfaces depending on the line speed.

**curses.beep()**

Emit a short attention sound.

**curses.can_change_color()**

Returns true or false, depending on whether the programmer can change the colors displayed by the terminal.

**curses.cbreak()**

Enter cbreak mode. In cbreak mode (sometimes called “rare” mode) normal tty line buffering is turned off and characters are available to be read one by one. However, unlike raw mode, special characters (interrupt, quit, suspend, and flow control) retain their effects on the tty driver and calling program. Calling
first `raw()` then `cbreak()` leaves the terminal in cbreak mode.

curses. `color_content(color_number)`
Returns the intensity of the red, green, and blue (RGB) components in the color `color_number`, which must be between 0 and `COLORS`. A 3-tuple is returned, containing the R,G,B values for the given color, which will be between 0 (no component) and 1000 (maximum amount of component).

curses. `color_pair(color_number)`
Returns the attribute value for displaying text in the specified color. This attribute value can be combined with `A_STANDOUT`, `A_REVERSE`, and the other `A_*` attributes. `pair_number()` is the counterpart to this function.

curses. `curs_set(visibility)`
Sets the cursor state. `visibility` can be set to 0, 1, or 2, for invisible, normal, or very visible. If the terminal supports the visibility requested, the previous cursor state is returned; otherwise, an exception is raised. On many terminals, the “visible” mode is an underline cursor and the “very visible” mode is a block cursor.

curses. `def_prog_mode()`
Saves the current terminal mode as the “program” mode, the mode when the running program is using curses. (Its counterpart is the “shell” mode, for when the program is not in curses.) Subsequent calls to `reset_prog_mode()` will restore this mode.

curses. `def_shell_mode()`
Saves the current terminal mode as the “shell” mode, the mode when the running program is not using curses. (Its counterpart is the “program” mode, when the program is using curses
capabilities.) Subsequent calls to reset_shell_mode() will restore this mode.

curses. **delay_output(ms)**

Inserts an *ms* millisecond pause in output.

curses. **doupdate()**

Update the physical screen. The curses library keeps two data structures, one representing the current physical screen contents and a virtual screen representing the desired next state. The doupdate() ground updates the physical screen to match the virtual screen.

The virtual screen may be updated by a noutrefresh() call after write operations such as addstr() have been performed on a window. The normal refresh() call is simply noutrefresh() followed by doupdate(); if you have to update multiple windows, you can speed performance and perhaps reduce screen flicker by issuing noutrefresh() calls on all windows, followed by a single doupdate().

curses. **echo()**

Enter echo mode. In echo mode, each character input is echoed to the screen as it is entered.

curses. **endwin()**

De-initialize the library, and return terminal to normal status.

curses. **erasechar()**

Returns the user’s current erase character. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

curses. **filter()**
The `filter()` routine, if used, must be called before `initscr()` is called. The effect is that, during those calls, LINES is set to 1; the capabilities clear, cup, cud, cud1, cuu1, cuu, vpa are disabled; and the home string is set to the value of cr. The effect is that the cursor is confined to the current line, and so are screen updates. This may be used for enabling character-at-a-time line editing without touching the rest of the screen.

curses. `flash()`

Flash the screen. That is, change it to reverse-video and then change it back in a short interval. Some people prefer such as ‘visible bell’ to the audible attention signal produced by `beep()`.

curses. `flushinp()`

Flush all input buffers. This throws away any typeahead that has been typed by the user and has not yet been processed by the program.

curses. `getmouse()`

After `getch()` returns `KEY_MOUSE` to signal a mouse event, this method should be call to retrieve the queued mouse event, represented as a 5-tuple `(id, x, y, z, bstate)`. `id` is an ID value used to distinguish multiple devices, and `x, y, z` are the event's coordinates. (z is currently unused.) `bstate` is an integer value whose bits will be set to indicate the type of event, and will be the bitwise OR of one or more of the following constants, where `n` is the button number from 1 to 4: `BUTTONn_PRESSED`, `BUTTONn_RELEASED`, `BUTTONn_CLICKED`, `BUTTONn_DOUBLE_CLICKED`, `BUTTONn_TRIPLE_CLICKED`, `BUTTON_SHIFT`, `BUTTON_CTRL`, `BUTTON_ALT`.

curses. `getsyx()`

Returns the current coordinates of the virtual screen cursor in `y` and `x`. If `leaveok` is currently true, then -1,-1 is returned.
**curses.getwin(file)**

Reads window related data stored in the file by an earlier `putwin()` call. The routine then creates and initializes a new window using that data, returning the new window object.

**curses.has_colors()**

Returns true if the terminal can display colors; otherwise, it returns false.

**curses.has_ic()**

Returns true if the terminal has insert- and delete-character capabilities. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

**curses.has_il()**

Returns true if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

**curses.has_key(ch)**

Takes a key value `ch`, and returns true if the current terminal type recognizes a key with that value.

**curses.halfdelay(tenths)**

Used for half-delay mode, which is similar to cbreak mode in that characters typed by the user are immediately available to the program. However, after blocking for `tenths` tenths of seconds, an exception is raised if nothing has been typed. The value of `tenths` must be a number between 1 and 255. Use `nocbreak()` to leave half-delay mode.

**curses.init_color(color_number, r, g, b)**

Changes the definition of a color, taking the number of the color
to be changed followed by three RGB values (for the amounts of red, green, and blue components). The value of `color_number` must be between $\theta$ and `COLORS`. Each of $r$, $g$, $b$, must be a value between $\theta$ and $1000$. When `init_color()` is used, all occurrences of that color on the screen immediately change to the new definition. This function is a no-op on most terminals; it is active only if `can_change_color()` returns 1.

```c
io
```

**curses.** `init_pair(pair_number, fg, bg)`

Changes the definition of a color-pair. It takes three arguments: the number of the color-pair to be changed, the foreground color number, and the background color number. The value of `pair_number` must be between $1$ and `COLOR_PAIRS - 1` (the $0$ color pair is wired to white on black and cannot be changed). The value of `fg` and `bg` arguments must be between $0$ and `COLORS`. If the color-pair was previously initialized, the screen is refreshed and all occurrences of that color-pair are changed to the new definition.

```c
io
```

**curses.** `initscr()`

Initialize the library. Returns a `WindowObject` which represents the whole screen.

```c
io
```

**Note:** If there is an error opening the terminal, the underlying `curses` library may cause the interpreter to exit.

```c
io
```

**curses.** `isendwin()`

Returns true if `endwin()` has been called (that is, the `curses` library has been deinitialized).

```c
io
```

**curses.** `keyname(k)`

Return the name of the key numbered $k$. The name of a key generating printable ASCII character is the key's character. The
name of a control-key combination is a two-character string consisting of a caret followed by the corresponding printable ASCII character. The name of an alt-key combination (128-255) is a string consisting of the prefix ‘M-‘ followed by the name of the corresponding ASCII character.

curses.\texttt{killchar()}
Returns the user’s current line kill character. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

curses.\texttt{longname()}
Returns a string containing the terminfo long name field describing the current terminal. The maximum length of a verbose description is 128 characters. It is defined only after the call to \texttt{initscr()}.

curses.\texttt{meta(yes)}
If yes is 1, allow 8-bit characters to be input. If yes is 0, allow only 7-bit chars.

curses.\texttt{mouseinterval(interval)}
Sets the maximum time in milliseconds that can elapse between press and release events in order for them to be recognized as a click, and returns the previous interval value. The default value is 200 msec, or one fifth of a second.

curses.\texttt{mousemask(mousemask)}
Sets the mouse events to be reported, and returns a tuple \texttt{(availmask, oldmask)}. \texttt{availmask} indicates which of the specified mouse events can be reported; on complete failure it returns 0. \texttt{oldmask} is the previous value of the given window’s mouse event mask. If this function is never called, no mouse events are ever reported.
curses.\texttt{napms}(ms)

Sleep for \textit{ms} milliseconds.

curses.\texttt{newpad}(nlines, ncols)

Creates and returns a pointer to a new pad data structure with the given number of lines and columns. A pad is returned as a window object.

A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (such as from scrolling or echoing of input) do not occur. The \texttt{refresh()} and \texttt{noutrefresh()} methods of a pad require 6 arguments to specify the part of the pad to be displayed and the location on the screen to be used for the display. The arguments are pminrow, pmincol, sminrow, smincol, smaxrow, smaxcol; the p arguments refer to the upper left corner of the pad region to be displayed and the s arguments define a clipping box on the screen within which the pad region is to be displayed.

curses.\texttt{newwin}([nlines, ncols], begin\_y, begin\_x)

Return a new window, whose left-upper corner is at \texttt{(begin\_y, begin\_x)}, and whose height/width is \texttt{nlines/ncols}.

By default, the window will extend from the specified position to the lower right corner of the screen.

curses.\texttt{nl}()

Enter newline mode. This mode translates the return key into newline on input, and translates newline into return and line-feed on output. Newline mode is initially on.
curses.nocbreak()
Leave cbreak mode. Return to normal “cooked” mode with line buffering.

curses.noecho()
Leave echo mode. Echoing of input characters is turned off.

curses.nonl()
Leave newline mode. Disable translation of return into newline on input, and disable low-level translation of newline into newline/return on output (but this does not change the behavior of addch('n'), which always does the equivalent of return and line feed on the virtual screen). With translation off, curses can sometimes speed up vertical motion a little; also, it will be able to detect the return key on input.

curses.noqiflush()
When the noqiflush routine is used, normal flush of input and output queues associated with the INTR, QUIT and SUSP characters will not be done. You may want to call noqiflush() in a signal handler if you want output to continue as though the interrupt had not occurred, after the handler exits.

curses.noraw()
Leave raw mode. Return to normal “cooked” mode with line buffering.

curses.pair_content(pair_number)
Returns a tuple (fg, bg) containing the colors for the requested color pair. The value of pair_number must be between 1 and COLOR_PAIRS - 1.

curses.pair_number(attr)
Returns the number of the color-pair set by the attribute value
attr. color_pair() is the counterpart to this function.

curses.putp(string)
Equivalent to puts(str, 1, putchar); emits the value of a specified terminfo capability for the current terminal. Note that the output of putp always goes to standard output.

curses.qiflush([flag])
If flag is false, the effect is the same as calling noqiflush(). If flag is true, or no argument is provided, the queues will be flushed when these control characters are read.

curses.raw()
Enter raw mode. In raw mode, normal line buffering and processing of interrupt, quit, suspend, and flow control keys are turned off; characters are presented to curses input functions one by one.

curses.reset_prog_mode()
Restores the terminal to “program” mode, as previously saved by def_prog_mode().

curses.reset_shell_mode()
Restores the terminal to “shell” mode, as previously saved by def_shell_mode().

curses.setsyx(y, x)
Sets the virtual screen cursor to y, x. If y and x are both -1, then leaveok is set.

curses.setupterm([termstr, fd])
Initializes the terminal. termstr is a string giving the terminal name; if omitted, the value of the TERM environment variable will be used. fd is the file descriptor to which any initialization
sequences will be sent; if not supplied, the file descriptor for \texttt{sys.stdout} will be used.

curses.\texttt{start\_color()}
Must be called if the programmer wants to use colors, and before any other color manipulation routine is called. It is good practice to call this routine right after \texttt{initscr()}.

\texttt{start\_color()} initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white), and two global variables in the curses module, \texttt{COLORS} and \texttt{COLOR\_PAIRS}, containing the maximum number of colors and color-pairs the terminal can support. It also restores the colors on the terminal to the values they had when the terminal was just turned on.

curses.\texttt{termattrs()}
Returns a logical OR of all video attributes supported by the terminal. This information is useful when a curses program needs complete control over the appearance of the screen.

curses.\texttt{termname()}
Returns the value of the environment variable \texttt{TERM}, truncated to 14 characters.

curses.\texttt{tigetflag(capname)}
Returns the value of the Boolean capability corresponding to the terminfo capability name \textit{capname}. The value \texttt{-1} is returned if \textit{capname} is not a Boolean capability, or \texttt{0} if it is canceled or absent from the terminal description.

curses.\texttt{tigetnum(capname)}
Returns the value of the numeric capability corresponding to the terminfo capability name \textit{capname}. The value \texttt{-2} is returned if \textit{capname} is not a numeric capability, or \texttt{-1} if it is canceled or
absent from the terminal description.

curses.\textbf{tigetstr}(\textit{capname})
Returns the value of the string capability corresponding to the terminfo capability name \textit{capname}. \texttt{None} is returned if \textit{capname} is not a string capability, or is canceled or absent from the terminal description.

curses.\textbf{tparm}(\textit{str}[,...])
Instantiates the string \textit{str} with the supplied parameters, where \textit{str} should be a parameterized string obtained from the terminfo database. E.g. \texttt{tparm(tigetstr("cup"), 5, 3)} could result in \texttt{\textbackslash 033[6;4H}, the exact result depending on terminal type.

curses.\textbf{typeahead}(\textit{fd})
Specifies that the file descriptor \textit{fd} be used for typeahead checking. If \textit{fd} is \texttt{-1}, then no typeahead checking is done.

The curses library does “line-breakout optimization” by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until refresh or doupdate is called again, allowing faster response to commands typed in advance. This function allows specifying a different file descriptor for typeahead checking.

curses.\textbf{unctrl}(\textit{ch})
Returns a string which is a printable representation of the character \textit{ch}. Control characters are displayed as a caret followed by the character, for example as \texttt{\textasciicircum c}. Printing characters are left as they are.

curses.\textbf{ungetch}(\textit{ch})
Push \textit{ch} so the next \texttt{getch()} will return it.
**Note:** Only one `ch` can be pushed before `getch()` is called.

The `ungetmouse(id, x, y, z, bstate)` function allows pushing a `KEY_MOUSE` event onto the input queue, associating the given state data with it.

The `use_env(flag)` function should be called before `initscr()` or `newterm` are called. When `flag` is false, the values of lines and columns specified in the terminfo database will be used, even if environment variables `LINES` and `COLUMNS` (used by default) are set, or if curses is running in a window (in which case default behavior would be to use the window size if `LINES` and `COLUMNS` are not set).

The `use_default_colors()` function allows use of default values for colors on terminals supporting this feature. Use this to support transparency in your application. The default color is assigned to the color number -1. After calling this function, `init_pair(x, curses.COLOR_RED, -1)` initializes, for instance, color pair `x` to a red foreground color on the default background.
15.11.2. Window Objects

Window objects, as returned by `initscr()` and `newwin()` above, have the following methods:

```python
window.addch([y, x], ch[, attr])
```

**Note:** A character means a C character (an ASCII code), rather than a Python character (a string of length 1). (This note is true whenever the documentation mentions a character.) The built-in `ord()` is handy for conveying strings to codes.

Paint character `ch` at `(y, x)` with attributes `attr`, overwriting any character previously painter at that location. By default, the character position and attributes are the current settings for the window object.

```python
window.addnstr([y, x], str, n[, attr])
```

Paint at most `n` characters of the string `str` at `(y, x)` with attributes `attr`, overwriting anything previously on the display.

```python
window.addstr([y, x], str[, attr])
```

Paint the string `str` at `(y, x)` with attributes `attr`, overwriting anything previously on the display.

```python
window.attroff(attr)
```

Remove attribute `attr` from the “background” set applied to all writes to the current window.

```python
window.attron(attr)
```

Add attribute `attr` from the “background” set applied to all writes to the current window.
window.attrset(attr)

Set the “background” set of attributes to attr. This set is initially 0 (no attributes).

window.bkgd(ch[, attr])

Sets the background property of the window to the character ch, with attributes attr. The change is then applied to every character position in that window:

- The attribute of every character in the window is changed to the new background attribute.
- Wherever the former background character appears, it is changed to the new background character.

window.bkgdset(ch[, attr])

Sets the window's background. A window's background consists of a character and any combination of attributes. The attribute part of the background is combined (OR'ed) with all non-blank characters that are written into the window. Both the character and attribute parts of the background are combined with the blank characters. The background becomes a property of the character and moves with the character through any scrolling and insert/delete line/character operations.

window.border([ls[, rs[, ts[, bs[, tl[, tr[, bl[, br]]]]]]]])

Draw a border around the edges of the window. Each parameter specifies the character to use for a specific part of the border; see the table below for more details. The characters can be specified as integers or as one-character strings.

**Note:** A 0 value for any parameter will cause the default character to be used for that parameter. Keyword parameters can not be used. The defaults are listed in this table:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ls</td>
<td>Left side</td>
<td>ACS_VLINE</td>
</tr>
<tr>
<td>rs</td>
<td>Right side</td>
<td>ACS_VLINE</td>
</tr>
<tr>
<td>ts</td>
<td>Top</td>
<td>ACS_HLINE</td>
</tr>
<tr>
<td>bs</td>
<td>Bottom</td>
<td>ACS_HLINE</td>
</tr>
<tr>
<td>tl</td>
<td>Upper-left corner</td>
<td>ACS_ULCORNER</td>
</tr>
<tr>
<td>tr</td>
<td>Upper-right corner</td>
<td>ACS_URCORNER</td>
</tr>
<tr>
<td>bl</td>
<td>Bottom-left corner</td>
<td>ACS_LLCORNER</td>
</tr>
<tr>
<td>br</td>
<td>Bottom-right corner</td>
<td>ACS_LRCORNER</td>
</tr>
</tbody>
</table>

**window.box([vertch, horch])**
Similar to `border()`, but both `ls` and `rs` are `vertch` and both `ts` and `bs` are `horch`. The default corner characters are always used by this function.

**window.chgat([y, x], num, attr)**
Sets the attributes of `num` characters at the current cursor position, or at position `(y, x)` if supplied. If no value of `num` is given or `num = -1`, the attribute will be set on all the characters to the end of the line. This function does not move the cursor. The changed line will be touched using the `touchline()` method so that the contents will be redisplayed by the next window refresh.

**window.clear()**
Like `erase()`, but also causes the whole window to be repainted upon next call to `refresh()`.

**window.clearok(yes)**
If `yes` is 1, the next call to `refresh()` will clear the window completely.

**window.clrtobot()**
Erase from cursor to the end of the window: all lines below the
cursor are deleted, and then the equivalent of `clrtoeol()` is performed.

```c
window.clrtoeol()
Erase from cursor to the end of the line.
```

```c
window.cursyncup()
Updates the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.
```

```c
window.delch([y, x])
Delete any character at (y, x).
```

```c
window.delete1n()
Delete the line under the cursor. All following lines are moved up by 1 line.
```

```c
window.derwin([nlines, ncols], begin_y, begin_x)
An abbreviation for “derive window”, `derwin()` is the same as calling `subwin()`, except that `begin_y` and `begin_x` are relative to the origin of the window, rather than relative to the entire screen. Returns a window object for the derived window.
```

```c
window.echochar(ch[, attr])
Add character `ch` with attribute `attr`, and immediately call `refresh()` on the window.
```

```c
window.enclose(y, x)
Tests whether the given pair of screen-relative character-cell coordinates are enclosed by the given window, returning true or false. It is useful for determining what subset of the screen windows enclose the location of a mouse event.
```

```c
window.erase()
```
Clear the window.

\[ \text{window. getbegyx()} \]
Return a tuple \((y, x)\) of co-ordinates of upper-left corner.

\[ \text{window. getch([y, x])} \]
Get a character. Note that the integer returned does \textit{not} have to be in ASCII range: function keys, keypad keys and so on return numbers higher than 256. In no-delay mode, -1 is returned if there is no input, else \texttt{getch()} waits until a key is pressed.

\[ \text{window. getkey([y, x])} \]
Get a character, returning a string instead of an integer, as \texttt{getch()} does. Function keys, keypad keys and so on return a multibyte string containing the key name. In no-delay mode, an exception is raised if there is no input.

\[ \text{window. getmaxyx()} \]
Return a tuple \((y, x)\) of the height and width of the window.

\[ \text{window. getparyx()} \]
Returns the beginning coordinates of this window relative to its parent window into two integer variables \(y\) and \(x\). Returns \(-1, -1\) if this window has no parent.

\[ \text{window. getstr([y, x])} \]
Read a string from the user, with primitive line editing capacity.

\[ \text{window. getyx()} \]
Return a tuple \((y, x)\) of current cursor position relative to the window’s upper-left corner.

\[ \text{window. hline([y, x], ch, n)} \]
Display a horizontal line starting at \((y, x)\) with length \(n\) consisting of the character \(ch\).

`window.idcok(flag)`

If \(flag\) is false, curses no longer considers using the hardware insert/delete character feature of the terminal; if \(flag\) is true, use of character insertion and deletion is enabled. When curses is first initialized, use of character insert/delete is enabled by default.

`window.idlok(yes)`

If called with \(yes\) equal to 1, `curses` will try and use hardware line editing facilities. Otherwise, line insertion/deletion are disabled.

`window.immedok(flag)`

If \(flag\) is true, any change in the window image automatically causes the window to be refreshed; you no longer have to call `refresh()` yourself. However, it may degrade performance considerably, due to repeated calls to `wrefresh`. This option is disabled by default.

`window.inch([[y, x]])`

Return the character at the given position in the window. The bottom 8 bits are the character proper, and upper bits are the attributes.

`window.insch([[y, x]], ch, [attr])`

Paint character \(ch\) at \((y, x)\) with attributes \(attr\), moving the line from position \(x\) right by one character.

`window.insdelln(nlines)`

Inserts \(nlines\) lines into the specified window above the current line. The \(nlines\) bottom lines are lost. For negative \(nlines\), delete \(nlines\) lines starting with the one under the cursor, and move the
remaining lines up. The bottom $n$ lines lines are cleared. The current cursor position remains the same.

`window.insertln()`
Insert a blank line under the cursor. All following lines are moved down by 1 line.

`window.insnstr([y, x], str, n[, attr])`
Insert a character string (as many characters as will fit on the line) before the character under the cursor, up to $n$ characters. If $n$ is zero or negative, the entire string is inserted. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to $y$, $x$, if specified).

`window.insstr([y, x], str[, attr])`
Insert a character string (as many characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to $y$, $x$, if specified).

`window.instr([y, x][, n])`
Returns a string of characters, extracted from the window starting at the current cursor position, or at $y$, $x$ if specified. Attributes are stripped from the characters. If $n$ is specified, `instr()` returns return a string at most $n$ characters long (exclusive of the trailing NUL).

`window.is_linetouched(line)`
Returns true if the specified line was modified since the last call to `refresh()`; otherwise returns false. Raises a `curses.error` exception if $line$ is not valid for the given window.
window.is_wintouched()
Returns true if the specified window was modified since the last call to refresh(); otherwise returns false.

window.keypad(yes)
If yes is 1, escape sequences generated by some keys (keypad, function keys) will be interpreted by curses. If yes is 0, escape sequences will be left as is in the input stream.

window.leaveok(yes)
If yes is 1, cursor is left where it is on update, instead of being at “cursor position.” This reduces cursor movement where possible. If possible the cursor will be made invisible.

If yes is 0, cursor will always be at “cursor position” after an update.

window.move(new_y, new_x)
Move cursor to (new_y, new_x).

window.mvderwin(y, x)
Moves the window inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

window.mvwin(new_y, new_x)
Move the window so its upper-left corner is at (new_y, new_x).

window.nodelay(yes)
If yes is 1, getch() will be non-blocking.

window.notimeout(yes)
If yes is 1, escape sequences will not be timed out.
If yes is 0, after a few milliseconds, an escape sequence will not be interpreted, and will be left in the input stream as is.

window. noutrefresh()
Mark for refresh but wait. This function updates the data structure representing the desired state of the window, but does not force an update of the physical screen. To accomplish that, call doupdate().

window. overlay(destwin[, sminrow, smincol, dminrow, dmincol, dmaxrow, dmaxcol])
Overlay the window on top of destwin. The windows need not be the same size, only the overlapping region is copied. This copy is non-destructive, which means that the current background character does not overwrite the old contents of destwin.

To get fine-grained control over the copied region, the second form of overlay() can be used. sminrow and smincol are the upper-left coordinates of the source window, and the other variables mark a rectangle in the destination window.

window. overwrite(destwin[, sminrow, smincol, dminrow, dmincol, dmaxrow, dmaxcol])
Overwrite the window on top of destwin. The windows need not be the same size, in which case only the overlapping region is copied. This copy is destructive, which means that the current background character overwrites the old contents of destwin.

To get fine-grained control over the copied region, the second form of overwrite() can be used. sminrow and smincol are the upper-left coordinates of the source window, the other variables mark a rectangle in the destination window.

window. putwin(file)
Writes all data associated with the window into the provided file object. This information can be later retrieved using the `getwin()` function.

```c
window.redrawln(beg, num)
```
Indicates that the `num` screen lines, starting at line `beg`, are corrupted and should be completely redrawn on the next `refresh()` call.

```c
window.redrawwin()
```
Touches the entire window, causing it to be completely redrawn on the next `refresh()` call.

```c
window.refresh([pminrow, pmincol, sminrow, smincol, smaxrow, smaxcol])
```
Update the display immediately (sync actual screen with previous drawing/deleting methods).

The 6 optional arguments can only be specified when the window is a pad created with `newpad()`. The additional parameters are needed to indicate what part of the pad and screen are involved. `pminrow` and `pmincol` specify the upper left-hand corner of the rectangle to be displayed in the pad. `sminrow`, `smincol`, `smaxrow`, and `smaxcol` specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of `pminrow`, `pmincol`, `sminrow`, or `smincol` are treated as if they were zero.

```c
window.scroll([lines=1])
```
Scroll the screen or scrolling region upward by `lines` lines.
window. **scrollok**(*flag*)

Controls what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If *flag* is false, the cursor is left on the bottom line. If *flag* is true, the window is scrolled up one line. Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call `idlok()`.

window. **setscrreg**(top, bottom)

Set the scrolling region from line *top* to line *bottom*. All scrolling actions will take place in this region.

window. **standend**()

Turn off the standout attribute. On some terminals this has the side effect of turning off all attributes.

window. **standout**()

Turn on attribute A_STANDOUT.

window. **subpad**([nlines, ncols], begin_y, begin_x)

Return a sub-window, whose upper-left corner is at (begin_y, begin_x), and whose width/height is ncols/nlines.

window. **subwin**([nlines, ncols], begin_y, begin_x)

Return a sub-window, whose upper-left corner is at (begin_y, begin_x), and whose width/height is ncols/nlines.

   By default, the sub-window will extend from the specified position to the lower right corner of the window.

window. **syncdown**()

Touches each location in the window that has been touched in any of its ancestor windows. This routine is called by `refresh()`,
so it should almost never be necessary to call it manually.

window. **syncok**(flag)

If called with flag set to true, then **syncup()** is called automatically whenever there is a change in the window.

window. **syncup()**

Touches all locations in ancestors of the window that have been changed in the window.

window. **timeout**(delay)

Sets blocking or non-blocking read behavior for the window. If delay is negative, blocking read is used (which will wait indefinitely for input). If delay is zero, then non-blocking read is used, and -1 will be returned by **getch()** if no input is waiting. If delay is positive, then **getch()** will block for delay milliseconds, and return -1 if there is still no input at the end of that time.

window. **touchline**(start, count[, changed])

Pretend count lines have been changed, starting with line start. If changed is supplied, it specifies whether the affected lines are marked as having been changed (changed=1) or unchanged (changed=0).

window. **touchwin()**

Pretend the whole window has been changed, for purposes of drawing optimizations.

window. **untouchwin()**

Marks all lines in the window as unchanged since the last call to **refresh()**.

window. **vline**([y, x], ch, n)

Display a vertical line starting at \((y, x)\) with length \(n\) consisting
of the character \textit{ch}. 
15.11.3. Constants

The `curses` module defines the following data members:

**curses.ERR**
Some curses routines that return an integer, such as `getch()`, return `ERR` upon failure.

**curses.OK**
Some curses routines that return an integer, such as `napms()`, return `OK` upon success.

**curses.version**
A string representing the current version of the module. Also available as `__version__`.

Several constants are available to specify character cell attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>A_ALTCHSET</td>
<td>Alternate character set mode.</td>
</tr>
<tr>
<td>A_BLINK</td>
<td>Blink mode.</td>
</tr>
<tr>
<td>A_BOLD</td>
<td>Bold mode.</td>
</tr>
<tr>
<td>A_DIM</td>
<td>Dim mode.</td>
</tr>
<tr>
<td>A_NORMAL</td>
<td>Normal attribute.</td>
</tr>
<tr>
<td>A_REVERSE</td>
<td>Reverse background and foreground colors.</td>
</tr>
<tr>
<td>A_STANDOUT</td>
<td>Standout mode.</td>
</tr>
<tr>
<td>A_UNDERLINE</td>
<td>Underline mode.</td>
</tr>
</tbody>
</table>

Keys are referred to by integer constants with names starting with `KEY_`. The exact keycaps available are system dependent.

<table>
<thead>
<tr>
<th>Key constant</th>
<th>Key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------------------------------------</td>
</tr>
<tr>
<td>KEY_MIN</td>
<td>Minimum key value</td>
</tr>
<tr>
<td>KEY_BREAK</td>
<td>Break key (unreliable)</td>
</tr>
<tr>
<td>KEY_DOWN</td>
<td>Down-arrow</td>
</tr>
<tr>
<td>KEY_UP</td>
<td>Up-arrow</td>
</tr>
<tr>
<td>KEY_LEFT</td>
<td>Left-arrow</td>
</tr>
<tr>
<td>KEY_RIGHT</td>
<td>Right-arrow</td>
</tr>
<tr>
<td>KEY_HOME</td>
<td>Home key (upward+left arrow)</td>
</tr>
<tr>
<td>KEY_BACKSPACE</td>
<td>Backspace (unreliable)</td>
</tr>
<tr>
<td>KEY_F0</td>
<td>Function keys. Up to 64 function keys are supported.</td>
</tr>
<tr>
<td>KEY_Fn</td>
<td>Value of function key ( n )</td>
</tr>
<tr>
<td>KEY_DL</td>
<td>Delete line</td>
</tr>
<tr>
<td>KEY_IL</td>
<td>Insert line</td>
</tr>
<tr>
<td>KEY_DC</td>
<td>Delete character</td>
</tr>
<tr>
<td>KEY_IC</td>
<td>Insert char or enter insert mode</td>
</tr>
<tr>
<td>KEY_EIC</td>
<td>Exit insert char mode</td>
</tr>
<tr>
<td>KEY_CLEAR</td>
<td>Clear insert screen</td>
</tr>
<tr>
<td>KEY_EOS</td>
<td>Clear to end of screen</td>
</tr>
<tr>
<td>KEY_EOL</td>
<td>Clear to end of line</td>
</tr>
<tr>
<td>KEY_SF</td>
<td>Scroll 1 line forward</td>
</tr>
<tr>
<td>KEY_SR</td>
<td>Scroll 1 line backward (reverse)</td>
</tr>
<tr>
<td>KEY_NPAGE</td>
<td>Next page</td>
</tr>
<tr>
<td>KEY_PPAGE</td>
<td>Previous page</td>
</tr>
<tr>
<td>KEY_STAB</td>
<td>Set tab</td>
</tr>
<tr>
<td>KEY_CTAB</td>
<td>Clear tab</td>
</tr>
<tr>
<td>KEY_CATAB</td>
<td>Clear all tabs</td>
</tr>
<tr>
<td>KEY_ENTER</td>
<td>Enter or send (unreliable)</td>
</tr>
<tr>
<td>KEY_SRESET</td>
<td>Soft (partial) reset (unreliable)</td>
</tr>
<tr>
<td>KEY_RESET</td>
<td>Reset or hard reset (unreliable)</td>
</tr>
<tr>
<td>KEY_PRINT</td>
<td>Print</td>
</tr>
<tr>
<td>KEY_LL</td>
<td>Home down or bottom (lower left)</td>
</tr>
<tr>
<td>KEY_A1</td>
<td>Upper left of keypad</td>

</tbody>
</table>
On VT100s and their software emulations, such as X terminal emulators, there are normally at least four function keys (KEY_F1, KEY_F2, KEY_F3, KEY_F4) available, and the arrow keys mapped to KEY_UP, KEY_DOWN, KEY_LEFT and KEY_RIGHT in the obvious way. If your machine has a PC keyboard, it is safe to expect arrow keys and twelve function keys (older PC keyboards may have only ten function keys); also, the following keypad mappings are standard:

<table>
<thead>
<tr>
<th>Keycap</th>
<th>Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insert</td>
<td>KEY_IC</td>
</tr>
<tr>
<td>Delete</td>
<td>KEY_DC</td>
</tr>
<tr>
<td>Home</td>
<td>KEY_HOME</td>
</tr>
<tr>
<td>End</td>
<td>KEY_END</td>
</tr>
<tr>
<td>Page Up</td>
<td>KEY_NPAGE</td>
</tr>
<tr>
<td>Page Down</td>
<td>KEY_PPAGE</td>
</tr>
</tbody>
</table>

The following table lists characters from the alternate character set. These are inherited from the VT100 terminal, and will generally be available on software emulations such as X terminals. When there is no graphic available, curses falls back on a crude printable ASCII approximation.

<table>
<thead>

<tr>
<td>COLOR_YELLOW</td>
<td>Yellow</td>
</tr>
</tbody>
</table>
The `curses.textpad` module provides a `Textbox` class that handles elementary text editing in a curses window, supporting a set of keybindings resembling those of Emacs (thus, also of Netscape Navigator, BBedit 6.x, FrameMaker, and many other programs). The module also provides a rectangle-drawing function useful for framing text boxes or for other purposes.

The module `curses.textpad` defines the following function:

```python

curses.textpad.rectangle(win, uly, ulx, lry, lrx)
```

Draw a rectangle. The first argument must be a window object; the remaining arguments are coordinates relative to that window. The second and third arguments are the y and x coordinates of the upper left hand corner of the rectangle to be drawn; the fourth and fifth arguments are the y and x coordinates of the lower right hand corner. The rectangle will be drawn using VT100/IBM PC forms characters on terminals that make this possible (including xterm and most other software terminal emulators). Otherwise it will be drawn with ASCII dashes, vertical bars, and plus signs.
15.12.1. Textbox objects

You can instantiate a `Textbox` object as follows:

```python
class curses.textpad.Textbox(win)
```

Return a textbox widget object. The `win` argument should be a `curses WindowObject` in which the textbox is to be contained. The edit cursor of the textbox is initially located at the upper left hand corner of the containing window, with coordinates \((0, 0)\). The instance's `stripspaces` flag is initially on.

`Textbox` objects have the following methods:

```
edit([validator])
```

This is the entry point you will normally use. It accepts editing keystrokes until one of the termination keystrokes is entered. If `validator` is supplied, it must be a function. It will be called for each keystroke entered with the keystroke as a parameter; command dispatch is done on the result. This method returns the window contents as a string; whether blanks in the window are included is affected by the `stripspaces` member.

```
do_command(ch)
```

Process a single command keystroke. Here are the supported special keystrokes:

<table>
<thead>
<tr>
<th>Keystroke</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Control-A</td>
<td>Go to left edge of window.</td>
</tr>
<tr>
<td>Control-B</td>
<td>Cursor left, wrapping to previous line if appropriate.</td>
</tr>
<tr>
<td>Control-D</td>
<td>Delete character under cursor.</td>
</tr>
<tr>
<td>Control-E</td>
<td>Go to right edge (stripspaces off) or end of line (stripspaces on).</td>
</tr>
<tr>
<td>Keystroke</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>Control-F</td>
<td>Cursor right, wrapping to next line when appropriate.</td>
</tr>
<tr>
<td>Control-G</td>
<td>Terminate, returning the window contents.</td>
</tr>
<tr>
<td>Control-H</td>
<td>Delete character backward.</td>
</tr>
<tr>
<td>Control-J</td>
<td>Terminate if the window is 1 line, otherwise insert newline.</td>
</tr>
<tr>
<td>Control-K</td>
<td>If line is blank, delete it, otherwise clear to end of line.</td>
</tr>
<tr>
<td>Control-L</td>
<td>Refresh screen.</td>
</tr>
<tr>
<td>Control-N</td>
<td>Cursor down; move down one line.</td>
</tr>
<tr>
<td>Control-O</td>
<td>Insert a blank line at cursor location.</td>
</tr>
<tr>
<td>Control-P</td>
<td>Cursor up; move up one line.</td>
</tr>
</tbody>
</table>

Move operations do nothing if the cursor is at an edge where the movement is not possible. The following synonyms are supported where possible:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Keystroke</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEY_LEFT</td>
<td>Control-B</td>
</tr>
<tr>
<td>KEY_RIGHT</td>
<td>Control-F</td>
</tr>
<tr>
<td>KEY_UP</td>
<td>Control-P</td>
</tr>
<tr>
<td>KEY_DOWN</td>
<td>Control-N</td>
</tr>
<tr>
<td>KEY_BACKSPACE</td>
<td>Control-h</td>
</tr>
</tbody>
</table>

All other keystrokes are treated as a command to insert the given character and move right (with line wrapping).

gather()
This method returns the window contents as a string; whether blanks in the window are included is affected by the stripspaces member.

stripspaces
This data member is a flag which controls the interpretation of blanks in the window. When it is on, trailing blanks on each line are ignored; any cursor motion that would land the cursor
on a trailing blank goes to the end of that line instead, and trailing blanks are stripped when the window contents are gathered.
15.13. 

**curses.wrapper — Terminal handler for curses programs**

*New in version 1.6.*

This module supplies one function, `wrapper()`, which runs another function which should be the rest of your curses-using application. If the application raises an exception, `wrapper()` will restore the terminal to a sane state before re-raising the exception and generating a traceback.

```python
curses.wrapper(func, ...)  # Wrapper function that initializes curses and calls another function, func, restoring normal keyboard/screen behavior on error. The callable object func is then passed the main window 'stdscr' as its first argument, followed by any other arguments passed to wrapper().
```

Before calling the hook function, `wrapper()` turns on cbreak mode, turns off echo, enables the terminal keypad, and initializes colors if the terminal has color support. On exit (whether normally or by exception) it restores cooked mode, turns on echo, and disables the terminal keypad.
New in version 1.6.

The `curses.ascii` module supplies name constants for ASCII characters and functions to test membership in various ASCII character classes. The constants supplied are names for control characters as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUL</td>
<td>Start of heading, console interrupt</td>
</tr>
<tr>
<td>SOH</td>
<td>Start of text</td>
</tr>
<tr>
<td>STX</td>
<td>End of text</td>
</tr>
<tr>
<td>ETX</td>
<td>End of text</td>
</tr>
<tr>
<td>EOT</td>
<td>End of transmission</td>
</tr>
<tr>
<td>ENQ</td>
<td>Enquiry, goes with ACK flow control</td>
</tr>
<tr>
<td>ACK</td>
<td>Acknowledgement</td>
</tr>
<tr>
<td>BEL</td>
<td>Bell</td>
</tr>
<tr>
<td>BS</td>
<td>Backspace</td>
</tr>
<tr>
<td>TAB</td>

<td>Alias for LF: “New line”</td>
</tr>
<tr>
<td>VT</td>
<td>Vertical tab</td>
</tr>
<tr>
<td>FF</td>
<td>Form feed</td>
</tr>
<tr>
<td>CR</td>
<td>Carriage return</td>
</tr>
<tr>
<td>SO</td>
<td>Shift-out, begin alternate character set</td>
</tr>
<tr>
<td>SI</td>
<td>Shift-in, resume default character set</td>
</tr>
<tr>
<td>DLE</td>
<td>Data-link escape</td>
</tr>
<tr>
<td>DC1</td>
<td>XON, for flow control</td>
</tr>
<tr>
<td>Code</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-----------------------------------------------------------</td>
</tr>
<tr>
<td>DC2</td>
<td>Device control 2, block-mode flow control</td>
</tr>
<tr>
<td>DC3</td>
<td>XOFF, for flow control</td>
</tr>
<tr>
<td>DC4</td>
<td>Device control 4</td>
</tr>
<tr>
<td>NAK</td>
<td>Negative acknowledgement</td>
</tr>
<tr>
<td>SYN</td>
<td>Synchronous idle</td>
</tr>
<tr>
<td>ETB</td>
<td>End transmission block</td>
</tr>
<tr>
<td>CAN</td>
<td>Cancel</td>
</tr>
<tr>
<td>EM</td>
<td>End of medium</td>
</tr>
<tr>
<td>SUB</td>
<td>Substitute</td>
</tr>
<tr>
<td>ESC</td>
<td>Escape</td>
</tr>
<tr>
<td>FS</td>
<td>File separator</td>
</tr>
<tr>
<td>GS</td>
<td>Group separator</td>
</tr>
<tr>
<td>RS</td>
<td>Record separator, block-mode terminator</td>
</tr>
<tr>
<td>US</td>
<td>Unit separator</td>
</tr>
<tr>
<td>SP</td>
<td>Space</td>
</tr>
<tr>
<td>DEL</td>
<td>Delete</td>
</tr>
</tbody>
</table>

Note that many of these have little practical significance in modern usage. The mnemonics derive from teleprinter conventions that predate digital computers.

The module supplies the following functions, patterned on those in the standard C library:

- `curses.ascii.isalnum(c)`
  Checks for an ASCII alphanumerical character; it is equivalent to `isalpha(c)` or `isdigit(c)`.`

- `curses.ascii.isalpha(c)`
  Checks for an ASCII alphabetic character; it is equivalent to `isupper(c)` or `islower(c)`.`

- `curses.ascii.isascii(c)`
Checks for a character value that fits in the 7-bit ASCII set.

curses.ascii.isblank(c)
Checks for an ASCII whitespace character.

curses.ascii.iscntrl(c)
Checks for an ASCII control character (in the range 0x00 to 0x1f).

curses.ascii.isdigit(c)
Checks for an ASCII decimal digit, '0' through '9'. This is equivalent to c in string.digits.

curses.ascii.isgraph(c)
Checks for ASCII any printable character except space.

curses.ascii.islower(c)
Checks for an ASCII lower-case character.

curses.ascii.isprint(c)
Checks for any ASCII printable character including space.

curses.ascii.ispunct(c)
Checks for any printable ASCII character which is not a space or an alphanumeric character.

curses.ascii.isspace(c)
Checks for ASCII white-space characters; space, line feed, carriage return, form feed, horizontal tab, vertical tab.

curses.ascii.isupper(c)
Checks for an ASCII uppercase letter.

curses.ascii.isxdigit(c)
Checks for an ASCII hexadecimal digit. This is equivalent to c in
curses.ascii.isctrl(c)

Checks for an ASCII control character (ordinal values 0 to 31).

curses.ascii.ismeta(c)

Checks for a non-ASCII character (ordinal values 0x80 and above).

These functions accept either integers or strings; when the argument is a string, it is first converted using the built-in function `ord()`.

Note that all these functions check ordinal bit values derived from the first character of the string you pass in; they do not actually know anything about the host machine's character encoding. For functions that know about the character encoding (and handle internationalization properly) see the `string` module.

The following two functions take either a single-character string or integer byte value; they return a value of the same type.

curses.ascii.ascii(c)

Return the ASCII value corresponding to the low 7 bits of c.

curses.ascii.ctrl(c)

Return the control character corresponding to the given character (the character bit value is bitwise-anded with 0x1f).

curses.ascii.alt(c)

Return the 8-bit character corresponding to the given ASCII character (the character bit value is bitwise-ored with 0x80).

The following function takes either a single-character string or integer value; it returns a string.
curses.ascii.unctrl(c)

Return a string representation of the ASCII character c. If c is printable, this string is the character itself. If the character is a control character (0x00-0x1f) the string consists of a caret (\'^\') followed by the corresponding uppercase letter. If the character is an ASCII delete (0x7f) the string is '^[?'. If the character has its meta bit (0x80) set, the meta bit is stripped, the preceding rules applied, and '!' prepended to the result.

curses.ascii.controlnames

A 33-element string array that contains the ASCII mnemonics for the thirty-two ASCII control characters from 0 (NUL) to 0x1f (US), in order, plus the mnemonic sp for the space character.
Panels are windows with the added feature of depth, so they can be stacked on top of each other, and only the visible portions of each window will be displayed. Panels can be added, moved up or down in the stack, and removed.
15.15.1. Functions

The module `curses.panel` defines the following functions:

- `curses.panel.bottom_panel()`: Returns the bottom panel in the panel stack.

- `curses.panel.new_panel(win)`: Returns a panel object, associating it with the given window `win`. Be aware that you need to keep the returned panel object referenced explicitly. If you don't, the panel object is garbage collected and removed from the panel stack.

- `curses.panel.top_panel()`: Returns the top panel in the panel stack.

- `curses.panel.update_panels()`: Updates the virtual screen after changes in the panel stack. This does not call `curses.doupdate()`, so you'll have to do this yourself.
15.15.2. Panel Objects

Panel objects, as returned by new_panel() above, are windows with a stacking order. There's always a window associated with a panel which determines the content, while the panel methods are responsible for the window's depth in the panel stack.

Panel objects have the following methods:

Panel. above()
  Returns the panel above the current panel.

Panel. below()
  Returns the panel below the current panel.

Panel. bottom()
  Push the panel to the bottom of the stack.

Panel. hidden()
  Returns true if the panel is hidden (not visible), false otherwise.

Panel. hide()
  Hide the panel. This does not delete the object, it just makes the window on screen invisible.

Panel. move(y, x)
  Move the panel to the screen coordinates (y, x).

Panel. replace(win)
  Change the window associated with the panel to the window win.

Panel. set_userptr(obj)
  Set the panel's user pointer to obj. This is used to associate an
arbitrary piece of data with the panel, and can be any Python object.

Panel\texttt{.show()} 
Display the panel (which might have been hidden).

Panel\texttt{.top()} 
Push panel to the top of the stack.

Panel\texttt{.userptr()} 
Returns the user pointer for the panel. This might be any Python object.

Panel\texttt{.window()} 
Returns the window object associated with the panel.
15.16. **platform** — Access to underlying platform’s identifying data

*New in version 2.3.*

**Note:** Specific platforms listed alphabetically, with Linux included in the Unix section.
15.16.1. Cross Platform

```
platform.architecture(executable=sys.executable, bits='',
linkage='')
```

Queries the given executable (defaults to the Python interpreter binary) for various architecture information.

Returns a tuple (bits, linkage) which contain information about the bit architecture and the linkage format used for the executable. Both values are returned as strings.

Values that cannot be determined are returned as given by the parameter presets. If bits is given as '', the `sizeof(pointer)()` (or `sizeof(long)()` on Python version < 1.5.2) is used as indicator for the supported pointer size.

The function relies on the system’s `file` command to do the actual work. This is available on most if not all Unix platforms and some non-Unix platforms and then only if the executable points to the Python interpreter. Reasonable defaults are used when the above needs are not met.

**Note:** On Mac OS X (and perhaps other platforms), executable files may be universal files containing multiple architectures.
To get at the “64-bitness” of the current interpreter, it is more reliable to query the `sys.maxsize` attribute:

```
is_64bits = sys.maxsize > 2**32
```

```
platform.machine()
```

Returns the machine type, e.g. 'i386'. An empty string is
returned if the value cannot be determined.

platform.node()
Returns the computer’s network name (may not be fully qualified!). An empty string is returned if the value cannot be determined.

platform.platform(aliaised=0, terse=0)
Returns a single string identifying the underlying platform with as much useful information as possible.

The output is intended to be human readable rather than machine parseable. It may look different on different platforms and this is intended.

If aliaised is true, the function will use aliases for various platforms that report system names which differ from their common names, for example SunOS will be reported as Solaris. The system_alias() function is used to implement this.

Setting terse to true causes the function to return only the absolute minimum information needed to identify the platform.

platform.processor()
Returns the (real) processor name, e.g. 'amdk6'.

An empty string is returned if the value cannot be determined. Note that many platforms do not provide this information or simply return the same value as for machine(). NetBSD does this.

platform.python_build()
Returns a tuple (buildno, builddate) stating the Python build number and date as strings.

platform.python_compiler()
Returns a string identifying the compiler used for compiling Python.

```
platform.python_branch()
```
Returns a string identifying the Python implementation SCM branch.

*New in version 2.6.*

```
platform.python_implementation()
```

*New in version 2.6.*

```
platform.python_revision()
```
Returns a string identifying the Python implementation SCM revision.

*New in version 2.6.*

```
platform.python_version()
```
Returns the Python version as string 'major.minor.patchlevel'

Note that unlike the Python `sys.version`, the returned value will always include the patchlevel (it defaults to 0).

```
platform.python_version_tuple()
```
Returns the Python version as tuple `(major, minor, patchlevel)` of strings.

Note that unlike the Python `sys.version`, the returned value will always include the patchlevel (it defaults to '0').

```
platform.release()
```
Returns the system's release, e.g. '2.2.0' or 'NT'. An empty string is returned if the value cannot be determined.

```
platform.system()
```

Returns the system/OS name, e.g. 'Linux', 'Windows', or 'Java'. An empty string is returned if the value cannot be determined.

```
platform.system_alias(system, release, version)
```

Returns (system, release, version) aliased to common marketing names used for some systems. It also does some reordering of the information in some cases where it would otherwise cause confusion.

```
platform.version()
```

Returns the system's release version, e.g. '#3 on degas'. An empty string is returned if the value cannot be determined.

```
platform.uname()
```

Fairly portable uname interface. Returns a tuple of strings (system, node, release, version, machine, processor) identifying the underlying platform.

Note that unlike the os.uname() function this also returns possible processor information as additional tuple entry.

Entries which cannot be determined are set to ''. 
15.16.2. Java Platform

```
platform.java_ver(release='', vendor='', vminfo=('', '', ''), osinfo=(''

Version interface for Jython.

Returns a tuple (release, vendor, vminfo, osinfo) with vminfo
being a tuple (vm_name, vm_release, vm_vendor) and osinfo
being a tuple (os_name, os_version, os_arch). Values which
cannot be determined are set to the defaults given as parameters
(which all default to '').
```
15.16.3. Windows Platform

platform.win32_ver(release='', version='', csd='', ptype='')

Get additional version information from the Windows Registry and return a tuple \((version, csd, ptype)\) referring to version number, CSD level and OS type (multi/single processor).

As a hint: \(ptype\) is 'Uniprocessor Free' on single processor NT machines and 'Multiprocessor Free' on multi processor machines. The ‘Free’ refers to the OS version being free of debugging code. It could also state ‘Checked’ which means the OS version uses debugging code, i.e. code that checks arguments, ranges, etc.

**Note:** This function works best with Mark Hammond’s win32all package installed, but also on Python 2.3 and later (support for this was added in Python 2.6). It obviously only runs on Win32 compatible platforms.

15.16.3.1. Win95/98 specific

platform.popen(cmd, mode='r', bufsize=None)

Portable \(popen()\) interface. Find a working popen implementation preferring \( \text{win32pipe.popen()}\). On Windows NT, \( \text{win32pipe.popen()}\) should work; on Windows 9x it hangs due to bugs in the MS C library.
15.16.4. Mac OS Platform

platform.mac_ver(release='', versioninfo=('', '', ''), machine='')

Get Mac OS version information and return it as tuple (release, versioninfo, machine) with versioninfo being a tuple (version, dev_stage, non_release_version).

Entries which cannot be determined are set to ''. All tuple entries are strings.

Documentation for the underlying gestalt() API is available online at http://www.rgaros.nl/gestalt/.
15.16.5. Unix Platforms

platform.dist(distname='', version='', id='', supported_dists=('SuSE', 'debian', 'redhat', 'mandrake', ...))

This is an old version of the functionality now provided by linux_distribution(). For new code, please use the linux_distribution().

The only difference between the two is that dist() always returns the short name of the distribution taken from the supported_dists parameter.

Deprecated since version 2.6.

platform.linux_distribution(distname='', version='', id='', supported_dists=('SuSE', 'debian', 'redhat', 'mandrake', ...), full_distribution_name=1)

Tries to determine the name of the Linux OS distribution name.

supported_dists may be given to define the set of Linux distributions to look for. It defaults to a list of currently supported Linux distributions identified by their release file name.

If full_distribution_name is true (default), the full distribution read from the OS is returned. Otherwise the short name taken from supported_dists is used.

Returns a tuple (distname,version,id) which defaults to the args given as parameters. id is the item in parentheses after the version number. It is usually the version codename.

New in version 2.6.
platform.libc_ver(executable=sys.executable, lib='', version='', chunksize=2048)

Tries to determine the libc version against which the file executable (defaults to the Python interpreter) is linked. Returns a tuple of strings (lib, version) which default to the given parameters in case the lookup fails.

Note that this function has intimate knowledge of how different libc versions add symbols to the executable is probably only usable for executables compiled using gcc.

The file is read and scanned in chunks of chunksize bytes.
15. Generic Operating System Services
15.17. **errno — Standard errno system symbols**

This module makes available standard *errno* system symbols. The value of each symbol is the corresponding integer value. The names and descriptions are borrowed from `linux/include/errno.h`, which should be pretty all-inclusive.

**errno.errorcode**

Dictionary providing a mapping from the errno value to the string name in the underlying system. For instance, `errno.errorcode[errno.EPERM]` maps to `'EPERM'`.

To translate a numeric error code to an error message, use `os.strerror()`.

Of the following list, symbols that are not used on the current platform are not defined by the module. The specific list of defined symbols is available as `errno.errorcode.keys()`. Symbols available can include:

**errno.EPERM**

Operation not permitted

**errno.ENOENT**

No such file or directory

**errno.ESRCH**

No such process

**errno.EINTR**

Interrupted system call

**errno.EIO**
I/O error

errno. **ENXIO**
   No such device or address

errno. **E2BIG**
   Arg list too long

errno. **ENOEXEC**
   Exec format error

errno. **EBADF**
   Bad file number

errno. **ECHILD**
   No child processes

errno. **EAGAIN**
   Try again

errno. **ENOMEM**
   Out of memory

errno. **EACCES**
   Permission denied

errno. **EFAULT**
   Bad address

errno. **ENOTBLK**
   Block device required

errno. **EBUSY**
   Device or resource busy

errno. **EEXIST**
   File exists
errno. **EXDEV**
Cross-device link

errno. **ENODEV**
No such device

errno. **ENOTDIR**
Not a directory

errno. **EISDIR**
Is a directory

errno. **EINVAL**
Invalid argument

errno. **ENFILE**
File table overflow

errno. **EMFILE**
Too many open files

errno. **ENOTTY**
Not a typewriter

errno. **ETXTBSY**
Text file busy

errno. **EBIG**
File too large

errno. **ENOSPC**
No space left on device

errno. **ESPIPE**
Illegal seek

errno. **EROFS**
Read-only file system
errno. **EMLINK**
    Too many links

errno. **EPIPE**
    Broken pipe

errno. **EDOM**
    Math argument out of domain of func

errno. **ERANGE**
    Math result not representable

errno. **EDEADLK**
    Resource deadlock would occur

errno. **ENAMETOOLONG**
    File name too long

errno. **ENOLCK**
    No record locks available

errno. **ENOSYS**
    Function not implemented

errno. **ENOTEMPTY**
    Directory not empty

errno. **ELOOP**
    Too many symbolic links encountered

errno. **EWOULDBLOCK**
    Operation would block

errno. **ENOMSG**
    No message of desired type

errno. **EIDRM**
    Identifier removed
errno. **ECHRN**G
    Channel number out of range

errno. **EL2NSYNC**
    Level 2 not synchronized

errno. **EL3HLT**
    Level 3 halted

errno. **EL3RST**
    Level 3 reset

errno. **ELNRNG**
    Link number out of range

errno. **EUNATCH**
    Protocol driver not attached

errno. **ENOCSI**
    No CSI structure available

errno. **EL2HLT**
    Level 2 halted

errno. **EBADE**
    Invalid exchange

errno. **EBADR**
    Invalid request descriptor

errno. **EXFULL**
    Exchange full

errno. **ENOANO**
    No anode

errno. **EBADRQC**
    Invalid request code
errno. **EBADSLT**
Invalid slot

errno. **EDEADLOCK**
File locking deadlock error

errno. **EBFONT**
Bad font file format

errno. **ENOSTR**
Device not a stream

errno. **ENODATA**
No data available

errno. **ETIME**
Timer expired

errno. **ENOSR**
Out of streams resources

errno. **ENONET**
Machine is not on the network

errno. **ENOPKG**
Package not installed

errno. **EREMOTE**
Object is remote

errno. **ENOLINK**
Link has been severed

errno. **EADV**
Advertise error

errno. **ESRMNT**
Srmount error
errno. **ECOMM**
Communication error on send

errno. **EPROTO**
Protocol error

errno. **EMULTIHOP**
Multihop attempted

errno. **EDOTDOT**
RFS specific error

errno. **EBADMSG**
Not a data message

errno. **EOVERFLOW**
Value too large for defined data type

errno. **ENOTUNIQ**
Name not unique on network

errno. **EBADFD**
File descriptor in bad state

errno. **EREMCHG**
Remote address changed

errno. **ELIBACC**
Can not access a needed shared library

errno. **ELIBBAD**
Accessing a corrupted shared library

errno. **ELIBSCN**
.lib section in a.out corrupted

errno. **ELIBMAX**
Attempting to link in too many shared libraries
errno. **ELIBEXEC**
Cannot exec a shared library directly

errno. **EILSEQ**
Illegal byte sequence

errno. **ERESTART**
Interrupted system call should be restarted

errno. **ESTRPIPE**
Streams pipe error

errno. **EUSERS**
Too many users

errno. **ENOTSOCK**
Socket operation on non-socket

errno. **EDESTADDRREQ**
Destination address required

errno. **EMSGSIZE**
Message too long

errno. **EPROTOTYPE**
Protocol wrong type for socket

errno. **ENOPROTOOPT**
Protocol not available

errno. **EPROTONOSUPPORT**
Protocol not supported

errno. **ESOCKTNOSUPPORT**
Socket type not supported

errno. **EOPNOTSUPP**
Operation not supported on transport endpoint
errno. **EPFNOSUPPORT**
   Protocol family not supported

errno. **EAFNOSUPPORT**
   Address family not supported by protocol

errno. **EADDRINUSE**
   Address already in use

errno. **EADDRNOTAVAIL**
   Cannot assign requested address

errno. **ENETDOWN**
   Network is down

errno. **ENETUNREACH**
   Network is unreachable

errno. **ENETRESET**
   Network dropped connection because of reset

errno. **ECONNABORTED**
   Software caused connection abort

errno. **ECONNRESET**
   Connection reset by peer

errno. **ENOBUFFS**
   No buffer space available

errno. **EISCONN**
   Transport endpoint is already connected

errno. **ENOTCONN**
   Transport endpoint is not connected

errno. **ESHUTDOWN**
   Cannot send after transport endpoint shutdown
errno. **ETOOMANYREFS**
   Too many references: cannot splice

errno. **ETIMEDOUT**
   Connection timed out

errno. **ECONNREFUSED**
   Connection refused

errno. **EHOSTDOWN**
   Host is down

errno. **EHOSTUNREACH**
   No route to host

errno. **EALREADY**
   Operation already in progress

errno. **EINPROGRESS**
   Operation now in progress

errno. **ESTALE**
   Stale NFS file handle

errno. **EUCLEAN**
   Structure needs cleaning

errno. **ENOTNAM**
   Not a XENIX named type file

errno. **ENAVAIL**
   No XENIX semaphores available

errno. **EISNAM**
   Is a named type file

errno. **EREMOTEIO**
   Remote I/O error
errno. **EDQUOT**

Quota exceeded
15. Generic Operating System Services
New in version 2.5.

`ctypes` is a foreign function library for Python. It provides C compatible data types, and allows calling functions in DLLs or shared libraries. It can be used to wrap these libraries in pure Python.
15.18.1. ctypes tutorial

Note: The code samples in this tutorial use doctest to make sure that they actually work. Since some code samples behave differently under Linux, Windows, or Mac OS X, they contain doctest directives in comments.

Note: Some code samples reference the ctypes c_int type. This type is an alias for the c_long type on 32-bit systems. So, you should not be confused if c_long is printed if you would expect c_int — they are actually the same type.

15.18.1.1. Loading dynamic link libraries

cypes exports the cdll, and on Windows windll and oledll objects, for loading dynamic link libraries.

You load libraries by accessing them as attributes of these objects. cdll loads libraries which export functions using the standard cdecl calling convention, while windll libraries call functions using the stdcall calling convention. oledll also uses the stdcall calling convention, and assumes the functions return a Windows HRESULT error code. The error code is used to automatically raise a WindowsError exception when the function call fails.

Here are some examples for Windows. Note that msvcr is the MS standard C library containing most standard C functions, and uses the cdecl calling convention:

```python
>>> from ctypes import *
>>> print windll.kernel32 # doctest: +WINDOWS
<WinDLL 'kernel32', handle ... at ...>
>>> print cdll.msvcr # doctest: +WINDOWS
<CDLL 'msvcr', handle ... at ...>
```
Windows appends the usual `.dll` file suffix automatically.

On Linux, it is required to specify the filename *including* the extension to load a library, so attribute access cannot be used to load libraries. Either the `LoadLibrary()` method of the dll loaders should be used, or you should load the library by creating an instance of `CDLL` by calling the constructor:

```python
>>> cdll.LoadLibrary("libc.so.6") # doctest: +LINUX
<CDLL 'libc.so.6', handle ... at ...>
>>> libc = CDLL("libc.so.6")    # doctest: +LINUX
>>> libc                     # doctest: +LINUX
<CDLL 'libc.so.6', handle ... at ...>
```

15.18.1.2. Accessing functions from loaded dlls

Functions are accessed as attributes of dll objects:

```python
>>> from ctypes import *
>>> libc.printf
<_FuncPtr object at 0x...>
>>> print windll.kernel32.GetModuleHandleA # doctest: +WINDOWS
<_FuncPtr object at 0x...>
>>> print windll.kernel32.MyOwnFunction # doctest: +WINDOWS
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
  File "ctypes.py", line 239, in __getattr__
    func = _StdcallFuncPtr(name, self)
AttributeError: function 'MyOwnFunction' not found
```

Note that win32 system dlls like `kernel32` and `user32` often export ANSI as well as UNICODE versions of a function. The UNICODE version is exported with an `w` appended to the name, while the ANSI version is exported with an `A` appended to the name. The win32
GetModuleHandle function, which returns a *module handle* for a given module name, has the following C prototype, and a macro is used to expose one of them as GetModuleHandle depending on whether UNICODE is defined or not:

```c
/* ANSI version */
HMODULE GetModuleHandleA(LPCSTR lpModuleName);
/* UNICODE version */
HMODULE GetModuleHandleW(LPCWSTR lpModuleName);
```

*windll* does not try to select one of them by magic, you must access the version you need by specifying GetModuleHandleA or GetModuleHandleW explicitly, and then call it with strings or unicode strings respectively.

Sometimes, dlls export functions with names which aren’t valid Python identifiers, like "??2@YAPAXI@Z". In this case you have to use `getattr()` to retrieve the function:

```python
>>> getattr(cdll.msvcr, "??2@YAPAXI@Z") # doctest: +WINDOWS
<_FuncPtr object at 0x...>
```

On Windows, some dlls export functions not by name but by ordinal. These functions can be accessed by indexing the dll object with the ordinal number:

```python
>>> cdll.kernel32[1] # doctest: +WINDOWS
<_FuncPtr object at 0x...>
>>> cdll.kernel32[0] # doctest: +WINDOWS
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
  File "ctypes.py", line 310, in __getitem__
    func = _StdcallFuncPtr(name, self)
AttributeError: function ordinal 0 not found
```
You can call these functions like any other Python callable. This example uses the `time()` function, which returns system time in seconds since the Unix epoch, and the `GetModuleHandleA()` function, which returns a win32 module handle.

This example calls both functions with a NULL pointer (None should be used as the NULL pointer):

```python
>>> print libc.time(None)  # doctest: +SKIP
1150640792
>>> print hex(windll.kernel32.GetModuleHandleA(None))  # doctest:
0x1d000000
```

ctypes tries to protect you from calling functions with the wrong number of arguments or the wrong calling convention. Unfortunately this only works on Windows. It does this by examining the stack after the function returns, so although an error is raised the function has been called:

```python
>>> windll.kernel32.GetModuleHandleA()  # doctest: +WINDOWS
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
ValueError: Procedure probably called with not enough arguments
```

The same exception is raised when you call an `stdcall` function with the cdecl calling convention, or vice versa:

```python
>>> cdll.kernel32.GetModuleHandleA(None)  # doctest: +WINDOWS
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
```
To find out the correct calling convention you have to look into the C header file or the documentation for the function you want to call.

On Windows, ctypes uses win32 structured exception handling to prevent crashes from general protection faults when functions are called with invalid argument values:

```python
>>> windll.kernel32.GetModuleHandleA(32) # doctest: +WINDOWS
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
WindowsError: exception: access violation reading 0x00000020
>>> 
```

There are, however, enough ways to crash Python with ctypes, so you should be careful anyway.

None, integers, longs, byte strings and unicode strings are the only native Python objects that can directly be used as parameters in these function calls. None is passed as a C NULL pointer, byte strings and unicode strings are passed as pointer to the memory block that contains their data (char * or wchar_t *). Python integers and Python longs are passed as the platforms default C int type, their value is masked to fit into the C type.

Before we move on calling functions with other parameter types, we have to learn more about ctypes data types.

15.18.1.4. Fundamental data types
**ctypes** defines a number of primitive C compatible data types:

<table>
<thead>
<tr>
<th>ctypes type</th>
<th>C type</th>
<th>Python type</th>
</tr>
</thead>
<tbody>
<tr>
<td>c_bool</td>
<td>_Bool</td>
<td>bool (1)</td>
</tr>
<tr>
<td>c_char</td>
<td>char</td>
<td>1-character string</td>
</tr>
<tr>
<td>c_wchar</td>
<td>wchar_t</td>
<td>1-character unicode string</td>
</tr>
<tr>
<td>c_byte</td>
<td>char</td>
<td>int/long</td>
</tr>
<tr>
<td>c_ubyte</td>
<td>unsigned char</td>
<td>int/long</td>
</tr>
<tr>
<td>c_short</td>
<td>short</td>
<td>int/long</td>
</tr>
<tr>
<td>c_ushort</td>
<td>unsigned short</td>
<td>int/long</td>
</tr>
<tr>
<td>c_int</td>
<td>int</td>
<td>int/long</td>
</tr>
<tr>
<td>c_uint</td>
<td>unsigned int</td>
<td>int/long</td>
</tr>
<tr>
<td>c_long</td>
<td>long</td>
<td>int/long</td>
</tr>
<tr>
<td>c_ulong</td>
<td>unsigned long</td>
<td>int/long</td>
</tr>
<tr>
<td>c_longlong</td>
<td>__int64 Or long long</td>
<td>int/long</td>
</tr>
<tr>
<td>c_ulonglong</td>
<td>unsigned __int64 Or unsigned long long</td>
<td>int/long</td>
</tr>
<tr>
<td>c_float</td>
<td>float</td>
<td>float</td>
</tr>
<tr>
<td>c_double</td>
<td>double</td>
<td>float</td>
</tr>
<tr>
<td>c_longdouble</td>
<td>long double</td>
<td>float</td>
</tr>
<tr>
<td>c_char_p</td>
<td>char * (NUL terminated)</td>
<td>string Or None</td>
</tr>
<tr>
<td>c_wchar_p</td>
<td>wchar_t * (NUL terminated)</td>
<td>unicode Or None</td>
</tr>
<tr>
<td>c_void_p</td>
<td>void *</td>
<td>int/long Or None</td>
</tr>
</tbody>
</table>

1. The constructor accepts any object with a truth value.

All these types can be created by calling them with an optional initializer of the correct type and value:

```python
c_int()
c_long(0)
c_char_p("Hello, World")
c_char_p('Hello, World')
c_ushort(-3)
```
Since these types are mutable, their value can also be changed afterwards:

```python
>>> i = c_int(42)
>>> print i
42
>>> print i.value
42
>>> i.value = -99
>>> print i.value
-99
```  
Assigning a new value to instances of the pointer types `c_char_p`, `c_wchar_p`, and `c_void_p` changes the memory location they point to, not the contents of the memory block (of course not, because Python strings are immutable):

```python
>>> s = "Hello, World"
>>> c_s = c_char_p(s)
>>> print c_s
'Hello, World'
>>> c_s.value = "Hi, there"
>>> print c_s
'Hi, there'
>>> print s # first string is unchanged
Hello, World
```  
You should be careful, however, not to pass them to functions expecting pointers to mutable memory. If you need mutable memory blocks, ctypes has a `create_string_buffer()` function which creates these in various ways. The current memory block contents can be accessed (or changed) with the `raw` property; if you want to access it as NUL terminated string, use the `value` property:
The `create_string_buffer()` function replaces the `c_buffer()` function (which is still available as an alias), as well as the `c_string()` function from earlier ctypes releases. To create a mutable memory block containing unicode characters of the C type `wchar_t` use the `create_unicode_buffer()` function.

### 15.18.1.5. Calling functions, continued

Note that `printf` prints to the real standard output channel, not to `sys.stdout`, so these examples will only work at the console prompt, not from within `IDLE` or `PythonWin`:

```python
>>> printf = libc.printf
>>> printf("Hello, %s\n", "World!")
Hello, World!
14
>>> printf("Hello, %S\n", u"World!")
Hello, World!
14
>>> printf("%d bottles of beer\n", 42)
42 bottles of beer
19
>>> printf("%f bottles of beer\n", 42.5)
```
As has been mentioned before, all Python types except integers, strings, and unicode strings have to be wrapped in their corresponding ctypes type, so that they can be converted to the required C data type:

```python
>>> printf("An int %d, a double %f\n", 1234, c_double(3.14))
An int 1234, a double 3.140000
31
>>> 
```

### 15.18.1.6. Calling functions with your own custom data types

You can also customize ctypes argument conversion to allow instances of your own classes be used as function arguments. ctypes looks for an `_as_parameter_` attribute and uses this as the function argument. Of course, it must be one of integer, string, or unicode:

```python
>>> class Bottles(object):
...    def __init__(self, number):
...        self._as_parameter_ = number
...
>>> bottles = Bottles(42)
>>> printf("%d bottles of beer\n", bottles)
42 bottles of beer
19
>>> 
```

If you don’t want to store the instance’s data in the `_as_parameter_` instance variable, you could define a `property()` which makes the data available.
15.18.1.7. Specifying the required argument types (function prototypes)

It is possible to specify the required argument types of functions exported from DLLs by setting the `argtypes` attribute.

`argtypes` must be a sequence of C data types (the `printf` function is probably not a good example here, because it takes a variable number and different types of parameters depending on the format string, on the other hand this is quite handy to experiment with this feature):

```python
>>> printf.argtypes = [c_char_p, c_char_p, c_int, c_double]
>>> printf("String '\%s', Int \%d, Double \%f\n", "Hi", 10, 2.2)
String 'Hi', Int 10, Double 2.200000
37
>>> 
```

Specifying a format protects against incompatible argument types (just as a prototype for a C function), and tries to convert the arguments to valid types:

```python
>>> printf("\%d \%d \%d", 1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
ArgumentError: argument 2: exceptions.TypeError: wrong type
>>> printf("\%s \%d \%f\n", "x", 2, 3)
x 2 3.000000
13
>>> 
```

If you have defined your own classes which you pass to function calls, you have to implement a `from_param()` class method for them to be able to use them in the `argtypes` sequence. The `from_param()` class method receives the Python object passed to the function call, it should do a typecheck or whatever is needed to make sure this object is acceptable, and then return the object itself, its
_as_parameter_ attribute, or whatever you want to pass as the C function argument in this case. Again, the result should be an integer, string, unicode, a ctypes instance, or an object with an _as_parameter_ attribute.

15.18.1.8. Return types

By default functions are assumed to return the C int type. Other return types can be specified by setting the restype attribute of the function object.

Here is a more advanced example, it uses the strchr function, which expects a string pointer and a char, and returns a pointer to a string:

```python
>>> strchr = libc.strchr
>>> strchr("abcdef", ord("d")) # doctest: +SKIP 8059983
>>> strchr.restype = c_char_p # c_char_p is a pointer to a string
>>> strchr("abcdef", ord("d"))
'def'
>>> print strchr("abcdef", ord("x"))
None
>>>
```

If you want to avoid the `ord("x")` calls above, you can set the argtypes attribute, and the second argument will be converted from a single character Python string into a C char:

```python
>>> strchr.restype = c_char_p
>>> strchr.argtypes = [c_char_p, c_char]
>>> strchr("abcdef", "d")
'def'
>>> strchr("abcdef", "def")
```

Traceback (most recent call last):
  File "<stdin>", line 1, in ?
ArgumentError: argument 2: exceptions.TypeError: one character
>>> print strchr("abcdef", "x")
```

None
You can also use a callable Python object (a function or a class for example) as the `restype` attribute, if the foreign function returns an integer. The callable will be called with the `integer` the C function returns, and the result of this call will be used as the result of your function call. This is useful to check for error return values and automatically raise an exception:

```
>>> GetModuleHandle = windll.kernel32.GetModuleHandleA  # doctest: +WINDOWS
>>> def ValidHandle(value):
...     if value == 0:
...         raise WinError()
...     return value
...  
>>> GetModuleHandle(None)  # doctest: +WINDOWS
486539264
>>> GetModuleHandle("something silly")  # doctest: +WINDOWS
Traceback (most recent call last):
  File "<stdin>"", line 1, in ?
  File "<stdin>"", line 3, in ValidHandle
WindowsError: [Errno 126] The specified module could not be found.
```

`WinError` is a function which will call Windows `FormatMessage()` api to get the string representation of an error code, and `returns` an exception. `WinError` takes an optional error code parameter, if no one is used, it calls `GetLastError()` to retrieve it.

Please note that a much more powerful error checking mechanism is available through the `errcheck` attribute; see the reference manual for details.

15.18.1.9. Passing pointers (or: passing
Sometimes a C api function expects a pointer to a data type as parameter, probably to write into the corresponding location, or if the data is too large to be passed by value. This is also known as passing parameters by reference.

ctypes exports the byref() function which is used to pass parameters by reference. The same effect can be achieved with the pointer() function, although pointer() does a lot more work since it constructs a real pointer object, so it is faster to use byref() if you don't need the pointer object in Python itself:

```python
>>> i = c_int()
>>> f = c_float()
>>> s = create_string_buffer('\000' * 32)
>>> print i.value, f.value, repr(s.value)
0 0.0 ''
>>> libc sscanf("1 3.14 Hello", "%d %f %s", ... byref(i), byref(f), s)
3
>>> print i.value, f.value, repr(s.value)
1 3.1400001049 'Hello'
>>>
```

15.18.1.10. Structures and unions

Structures and unions must derive from the Structure and Union base classes which are defined in the ctypes module. Each subclass must define a _fields_ attribute. _fields_ must be a list of 2-tuples, containing a field name and a field type.

The field type must be a ctypes type like c_int, or any other derived ctypes type: structure, union, array, pointer.

Here is a simple example of a POINT structure, which contains two
integers named $x$ and $y$, and also shows how to initialize a structure in the constructor:

```python
>>> from ctypes import *
>>> class POINT(Structure):
...    _fields_ = [("x", c_int),
...                ("y", c_int)]
...
>>> point = POINT(10, 20)
>>> print point.x, point.y
10 20
>>> point = POINT(y=5)
>>> print point.x, point.y
0 5
>>> POINT(1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
ValueError: too many initializers
```

You can, however, build much more complicated structures. Structures can itself contain other structures by using a structure as a field type.

Here is a RECT structure which contains two POINTs named `upperleft` and `lowerright`:

```python
>>> class RECT(Structure):
...    _fields_ = [("upperleft", POINT),
...                ("lowerright", POINT)]
...
>>> rc = RECT(point)
>>> print rc.upperleft.x, rc.upperleft.y
0 5
>>> print rc.lowerright.x, rc.lowerright.y
0 0
``` 

Nested structures can also be initialized in the constructor in several ways:

```python
>>> r = RECT(POINT(1, 2), POINT(3, 4))
```
Field descriptors can be retrieved from the class, they are useful for debugging because they can provide useful information:

```python
>>> print POINT.x
<Field type=c_long, ofs=0, size=4>
>>> print POINT.y
<Field type=c_long, ofs=4, size=4>
>>>```

15.18.1.11. Structure/union alignment and byte order

By default, Structure and Union fields are aligned in the same way the C compiler does it. It is possible to override this behavior by specifying a `_pack_` class attribute in the subclass definition. This must be set to a positive integer and specifies the maximum alignment for the fields. This is what `#pragma pack(n)` also does in MSVC.

c types uses the native byte order for Structures and Unions. To build structures with non-native byte order, you can use one of the `BigEndianStructure`, `LittleEndianStructure`, `BigEndianUnion`, and `LittleEndianUnion` base classes. These classes cannot contain pointer fields.

15.18.1.12. Bit fields in structures and unions

It is possible to create structures and unions containing bit fields. Bit fields are only possible for integer fields, the bit width is specified as the third item in the `_fields_` tuples:

```python
>>> class Int(Structure):
...     _fields_ = ["first_16", c_int, 16],
```
... (["second_16", c_int, 16])
...

>>> print Int.first_16
<Field type=c_long, ofs=0:0, bits=16>
>>> print Int.second_16
<Field type=c_long, ofs=0:16, bits=16>

15.18.1.13. Arrays

Arrays are sequences, containing a fixed number of instances of the same type.

The recommended way to create array types is by multiplying a data type with a positive integer:

TenPointsArrayType = POINT * 10

Here is an example of an somewhat artificial data type, a structure containing 4 POINTs among other stuff:

>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
... 
>>> class MyStruct(Structure):
...     _fields_ = [("a", c_int),
...                 ("b", c_float),
...                 ("point_array", POINT * 4)]

>>> print len(MyStruct().point_array)
4

Instances are created in the usual way, by calling the class:

arr = TenPointsArrayType()
for pt in arr:
    print pt.x, pt.y
The above code prints a series of 0 lines, because the array contents is initialized to zeros.

Initializers of the correct type can also be specified:

```python
>>> from ctypes import *
>>> TenIntegers = c_int * 10
>>> ii = TenIntegers(1, 2, 3, 4, 5, 6, 7, 8, 9, 10)
>>> print ii
<c_long_Array_10 object at 0x...>
>>> for i in ii: print i,
... 1 2 3 4 5 6 7 8 9 10

15.18.1.14. Pointers

Pointer instances are created by calling the `pointer()` function on a `ctypes` type:

```python
>>> from ctypes import *
>>> i = c_int(42)
>>> pi = pointer(i)
```

Pointer instances have a `contents` attribute which returns the object to which the pointer points, the `i` object above:

```python
>>> pi.contents
c_long(42)
```

Note that `ctypes` does not have OOR (original object return), it constructs a new, equivalent object each time you retrieve an attribute:

```python
>>> pi.contents is i
False
```
Assigning another `c_int` instance to the pointer’s contents attribute would cause the pointer to point to the memory location where this is stored:

```
>>> i = c_int(99)
>>> pi.contents = i
>>> pi.contents
c_long(99)
```  

Pointer instances can also be indexed with integers:

```
>>> pi[0]
99
```  

Assigning to an integer index changes the pointed to value:

```
>>> print i
c_long(99)
>>> pi[0] = 22
>>> print i
c_long(22)
```  

It is also possible to use indexes different from 0, but you must know what you’re doing, just as in C: You can access or change arbitrary memory locations. Generally you only use this feature if you receive a pointer from a C function, and you know that the pointer actually points to an array instead of a single item.

Behind the scenes, the `pointer()` function does more than simply create pointer instances, it has to create pointer types first. This is done with the `POINTER()` function, which accepts any `ctypes` type, and returns a new type:
Calling the pointer type without an argument creates a **NULL** pointer. **NULL** pointers have a **False** boolean value:

```python
>>> null_ptr = POINTER(c_int)()
>>> print bool(null_ptr)
False
```

**ctypes** checks for **NULL** when dereferencing pointers (but dereferencing invalid non-**NULL** pointers would crash Python):

```python
>>> null_ptr[0]
Traceback (most recent call last):
 ....
ValueError: NULL pointer access

>>> null_ptr[0] = 1234
Traceback (most recent call last):
 ....
ValueError: NULL pointer access
```

**15.18.1.15. Type conversions**

Usually, **ctypes** does strict type checking. This means, if you have **POINTER(c_int)** in the **argtypes** list of a function or as the type of a member field in a structure definition, only instances of exactly the same type are accepted. There are some exceptions to this rule,
where ctypes accepts other objects. For example, you can pass compatible array instances instead of pointer types. So, for `POINTER(c_int)`, ctypes accepts an array of `c_int`:

```python
>>> class Bar(Structure):
...    _fields_ = [("count", c_int), ("values", POINTER(c_int))
...    
... bar = Bar()
>>> bar.values = (c_int * 3)(1, 2, 3)
>>> bar.count = 3
>>> for i in range(bar.count):
...    print bar.values[i]
...
1
2
3
>>> bar.values = None
>>> bar.values = (c_byte * 4)()
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
TypeError: incompatible types, c_byte_Array_4 instance instead
>>> cast()
```

To set a POINTER type field to `NULL`, you can assign `None`:

```python
>>> bar.values = None
>>> bar.values = (c_byte * 4)()
```

Sometimes you have instances of incompatible types. In C, you can cast one type into another type. ctypes provides a `cast()` function which can be used in the same way. The `Bar` structure defined above accepts `POINTER(c_int)` pointers or `c_int` arrays for its `values` field, but not instances of other types:

```python
>>> bar.values = (c_byte * 4)()
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
TypeError: incompatible types, c_byte_Array_4 instance instead
>>> cast()
```

For these cases, the `cast()` function is handy.

The `cast()` function can be used to cast a ctypes instance into a
pointer to a different ctypes data type. \texttt{cast()} takes two parameters, an ctypes object that is or can be converted to a pointer of some kind, and a ctypes pointer type. It returns an instance of the second argument, which references the same memory block as the first argument:

\begin{Verbatim}
>>> a = (c_byte * 4)()
>>> cast(a, POINTER(c_int))
<ctypes.LP_c_long object at ...>
\end{Verbatim}

So, \texttt{cast()} can be used to assign to the \texttt{values} field of \texttt{Bar} the structure:

\begin{Verbatim}
>>> bar = Bar()
>>> bar.values = cast((c_byte * 4)(), POINTER(c_int))
>>> print bar.values[0]
0
\end{Verbatim}

### 15.18.1.16. Incomplete Types

\textit{Incomplete Types} are structures, unions or arrays whose members are not yet specified. In C, they are specified by forward declarations, which are defined later:

```c
struct cell; /* forward declaration */

struct {
    char *name;
    struct cell *next;
} cell;
```

The straightforward translation into ctypes code would be this, but it does not work:

```python
>>> class cell(Structure):
...     _fields_ = ["name", c_char_p],
```
because the new class `cell` is not available in the class statement itself. In ctypes, we can define the `cell` class and set the `_fields_` attribute later, after the class statement:

```python
>>> from ctypes import *
>>> class cell(Structure):
...     pass
...
>>> cell._fields_ = [('name', c_char_p),
...                     ('next', POINTER(cell))]
```

Lets try it. We create two instances of `cell`, and let them point to each other, and finally follow the pointer chain a few times:

```python
>>> c1 = cell()
>>> c1.name = "foo"
>>> c2 = cell()
>>> c2.name = "bar"
>>> c1.next = pointer(c2)
>>> c2.next = pointer(c1)
>>> p = c1
>>> for i in range(8):
...     print p.name,
...     p = p.next[0]
foo bar foo bar foo bar foo bar
```

### 15.18.1.17. Callback functions

c ctypes allows to create C callable function pointers from Python callables. These are sometimes called *callback functions*. 
First, you must create a class for the callback function, the class knows the calling convention, the return type, and the number and types of arguments this function will receive.

The CFUNCTYPE factory function creates types for callback functions using the normal cdecl calling convention, and, on Windows, the WINFUNCTYPE factory function creates types for callback functions using the stdcall calling convention.

Both of these factory functions are called with the result type as first argument, and the callback functions expected argument types as the remaining arguments.

I will present an example here which uses the standard C library's `qsort()` function, this is used to sort items with the help of a callback function. `qsort()` will be used to sort an array of integers:

```python
>>> IntArray5 = c_int * 5
>>> ia = IntArray5(5, 1, 7, 33, 99)
>>> qsort = libc.qsort
>>> qsort.restype = None
```

`qsort()` must be called with a pointer to the data to sort, the number of items in the data array, the size of one item, and a pointer to the comparison function, the callback. The callback will then be called with two pointers to items, and it must return a negative integer if the first item is smaller than the second, a zero if they are equal, and a positive integer else.

So our callback function receives pointers to integers, and must return an integer. First we create the type for the callback function:

```python
>>> CMPFUNC = CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
```
For the first implementation of the callback function, we simply print the arguments we get, and return 0 (incremental development ;-):

```python
>>> def py_cmp_func(a, b):
...     print "py_cmp_func", a, b
...     return 0
... >>>
```

Create the C callable callback:

```python
>>> cmp_func = CMPFUNC(py_cmp_func)
```

And we're ready to go:

```python
>>> qsort(ia, len(ia), sizeof(c_int), cmp_func) # doctest: +WINDOWS
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
py_cmp_func <ctypes.LP_c_long object at 0x00...> <ctypes.LP_c_long object at 0x00...>
```

We know how to access the contents of a pointer, so let's redefine our callback:

```python
>>> def py_cmp_func(a, b):
...     print "py_cmp_func", a[0], b[0]
...     return 0
... >>>
```

Here is what we get on Windows:
It is funny to see that on Linux the sort function seems to work much more efficiently, it is doing less comparisons:

Ah, we're nearly done! The last step is to actually compare the two items and return a useful result:

Final run on Windows:

```
```
and on Linux:

```python
>>> qsort(ia, len(ia), sizeof(c_int), CMPFUNC(py_cmp_func))  # doc
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 1 7
py_cmp_func 5 7
```  

It is quite interesting to see that the Windows `qsort()` function needs more comparisons than the linux version!

As we can easily check, our array is sorted now:

```python
>>> for i in ia: print i,
...
1 5 7 33 99
```  

**Important note for callback functions:**

Make sure you keep references to CFUNCTYPE objects as long as they are used from C code. `ctypes` doesn't, and if you don't, they may be garbage collected, crashing your program when a callback is made.

**15.18.1.18. Accessing values exported from dlls**

Some shared libraries not only export functions, they also export variables. An example in the Python library itself is the
Py_OptimizeFlag, an integer set to 0, 1, or 2, depending on the -O or -OO flag given on startup.

ctypes can access values like this with the in_dll() class methods of the type. pythonapi is a predefined symbol giving access to the Python C api:

```python
>>> opt_flag = c_int.in_dll(pythonapi, "Py_OptimizeFlag")
>>> print opt_flag
\n```

If the interpreter would have been started with -O, the sample would have printed \n\nc_long(1), or c_long(2) if -OO would have been specified.

An extended example which also demonstrates the use of pointers accesses the PyImport_FrozenModules pointer exported by Python.

Quoting the Python docs: This pointer is initialized to point to an array of “struct _frozen” records, terminated by one whose members are all NULL or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.

So manipulating this pointer could even prove useful. To restrict the example size, we show only how this table can be read with ctypes:

```python
>>> from ctypes import *

>>> class struct_frozen(Structure):
    ...
    _fields_ = [('name', c_char_p),
    ...
    ('code', POINTER(c_ubyte)),
    ...
    ('size', c_int)]
```

We have defined the struct _frozen data type, so we can get the
pointer to the table:

```python
>>> FrozenTable = POINTER(struct_frozen)
>>> table = FrozenTable.in_dll(pythonapi, "PyImport_FrozenModules")
```

Since `table` is a pointer to the array of `struct_frozen` records, we can iterate over it, but we just have to make sure that our loop terminates, because pointers have no size. Sooner or later it would probably crash with an access violation or whatever, so it's better to break out of the loop when we hit the NULL entry:

```python
>>> for item in table:
...     print item.name, item.size
...     if item.name is None:
...         break
...__hello__ 104
__phello__ -104
__phello__.spam 104
None 0
```

The fact that standard Python has a frozen module and a frozen package (indicated by the negative size member) is not well known, it is only used for testing. Try it out with `import __hello__` for example.

15.18.1.19. Surprises

There are some edges in `ctypes` where you may be expect something else than what actually happens.

Consider the following example:

```python
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
```
Hm. We certainly expected the last statement to print 3 4 1 2. What happened? Here are the steps of the `rc.a, rc.b = rc.b, rc.a` line above:

```python
>>> temp0, temp1 = rc.b, rc.a
>>> rc.a = temp0
>>> rc.b = temp1
```

Note that `temp0` and `temp1` are objects still using the internal buffer of the `rc` object above. So executing `rc.a = temp0` copies the buffer contents of `temp0` into `rc`'s buffer. This, in turn, changes the contents of `temp1`. So, the last assignment `rc.b = temp1`, doesn't have the expected effect.

Keep in mind that retrieving sub-objects from Structure, Unions, and Arrays doesn't copy the sub-object, instead it retrieves a wrapper object accessing the root-object's underlying buffer.

Another example that may behave different from what one would expect is this:

```python
>>> s = c_char_p()
>>> s.value = "abc def ghi"
>>> s.value
```
Why is it printing False? ctypes instances are objects containing a
memory block plus some descriptors accessing the contents of the
memory. Storing a Python object in the memory block does not store
the object itself, instead the contents of the object is stored.
Accessing the contents again constructs a new Python object each
time!

15.18.1.20. Variable-sized data types

ctypes provides some support for variable-sized arrays and
structures.

The resize() function can be used to resize the memory buffer of an
existing ctypes object. The function takes the object as first
argument, and the requested size in bytes as the second argument.
The memory block cannot be made smaller than the natural memory
block specified by the objects type, a ValueError is raised if this is tried:

```python
>>> short_array = (c_short * 4)()
>>> print sizeof(short_array)
8
>>> resize(short_array, 4)
Traceback (most recent call last):
  ... ValueError: minimum size is 8
>>> resize(short_array, 32)
>>> sizeof(short_array)
32
>>> sizeof(type(short_array))
8
>>> ```
This is nice and fine, but how would one access the additional elements contained in this array? Since the type still only knows about 4 elements, we get errors accessing other elements:

```python
>>> short_array[:]
[0, 0, 0, 0]
```
```python
>>> short_array[7]
Traceback (most recent call last):
...
IndexError: invalid index
```n
Another way to use variable-sized data types with `ctypes` is to use the dynamic nature of Python, and (re-)define the data type after the required size is already known, on a case by case basis.
When programming in a compiled language, shared libraries are accessed when compiling/linking a program, and when the program is run.

The purpose of the `find_library()` function is to locate a library in a way similar to what the compiler does (on platforms with several versions of a shared library the most recent should be loaded), while the ctypes library loaders act like when a program is run, and call the runtime loader directly.

The `ctypes.util` module provides a function which can help to determine the library to load.

```python
from ctypes.util import find_library
```

`ctypes.util.find_library(name)`

Try to find a library and return a pathname. `name` is the library name without any prefix like `lib`, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

On Linux, `find_library()` tries to run external programs (`/sbin/ldconfig`, `gcc`, and `objdump`) to find the library file. It returns the filename of the library file. Here are some examples:

```python
>>> from ctypes.util import find_library
>>> find_library("m")
'libm.so.6'
>>> find_library("c")
'libc.so.6'
```
On OS X, `find_library()` tries several predefined naming schemes and paths to locate the library, and returns a full pathname if successful:

```python
>>> from ctypes.util import find_library
>>> find_library("c")
'/usr/lib/libc.dylib'
>>> find_library("m")
'/usr/lib/libm.dylib'
>>> find_library("bz2")
'/usr/lib/libbz2.dylib'
>>> find_library("AGL")
'/System/Library/Frameworks/AGL.framework/AGL'
```

On Windows, `find_library()` searches along the system search path, and returns the full pathname, but since there is no predefined naming scheme a call like `find_library("c")` will fail and return `None`.

If wrapping a shared library with `ctypes`, it *may* be better to determine the shared library name at development type, and hardcode that into the wrapper module instead of using `find_library()` to locate the library at runtime.

### 15.18.2.2. Loading shared libraries

There are several ways to loaded shared libraries into the Python process. One way is to instantiate one of the following classes:

```python
class ctypes.CDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False, use_last_error=False)
```

Instances of this class represent loaded shared libraries.
Functions in these libraries use the standard C calling convention, and are assumed to return \texttt{int}.

\begin{verbatim}
class ctypes.OleDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False, use_last_error=False)
    Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the \texttt{stdcall} calling convention, and are assumed to return the windows specific \texttt{HRESULT} code. \texttt{HRESULT} values contain information specifying whether the function call failed or succeeded, together with additional error code. If the return value signals a failure, an \texttt{WindowsError} is automatically raised.
\end{verbatim}

\begin{verbatim}
class ctypes.WinDLL(name, mode=DEFAULT_MODE, handle=None, use_errno=False, use_last_error=False)
    Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the \texttt{stdcall} calling convention, and are assumed to return \texttt{int} by default.
\end{verbatim}

On Windows CE only the standard calling convention is used, for convenience the \texttt{WinDLL} and \texttt{OleDLL} use the standard calling convention on this platform.

The Python \textit{global interpreter lock} is released before calling any function exported by these libraries, and reacquired afterwards.

\begin{verbatim}
class ctypes.PyDLL(name, mode=DEFAULT_MODE, handle=None)
    Instances of this class behave like \texttt{CDLL} instances, except that the Python GIL is \textit{not} released during the function call, and after the function execution the Python error flag is checked. If the error flag is set, a Python exception is raised.
\end{verbatim}

Thus, this is only useful to call Python C api functions directly.
All these classes can be instantiated by calling them with at least one argument, the pathname of the shared library. If you have an existing handle to an already loaded shared library, it can be passed as the handle named parameter, otherwise the underlying platforms `dlopen` or `LoadLibrary` function is used to load the library into the process, and to get a handle to it.

The `mode` parameter can be used to specify how the library is loaded. For details, consult the `dlopen(3)` manpage, on Windows, `mode` is ignored.

The `use_errno` parameter, when set to True, enables a ctypes mechanism that allows to access the system `errno` error number in a safe way. ctypes maintains a thread-local copy of the systems `errno` variable; if you call foreign functions created with `use_errno=True` then the `errno` value before the function call is swapped with the ctypes private copy, the same happens immediately after the function call.

The function `ctypes.get_errno()` returns the value of the ctypes private copy, and the function `ctypes.set_errno()` changes the ctypes private copy to a new value and returns the former value.

The `use_last_error` parameter, when set to True, enables the same mechanism for the Windows error code which is managed by the `GetLastError()` and `SetLastError()` Windows API functions; `ctypes.get_last_error()` and `ctypes.set_last_error()` are used to request and change the ctypes private copy of the windows error code.

*New in version 2.6:* The `use_last_error` and `use_errno` optional parameters were added.

`ctypes.RTLD_GLOBAL`
Flag to use as `mode` parameter. On platforms where this flag is not available, it is defined as the integer zero.

**ctypes. **`RTLD_LOCAL`

Flag to use as `mode` parameter. On platforms where this is not available, it is the same as `RTLD_GLOBAL`.

**ctypes. **`DEFAULT_MODE`

The default mode which is used to load shared libraries. On OSX 10.3, this is `RTLD_GLOBAL`, otherwise it is the same as `RTLD_LOCAL`.

Instances of these classes have no public methods, however `__getattr__()` and `__getitem__()` have special behavior: functions exported by the shared library can be accessed as attributes of by index. Please note that both `__getattr__()` and `__getitem__()` cache their result, so calling them repeatedly returns the same object each time.

The following public attributes are available, their name starts with an underscore to not clash with exported function names:

**PyDLL. **`__handle`

The system handle used to access the library.

**PyDLL. **`__name`

The name of the library passed in the constructor.

Shared libraries can also be loaded by using one of the prefabricated objects, which are instances of the `LibraryLoader` class, either by calling the `LoadLibrary()` method, or by retrieving the library as attribute of the loader instance.

```python
class ctypes. LibraryLoader(dlltype)
    Class which loads shared libraries. dlltype should be one of the
    CDLL, PyDLL, WinDLL, or OleDLL types.
```
__getattr__() has special behavior: It allows to load a shared library by accessing it as attribute of a library loader instance. The result is cached, so repeated attribute accesses return the same library each time.

**LoadLibrary**(name)

Load a shared library into the process and return it. This method always returns a new instance of the library.

These prefabricated library loaders are available:

c types. cdll

Creates CDLL instances.

c types. windll

Windows only: Creates WinDLL instances.

c types. oledll

Windows only: Creates OleDLL instances.

c types. pydll

Creates PyDLL instances.

For accessing the C Python api directly, a ready-to-use Python shared library object is available:

c types. pythonapi

An instance of PyDLL that exposes Python C API functions as attributes. Note that all these functions are assumed to return C `int`, which is of course not always the truth, so you have to assign the correct `restype` attribute to use these functions.

15.18.2.3. Foreign functions

As explained in the previous section, foreign functions can be
accessed as attributes of loaded shared libraries. The function objects created in this way by default accept any number of arguments, accept any ctypes data instances as arguments, and return the default result type specified by the library loader. They are instances of a private class:

```python
class ctypes._FuncPtr
    Base class for C callable foreign functions.
    
    Instances of foreign functions are also C compatible data types; they represent C function pointers.
    
    This behavior can be customized by assigning to special attributes of the foreign function object.
```

**restype**

Assign a ctypes type to specify the result type of the foreign function. Use `None` for `void`, a function not returning anything.

It is possible to assign a callable Python object that is not a ctypes type, in this case the function is assumed to return a C `int`, and the callable will be called with this integer, allowing to do further processing or error checking. Using this is deprecated, for more flexible post processing or error checking use a ctypes data type as `restype` and assign a callable to the `errcheck` attribute.

**argtypes**

Assign a tuple of ctypes types to specify the argument types that the function accepts. Functions using the `stdcall` calling convention can only be called with the same number of arguments as the length of this tuple; functions using the C calling convention accept additional, unspecified arguments as well.
When a foreign function is called, each actual argument is passed to the `from_param()` class method of the items in the `argtypes` tuple, this method allows to adapt the actual argument to an object that the foreign function accepts. For example, a `c_char_p` item in the `argtypes` tuple will convert a unicode string passed as argument into an byte string using ctypes conversion rules.

New: It is now possible to put items in `argtypes` which are not ctypes types, but each item must have a `from_param()` method which returns a value usable as argument (integer, string, ctypes instance). This allows to define adapters that can adapt custom objects as function parameters.

**errcheck**

Assign a Python function or another callable to this attribute. The callable will be called with three or more arguments:

\[
\text{callable}(\text{result}, \text{func}, \text{arguments})
\]

\text{result} is what the foreign function returns, as specified by the `restype` attribute.

\text{func} is the foreign function object itself, this allows to reuse the same callable object to check or post process the results of several functions.

\text{arguments} is a tuple containing the parameters originally passed to the function call, this allows to specialize the behavior on the arguments used.

The object that this function returns will be returned from the foreign function call, but it can also check the result value and raise an exception if the foreign function call failed.
This exception is raised when a foreign function call cannot convert one of the passed arguments.

15.18.2.4. Function prototypes

Foreign functions can also be created by instantiating function prototypes. Function prototypes are similar to function prototypes in C; they describe a function (return type, argument types, calling convention) without defining an implementation. The factory functions must be called with the desired result type and the argument types of the function.

```python
ctypes.CFUNCTYPE(restype, *argtypes, use_errno=False, use_last_error=False)
```

The returned function prototype creates functions that use the standard C calling convention. The function will release the GIL during the call. If `use_errno` is set to True, the ctypes private copy of the system `errno` variable is exchanged with the real `errno` value before and after the call; `use_last_error` does the same for the Windows error code.

*Changed in version 2.6:* The optional `use_errno` and `use_last_error` parameters were added.

```python
ctypes.WINFUNCTYPE(restype, *argtypes, use_errno=False, use_last_error=False)
```

Windows only: The returned function prototype creates functions that use the `stdcall` calling convention, except on Windows CE where `WINFUNCTYPE()` is the same as `CFUNCTYPE()`. The function will release the GIL during the call. `use_errno` and `use_last_error` have the same meaning as above.

```python
ctypes.PYFUNCTYPE(restype, *argtypes)
```

The returned function prototype creates functions that use the
Python calling convention. The function will *not* release the GIL during the call.

Function prototypes created by these factory functions can be instantiated in different ways, depending on the type and number of the parameters in the call:

**prototype(address)**

Returns a foreign function at the specified address which must be an integer.

**prototype(callable)**

Create a C callable function (a callback function) from a Python *callable*.

**prototype(func_spec[, paramflags])**

Returns a foreign function exported by a shared library. `func_spec` must be a 2-tuple `(name_or_ordinal, library)`. The first item is the name of the exported function as string, or the ordinal of the exported function as small integer. The second item is the shared library instance.

**prototype(vtbl_index, name[, paramflags[, iid]])**

Returns a foreign function that will call a COM method. `vtbl_index` is the index into the virtual function table, a small non-negative integer. `name` is name of the COM method. `iid` is an optional pointer to the interface identifier which is used in extended error reporting.

COM methods use a special calling convention: They require a pointer to the COM interface as first argument, in addition to those parameters that are specified in the `argtypes` tuple.

The optional `paramflags` parameter creates foreign function
wrappers with much more functionality than the features described above.

`paramflags` must be a tuple of the same length as `argtypes`.

Each item in this tuple contains further information about a parameter, it must be a tuple containing one, two, or three items.

The first item is an integer containing a combination of direction flags for the parameter:

1  
   Specifies an input parameter to the function.

2  
   Output parameter. The foreign function fills in a value.

4  
   Input parameter which defaults to the integer zero.

The optional second item is the parameter name as string. If this is specified, the foreign function can be called with named parameters.

The optional third item is the default value for this parameter.

This example demonstrates how to wrap the Windows `MessageBoxA` function so that it supports default parameters and named arguments. The C declaration from the windows header file is this:

```c
WINUSERAPI int WINAPI MessageBoxA(
    HWND hWnd ,
    LPCSTR lpText,
    LPCSTR lpCaption,
    UINT uType);
```

Here is the wrapping with `ctypes`:
The MessageBox foreign function can now be called in these ways:

```python
>>> MessageBox()
>>> MessageBox(text="Spam, spam, spam")
>>> MessageBox(flags=2, text="foo bar")
```

A second example demonstrates output parameters. The win32 GetWindowRect function retrieves the dimensions of a specified window by copying them into RECT structure that the caller has to supply. Here is the C declaration:

```
WINUSERAPI BOOL WINAPI GetWindowRect(
    HWND hWnd,
    LPRECT lpRect);
```

Here is the wrapping with ctypes:

```python
>>> from ctypes import POINTER, WINFUNCTYPE, windll, WinError
>>> from ctypes.wintypes import BOOL, HWND, RECT
>>> prototype = WINFUNCTYPE(BOOL, HWND, POINTER(RECT))
>>> paramflags = (1, "hwnd"), (2, "lprect")
>>> GetWindowRect = prototype(("GetWindowRect", windll.user32), paramflags)
```

Functions with output parameters will automatically return the output parameter value if there is a single one, or a tuple containing the output parameter values when there are more than one, so the GetWindowRect function now returns a RECT instance, when called.
Output parameters can be combined with the `errcheck` protocol to do further output processing and error checking. The win32 `GetWindowRect` api function returns a `BOOL` to signal success or failure, so this function could do the error checking, and raises an exception when the api call failed:

```python
>>> def errcheck(result, func, args):
...    if not result:
...        raise WinError()
...    return args
...
>>> GetWindowRect.errcheck = errcheck

If the `errcheck` function returns the argument tuple it receives unchanged, `ctypes` continues the normal processing it does on the output parameters. If you want to return a tuple of window coordinates instead of a `RECT` instance, you can retrieve the fields in the function and return them instead, the normal processing will no longer take place:

```python
>>> def errcheck(result, func, args):
...    if not result:
...        raise WinError()
...    rc = args[1]
...    return rc.left, rc.top, rc.bottom, rc.right
...
>>> GetWindowRect.errcheck = errcheck

15.18.2.5. Utility functions

clicked. **addressof**(obj)

Returns the address of the memory buffer as integer. `obj` must be an instance of a ctypes type.

clicked. **alignment**(obj_or_type)
Returns the alignment requirements of a ctypes type. *obj_or_type* must be a ctypes type or instance.

`ctypes.byref(obj[, offset])`

Returns a light-weight pointer to *obj*, which must be an instance of a ctypes type. *offset* defaults to zero, and must be an integer that will be added to the internal pointer value.

`byref(obj, offset)` corresponds to this C code:

```
(((char *)&obj) + offset)
```

The returned object can only be used as a foreign function call parameter. It behaves similar to `pointer(obj)`, but the construction is a lot faster.

*New in version 2.6:* The *offset* optional argument was added.

`ctypes.cast(obj, type)`

This function is similar to the cast operator in C. It returns a new instance of *type* which points to the same memory block as *obj*. *type* must be a pointer type, and *obj* must be an object that can be interpreted as a pointer.

`ctypes.create_string_buffer(init_or_size[, size])`

This function creates a mutable character buffer. The returned object is a ctypes array of *c_char*.

*init_or_size* must be an integer which specifies the size of the array, or a string which will be used to initialize the array items.

If a string is specified as first argument, the buffer is made one item larger than the length of the string so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows to specify the size of
the array if the length of the string should not be used.

If the first parameter is a unicode string, it is converted into an 8-bit string according to ctypes conversion rules.

```
ctypes.create_unicode_buffer(init_or_size[, size])
```
This function creates a mutable unicode character buffer. The returned object is a ctypes array of `c_wchar`.

`init_or_size` must be an integer which specifies the size of the array, or a unicode string which will be used to initialize the array items.

If a unicode string is specified as first argument, the buffer is made one item larger than the length of the string so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows to specify the size of the array if the length of the string should not be used.

If the first parameter is a 8-bit string, it is converted into an unicode string according to ctypes conversion rules.

```
ctypes.DllCanUnloadNow()
```
Windows only: This function is a hook which allows to implement in-process COM servers with ctypes. It is called from the DllCanUnloadNow function that the _ctypes extension dll exports.

```
ctypes.DllGetClassObject()
```
Windows only: This function is a hook which allows to implement in-process COM servers with ctypes. It is called from the DllGetClassObject function that the _ctypes extension dll exports.

```
ctypes.util.find_library(name)
```
Try to find a library and return a pathname. `name` is the library name without any prefix like `lib`, suffix like `.so`, `.dylib` or version
number (this is the form used for the posix linker option -l). If no library can be found, returns None.

The exact functionality is system dependent.

*Changed in version 2.6:* Windows only: `find_library("m")` or `find_library("c")` return the result of a call to `find_msvcrt()`.

call to `find_msvcrt()`

Windows only: return the filename of the VC runtype library used by Python, and by the extension modules. If the name of the library cannot be determined, `None` is returned.

If you need to free memory, for example, allocated by an extension module with a call to the `free(void *)`, it is important that you use the function in the same library that allocated the memory.

*New in version 2.6.*

`ctypes.util.find_msvcrt()`

Windows only: return the filename of the VC runtype library used by Python, and by the extension modules. If the name of the library cannot be determined, `None` is returned.

If you need to free memory, for example, allocated by an extension module with a call to the `free(void *)`, it is important that you use the function in the same library that allocated the memory.

*New in version 2.6.*

`ctypes.FormatError([code])`

Windows only: Returns a textual description of the error code `code`. If no error code is specified, the last error code is used by calling the Windows api function GetLastError.

`ctypes.GetLastError()`

Windows only: Returns the last error code set by Windows in the calling thread. This function calls the Windows `GetLastError()` function directly, it does not return the ctypes-private copy of the error code.

`ctypes.get_errno()`

Returns the current value of the ctypes-private copy of the system `errno` variable in the calling thread.
New in version 2.6.

`ctypes.get_last_error()`

Windows only: returns the current value of the ctypes-private copy of the system `LastError` variable in the calling thread.

New in version 2.6.

`ctypes.memmove(dst, src, count)`

Same as the standard C `memmove` library function: copies `count` bytes from `src` to `dst`. `dst` and `src` must be integers or ctypes instances that can be converted to pointers.

`ctypes.memset(dst, c, count)`

Same as the standard C `memset` library function: fills the memory block at address `dst` with `count` bytes of value `c`. `dst` must be an integer specifying an address, or a ctypes instance.

`ctypes.POINTER(type)`

This factory function creates and returns a new ctypes pointer type. Pointer types are cached and reused internally, so calling this function repeatedly is cheap. `type` must be a ctypes type.

`ctypes.pointer(obj)`

This function creates a new pointer instance, pointing to `obj`. The returned object is of the type `POINTER(type(obj))`.

Note: If you just want to pass a pointer to an object to a foreign function call, you should use `byref(obj)` which is much faster.

`ctypes.resize(obj, size)`

This function resizes the internal memory buffer of `obj`, which must be an instance of a ctypes type. It is not possible to make the buffer smaller than the native size of the objects type, as given by `sizeof(type(obj))`, but it is possible to enlarge the
buffer.

call 

**ctypes.set_conversion_mode(encoding, errors)**

This function sets the rules that ctypes objects use when converting between 8-bit strings and unicode strings. *encoding* must be a string specifying an encoding, like 'utf-8' or 'mbcs', *errors* must be a string specifying the error handling on encoding/decoding errors. Examples of possible values are "strict", "replace", or "ignore".

*set_conversion_mode()* returns a 2-tuple containing the previous conversion rules. On windows, the initial conversion rules are ('mbcs', 'ignore'), on other systems ('ascii', 'strict').

call 

**ctypes.set_errno(value)**

Set the current value of the ctypes-private copy of the system *errno* variable in the calling thread to *value* and return the previous value.

*New in version 2.6.*

call 

**ctypes.set_last_error(value)**

Windows only: set the current value of the ctypes-private copy of the system LastError variable in the calling thread to *value* and return the previous value.

*New in version 2.6.*

call 

**ctypes.sizeof(obj_or_type)**

Returns the size in bytes of a ctypes type or instance memory buffer. Does the same as the C *sizeof()* function.

call 

**ctypes.string_at(address, size)**

This function returns the string starting at memory address
address. If size is specified, it is used as size, otherwise the string is assumed to be zero-terminated.

ctypes.WinError(code=None, descr=None)

Windows only: this function is probably the worst-named thing in ctypes. It creates an instance of WindowsError. If code is not specified, GetLastError is called to determine the error code. If descr is not specified, FormatError() is called to get a textual description of the error.

ctypes.wstring_at(address[, size])

This function returns the wide character string starting at memory address address as unicode string. If size is specified, it is used as the number of characters of the string, otherwise the string is assumed to be zero-terminated.

15.18.2.6. Data types

class ctypes._CData

This non-public class is the common base class of all ctypes data types. Among other things, all ctypes type instances contain a memory block that hold C compatible data; the address of the memory block is returned by the addressof() helper function. Another instance variable is exposed as _objects; this contains other Python objects that need to be kept alive in case the memory block contains pointers.

Common methods of ctypes data types, these are all class methods (to be exact, they are methods of the metaclass):

from_buffer(source[, offset])

This method returns a ctypes instance that shares the buffer of the source object. The source object must support the writeable buffer interface. The optional offset parameter
specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a `ValueError` is raised.

*New in version 2.6.*

```
from_buffer_copy(source[, offset])
```

This method creates a ctypes instance, copying the buffer from the `source` object buffer which must be readable. The optional `offset` parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a `ValueError` is raised.

*New in version 2.6.*

```
from_address(address)
```

This method returns a ctypes type instance using the memory specified by `address` which must be an integer.

```
from_param(obj)
```

This method adapts `obj` to a ctypes type. It is called with the actual object used in a foreign function call when the type is present in the foreign function’s `argtypes` tuple; it must return an object that can be used as a function call parameter.

All ctypes data types have a default implementation of this classmethod that normally returns `obj` if that is an instance of the type. Some types accept other objects as well.

```
in_dll(library, name)
```

This method returns a ctypes type instance exported by a shared library. `name` is the name of the symbol that exports the data, `library` is the loaded shared library.

Common instance variables of ctypes data types:
Sometimes ctypes data instances do not own the memory block they contain, instead they share part of the memory block of a base object. The \_\_b\_base\_ read-only member is the root ctypes object that owns the memory block.

\_\_b\_needsfree\_

This read-only variable is true when the ctypes data instance has allocated the memory block itself, false otherwise.

\_\_objects

This member is either None or a dictionary containing Python objects that need to be kept alive so that the memory block contents is kept valid. This object is only exposed for debugging; never modify the contents of this dictionary.

15.18.2.7. Fundamental data types

class ctypes.\_\_SimpleCData

This non-public class is the base class of all fundamental ctypes data types. It is mentioned here because it contains the common attributes of the fundamental ctypes data types. \_\_SimpleCData is a subclass of \_\_CData, so it inherits their methods and attributes.

*Changed in version 2.6*: ctypes data types that are not and do not contain pointers can now be pickled.

Instances have a single attribute:

\_\_value\_

This attribute contains the actual value of the instance. For integer and pointer types, it is an integer, for character types, it is a single character string, for character pointer types it is a Python string or unicode string.

When the value attribute is retrieved from a ctypes instance,
usually a new object is returned each time. `ctypes` does not implement original object return, always a new object is constructed. The same is true for all other ctypes object instances.

Fundamental data types, when returned as foreign function call results, or, for example, by retrieving structure field members or array items, are transparently converted to native Python types. In other words, if a foreign function has a `restype` of `c_char_p`, you will always receive a Python string, *not* a `c_char_p` instance.

Subclasses of fundamental data types do *not* inherit this behavior. So, if a foreign functions `restype` is a subclass of `c_void_p`, you will receive an instance of this subclass from the function call. Of course, you can get the value of the pointer by accessing the `value` attribute.

These are the fundamental ctypes data types:

```python
class ctypes.c_byte
    Represents the C `signed char` datatype, and interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_char
    Represents the C `char` datatype, and interprets the value as a single character. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

class ctypes.c_char_p
    Represents the C `char` * datatype when it points to a zero-terminated string. For a general character pointer that may also point to binary data, `POINTER(c_char)` must be used. The constructor accepts an integer address, or a string.

class ctypes.c_double
```
Represents the C `double` datatype. The constructor accepts an optional float initializer.

```python
class ctypes.c_double
```
Represents the C `long double` datatype. The constructor accepts an optional float initializer. On platforms where `sizeof(long double) == sizeof(double)` it is an alias to `c_double`.

*New in version 2.6.*

```python
class ctypes.c_float
```
Represents the C `float` datatype. The constructor accepts an optional float initializer.

```python
class ctypes.c_int
```
Represents the C `signed int` datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias to `c_long`.

```python
class ctypes.c_int8
```
Represents the C 8-bit `signed int` datatype. Usually an alias for `c_byte`.

```python
class ctypes.c_int16
```
Represents the C 16-bit `signed int` datatype. Usually an alias for `c_short`.

```python
class ctypes.c_int32
```
Represents the C 32-bit `signed int` datatype. Usually an alias for `c_int`.

```python
class ctypes.c_int64
```
Represents the C 64-bit `signed int` datatype. Usually an alias for
class ctypes.c_long
 Represents the C **signed long** datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_longlong
 Represents the C **signed long long** datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_short
 Represents the C **signed short** datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_size_t
 Represents the C **size_t** datatype.

class ctypes.c_ssize_t
 Represents the C **ssize_t** datatype.

*New in version 2.7.*

class ctypes.c_ubyte
 Represents the C **unsigned char** datatype, it interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_uint
 Represents the C **unsigned int** datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias for c_ulong.
class ctypes.c_uint8
    Represents the C 8-bit unsigned int datatype. Usually an alias for c_ubyte.

class ctypes.c_uint16
    Represents the C 16-bit unsigned int datatype. Usually an alias for c_ushort.

class ctypes.c_uint32
    Represents the C 32-bit unsigned int datatype. Usually an alias for c_uint.

class ctypes.c_uint64
    Represents the C 64-bit unsigned int datatype. Usually an alias for c_ulonglong.

class ctypes.c_ulong
    Represents the C unsigned long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_ulonglong
    Represents the C unsigned long long datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_ushort
    Represents the C unsigned short datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_void_p
    Represents the C void * type. The value is represented as integer. The constructor accepts an optional integer initializer.
class ctypes.c_wchar

Represents the C wchar_t datatype, and interprets the value as a single character unicode string. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

class ctypes.c_wchar_p

Represents the C wchar_t * datatype, which must be a pointer to a zero-terminated wide character string. The constructor accepts an integer address, or a string.

class ctypes.c_bool

Represents the C bool datatype (more accurately, _Bool from C99). Its value can be True or False, and the constructor accepts any object that has a truth value.

New in version 2.6.

class ctypes.HRESULT

Windows only: Represents a HRESULT value, which contains success or error information for a function or method call.

class ctypes.py_object

Represents the C PyObject * datatype. Calling this without an argument creates a NULL PyObject * pointer.

The ctypes.wintypes module provides quite some other Windows specific data types, for example HWND, WPARAM, or DWORD. Some useful structures like MSG or RECT are also defined.

15.18.2.8. Structured data types

class ctypes.Union(*args, **kw)

Abstract base class for unions in native byte order.
class ctypes.BigEndianStructure(*args, **kw)
    Abstract base class for structures in big endian byte order.

class ctypes.LittleEndianStructure(*args, **kw)
    Abstract base class for structures in little endian byte order.

Structures with non-native byte order cannot contain pointer type fields, or any other data types containing pointer type fields.

class ctypes.Structure(*args, **kw)
    Abstract base class for structures in native byte order.

Concrete structure and union types must be created by subclassing one of these types, and at least define a _fields_ class variable. ctypes will create descriptors which allow reading and writing the fields by direct attribute accesses. These are the

_fields_
    A sequence defining the structure fields. The items must be 2-tuples or 3-tuples. The first item is the name of the field, the second item specifies the type of the field; it can be any ctypes data type.

    For integer type fields like c_int, a third optional item can be given. It must be a small positive integer defining the bit width of the field.

    Field names must be unique within one structure or union. This is not checked, only one field can be accessed when names are repeated.

    It is possible to define the _fields_ class variable after the class statement that defines the Structure subclass, this allows to create data types that directly or indirectly reference themselves:
```python
class List(Structure):
    pass
List._fields_ = ["pnext", POINTER(List)],
... ]
```

The `_fields_` class variable must, however, be defined before the type is first used (an instance is created, `sizeof()` is called on it, and so on). Later assignments to the `_fields_` class variable will raise an AttributeError.

Structure and union subclass constructors accept both positional and named arguments. Positional arguments are used to initialize the fields in the same order as they appear in the `_fields_` definition, named arguments are used to initialize the fields with the corresponding name.

It is possible to defined sub-subclasses of structure types, they inherit the fields of the base class plus the `_fields_` defined in the sub-subclass, if any.

`_pack_`
An optional small integer that allows to override the alignment of structure fields in the instance. `_pack_` must already be defined when `_fields_` is assigned, otherwise it will have no effect.

`_anonymous_`
An optional sequence that lists the names of unnamed (anonymous) fields. `_anonymous_` must be already defined when `_fields_` is assigned, otherwise it will have no effect.

The fields listed in this variable must be structure or union type fields. `ctypes` will create descriptors in the structure type that allows to access the nested fields directly, without the need to create the structure or union field.
Here is an example type (Windows):

```python
class _U(Union):
    _fields_ = ["lptdesc", POINTER(TYPEDESC)),
               "lpadesc", POINTER(ARRAYDESC)),
               "hreftype", HREFTYPE])

class TYPEDESC(Structure):
    _anonymous_ = ("u"),
    _fields_ = ["u", _U),
               "vt", VARTYPE])
```

The `TYPEDESC` structure describes a COM data type, the `vt` field specifies which one of the union fields is valid. Since the `u` field is defined as anonymous field, it is now possible to access the members directly off the `TYPEDESC` instance. `td.lptdesc` and `td.u.lptdesc` are equivalent, but the former is faster since it does not need to create a temporary union instance:

```python
td = TYPEDESC()
td.vt = VT_PTR
td.lptdesc = POINTER(some_type)
td.u.lptdesc = POINTER(some_type)
```

It is possible to defined sub-subclasses of structures, they inherit the fields of the base class. If the subclass definition has a separate `_fields_` variable, the fields specified in this are appended to the fields of the base class.

Structure and union constructors accept both positional and keyword arguments. Positional arguments are used to initialize member fields in the same order as they are appear in `_fields_`. Keyword arguments in the constructor are interpreted as attribute assignments, so they will initialize `_fields_` with the same name, or create new attributes for names not present in `_fields_`. 
15.18.2.9. Arrays and pointers

Not yet written - please see the sections *Pointers* and section *Arrays* in the tutorial.
16. Optional Operating System Services

The modules described in this chapter provide interfaces to operating system features that are available on selected operating systems only. The interfaces are generally modeled after the Unix or C interfaces but they are available on some other systems as well (e.g. Windows or NT). Here’s an overview:

- **16.1. select** — Waiting for I/O completion
  - 16.1.1. Edge and Level Trigger Polling (epoll) Objects
  - 16.1.2. Polling Objects
  - 16.1.3. Kqueue Objects
  - 16.1.4. Kevent Objects
- **16.2. threading** — Higher-level threading interface
  - 16.2.1. Thread Objects
  - 16.2.2. Lock Objects
  - 16.2.3. RLock Objects
  - 16.2.4. Condition Objects
  - 16.2.5. Semaphore Objects
    - 16.2.5.1. Semaphore Example
  - 16.2.6. Event Objects
  - 16.2.7. Timer Objects
  - 16.2.8. Using locks, conditions, and semaphores in the with statement
  - 16.2.9. Importing in threaded code
- **16.3. thread** — Multiple threads of control
- **16.4. dummy_threading** — Drop-in replacement for the threading module
- **16.5. dummy_thread** — Drop-in replacement for the thread module
- **16.6. multiprocessing** — Process-based “threading” interface
16.6.1. Introduction
- 16.6.1.1. The Process class
- 16.6.1.2. Exchanging objects between processes
- 16.6.1.3. Synchronization between processes
- 16.6.1.4. Sharing state between processes
- 16.6.1.5. Using a pool of workers

16.6.2. Reference
- 16.6.2.1. Process and exceptions

- 16.8.1. Example
- 16.9. `rlcompleter` — Completion function for GNU readline
  - 16.9.1. Completer Objects
16.1. select — Waiting for I/O completion

This module provides access to the `select()` and `poll()` functions available in most operating systems, `epoll()` available on Linux 2.5+ and `kqueue()` available on most BSD. Note that on Windows, it only works for sockets; on other operating systems, it also works for other file types (in particular, on Unix, it works on pipes). It cannot be used on regular files to determine whether a file has grown since it was last read.

The module defines the following:

**exception** `select.error`

The exception raised when an error occurs. The accompanying value is a pair containing the numeric error code from `errno` and the corresponding string, as would be printed by the C function `perror()`.

`select.epoll([sizehint=-1])`

(Only supported on Linux 2.5.44 and newer.) Returns an edge polling object, which can be used as Edge or Level Triggered interface for I/O events; see section *Edge and Level Trigger Polling (epoll) Objects* below for the methods supported by polling objects.

*New in version 2.6.*

`select.poll()`

(Not supported by all operating systems.) Returns a polling object, which supports registering and unregistering file descriptors, and then polling them for I/O events; see section
**Polling Objects** below for the methods supported by polling objects.

select. **kqueue()**
(Only supported on BSD.) Returns a kernel queue object; see section **Kqueue Objects** below for the methods supported by kqueue objects.

*New in version 2.6.*

select. **kevent(ident, filter=KQ_FILTER_READ, flags=KQ_EV_ADD, fflags=0, data=0, udata=0)**
(Only supported on BSD.) Returns a kernel event object; see section **Kevent Objects** below for the methods supported by kevent objects.

*New in version 2.6.*

select. **select(rlist, wlist, xlist[, timeout])**
This is a straightforward interface to the Unix `select()` system call. The first three arguments are sequences of ‘waitable objects’: either integers representing file descriptors or objects with a parameterless method named `fileno()` returning such an integer:

- **rlist**: wait until ready for reading
- **wlist**: wait until ready for writing
- **xlist**: wait for an “exceptional condition” (see the manual page for what your system considers such a condition)

Empty sequences are allowed, but acceptance of three empty sequences is platform-dependent. (It is known to work on Unix but not on Windows.) The optional **timeout** argument specifies a time-out as a floating point number in seconds. When the **timeout** argument is omitted the function blocks until at least one file
descriptor is ready. A time-out value of zero specifies a poll and never blocks.

The return value is a triple of lists of objects that are ready: subsets of the first three arguments. When the time-out is reached without a file descriptor becoming ready, three empty lists are returned.

Among the acceptable object types in the sequences are Python file objects (e.g. `sys.stdin`, or objects returned by `open()` or `os.popen()`), socket objects returned by `socket.socket()`. You may also define a wrapper class yourself, as long as it has an appropriate `fileno()` method (that really returns a file descriptor, not just a random integer).

**Note:** File objects on Windows are not acceptable, but sockets are. On Windows, the underlying `select()` function is provided by the WinSock library, and does not handle file descriptors that don’t originate from WinSock.

**select. PIPE_BUF**

Files reported as ready for writing by `select()`, `poll()` or similar interfaces in this module are guaranteed to not block on a write of up to `PIPE_BUF` bytes. This value is guaranteed by POSIX to be at least 512. Availability: Unix.

*New in version 2.7.*
16.1.1. Edge and Level Trigger Polling (epoll) Objects

http://linux.die.net/man/4/epoll

eventmask

<table>
<thead>
<tr>
<th>Constant</th>

</tr>
<tr>
<td>EPOLLMMSG</td>
<td>Ignored.</td>
</tr>
</tbody>
</table>

epoll.close()

Close the control file descriptor of the epoll object.

epoll.fileno()

Return the file descriptor number of the control fd.

epoll.fromfd(fd)

Create an epoll object from a given file descriptor.
**epoll.register**(*fd[, eventmask]*)
Register a fd descriptor with the epoll object.

**Note:** Registering a file descriptor that's already registered raises an IOError – contrary to *Polling Objects*'s register.

**epoll.modify**(*fd, eventmask*)
Modify a register file descriptor.

**epoll.unregister**(*fd*)
Remove a registered file descriptor from the epoll object.

**epoll.poll**(*[timeout=-1[, maxevents=-1]]*)
Wait for events. timeout in seconds (float)
16.1.2. Polling Objects

The `poll()` system call, supported on most Unix systems, provides better scalability for network servers that service many, many clients at the same time. `poll()` scales better because the system call only requires listing the file descriptors of interest, while `select()` builds a bitmap, turns on bits for the fds of interest, and then afterward the whole bitmap has to be linearly scanned again. `select()` is \(O(\text{highest file descriptor})\), while `poll()` is \(O(\text{number of file descriptors})\).

```c
poll.register(fd[, eventmask])
```

Register a file descriptor with the polling object. Future calls to the `poll()` method will then check whether the file descriptor has any pending I/O events. `fd` can be either an integer, or an object with a `fileno()` method that returns an integer. File objects implement `fileno()`, so they can also be used as the argument.

`eventmask` is an optional bitmask describing the type of events you want to check for, and can be a combination of the constants `POLLIN`, `POLLPRI`, and `POLLOUT`, described in the table below. If not specified, the default value used will check for all 3 types of events.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>POLLIN</td>
<td>There is data to read</td>
</tr>
<tr>
<td>POLLPRI</td>
<td>There is urgent data to read</td>
</tr>
<tr>
<td>POLLOUT</td>
<td>Ready for output: writing will not block</td>
</tr>
<tr>
<td>POLLERR</td>
<td>Error condition of some sort</td>
</tr>
<tr>
<td>POLLHUP</td>
<td>Hung up</td>
</tr>
<tr>
<td>POLLNVAL</td>
<td>Invalid request: descriptor not open</td>
</tr>
</tbody>
</table>
Registering a file descriptor that’s already registered is not an error, and has the same effect as registering the descriptor exactly once.

\texttt{poll.modify(fd, eventmask)}

Modifies an already registered fd. This has the same effect as \texttt{register(fd, eventmask)}. Attempting to modify a file descriptor that was never registered causes an \texttt{IOError} exception with \texttt{errno ENOENT} to be raised.

*New in version 2.6.*

\texttt{poll.unregister(fd)}

Remove a file descriptor being tracked by a polling object. Just like the \texttt{register()} method, \texttt{fd} can be an integer or an object with a \texttt{fileno()} method that returns an integer.

Attempting to remove a file descriptor that was never registered causes a \texttt{KeyError} exception to be raised.

\texttt{poll.poll([timeout])}

Polls the set of registered file descriptors, and returns a possibly-empty list containing \texttt{(fd, event)} 2-tuples for the descriptors that have events or errors to report. \texttt{fd} is the file descriptor, and \texttt{event} is a bitmask with bits set for the reported events for that descriptor — \texttt{POLLIN} for waiting input, \texttt{POLLOUT} to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If \texttt{timeout} is given, it specifies the length of time in milliseconds which the system will wait for events before returning. If \texttt{timeout} is omitted, negative, or \texttt{None}, the call will block until there is an event for this poll object.
16.1.3. Kqueue Objects

kqueue. **close()**
Close the control file descriptor of the kqueue object.

kqueue. **fileno()**
Return the file descriptor number of the control fd.

kqueue. **fromfd(fd)**
Create a kqueue object from a given file descriptor.

kqueue. **control(changelist, max_events[, timeout=None]) → eventlist**
Low level interface to kevent

- changelist must be an iterable of kevent object or None
- max_events must be 0 or a positive integer
- timeout in seconds (floats possible)
16.1.4. Kevent Objects

http://www.freebsd.org/cgi/man.cgi?query=kqueue&sektion=2

kevent. **ident**
Value used to identify the event. The interpretation depends on the filter but it's usually the file descriptor. In the constructor ident can either be an int or an object with a fileno() function. kevent stores the integer internally.

kevent. **filter**
Name of the kernel filter.

</table>

kevent.data

Filter specific data.

kevent.udata

User defined value.
16.2. threading — Higher-level threading interface

This module constructs higher-level threading interfaces on top of the lower level thread module. See also the mutex and Queue modules.

The dummy_threading module is provided for situations where threading cannot be used because thread is missing.

**Note:** Starting with Python 2.6, this module provides PEP 8 compliant aliases and properties to replace the camelCase names that were inspired by Java's threading API. This updated API is compatible with that of the multiprocessing module. However, no schedule has been set for the deprecation of the camelCase names and they remain fully supported in both Python 2.x and 3.x.

**Note:** Starting with Python 2.5, several Thread methods raise RuntimeError instead of AssertionError if called erroneously.

**CPython implementation detail:** Due to the Global Interpreter Lock, in CPython only one thread can execute Python code at once (even though certain performance-oriented libraries might overcome this limitation). If you want your application to make better use of the computational resources of multi-core machines, you are advised to use multiprocessing. However, threading is still an appropriate model if you want to run multiple I/O-bound tasks simultaneously.

**See also:** Latest version of the threading module Python source
This module defines the following functions and objects:

**threading.active_count()**

Return the number of Thread objects currently alive. The returned count is equal to the length of the list returned by `enumerate()`.

**threading.Condition()**

A factory function that returns a new condition variable object. A condition variable allows one or more threads to wait until they are notified by another thread.

See *Condition Objects*.

**threading.current_thread()**

Return the current Thread object, corresponding to the caller’s thread of control. If the caller’s thread of control was not created through the `threading` module, a dummy thread object with limited functionality is returned.

**threading.enumerate()**

Return a list of all Thread objects currently alive. The list includes daemonic threads, dummy thread objects created by `current_thread()`, and the main thread. It excludes terminated threads and threads that have not yet been started.

**threading.Event()**

A factory function that returns a new event object. An event manages a flag that can be set to true with the `set()` method and reset to false with the `clear()` method. The `wait()` method blocks until the flag is true.
See *Event Objects*.

**class** threading.**local**

A class that represents thread-local data. Thread-local data are data whose values are thread specific. To manage thread-local data, just create an instance of **local** (or a subclass) and store attributes on it:

```python
def main():
    mydata = threading.local()
    mydata.x = 42
    print(mydata.x)
```

The instance's values will be different for separate threads.

For more details and extensive examples, see the documentation string of the `_threading_local` module.

*New in version 2.4.*

**threading.****Lock()**

A factory function that returns a new primitive lock object. Once a thread has acquired it, subsequent attempts to acquire it block, until it is released; any thread may release it.

See *Lock Objects*.

**threading.****RLock()**

A factory function that returns a new reentrant lock object. A reentrant lock must be released by the thread that acquired it. Once a thread has acquired a reentrant lock, the same thread may acquire it again without blocking; the thread must release it once for each time it has acquired it.

See *RLock Objects*.

**threading.****Semaphore([value])**

A factory function that returns a new semaphore object. A
Semaphore manages a counter representing the number of release() calls minus the number of acquire() calls, plus an initial value. The acquire() method blocks if necessary until it can return without making the counter negative. If not given, value defaults to 1.

See Semaphore Objects.

threading. BoundedSemaphore([value])
A factory function that returns a new bounded semaphore object. A bounded semaphore checks to make sure its current value doesn't exceed its initial value. If it does, ValueError is raised. In most situations semaphores are used to guard resources with limited capacity. If the semaphore is released too many times it's a sign of a bug. If not given, value defaults to 1.

class threading. Thread
A class that represents a thread of control. This class can be safely subclassed in a limited fashion.

See Thread Objects.

class threading. Timer
A thread that executes a function after a specified interval has passed.

See Timer Objects.

threading. settrace(func)
Set a trace function for all threads started from the threading module. The func will be passed to sys.settrace() for each thread, before its run() method is called.

New in version 2.3.
threading.setprofile(func)

Set a profile function for all threads started from the threading module. The func will be passed to sys.setprofile() for each thread, before its run() method is called.

New in version 2.3.

threading.stack_size([size])

Return the thread stack size used when creating new threads. The optional size argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32kB). If changing the thread stack size is unsupported, a ThreadError is raised. If the specified stack size is invalid, a ValueError is raised and the stack size is unmodified. 32kB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32kB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4kB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information). Availability: Windows, systems with POSIX threads.

New in version 2.5.

Detailed interfaces for the objects are documented below.

The design of this module is loosely based on Java's threading model. However, where Java makes locks and condition variables basic behavior of every object, they are separate objects in Python. Python's Thread class supports a subset of the behavior of Java's Thread class; currently, there are no priorities, no thread groups, and
threads cannot be destroyed, stopped, suspended, resumed, or interrupted. The static methods of Java's Thread class, when implemented, are mapped to module-level functions.

All of the methods described below are executed atomically.
16.2.1. Thread Objects

This class represents an activity that is run in a separate thread of control. There are two ways to specify the activity: by passing a callable object to the constructor, or by overriding the `run()` method in a subclass. No other methods (except for the constructor) should be overridden in a subclass. In other words, only override the `__init__()` and `run()` methods of this class.

Once a thread object is created, its activity must be started by calling the thread's `start()` method. This invokes the `run()` method in a separate thread of control.

Once the thread's activity is started, the thread is considered 'alive'. It stops being alive when its `run()` method terminates – either normally, or by raising an unhandled exception. The `is_alive()` method tests whether the thread is alive.

Other threads can call a thread's `join()` method. This blocks the calling thread until the thread whose `join()` method is called is terminated.

A thread has a name. The name can be passed to the constructor, and read or changed through the `name` attribute.

A thread can be flagged as a “daemon thread”. The significance of this flag is that the entire Python program exits when only daemon threads are left. The initial value is inherited from the creating thread. The flag can be set through the `daemon` property.

There is a “main thread” object; this corresponds to the initial thread of control in the Python program. It is not a daemon thread.
There is the possibility that “dummy thread objects” are created. These are thread objects corresponding to “alien threads”, which are threads of control started outside the threading module, such as directly from C code. Dummy thread objects have limited functionality; they are always considered alive and daemonic, and cannot be `join()`ed. They are never deleted, since it is impossible to detect the termination of alien threads.

```python
class threading.Thread(group=None, target=None, name=None, args=(), kwargs={}):
    This constructor should always be called with keyword arguments. Arguments are:

    `group` should be `None`; reserved for future extension when a `ThreadGroup` class is implemented.

    `target` is the callable object to be invoked by the `run()` method. Defaults to `None`, meaning nothing is called.

    `name` is the thread name. By default, a unique name is constructed of the form “Thread-N” where N is a small decimal number.

    `args` is the argument tuple for the target invocation. Defaults to `()`.  

    `kwargs` is a dictionary of keyword arguments for the target invocation. Defaults to `{}`.

    If the subclass overrides the constructor, it must make sure to invoke the base class constructor (`Thread.__init__()` before doing anything else to the thread.

    `start()`
    Start the thread's activity.
```
It must be called at most once per thread object. It arranges for the object’s `run()` method to be invoked in a separate thread of control.

This method will raise a `RuntimeError` if called more than once on the same thread object.

**run()**

Method representing the thread’s activity.

You may override this method in a subclass. The standard `run()` method invokes the callable object passed to the object’s constructor as the `target` argument, if any, with sequential and keyword arguments taken from the `args` and `kwargs` arguments, respectively.

**join([timeout])**

Wait until the thread terminates. This blocks the calling thread until the thread whose `join()` method is called terminates – either normally or through an unhandled exception – or until the optional timeout occurs.

When the *timeout* argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof). As `join()` always returns `None`, you must call `isAlive()` after `join()` to decide whether a timeout happened – if the thread is still alive, the `join()` call timed out.

When the *timeout* argument is not present or `None`, the operation will block until the thread terminates.

A thread can be `join()`ed many times.
join() raises a RuntimeError if an attempt is made to join the current thread as that would cause a deadlock. It is also an error to join() a thread before it has been started and attempts to do so raises the same exception.

getName()
setName()
    Old API for name.

name
    A string used for identification purposes only. It has no semantics. Multiple threads may be given the same name. The initial name is set by the constructor.

ident
    The ‘thread identifier’ of this thread or None if the thread has not been started. This is a nonzero integer. See the thread.get_ident() function. Thread identifiers may be recycled when a thread exits and another thread is created. The identifier is available even after the thread has exited.

    New in version 2.6.

is_alive()
isAlive()
    Return whether the thread is alive.

    This method returns True just before the run() method starts until just after the run() method terminates. The module function enumerate() returns a list of all alive threads.

isDaemon()
setDaemon()
    Old API for daemon.
daemon

A boolean value indicating whether this thread is a daemon thread (True) or not (False). This must be set before \texttt{start()} is called, otherwise \texttt{RuntimeError} is raised. Its initial value is inherited from the creating thread; the main thread is not a daemon thread and therefore all threads created in the main thread default to \texttt{daemon = False}.

The entire Python program exits when no alive non-daemon threads are left.
A primitive lock is a synchronization primitive that is not owned by a particular thread when locked. In Python, it is currently the lowest level synchronization primitive available, implemented directly by the thread extension module.

A primitive lock is in one of two states, “locked” or “unlocked”. It is created in the unlocked state. It has two basic methods, `acquire()` and `release()`. When the state is unlocked, `acquire()` changes the state to locked and returns immediately. When the state is locked, `acquire()` blocks until a call to `release()` in another thread changes it to unlocked, then the `acquire()` call resets it to locked and returns. The `release()` method should only be called in the locked state; it changes the state to unlocked and returns immediately. If an attempt is made to release an unlocked lock, a `RuntimeError` will be raised.

When more than one thread is blocked in `acquire()` waiting for the state to turn to unlocked, only one thread proceeds when a `release()` call resets the state to unlocked; which one of the waiting threads proceeds is not defined, and may vary across implementations.

All methods are executed atomically.

```python
Lock.acquire([blocking])
```

Acquire a lock, blocking or non-blocking.

When invoked without arguments, block until the lock is unlocked, then set it to locked, and return true.

When invoked with the `blocking` argument set to true, do the same thing as when called without arguments, and return true.
When invoked with the \textit{blocking} argument set to false, do not block. If a call without an argument would block, return false immediately; otherwise, do the same thing as when called without arguments, and return true.

\textbf{Lock. \texttt{release}()}

Release a lock.

When the lock is locked, reset it to unlocked, and return. If any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

Do not call this method when the lock is unlocked.

There is no return value.
16.2.3. RLock Objects

A reentrant lock is a synchronization primitive that may be acquired multiple times by the same thread. Internally, it uses the concepts of “owning thread” and “recursion level” in addition to the locked/unlocked state used by primitive locks. In the locked state, some thread owns the lock; in the unlocked state, no thread owns it.

To lock the lock, a thread calls its `acquire()` method; this returns once the thread owns the lock. To unlock the lock, a thread calls its `release()` method. `acquire()`/`release()` call pairs may be nested; only the final `release()` (the `release()` of the outermost pair) resets the lock to unlocked and allows another thread blocked in `acquire()` to proceed.

```python
RLock. acquire([blocking=1])
```

Acquire a lock, blocking or non-blocking.

When invoked without arguments: if this thread already owns the lock, increment the recursion level by one, and return immediately. Otherwise, if another thread owns the lock, block until the lock is unlocked. Once the lock is unlocked (not owned by any thread), then grab ownership, set the recursion level to one, and return. If more than one thread is blocked waiting until the lock is unlocked, only one at a time will be able to grab ownership of the lock. There is no return value in this case.

When invoked with the `blocking` argument set to true, do the same thing as when called without arguments, and return true.

When invoked with the `blocking` argument set to false, do not block. If a call without an argument would block, return false immediately; otherwise, do the same thing as when called without
arguments, and return true.

**RLock.release()**

Release a lock, decrementing the recursion level. If after the decrement it is zero, reset the lock to unlocked (not owned by any thread), and if any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling thread.

Only call this method when the calling thread owns the lock. A `RuntimeError` is raised if this method is called when the lock is unlocked.

There is no return value.
A condition variable is always associated with some kind of lock; this can be passed in or one will be created by default. (Passing one in is useful when several condition variables must share the same lock.)

A condition variable has acquire() and release() methods that call the corresponding methods of the associated lock. It also has a wait() method, and notify() and notifyAll() methods. These three must only be called when the calling thread has acquired the lock, otherwise a RuntimeException is raised.

The wait() method releases the lock, and then blocks until it is awakened by a notify() or notifyAll() call for the same condition variable in another thread. Once awakened, it re-acquires the lock and returns. It is also possible to specify a timeout.

The notify() method wakes up one of the threads waiting for the condition variable, if any are waiting. The notifyAll() method wakes up all threads waiting for the condition variable.

Note: the notify() and notifyAll() methods don't release the lock; this means that the thread or threads awakened will not return from their wait() call immediately, but only when the thread that called notify() or notifyAll() finally relinquishes ownership of the lock.

Tip: the typical programming style using condition variables uses the lock to synchronize access to some shared state; threads that are interested in a particular change of state call wait() repeatedly until they see the desired state, while threads that modify the state call notify() or notifyAll() when they change the state in such a way that it could possibly be a desired state for one of the waiters. For example, the following code is a generic producer-consumer
situation with unlimited buffer capacity:

```python
# Consume one item
cv.acquire()
while not an_item_is_available():
    cv.wait()
get_an_available_item()
cv.release()

# Produce one item
cv.acquire()
make_an_item_available()
cv.notify()
cv.release()
```

To choose between `notify()` and `notifyAll()`, consider whether one state change can be interesting for only one or several waiting threads. E.g. in a typical producer-consumer situation, adding one item to the buffer only needs to wake up one consumer thread.

```
class threading.Condition([lock])
    If the lock argument is given and not None, it must be a Lock or RLock object, and it is used as the underlying lock. Otherwise, a new RLock object is created and used as the underlying lock.

    acquire(*args)
        Acquire the underlying lock. This method calls the corresponding method on the underlying lock; the return value is whatever that method returns.

    release()
        Release the underlying lock. This method calls the corresponding method on the underlying lock; there is no return value.

    wait([timeout])
        Wait until notified or until a timeout occurs. If the calling thread
```
has not acquired the lock when this method is called, a
\texttt{RuntimeError} is raised.

This method releases the underlying lock, and then blocks
until it is awakened by a \texttt{notify()} or \texttt{notifyAll()} call for the
same condition variable in another thread, or until the optional
timeout occurs. Once awakened or timed out, it re-acquires
the lock and returns.

When the \texttt{timeout} argument is present and not \texttt{None}, it should
be a floating point number specifying a timeout for the
operation in seconds (or fractions thereof).

When the underlying lock is an \texttt{RLock}, it is not released using
its \texttt{release()} method, since this may not actually unlock the
lock when it was acquired multiple times recursively. Instead,
an internal interface of the \texttt{RLock} class is used, which really
unlocks it even when it has been recursively acquired several
times. Another internal interface is then used to restore the
recursion level when the lock is reacquired.

\texttt{notify()}

Wake up a thread waiting on this condition, if any. If the calling
thread has not acquired the lock when this method is called, a
\texttt{RuntimeError} is raised.

This method wakes up one of the threads waiting for the
condition variable, if any are waiting; it is a no-op if no threads
are waiting.

The current implementation wakes up exactly one thread, if
any are waiting. However, it's not safe to rely on this behavior.
A future, optimized implementation may occasionally wake up
more than one thread.
Note: the awakened thread does not actually return from its wait() call until it can reacquire the lock. Since notify() does not release the lock, its caller should.

**notify_all()**
**notifyAll()**

Wake up all threads waiting on this condition. This method acts like notify(), but wakes up all waiting threads instead of one. If the calling thread has not acquired the lock when this method is called, a RuntimeError is raised.
16.2.5. Semaphore Objects

This is one of the oldest synchronization primitives in the history of computer science, invented by the early Dutch computer scientist Edsger W. Dijkstra (he used P() and V() instead of acquire() and release()).

A semaphore manages an internal counter which is decremented by each acquire() call and incremented by each release() call. The counter can never go below zero; when acquire() finds that it is zero, it blocks, waiting until some other thread calls release().

```python
class threading.Semaphore([value])
```

The optional argument gives the initial value for the internal counter; it defaults to 1. If the value given is less than 0, ValueError is raised.

```python
acquire([blocking])
```

Acquire a semaphore.

When invoked without arguments: if the internal counter is larger than zero on entry, decrement it by one and return immediately. If it is zero on entry, block, waiting until some other thread has called release() to make it larger than zero. This is done with proper interlocking so that if multiple acquire() calls are blocked, release() will wake exactly one of them up. The implementation may pick one at random, so the order in which blocked threads are awakened should not be relied on. There is no return value in this case.

When invoked with blocking set to true, do the same thing as when called without arguments, and return true.
When invoked with `blocking` set to false, do not block. If a call without an argument would block, return false immediately; otherwise, do the same thing as when called without arguments, and return true.

`release()`

Release a semaphore, incrementing the internal counter by one. When it was zero on entry and another thread is waiting for it to become larger than zero again, wake up that thread.

16.2.5.1. Semaphore Example

Semaphores are often used to guard resources with limited capacity, for example, a database server. In any situation where the size of the resource is fixed, you should use a bounded semaphore. Before spawning any worker threads, your main thread would initialize the semaphore:

```python
maxconnections = 5
...
pool_sema = BoundedSemaphore(value=maxconnections)
```

Once spawned, worker threads call the semaphore's acquire and release methods when they need to connect to the server:

```python
pool_sema.acquire()
conn = connectdb()
... use connection ...
conn.close()
pool_sema.release()
```

The use of a bounded semaphore reduces the chance that a programming error which causes the semaphore to be released more than it's acquired will go undetected.
16.2.6. Event Objects

This is one of the simplest mechanisms for communication between threads: one thread signals an event and other threads wait for it.

An event object manages an internal flag that can be set to true with the `set()` method and reset to false with the `clear()` method. The `wait()` method blocks until the flag is true.

class threading.Event

The internal flag is initially false.

    is_set()
    isSet()

    Return true if and only if the internal flag is true.

    Changed in version 2.6: The `is_set()` syntax is new.

    set()

    Set the internal flag to true. All threads waiting for it to become true are awakened. Threads that call `wait()` once the flag is true will not block at all.

    clear()

    Reset the internal flag to false. Subsequently, threads calling `wait()` will block until `set()` is called to set the internal flag to true again.

    wait([timeout])

    Block until the internal flag is true. If the internal flag is true on entry, return immediately. Otherwise, block until another thread calls `set()` to set the flag to true, or until the optional timeout occurs.
When the timeout argument is present and not \texttt{None}, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof).

This method returns the internal flag on exit, so it will always return \texttt{True} except if a timeout is given and the operation times out.

\textit{Changed in version 2.7:} Previously, the method always returned \texttt{None}. 
16.2.7. Timer Objects

This class represents an action that should be run only after a certain amount of time has passed — a timer. `Timer` is a subclass of `Thread` and as such also functions as an example of creating custom threads.

Timers are started, as with threads, by calling their `start()` method. The timer can be stopped (before its action has begun) by calling the `cancel()` method. The interval the timer will wait before executing its action may not be exactly the same as the interval specified by the user.

For example:

```python
def hello():
    print "hello, world"

t = Timer(30.0, hello)
t.start() # after 30 seconds, "hello, world" will be printed
```

```
class threading.Timer(interval, function, args=[], kwargs={})

Create a timer that will run function with arguments args and keyword arguments kwargs, after interval seconds have passed.

cancel()

Stop the timer, and cancel the execution of the timer’s action. This will only work if the timer is still in its waiting stage.
```
16.2.8. Using locks, conditions, and semaphores in the `with` statement

All of the objects provided by this module that have `acquire()` and `release()` methods can be used as context managers for a `with` statement. The `acquire()` method will be called when the block is entered, and `release()` will be called when the block is exited.

Currently, `Lock`, `RLock`, `Condition`, `Semaphore`, and `BoundedSemaphore` objects may be used as `with` statement context managers. For example:

```python
import threading

some_rlock = threading.RLock()

with some_rlock:
    print "some_rlock is locked while this executes"
```
16.2.9. Importing in threaded code

While the import machinery is thread-safe, there are two key restrictions on threaded imports due to inherent limitations in the way that thread-safety is provided:

- Firstly, other than in the main module, an import should not have the side effect of spawning a new thread and then waiting for that thread in any way. Failing to abide by this restriction can lead to a deadlock if the spawned thread directly or indirectly attempts to import a module.
- Secondly, all import attempts must be completed before the interpreter starts shutting itself down. This can be most easily achieved by only performing imports from non-daemon threads created through the threading module. Daemon threads and threads created directly with the thread module will require some other form of synchronization to ensure they do not attempt imports after system shutdown has commenced. Failure to abide by this restriction will lead to intermittent exceptions and crashes during interpreter shutdown (as the late imports attempt to access machinery which is no longer in a valid state).
16. Optional Operating System Services
16.3. thread — Multiple threads of control

**Note:** The `thread` module has been renamed to `_thread` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0; however, you should consider using the high-level `threading` module instead.

This module provides low-level primitives for working with multiple threads (also called light-weight processes or tasks) — multiple threads of control sharing their global data space. For synchronization, simple locks (also called mutexes or binary semaphores) are provided. The `threading` module provides an easier to use and higher-level threading API built on top of this module.

The module is optional. It is supported on Windows, Linux, SGI IRIX, Solaris 2.x, as well as on systems that have a POSIX thread (a.k.a. “pthread”) implementation. For systems lacking the `thread` module, the `dummy_thread` module is available. It duplicates this module’s interface and can be used as a drop-in replacement.

It defines the following constant and functions:

- `exception thread.error`  
  Raised on thread-specific errors.

- `thread.LockType`  
  This is the type of lock objects.

- `thread.start_new_thread(function, args[, kwargs])`  
  Start a new thread and return its identifier. The thread executes the function `function` with the argument list `args` (which must be a
tuple). The optional *kw*args argument specifies a dictionary of keyword arguments. When the function returns, the thread silently exits. When the function terminates with an unhandled exception, a stack trace is printed and then the thread exits (but other threads continue to run).

**thread.interrupt_main()**

Raise a *KeyboardInterrupt* exception in the main thread. A subthread can use this function to interrupt the main thread.

*New in version 2.3.*

**thread.exit()**

Raise the *SystemExit* exception. When not caught, this will cause the thread to exit silently.

**thread.allocate_lock()**

Return a new lock object. Methods of locks are described below. The lock is initially unlocked.

**thread.get_ident()**

Return the ‘thread identifier’ of the current thread. This is a nonzero integer. Its value has no direct meaning; it is intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

**thread.stack_size([size])**

Return the thread stack size used when creating new threads. The optional size argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32kB). If changing the thread stack size is unsupported, the *error* exception is raised. If the specified stack size is invalid, a
**ValueError** is raised and the stack size is unmodified. 32kB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32kB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4kB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information). Availability: Windows, systems with POSIX threads.

*New in version 2.5.*

Lock objects have the following methods:

lock.

**acquire([waitflag])**

Without the optional argument, this method acquires the lock unconditionally, if necessary waiting until it is released by another thread (only one thread at a time can acquire a lock — that's their reason for existence). If the integer `waitflag` argument is present, the action depends on its value: if it is zero, the lock is only acquired if it can be acquired immediately without waiting; while if it is nonzero, the lock is acquired unconditionally as before. The return value is `True` if the lock is acquired successfully, `False` if not.

lock.

**release**

Releases the lock. The lock must have been acquired earlier, but not necessarily by the same thread.

lock.

**locked()**

Return the status of the lock: `True` if it has been acquired by some thread, `False` if not.
In addition to these methods, lock objects can also be used via the with statement, e.g.:

```python
import thread

a_lock = thread.allocate_lock()

with a_lock:
    print "a_lock is locked while this executes"
```

Caveats:

- Threads interact strangely with interrupts: the `KeyboardInterrupt` exception will be received by an arbitrary thread. (When the `signal` module is available, interrupts always go to the main thread.)

- Calling `sys.exit()` or raising the `SystemExit` exception is equivalent to calling `thread.exit()`.

- Not all built-in functions that may block waiting for I/O allow other threads to run. (The most popular ones (`time.sleep()`, `file.read()`, `select.select()`) work as expected.)

- It is not possible to interrupt the `acquire()` method on a lock — the `KeyboardInterrupt` exception will happen after the lock has been acquired.

- When the main thread exits, it is system defined whether the other threads survive. On SGI IRIX using the native thread implementation, they survive. On most other systems, they are killed without executing `try ... finally` clauses or executing object destructors.

- When the main thread exits, it does not do any of its usual cleanup (except that `try ... finally` clauses are honored), and
the standard I/O files are not flushed.
This module provides a duplicate interface to the `threading` module. It is meant to be imported when the `thread` module is not provided on a platform.

Suggested usage is:

```python
try:
    import threading as _threading
except ImportError:
    import dummy_threading as _threading
```

Be careful to not use this module where deadlock might occur from a thread being created that blocks waiting for another thread to be created. This often occurs with blocking I/O.
16.5. dummy_thread — Drop-in replacement for the thread module

**Note:** The `dummy_thread` module has been renamed to `_dummy_thread` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0; however, you should consider using the high-lever `dummy_threading` module instead.

This module provides a duplicate interface to the `thread` module. It is meant to be imported when the `thread` module is not provided on a platform.

Suggested usage is:

```python
try:
    import thread as _thread
except ImportError:
    import dummy_thread as _thread
```

Be careful to not use this module where deadlock might occur from a thread being created that blocks waiting for another thread to be created. This often occurs with blocking I/O.
16.6. multiprocessing — Process-based “threading” interface

New in version 2.6.
16.6.1. Introduction

`multiprocessing` is a package that supports spawning processes using an API similar to the `threading` module. The `multiprocessing` package offers both local and remote concurrency, effectively sidestepping the `Global Interpreter Lock` by using subprocesses instead of threads. Due to this, the `multiprocessing` module allows the programmer to fully leverage multiple processors on a given machine. It runs on both Unix and Windows.

**Warning:** Some of this package's functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the `multiprocessing.synchronize` module will be disabled, and attempts to import it will result in an `ImportError`. See issue 3770 for additional information.

**Note:** Functionality within this package requires that the `__main__` module be importable by the children. This is covered in `Programming guidelines` however it is worth pointing out here. This means that some examples, such as the `multiprocessing.Pool` examples will not work in the interactive interpreter. For example:

```python
>>> from multiprocessing import Pool
>>> p = Pool(5)
>>> def f(x):
...     return x*x
...
>>> p.map(f, [1,2,3])
Process PoolWorker-1:
Process PoolWorker-2:
Process PoolWorker-3:
Traceback (most recent call last):
  File "", line 1, in 
AttributeError: 'module' object has no attribute 'f'
AttributeError: 'module' object has no attribute 'f'
AttributeError: 'module' object has no attribute 'f'
```
(If you try this it will actually output three full tracebacks interleaved in a semi-random fashion, and then you may have to stop the master process somehow.)

16.6.1.1. The Process class

In multiprocessing, processes are spawned by creating a Process object and then calling its `start()` method. Process follows the API of threading.Thread. A trivial example of a multiprocess program is

```python
from multiprocessing import Process

def f(name):
    print 'hello', name

if __name__ == '__main__':
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()
```

To show the individual process IDs involved, here is an expanded example:

```python
from multiprocessing import Process
import os

def info(title):
    print title
    print 'module name:', __name__
    print 'parent process:', os.getppid()
    print 'process id:', os.getpid()

def f(name):
    info('function f')
    print 'hello', name

if __name__ == '__main__':
    info('main line')
    p = Process(target=f, args=('bob',))
    p.start()
```
For an explanation of why (on Windows) the `if __name__ == '__main__'` part is necessary, see *Programming guidelines*.

### 16.6.1.2. Exchanging objects between processes

`multiprocessing` supports two types of communication channel between processes:

#### Queues

The `Queue` class is a near clone of `Queue.Queue`. For example:

```python
from multiprocessing import Process, Queue

def f(q):
    q.put([42, None, 'hello'])

if __name__ == '__main__':
    q = Queue()
    p = Process(target=f, args=(q,))
    p.start()
    print q.get()  # prints '[42, None, 'hello']'
    p.join()
```

Queues are thread and process safe.

#### Pipes

The `Pipe()` function returns a pair of connection objects connected by a pipe which by default is duplex (two-way). For example:

```python
from multiprocessing import Process, Pipe

def f(conn):
    conn.send([42, None, 'hello'])
    conn.close()
```
if __name__ == '__main__':
    parent_conn, child_conn = Pipe()
    p = Process(target=f, args=(child_conn,))
    p.start()
    print parent_conn.recv()  # prints '[42, None, 'hello']
    p.join()

The two connection objects returned by `Pipe()` represent the two ends of the pipe. Each connection object has `send()` and `recv()` methods (among others). Note that data in a pipe may become corrupted if two processes (or threads) try to read from or write to the same end of the pipe at the same time. Of course there is no risk of corruption from processes using different ends of the pipe at the same time.

### 16.6.1.3. Synchronization between processes

`multiprocessing` contains equivalents of all the synchronization primitives from `threading`. For instance one can use a lock to ensure that only one process prints to standard output at a time:

```python
from multiprocessing import Process, Lock

def f(l, i):
    l.acquire()
    print 'hello world', i
    l.release()

if __name__ == '__main__':
    lock = Lock()

    for num in range(10):
        Process(target=f, args=(lock, num)).start()
```

Without using the lock output from the different processes is liable to get all mixed up.
16.6.1.4. Sharing state between processes

As mentioned above, when doing concurrent programming it is usually best to avoid using shared state as far as possible. This is particularly true when using multiple processes.

However, if you really do need to use some shared data then multiprocessing provides a couple of ways of doing so.

Shared memory

Data can be stored in a shared memory map using Value or Array. For example, the following code

```python
from multiprocessing import Process, Value, Array

def f(n, a):
    n.value = 3.1415927
    for i in range(len(a)):
        a[i] = -a[i]

if __name__ == '__main__':
    num = Value('d', 0.0)
    arr = Array('i', range(10))

    p = Process(target=f, args=(num, arr))
p.start()
p.join()

    print num.value
    print arr[:]
```

will print

```
3.1415927
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
```

The 'd' and 'i' arguments used when creating num and arr are typecodes of the kind used by the array module: 'd'
indicates a double precision float and 'i' indicates a signed integer. These shared objects will be process and thread-safe.

For more flexibility in using shared memory one can use the `multiprocessing.sharedctypes` module which supports the creation of arbitrary ctypes objects allocated from shared memory.

**Server process**

A manager object returned by `Manager()` controls a server process which holds Python objects and allows other processes to manipulate them using proxies.

A manager returned by `Manager()` will support types `list`, `dict`, `Namespace`, `Lock`, `RLock`, `Semaphore`, `BoundedSemaphore`, `Condition`, `Event`, `Queue`, `Value` and `Array`. For example,

```python
from multiprocessing import Process, Manager

def f(d, l):
    d[1] = '1'
    d['2'] = 2
    d[0.25] = None
    l.reverse()

if __name__ == '__main__':
    manager = Manager()

    d = manager.dict()
    l = manager.list(range(10))

    p = Process(target=f, args=(d, l))
    p.start()
    p.join()

    print d
    print l
```

will print
Server process managers are more flexible than using shared memory objects because they can be made to support arbitrary object types. Also, a single manager can be shared by processes on different computers over a network. They are, however, slower than using shared memory.

16.6.1.5. Using a pool of workers

The `Pool` class represents a pool of worker processes. It has methods which allows tasks to be offloaded to the worker processes in a few different ways.

For example:

```python
from multiprocessing import Pool

def f(x):
    return x*x

if __name__ == '__main__':
    pool = Pool(processes=4) # start 4 worker proc
    result = pool.apply_async(f, [10]) # evaluate "f(10)" a
    print result.get(timeout=1) # prints "100" unless
    print pool.map(f, range(10)) # prints "[0, 1, 4,..
```
16.6.2. Reference

The multiprocessing package mostly replicates the API of the threading module.

16.6.2.1. Process and exceptions

```python
class multiprocessing.Process([group[, target[, name[, args[, kwargs]]]]])
```

Process objects represent activity that is run in a separate process. The Process class has equivalents of all the methods of threading.Thread.

The constructor should always be called with keyword arguments. `group` should always be `None`; it exists solely for compatibility with threading.Thread. `target` is the callable object to be invoked by the `run()` method. It defaults to `None`, meaning nothing is called. `name` is the process name. By default, a unique name is constructed of the form 'Process-N₁:N₂:...:Nₖ' where N₁,N₂,...,Nₖ is a sequence of integers whose length is determined by the generation of the process. `args` is the argument tuple for the target invocation. `kwargs` is a dictionary of keyword arguments for the target invocation. By default, no arguments are passed to `target`.

If a subclass overrides the constructor, it must make sure it invokes the base class constructor (`Process.__init__()`) before doing anything else to the process.

```python
run()
```

Method representing the process’s activity.
You may override this method in a subclass. The standard `run()` method invokes the callable object passed to the object's constructor as the target argument, if any, with sequential and keyword arguments taken from the `args` and `kwargs` arguments, respectively.

**start()**

Start the process's activity.

This must be called at most once per process object. It arranges for the object's `run()` method to be invoked in a separate process.

**join([timeout])**

Block the calling thread until the process whose `join()` method is called terminates or until the optional timeout occurs.

If `timeout` is `None` then there is no timeout.

A process can be joined many times.

A process cannot join itself because this would cause a deadlock. It is an error to attempt to join a process before it has been started.

**name**

The process's name.

The name is a string used for identification purposes only. It has no semantics. Multiple processes may be given the same name. The initial name is set by the constructor.

**is_alive()**

Return whether the process is alive.
Roughly, a process object is alive from the moment the `start()` method returns until the child process terminates.

`daemon`

The process's daemon flag, a Boolean value. This must be set before `start()` is called.

The initial value is inherited from the creating process.

When a process exits, it attempts to terminate all of its daemonic child processes.

Note that a daemonic process is not allowed to create child processes. Otherwise a daemonic process would leave its children orphaned if it gets terminated when its parent process exits. Additionally, these are not Unix daemons or services, they are normal processes that will be terminated (and not joined) if non-daemonic processes have exited.

In addition to the `Threading.Thread` API, `Process` objects also support the following attributes and methods:

`pid`

Return the process ID. Before the process is spawned, this will be `None`.

`exitcode`

The child's exit code. This will be `None` if the process has not yet terminated. A negative value `-N` indicates that the child was terminated by signal `N`.

`authkey`

The process's authentication key (a byte string).

When `multiprocessing` is initialized the main process is assigned a random string using `os.random()`.
When a `Process` object is created, it will inherit the authentication key of its parent process, although this may be changed by setting `authkey` to another byte string.

See *Authentication keys*.

**terminate()**

Terminate the process. On Unix this is done using the `SIGTERM` signal; on Windows `TerminateProcess()` is used. Note that exit handlers and finally clauses, etc., will not be executed.

Note that descendant processes of the process will *not* be terminated – they will simply become orphaned.

**Warning:** If this method is used when the associated process is using a pipe or queue then the pipe or queue is liable to become corrupted and may become unusable by other process. Similarly, if the process has acquired a lock or semaphore etc. then terminating it is liable to cause other processes to deadlock.

Note that the `start()`, `join()`, `is_alive()` and `exit_code` methods should only be called by the process that created the process object.

Example usage of some of the methods of `Process`:

```python
>>> import multiprocessing, time, signal
>>> p = multiprocessing.Process(target=time.sleep, args=(100,
>>> print p, p.is_alive())
<Process(Process-1, initial)> False
>>> p.start()
>>> print p, p.is_alive())
<Process(Process-1, started)> True
>>> p.terminate()
>>> time.sleep(0.1)
>>> print p, p.is_alive())
```
exception multiprocessing.BufferTooShort

Exception raised by Connection.recv_bytes_into() when the supplied buffer object is too small for the message read.

If e is an instance of BufferTooShort then e.args[0] will give the message as a byte string.

16.6.2.2. Pipes and Queues

When using multiple processes, one generally uses message passing for communication between processes and avoids having to use any synchronization primitives like locks.

For passing messages one can use Pipe() (for a connection between two processes) or a queue (which allows multiple producers and consumers).

The Queue and JoinableQueue types are multi-producer, multi-consumer FIFO queues modelled on the Queue.Queue class in the standard library. They differ in that Queue lacks the task_done() and join() methods introduced into Python 2.5’s Queue.Queue class.

If you use JoinableQueue then you must call JoinableQueue.task_done() for each task removed from the queue or else the semaphore used to count the number of unfinished tasks may eventually overflow raising an exception.

Note that one can also create a shared queue by using a manager object – see Managers.
Note: multiprocessing uses the usual `Queue.Empty` and `Queue.Full` exceptions to signal a timeout. They are not available in the multiprocessing namespace so you need to import them from Queue.

Warning: If a process is killed using `Process.terminate()` or `os.kill()` while it is trying to use a Queue, then the data in the queue is likely to become corrupted. This may cause any other processes to get an exception when it tries to use the queue later on.

Warning: As mentioned above, if a child process has put items on a queue (and it has not used `JoinableQueue.cancel_join_thread()`), then that process will not terminate until all buffered items have been flushed to the pipe.

This means that if you try joining that process you may get a deadlock unless you are sure that all items which have been put on the queue have been consumed. Similarly, if the child process is non-daemonic then the parent process may hang on exit when it tries to join all its non-daemonic children.

Note that a queue created using a manager does not have this issue. See Programming guidelines.

For an example of the usage of queues for interprocess communication see Examples.

```
multiprocessing.Pipe([duplex])
```

Returns a pair `(conn1, conn2)` of `Connection` objects representing the ends of a pipe.

If `duplex` is `True` (the default) then the pipe is bidirectional. If
duplex is False then the pipe is unidirectional: conn1 can only be used for receiving messages and conn2 can only be used for sending messages.

```python
class multiprocessing.Queue(maxsize)
```
Returns a process shared queue implemented using a pipe and a few locks/semaphores. When a process first puts an item on the queue, a feeder thread is started which transfers objects from a buffer into the pipe.

The usual `Queue.Empty` and `Queue.Full` exceptions from the standard library's `Queue` module are raised to signal timeouts.

`Queue` implements all the methods of `Queue.Queue` except for `task_done()` and `join()`.

`qsise()`
Return the approximate size of the queue. Because of multithreading/multiprocessing semantics, this number is not reliable.

Note that this may raise `NotImplementedError` on Unix platforms like Mac OS X where `sem_getvalue()` is not implemented.

`empty()`
Return `True` if the queue is empty, `False` otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

`full()`
Return `True` if the queue is full, `False` otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.
`put(item[, block[, timeout]])`
Put item into the queue. If the optional argument `block` is `True` (the default) and `timeout` is `None` (the default), block if necessary until a free slot is available. If `timeout` is a positive number, it blocks at most `timeout` seconds and raises the `Queue.Full` exception if no free slot was available within that time. Otherwise (`block` is `False`), put an item on the queue if a free slot is immediately available, else raise the `Queue.Full` exception (`timeout` is ignored in that case).

`put_nowait(item)`
Equivalent to `put(item, False)`.

`get([block[, timeout]])`
Remove and return an item from the queue. If optional args `block` is `True` (the default) and `timeout` is `None` (the default), block if necessary until an item is available. If `timeout` is a positive number, it blocks at most `timeout` seconds and raises the `Queue.Empty` exception if no item was available within that time. Otherwise (`block` is `False`), return an item if one is immediately available, else raise the `Queue.Empty` exception (`timeout` is ignored in that case).

`get_nowait()`
`get_no_wait()`
Equivalent to `get(False)`.

`multiprocessing.Queue` has a few additional methods not found in `Queue.Queue`. These methods are usually unnecessary for most code:

`close()`
Indicate that no more data will be put on this queue by the
current process. The background thread will quit once it has flushed all buffered data to the pipe. This is called automatically when the queue is garbage collected.

**join_thread()**
Join the background thread. This can only be used after `close()` has been called. It blocks until the background thread exits, ensuring that all data in the buffer has been flushed to the pipe.

By default if a process is not the creator of the queue then on exit it will attempt to join the queue’s background thread. The process can call `cancel_join_thread()` to make `join_thread()` do nothing.

**cancel_join_thread()**
Prevent `join_thread()` from blocking. In particular, this prevents the background thread from being joined automatically when the process exits – see `join_thread()`.

```python
class multiprocessing.JoinableQueue([maxsize])

JoinableQueue, a Queue subclass, is a queue which additionally has task_done() and join() methods.
```

task_done()
Indicate that a formerly enqueued task is complete. Used by queue consumer threads. For each `get()` used to fetch a task, a subsequent call to `task_done()` tells the queue that the processing on the task is complete.

If a `join()` is currently blocking, it will resume when all items have been processed (meaning that a `task_done()` call was received for every item that had been `put()` into the queue).
Raises a `ValueError` if called more times than there were items placed in the queue.

**join()**
Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls `task_done()` to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, `join()` unblocks.

### 16.6.2.3. Miscellaneous

**multiprocessing.active_children()**
Return list of all live children of the current process.

Calling this has the side affect of “joining” any processes which have already finished.

**multiprocessing.cpu_count()**
Return the number of CPUs in the system. May raise `NotImplementedError`.

**multiprocessing.current_process()**
Return the `Process` object corresponding to the current process.

An analogue of `threading.current_thread()`.

**multiprocessing.freeze_support()**
Add support for when a program which uses `multiprocessing` has been frozen to produce a Windows executable. (Has been tested with `py2exe`, `PyInstaller` and `cx_Freeze`.)
One needs to call this function straight after the `if __name__ == '__main__'` line of the main module. For example:

```python
from multiprocessing import Process, freeze_support

def f():
    print 'hello world!

if __name__ == '__main__':
    freeze_support()
    Process(target=f).start()
```

If the `freeze_support()` line is omitted then trying to run the frozen executable will raise `RuntimeError`.

If the module is being run normally by the Python interpreter then `freeze_support()` has no effect.

`multiprocessing.set_executable()`
Sets the path of the Python interpreter to use when starting a child process. (By default `sys.executable` is used). Embedders will probably need to do some thing like

```python
setExecutable(os.path.join(sys.exec_prefix, 'pythonw.exe'))
```

before they can create child processes. (Windows only)

**Note:** `multiprocessing` contains no analogues of
`threading.active_count()`, `threading.enumerate()`,
`threading.settrace()`, `threading.setprofile()`, `threading.Timer`,
or `threading.local`.

### 16.6.2.4. Connection Objects

Connection objects allow the sending and receiving of picklable objects or strings. They can be thought of as message oriented
connected sockets.

Connection objects usually created using `Pipe()` — see also
Listeners and Clients.

```python
class multiprocessing.Connection
    send(obj)
        Send an object to the other end of the connection which
        should be read using `recv()`.

        The object must be picklable. Very large pickles
        (approximately 32 MB+, though it depends on the OS) may
        raise a ValueError exception.

    recv()
        Return an object sent from the other end of the connection
        using `send()`. Raises EOFError if there is nothing left to
        receive and the other end was closed.

    fileno()
        Returns the file descriptor or handle used by the connection.

    close()
        Close the connection.

        This is called automatically when the connection is garbage
        collected.

    poll([timeout])
        Return whether there is any data available to be read.

        If `timeout` is not specified then it will return immediately. If
        `timeout` is a number then this specifies the maximum time in
        seconds to block. If `timeout` is None then an infinite timeout is
        used.
```
send_bytes(buffer[, offset[, size]])
Send byte data from an object supporting the buffer interface as a complete message.

If offset is given then data is read from that position in buffer. If size is given then that many bytes will be read from buffer. Very large buffers (approximately 32 MB+, though it depends on the OS) may raise a ValueError exception.

recv_bytes([maxlength])
Return a complete message of byte data sent from the other end of the connection as a string. Raises EOFError if there is nothing left to receive and the other end has closed.

If maxlength is specified and the message is longer than maxlength then IOError is raised and the connection will no longer be readable.

recv_bytes_into(buffer[, offset])
Read into buffer a complete message of byte data sent from the other end of the connection and return the number of bytes in the message. Raises EOFError if there is nothing left to receive and the other end was closed.

buffer must be an object satisfying the writable buffer interface. If offset is given then the message will be written into the buffer from that position. Offset must be a non-negative integer less than the length of buffer (in bytes).

If the buffer is too short then a BufferTooShort exception is raised and the complete message is available as e.args[0] where e is the exception instance.

For example:
```python
>>> from multiprocessing import Pipe
>>> a, b = Pipe()
>>> a.send([1, 'hello', None])
[1, 'hello', None]
>>> a.send_bytes('thank you')
'thank you'
```
class multiprocessing.BoundedSemaphore([value])

(On Mac OS X, this is indistinguishable from Semaphore because sem_getvalue() is not implemented on that platform).

class multiprocessing.Condition([lock])

If lock is specified then it should be a Lock or RLock object from multiprocessing.

class multiprocessing.Event

A clone of threading.Event. This method returns the state of the internal semaphore on exit, so it will always return True except if a timeout is given and the operation times out.

Changed in version 2.7: Previously, the method always returned None.

class multiprocessing.Lock

A non-recursive lock object: a clone of threading.Lock.

class multiprocessing.RLock

A recursive lock object: a clone of threading.RLock.

class multiprocessing.Semaphore([value])

A semaphore object: a clone of threading.Semaphore.

Note: The acquire() method of BoundedSemaphore, Lock, RLock and Semaphore has a timeout parameter not supported by the equivalents in threading. The signature is acquire(block=True,
timeout=None) with keyword parameters being acceptable. If block is True and timeout is not None then it specifies a timeout in seconds. If block is False then timeout is ignored.

On Mac OS X, sem_timedwait is unsupported, so calling acquire() with a timeout will emulate that function’s behavior using a sleeping loop.

**Note:** If the SIGINT signal generated by Ctrl-C arrives while the main thread is blocked by a call to BoundedSemaphore.acquire(), Lock.acquire(), RLock.acquire(), Semaphore.acquire(), Condition.acquire() or Condition.wait() then the call will be immediately interrupted and KeyboardInterrupt will be raised.

This differs from the behaviour of threading where SIGINT will be ignored while the equivalent blocking calls are in progress.

### 16.6.2.6. Shared ctypes Objects

It is possible to create shared objects using shared memory which can be inherited by child processes.

```python
multiprocessing.Value(typecode_or_type, *args[, lock])
```

Return a ctypes object allocated from shared memory. By default the return value is actually a synchronized wrapper for the object.

`typecode_or_type` determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used by the array module. *args is passed on to the constructor for the type.

If `lock` is True (the default) then a new lock object is created to synchronize access to the value. If `lock` is a Lock or RLock object
then that will be used to synchronize access to the value. If lock is False then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that lock is a keyword-only argument.

```
multiprocessing.Array(typecode_or_type, size_or_initializer, *, lock=True)
```

Return a ctypes array allocated from shared memory. By default the return value is actually a synchronized wrapper for the array.

`typecode_or_type` determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the array module. If `size_or_initializer` is an integer, then it determines the length of the array, and the array will be initially zeroed. Otherwise, `size_or_initializer` is a sequence which is used to initialize the array and whose length determines the length of the array.

If lock is True (the default) then a new lock object is created to synchronize access to the value. If lock is a Lock or RLock object then that will be used to synchronize access to the value. If lock is False then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that lock is a keyword only argument.

Note that an array of ctypes.c_char has value and raw attributes which allow one to use it to store and retrieve strings.

16.6.2.6.1. The multiprocessing.sharedctypes module

The multiprocessing.sharedctypes module provides functions for
allocating **ctypes** objects from shared memory which can be inherited by child processes.

**Note:** Although it is possible to store a pointer in shared memory remember that this will refer to a location in the address space of a specific process. However, the pointer is quite likely to be invalid in the context of a second process and trying to dereference the pointer from the second process may cause a crash.

```python
multiprocessing.sharedctypes.RawArray(typecode_or_type, size_or_initializer)
```

Return a ctypes array allocated from shared memory.

* `typecode_or_type` determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the **array** module. If `size_or_initializer` is an integer then it determines the length of the array, and the array will be initially zeroed. Otherwise `size_or_initializer` is a sequence which is used to initialize the array and whose length determines the length of the array.

Note that setting and getting an element is potentially non-atomic – use **Array()** instead to make sure that access is automatically synchronized using a lock.

```python
multiprocessing.sharedctypes.RawValue(typecode_or_type, *args)
```

Return a ctypes object allocated from shared memory.

* `typecode_or_type` determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used by the **array** module. `*args` is passed on to the constructor for the type.

Note that setting and getting the value is potentially non-atomic –
use `Value()` instead to make sure that access is automatically synchronized using a lock.

Note that an array of `ctypes.c_char` has `value` and `raw` attributes which allow one to use it to store and retrieve strings – see documentation for `ctypes`.

```
multiprocessing.sharedctypes.Array(typecode_or_type, size_or_initializer, *args[, lock])
```

The same as `RawArray()` except that depending on the value of `lock` a process-safe synchronization wrapper may be returned instead of a raw ctypes array.

If `lock` is `True` (the default) then a new lock object is created to synchronize access to the value. If `lock` is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If `lock` is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be “process-safe”.

Note that `lock` is a keyword-only argument.

```
multiprocessing.sharedctypes.Value(typecode_or_type, *args[, lock])
```

The same as `RawValue()` except that depending on the value of `lock` a process-safe synchronization wrapper may be returned instead of a raw ctypes object.

If `lock` is `True` (the default) then a new lock object is created to synchronize access to the value. If `lock` is a `Lock` or `RLock` object then that will be used to synchronize access to the value. If `lock` is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be
“process-safe”.

Note that `lock` is a keyword-only argument.

```python
multiprocessing.sharedctypes.copy(obj)
```

Return a ctypes object allocated from shared memory which is a copy of the ctypes object `obj`.

```python
multiprocessing.sharedctypes.synchronized(obj[, lock])
```

Return a process-safe wrapper object for a ctypes object which uses `lock` to synchronize access. If `lock` is `None` (the default) then a `multiprocessing.RLock` object is created automatically.

A synchronized wrapper will have two methods in addition to those of the object it wraps: `get_obj()` returns the wrapped object and `get_lock()` returns the lock object used for synchronization.

Note that accessing the ctypes object through the wrapper can be a lot slower than accessing the raw ctypes object.

The table below compares the syntax for creating shared ctypes objects from shared memory with the normal ctypes syntax. (In the table `MyStruct` is some subclass of `ctypes.Structure`.)

<table>
<thead>
<tr>
<th>ctypes</th>
<th>sharedctypes using type</th>
<th>sharedctypes using typecode</th>
</tr>
</thead>
<tbody>
<tr>
<td>c_double(2.4)</td>
<td>RawValue(c_double, 2.4)</td>
<td>RawValue('d', 2.4)</td>
</tr>
<tr>
<td>MyStruct(4, 6)</td>
<td>RawValue(MyStruct, 4, 6)</td>
<td></td>
</tr>
<tr>
<td>(c_short * 7)()</td>
<td>RawArray(c_short, 7)</td>
<td>RawArray('h', 7)</td>
</tr>
<tr>
<td>(c_int * 3)(9, 2, 8)</td>
<td>RawArray(c_int, (9, 2, 8))</td>
<td>RawArray('i', (9, 2, 8))</td>
</tr>
</tbody>
</table>

Below is an example where a number of ctypes objects are modified
by a child process:

```python
from multiprocessing import Process, Lock
from multiprocessing.sharedctypes import Value, Array
from ctypes import Structure, c_double

class Point(Structure):
    _fields_ = [('x', c_double), ('y', c_double)]

def modify(n, x, s, A):
    n.value **= 2
    x.value **= 2
    s.value = s.value.upper()
    for a in A:
        a.x **= 2
        a.y **= 2

if __name__ == '__main__':
    lock = Lock()

    n = Value('i', 7)
    x = Value(c_double, 1.0/3.0, lock=False)
    s = Array('c', 'hello world', lock=lock)
    A = Array(Point, [(1.875, -6.25), (-5.75, 2.0), (2.375, 9.5)], lock)

    p = Process(target=modify, args=(n, x, s, A))
    p.start()
    p.join()

    print n.value
    print x.value
    print s.value
    print [(a.x, a.y) for a in A]
```

The results printed are

```
49
0.1111111111111111
HELLO WORLD
[(3.515625, 39.0625), (33.0625, 4.0), (5.640625, 90.25)]
```

16.6.2.7. Managers
Managers provide a way to create data which can be shared between different processes. A manager object controls a server process which manages *shared objects*. Other processes can access the shared objects by using proxies.

`multiprocessing.Manager()`

Returns a started `SyncManager` object which can be used for sharing objects between processes. The returned manager object corresponds to a spawned child process and has methods which will create shared objects and return corresponding proxies.

Manager processes will be shutdown as soon as they are garbage collected or their parent process exits. The manager classes are defined in the `multiprocessing.managers` module:

```python
class multiprocessing.managers.BaseManager([address[, authkey]])
```

Create a `BaseManager` object.

Once created one should call `start()` or `get_server().serve_forever()` to ensure that the manager object refers to a started manager process.

`address` is the address on which the manager process listens for new connections. If `address` is `None` then an arbitrary one is chosen.

`authkey` is the authentication key which will be used to check the validity of incoming connections to the server process. If `authkey` is `None` then `current_process().authkey`. Otherwise `authkey` is used and it must be a string.

`start([initializer[, initargs]])`
Start a subprocess to start the manager. If *initializer* is not None then the subprocess will call initializer(*initargs) when it starts.

get_server()

Returns a Server object which represents the actual server under the control of the Manager. The Server object supports the serve_forever() method:

```python
>>> from multiprocessing.managers import BaseManager
>>> manager = BaseManager(address=('', 50000), authkey='abc')
>>> server = manager.get_server()
>>> server.serve_forever()

Server additionally has an address attribute.

connect()

Connect a local manager object to a remote manager process:

```python
>>> from multiprocessing.managers import BaseManager
>>> m = BaseManager(address=('127.0.0.1', 5000), authkey='abc')
>>> m.connect()
```

shutdown()

Stop the process used by the manager. This is only available if start() has been used to start the server process.

This can be called multiple times.

register(typeid[, callable[, proxytype[, exposed[, method_to_typeid[, create_method]]]]])

A classmethod which can be used for registering a type or callable with the manager class.
typeid is a “type identifier” which is used to identify a particular type of shared object. This must be a string.

callable is a callable used for creating objects for this type identifier. If a manager instance will be created using the from_address() classmethod or if the create_method argument is False then this can be left as None.

proxytype is a subclass of BaseProxy which is used to create proxies for shared objects with this typeid. If None then a proxy class is created automatically.

exposed is used to specify a sequence of method names which proxies for this typeid should be allowed to access using BaseProxy._callMethod(). (If exposed is None then proxytype._exposed_ is used instead if it exists.) In the case where no exposed list is specified, all “public methods” of the shared object will be accessible. (Here a “public method” means any attribute which has a __call__() method and whose name does not begin with '_'.)

method_to_typeid is a mapping used to specify the return type of those exposed methods which should return a proxy. It maps method names to typeid strings. (If method_to_typeid is None then proxytype._method_to_typeid_ is used instead if it exists.) If a method's name is not a key of this mapping or if the mapping is None then the object returned by the method will be copied by value.

create_method determines whether a method should be created with name typeid which can be used to tell the server process to create a new shared object and return a proxy for it. By default it is True.
BaseManager instances also have one read-only property:

**address**
The address used by the manager.

class multiprocessing.managers.SyncManager
A subclass of BaseManager which can be used for the synchronization of processes. Objects of this type are returned by multiprocessing.Manager().

It also supports creation of shared lists and dictionaries.

BoundedSemaphore([value])
Create a shared threading.BoundedSemaphore object and return a proxy for it.

Condition([lock])
Create a shared threading.Condition object and return a proxy for it.

If lock is supplied then it should be a proxy for a threading.Lock or threading.RLock object.

Event()
Create a shared threading.Event object and return a proxy for it.

Lock()
Create a shared threading.Lock object and return a proxy for it.

Namespace()
Create a shared Namespace object and return a proxy for it.

Queue([maxsize])
Create a shared `queue.Queue` object and return a proxy for it.

**RLock()**
Create a shared `threading.RLock` object and return a proxy for it.

**Semaphore([value])**
Create a shared `threading.Semaphore` object and return a proxy for it.

**Array(typecode, sequence)**
Create an array and return a proxy for it.

**Value(typecode, value)**
Create an object with a writable `value` attribute and return a proxy for it.

**dict()**
**dict(mapping)**
**dict(sequence)**
Create a shared `dict` object and return a proxy for it.

**list()**
**list(sequence)**
Create a shared `list` object and return a proxy for it.

**Note:** Modifications to mutable values or items in dict and list proxies will not be propagated through the manager, because the proxy has no way of knowing when its values or items are modified. To modify such an item, you can re-assign the modified object to the container proxy:

```python
# create a list proxy and append a mutable object (a dictionary)
listproxy = manager.list()
listproxy.append({})
# now mutate the dictionary
```
16.6.2.7.1. Namespace objects

A namespace object has no public methods, but does have writable attributes. Its representation shows the values of its attributes.

However, when using a proxy for a namespace object, an attribute beginning with `_' will be an attribute of the proxy and not an attribute of the referent:

```
>>> manager = multiprocessing.Manager()
>>> Global = manager.Namespace()
>>> Global.x = 10
>>> Global.y = 'hello'
>>> Global._z = 12.3  # this is an attribute of the proxy
>>> print Global
Namespace(x=10, y='hello')
```

16.6.2.7.2. Customized managers

To create one’s own manager, one creates a subclass of `BaseManager` and use the `register()` classmethod to register new types or callables with the manager class. For example:

```
from multiprocessing.managers import BaseManager

class MathsClass(object):
    def add(self, x, y):
        return x + y
    def mul(self, x, y):
        return x * y

class MyManager(BaseManager):
```
pass
MyManager.register('Maths', MathsClass)

if __name__ == '__main__':
    manager = MyManager()
    manager.start()
    maths = manager.Maths()
    print maths.add(4, 3) # prints 7
    print maths.mul(7, 8) # prints 56

16.6.2.7.3. Using a remote manager

It is possible to run a manager server on one machine and have clients use it from other machines (assuming that the firewalls involved allow it).

Running the following commands creates a server for a single shared queue which remote clients can access:

```python
>>> from multiprocessing.managers import BaseManager
>>> import Queue
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue', callable=lambda:queue)
>>> m = QueueManager(address=('', 50000), authkey='abracadabra'
>>> s = m.get_server()
>>> s.serve_forever()
```

One client can access the server as follows:

```python
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey='a
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.put('hello')
```

Another client can also use it:
Local processes can also access that queue, using the code from above on the client to access it remotely:

```
>>> from multiprocessing import Process, Queue
>>> from multiprocessing.managers import BaseManager
>>> class Worker(Process):
...     def __init__(self, q):
...         self.q = q
...         super(Worker, self).__init__()
...     def run(self):
...         self.q.put('local hello')
...
>>> queue = Queue()
>>> w = Worker(queue)
>>> w.start()
>>> class QueueManager(BaseManager): pass
... >>> QueueManager.register('get_queue', callable=lambda: queue)
... >>> m = QueueManager(address=('foo.bar.org', 50000), authkey='abracadabra')
... >>> s = m.get_server()
... >>> s.serve_forever()
```

### 16.6.2.8. Proxy Objects

A proxy is an object which refers to a shared object which lives (presumably) in a different process. The shared object is said to be the referent of the proxy. Multiple proxy objects may have the same referent.

A proxy object has methods which invoke corresponding methods of its referent (although not every method of the referent will
necessarily be available through the proxy). A proxy can usually be used in most of the same ways that its referent can:

```python
>>> from multiprocessing import Manager
>>> manager = Manager()
>>> l = manager.list([i*i for i in range(10)])
>>> print l
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
>>> print repr(l)
<ListProxy object, typeid 'list' at 0x...>
>>> l[4]
16
>>> l[2:5]
[4, 9, 16]
```

Notice that applying `str()` to a proxy will return the representation of the referent, whereas applying `repr()` will return the representation of the proxy.

An important feature of proxy objects is that they are picklable so they can be passed between processes. Note, however, that if a proxy is sent to the corresponding manager’s process then unpickling it will produce the referent itself. This means, for example, that one shared object can contain a second:

```python
>>> a = manager.list()
>>> b = manager.list()
>>> a.append(b) # referent of a now contains referent of b
>>> print a, b
[['hello']]
>>> b.append('hello')
>>> print a, b
[['hello', 'hello']]
```

**Note:** The proxy types in `multiprocessing` do nothing to support comparisons by value. So, for instance, we have:

```python
>>> manager.list([1,2,3]) == [1,2,3]
False
```
One should just use a copy of the referent instead when making comparisons.

```python
class multiprocessing.managers.BaseProxy
    Proxy objects are instances of subclasses of BaseProxy.

    __callmethod__(methodname[, args[, kwds]])
    Call and return the result of a method of the proxy's referent.

    If proxy is a proxy whose referent is obj then the expression

    proxy.__callmethod__(methodname, args, kwds)

    will evaluate the expression

    getattr(obj, methodname)(*args, **kwds)

    in the manager's process.

    The returned value will be a copy of the result of the call or a
    proxy to a new shared object – see documentation for the
    method_to_typeid argument of BaseManager.register().

    If an exception is raised by the call, then then is re-raised by
    __callmethod__(). If some other exception is raised in the
    manager's process then this is converted into a RemoteError
    exception and is raised by __callmethod__().

    Note in particular that an exception will be raised if
    methodname has not been exposed

    An example of the usage of __callmethod__:

    >>> l = manager.list(range(10))
    >>> l.__callmethod__('__len__')
    10
```
>>> l._callmethod('__getslice__', (2, 7))  # equiv to `l[2:7]`
[2, 3, 4, 5, 6]
>>> l._callmethod('getitem__', (20,))  # equiv to `l[20]`
...

IndexError: list index out of range

_getvalue()
Return a copy of the referent.

If the referent is unpicklable then this will raise an exception.

__repr__()
Return a representation of the proxy object.

__str__()
Return the representation of the referent.

16.6.2.8.1. Cleanup

A proxy object uses a weakref callback so that when it gets garbage collected it deregisters itself from the manager which owns its referent.

A shared object gets deleted from the manager process when there are no longer any proxies referring to it.

16.6.2.9. Process Pools

One can create a pool of processes which will carry out tasks submitted to it with the Pool class.

```python
class multiprocessing.Pool([processes[, initializer[, initargs[, maxtasksperchild]]]]])
```

A process pool object which controls a pool of worker processes
to which jobs can be submitted. It supports asynchronous results with timeouts and callbacks and has a parallel map implementation.

`processes` is the number of worker processes to use. If `processes` is `None` then the number returned by `cpu_count()` is used. If `initializer` is not `None` then each worker process will call `initializer(*initargs)` when it starts.

*New in version 2.7:* `maxtasksperchild` is the number of tasks a worker process can complete before it will exit and be replaced with a fresh worker process, to enable unused resources to be freed. The default `maxtasksperchild` is `None`, which means worker processes will live as long as the pool.

**Note:** Worker processes within a `Pool` typically live for the complete duration of the Pool's work queue. A frequent pattern found in other systems (such as Apache, mod_wsgi, etc) to free resources held by workers is to allow a worker within a pool to complete only a set amount of work before being exiting, being cleaned up and a new process spawned to replace the old one. The `maxtasksperchild` argument to the `Pool` exposes this ability to the end user.

```python
apply(func[, args[, kwds]])
```
Equivalent of the `apply()` built-in function. It blocks till the result is ready. Given this blocks, `apply_async()` is better suited for performing work in parallel. Additionally, the passed in function is only executed in one of the workers of the pool.

```python
apply_async(func[, args[, kwds[, callback]]])
```
A variant of the `apply()` method which returns a result object.

If `callback` is specified then it should be a callable which
accepts a single argument. When the result becomes ready
\textit{callback} is applied to it (unless the call failed). \textit{callback} should
complete immediately since otherwise the thread which
handles the results will get blocked.

\texttt{\textbf{map}(\textit{func}, \textit{iterable}[, \textit{chunksize}])}

A parallel equivalent of the \texttt{map()} built-in function (it supports
only one \textit{iterable} argument though). It blocks till the result is
ready.

This method chops the iterable into a number of chunks which
it submits to the process pool as separate tasks. The
(approximate) size of these chunks can be specified by
setting \textit{chunksize} to a positive integer.

\texttt{\textbf{map\_async}(\textit{func}, \textit{iterable}[, \textit{chunksize}[, \textit{callback}])}

A variant of the \texttt{map()} method which returns a result object.

If \textit{callback} is specified then it should be a callable which
accepts a single argument. When the result becomes ready
\textit{callback} is applied to it (unless the call failed). \textit{callback} should
complete immediately since otherwise the thread which
handles the results will get blocked.

\texttt{\textbf{imap}(\textit{func}, \textit{iterable}[, \textit{chunksize}])}

An equivalent of \texttt{itertools.imap()}.

The \textit{chunksize} argument is the same as the one used by the
\texttt{map()} method. For very long iterables using a large value for
\textit{chunksize} can make the job complete \textbf{much} faster than
using the default value of \texttt{1}.

Also if \textit{chunksize} is \texttt{1} then the \texttt{next()} method of the iterator
returned by the \texttt{imap()} method has an optional \texttt{timeout}
parameter: **next(timeout)** will raise `multiprocessing.TimeoutError` if the result cannot be returned within `timeout` seconds.

**imap_unordered(func, iterable[, chunksize])**

The same as `imap()` except that the ordering of the results from the returned iterator should be considered arbitrary. (Only when there is only one worker process is the order guaranteed to be “correct”.)

**close()**

Prevents any more tasks from being submitted to the pool. Once all the tasks have been completed the worker processes will exit.

**terminate()**

Stops the worker processes immediately without completing outstanding work. When the pool object is garbage collected `terminate()` will be called immediately.

**join()**

Wait for the worker processes to exit. One must call `close()` or `terminate()` before using `join()`.

**class multiprocessing.pool.AsyncResult**

The class of the result returned by `Pool.apply_async()` and `Pool.map_async()`.

**get([timeout])**

Return the result when it arrives. If `timeout` is not `None` and the result does not arrive within `timeout` seconds then `multiprocessing.TimeoutError` is raised. If the remote call raised an exception then that exception will be reraised by `get()`.
**wait([timeout])**

Wait until the result is available or until *timeout* seconds pass.

**ready()**

Return whether the call has completed.

**successful()**

Return whether the call completed without raising an exception. Will raise *AssertionError* if the result is not ready.

The following example demonstrates the use of a pool:

```python
from multiprocessing import Pool

def f(x):
    return x * x

if __name__ == '__main__':
    pool = Pool(processes=4)  # start 4 worker processes

    result = pool.apply_async(f, (10,))  # evaluate "f(10)" asynchronously
    print(result.get(timeout=1))  # prints "100" unless your computer is *very* slow

    print(pool.map(f, range(10)))  # prints "[0, 1, 4, ...]

    it = pool.imap(f, range(10))
    print(it.next())  # prints "0"
    print(it.next())  # prints "1"
    print(it.next(timeout=1))  # prints "4" unless your computer is *very* slow

import time
result = pool.apply_async(time.sleep, (10,))
print(result.get(timeout=1))  # raises TimeoutError
```

### 16.6.2.10. Listeners and Clients

Usually message passing between processes is done using queues or by using *Connection* objects returned by *Pipe()*.
However, the `multiprocessing.connection` module allows some extra flexibility. It basically gives a high level message oriented API for dealing with sockets or Windows named pipes, and also has support for *digest authentication* using the `hmac` module.

```python
multiprocessing.connection.deliver_challenge(connection, authkey)
```

Send a randomly generated message to the other end of the connection and wait for a reply.

If the reply matches the digest of the message using `authkey` as the key then a welcome message is sent to the other end of the connection. Otherwise `AuthenticationError` is raised.

```python
multiprocessing.connection.answerChallenge(connection, authkey)
```

Receive a message, calculate the digest of the message using `authkey` as the key, and then send the digest back.

If a welcome message is not received, then `AuthenticationError` is raised.

```python
multiprocessing.connection.Client(address[, family[, authenticate[, authkey]]]])
```

Attempt to set up a connection to the listener which is using address `address`, returning a `Connection`.

The type of the connection is determined by `family` argument, but this can generally be omitted since it can usually be inferred from the format of `address`. (See `Address Formats`)

If `authenticate` is `True` or `authkey` is a string then digest authentication is used. The key used for authentication will be either `authkey` or `current_process().authkey` if `authkey` is `None`. 

If authentication fails then AuthenticationError is raised. See Authentication keys.

```python
class multiprocessing.connection.Listener([address[, family[, backlog[, authenticate[, authkey]]]]])
```

A wrapper for a bound socket or Windows named pipe which is ‘listening’ for connections.

**address** is the address to be used by the bound socket or named pipe of the listener object.

**Note:** If an address of ‘0.0.0.0’ is used, the address will not be a connectable end point on Windows. If you require a connectable end-point, you should use ‘127.0.0.1’.

**family** is the type of socket (or named pipe) to use. This can be one of the strings 'AF_INET' (for a TCP socket), 'AF_UNIX' (for a Unix domain socket) or 'AF_PIPE' (for a Windows named pipe). Of these only the first is guaranteed to be available. If **family** is **None** then the family is inferred from the format of **address**. If **address** is also **None** then a default is chosen. This default is the family which is assumed to be the fastest available. See **Address Formats**. Note that if **family** is 'AF_UNIX' and **address** is **None** then the socket will be created in a private temporary directory created using **tempfile.mkstemp()**.

If the listener object uses a socket then **backlog** (1 by default) is passed to the **listen()** method of the socket once it has been bound.

If **authenticate** is **True** (**False** by default) or **authkey** is not **None** then digest authentication is used.

If **authkey** is a string then it will be used as the authentication key;
otherwise it must be None.

If authkey is None and authenticate is True then current_process().authkey is used as the authentication key. If authkey is None and authenticate is False then no authentication is done. If authentication fails then AuthenticationError is raised. See Authentication keys.

accept()

Accept a connection on the bound socket or named pipe of the listener object and return a Connection object. If authentication is attempted and fails, then AuthenticationError is raised.

close()

Close the bound socket or named pipe of the listener object. This is called automatically when the listener is garbage collected. However it is advisable to call it explicitly.

Listener objects have the following read-only properties:

address

The address which is being used by the Listener object.

last_accepted

The address from which the last accepted connection came. If this is unavailable then it is None.

The module defines two exceptions:

exception multiprocessing.connection.AuthenticationError

Exception raised when there is an authentication error.

Examples

The following server code creates a listener which uses secret
password' as an authentication key. It then waits for a connection and sends some data to the client:

```python
from multiprocessing.connection import Listener
from array import array

address = ('localhost', 6000)  # family is deduced to be 'AF
listener = Listener(address, authkey='secret password')

conn = listener.accept()
print 'connection accepted from', listener.last_accepted
conn.send([2.25, None, 'junk', float])
conn.send_bytes('hello')
conn.send_bytes(array('i', [42, 1729]))
conn.close()
listener.close()
```

The following code connects to the server and receives some data from the server:

```python
from multiprocessing.connection import Client
from array import array

address = ('localhost', 6000)
conn = Client(address, authkey='secret password')

print conn.recv()  # => [2.25, None, 'junk', float]
print conn.recv_bytes()  # => 'hello'

arr = array('i', [0, 0, 0, 0, 0])
print conn.recv_bytes_into(arr)  # => 8
print arr  # => array('i', [42, 1729, 0, 0, 0])
conn.close()
```

16.6.2.10.1. Address Formats
- An 'AF_INET' address is a tuple of the form `(hostname, port)` where `hostname` is a string and `port` is an integer.

- An 'AF_UNIX' address is a string representing a filename on the filesystem.

- An 'AF_PIPE' address is a string of the form `r'\\\pipe\PipeName'`. To use `Client()` to connect to a named pipe on a remote computer called `ServerName` one should use an address of the form `r'\\ServerName\pipe\PipeName'` instead.

Note that any string beginning with two backslashes is assumed by default to be an 'AF_PIPE' address rather than an 'AF_UNIX' address.

## 16.6.2.11. Authentication keys

When one uses `Connection.recv()`, the data received is automatically unpickleed. Unfortunately unpickleing data from an untrusted source is a security risk. Therefore `Listener` and `Client()` use the `hmac` module to provide digest authentication.

An authentication key is a string which can be thought of as a password: once a connection is established both ends will demand proof that the other knows the authentication key. (Demonstrating that both ends are using the same key does **not** involve sending the key over the connection.)

If authentication is requested but do authentication key is specified then the return value of `current_process().authkey` is used (see `Process`). This value will automatically inherited by any `Process` object that the current process creates. This means that (by default) all processes of a multi-process program will share a single
authentication key which can be used when setting up connections between themselves.

Suitable authentication keys can also be generated by using `os.urandom()`.

### 16.6.2.12. Logging

Some support for logging is available. Note, however, that the `logging` package does not use process shared locks so it is possible (depending on the handler type) for messages from different processes to get mixed up.

`multiprocessing.get_logger()`

Returns the logger used by `multiprocessing`. If necessary, a new one will be created.

When first created the logger has level `logging.NOTSET` and no default handler. Messages sent to this logger will not by default propagate to the root logger.

Note that on Windows child processes will only inherit the level of the parent process's logger – any other customization of the logger will not be inherited.

`multiprocessing.log_to_stderr()`

This function performs a call to `get_logger()` but in addition to returning the logger created by get_logger, it adds a handler which sends output to `sys.stderr` using format `'[%(levelname)s/%(processName)s] %(message)s'`.

Below is an example session with logging turned on:

```
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
```
In addition to having these two logging functions, the multiprocessing also exposes two additional logging level attributes. These are **SUBWARNING** and **SUBDEBUG**. The table below illustrates where theses fit in the normal level hierarchy.

<table>
<thead>
<tr>
<th>Level</th>
<th>Numeric value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBWARNING</td>
<td>25</td>
</tr>
<tr>
<td>SUBDEBUG</td>
<td>5</td>
</tr>
</tbody>
</table>

For a full table of logging levels, see the `logging` module.

These additional logging levels are used primarily for certain debug messages within the multiprocessing module. Below is the same example as above, except with **SUBDEBUG** enabled:

```python
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
>>> logger.setLevel(multiprocessing.SUBDEBUG)
>>> logger.warning('doomed')
[WARNING/MainProcess] doomed
>>> m = multiprocessing.Manager()
[INFO/SyncManager-...] child process calling self.run()
[INFO/SyncManager-...] created temp directory /.../pymp-...
[INFO/SyncManager-...] manager serving at '/.../listener-...'
>>> del m
[INFO/MainProcess] sending shutdown message to manager
[INFO/SyncManager-...] manager exiting with exitcode 0
```

```python
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
>>> logger.setLevel(multiprocessing.SUBDEBUG)
>>> logger.warning('doomed')
[WARNING/MainProcess] doomed
>>> m = multiprocessing.Manager()
[INFO/SyncManager-...] child process calling self.run()
[INFO/SyncManager-...] created temp directory /.../pymp-...
[INFO/SyncManager-...] manager serving at '/.../pymp-djGBXN/listener-...'
>>> del m
[SUBDEBUG/MainProcess] finalizer calling ...
[INFO/MainProcess] sending shutdown message to manager
[DEBUG/SyncManager-...] manager received shutdown message
[SUBDEBUG/SyncManager-...] calling <Finalize object, callback=...>
[SUBDEBUG/SyncManager-...] finalizer calling <built-in function
```
16.6.2.13. The `multiprocessing.dummy` module

`multiprocessing.dummy` replicates the API of `multiprocessing` but is no more than a wrapper around the `threading` module.
16.6.3. Programming guidelines

There are certain guidelines and idioms which should be adhered to when using `multiprocessing`.

16.6.3.1. All platforms

Avoid shared state

As far as possible one should try to avoid shifting large amounts of data between processes.

It is probably best to stick to using queues or pipes for communication between processes rather than using the lower level synchronization primitives from the `threading` module.

Picklability

Ensure that the arguments to the methods of proxies are picklable.

Thread safety of proxies

Do not use a proxy object from more than one thread unless you protect it with a lock.

(There is never a problem with different processes using the `same` proxy.)

Joining zombie processes

On Unix when a process finishes but has not been joined it becomes a zombie. There should never be very many because each time a new process starts (or `active_children()` is called) all completed processes which have not yet been joined will be
joined. Also calling a finished process’s `Process.is_alive()` will join the process. Even so it is probably good practice to explicitly join all the processes that you start.

Better to inherit than pickle/unpickle

On Windows many types from `multiprocessing` need to be picklable so that child processes can use them. However, one should generally avoid sending shared objects to other processes using pipes or queues. Instead you should arrange the program so that a process which need access to a shared resource created elsewhere can inherit it from an ancestor process.

Avoid terminating processes

Using the `Process.terminate()` method to stop a process is liable to cause any shared resources (such as locks, semaphores, pipes and queues) currently being used by the process to become broken or unavailable to other processes.

Therefore it is probably best to only consider using `Process.terminate()` on processes which never use any shared resources.

Joining processes that use queues

Bear in mind that a process that has put items in a queue will wait before terminating until all the buffered items are fed by the “feeder” thread to the underlying pipe. (The child process can call the `Queue.cancel_join_thread()` method of the queue to avoid this behaviour.)

This means that whenever you use a queue you need to make sure that all items which have been put on the queue will eventually be removed before the process is joined. Otherwise you cannot be sure that processes which have put items on the
queue will terminate. Remember also that non-daemonic processes will be automatically be joined.

An example which will deadlock is the following:

```python
from multiprocessing import Process, Queue

def f(q):
    q.put('X' * 1000000)

if __name__ == '__main__':
    queue = Queue()
    p = Process(target=f, args=(queue,))
    p.start()
    p.join()  # this deadlocks
    obj = queue.get()
```

A fix here would be to swap the last two lines round (or simply remove the `p.join()` line).

Explicitly pass resources to child processes

On Unix a child process can make use of a shared resource created in a parent process using a global resource. However, it is better to pass the object as an argument to the constructor for the child process.

Apart from making the code (potentially) compatible with Windows this also ensures that as long as the child process is still alive the object will not be garbage collected in the parent process. This might be important if some resource is freed when the object is garbage collected in the parent process.

So for instance

```python
from multiprocessing import Process, Lock

def f():
    ... do something using "lock" ...
```
if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f).start()

should be rewritten as

from multiprocessing import Process, Lock

def f(l):
    ... do something using "l" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f, args=(lock,)).start()

Beware replacing sys.stdin with a “file like object”

multiprocessing originally unconditionally called:

os.close(sys.stdin.fileno())

in the multiprocessing.Process._bootstrap() method — this resulted in issues with processes-in-processes. This has been changed to:

sys.stdin.close()
sys.stdin = open(os.devnull)

Which solves the fundamental issue of processes colliding with each other resulting in a bad file descriptor error, but introduces a potential danger to applications which replace sys.stdin() with a “file-like object” with output buffering. This danger is that if multiple processes call close() on this file-like object, it could result in the same data being flushed to the object multiple times, resulting in corruption.
If you write a file-like object and implement your own caching, you can make it fork-safe by storing the pid whenever you append to the cache, and discarding the cache when the pid changes. For example:

```python
@property
def cache(self):
    pid = os.getpid()
    if pid != self._pid:
        self._pid = pid
        self._cache = []
    return self._cache
```

For more information, see issue 5155, issue 5313 and issue 5331

### 16.6.3.2. Windows

Since Windows lacks `os.fork()` it has a few extra restrictions:

More picklability

Ensure that all arguments to `Process.__init__()` are picklable. This means, in particular, that bound or unbound methods cannot be used directly as the `target` argument on Windows — just define a function and use that instead.

Also, if you subclass `Process` then make sure that instances will be picklable when the `Process.start()` method is called.

Global variables

Bear in mind that if code run in a child process tries to access a global variable, then the value it sees (if any) may not be the same as the value in the parent process at the time that `Process.start()` was called.
However, global variables which are just module level constants cause no problems.

Safe importing of main module

Make sure that the main module can be safely imported by a new Python interpreter without causing unintended side effects (such a starting a new process).

For example, under Windows running the following module would fail with a `RuntimeError`:

```python
from multiprocessing import Process

def foo():
    print 'hello'

p = Process(target=foo)
p.start()
```

Instead one should protect the “entry point” of the program by using `if __name__ == '__main__':` as follows:

```python
from multiprocessing import Process, freeze_support

def foo():
    print 'hello'

if __name__ == '__main__':
    freeze_support()
    p = Process(target=foo)
    p.start()
```

(The `freeze_support()` line can be omitted if the program will be run normally instead of frozen.)

This allows the newly spawned Python interpreter to safely import the module and then run the module's `foo()` function.
Similar restrictions apply if a pool or manager is created in the main module.
Demonstration of how to create and use customized managers and proxies:

```python
# This module shows how to use arbitrary callables with a subclass of `BaseManager`.
#
# Copyright (c) 2006-2008, R Oudkerk
# All rights reserved.
#
from multiprocessing import freeze_support
from multiprocessing.managers import BaseManager, BaseProxy
import operator

class Foo(object):
    def f(self):
        print 'you called Foo.f()'
    def g(self):
        print 'you called Foo.g()'
    def _h(self):
        print 'you called Foo._h()'

# A simple generator function
def baz():
    for i in xrange(10):
        yield i*i

# Proxy type for generator objects
class GeneratorProxy(BaseProxy):
    _exposed_ = ('next', '__next__')
    def __iter__(self):
        return self
    def next(self):
        return self._callmethod('next')
    def __next__(self):
        return self._callmethod('__next__')
```

# Function to return the operator module
def get_operator_module():
    return operator

##

class MyManager(BaseManager):
    pass

# register the Foo class; make `f()` and `g()` accessible via proxy
MyManager.register('Foo1', Foo)

# register the Foo class; make `g()` and `_h()` accessible via proxy
MyManager.register('Foo2', Foo, exposed=('g', '_h'))

# register the generator function baz; use `GeneratorProxy` to make proxies
MyManager.register('baz', baz, proxytype=GeneratorProxy)

# register get_operator_module(); make public functions accessible via proxy
MyManager.register('operator', get_operator_module)

##

def test():
    manager = MyManager()
    manager.start()

    print '-' * 20

    f1 = manager.Foo1()
    f1.f()
    f1.g()
    assert not hasattr(f1, '_h')
    assert sorted(f1._exposed_) == sorted(['f', 'g'])

    print '-' * 20

    f2 = manager.Foo2()
    f2.g()
    f2._h()
    assert not hasattr(f2, 'f')
    assert sorted(f2._exposed_) == sorted(['g', '_h'])

    print '-' * 20

    it = manager.baz()
    for i in it:
        print '<%d>' % i,
print

print '-' * 20

op = manager.operator()
print 'op.add(23, 45) =', op.add(23, 45)
print 'op.pow(2, 94) =', op.pow(2, 94)
print 'op.getslice(range(10), 2, 6) =', op.getslice(range(10), 2, 6)
print 'op.repeat(range(5), 3) =', op.repeat(range(5), 3)
print 'op._exposed_ =', op._exposed_

if __name__ == '__main__':
    freeze_support()
    test()

An example showing how to use queues to feed tasks to a collection of worker processes and collect the results:

```python
# Simple example which uses a pool of workers to carry out some tasks.
# Notice that the results will probably not come out of the output queue in the same order as the corresponding tasks put on the input queue. If it is important to get the results in the original order then consider using `Pool.map()` or `Pool.imap()` (which will save on the amount of code needed anyway).

import time
import random

16.7. mmap — Memory-mapped file support

Memory-mapped file objects behave like both strings and like file objects. Unlike normal string objects, however, these are mutable. You can use mmap objects in most places where strings are expected; for example, you can use the `re` module to search through a memory-mapped file. Since they're mutable, you can change a single character by doing `obj[index] = 'a'`, or change a substring by assigning to a slice: `obj[i1:i2] = '...'`. You can also read and write data starting at the current file position, and `seek()` through the file to different positions.

A memory-mapped file is created by the `mmap` constructor, which is different on Unix and on Windows. In either case you must provide a file descriptor for a file opened for update. If you wish to map an existing Python file object, use its `fileno()` method to obtain the correct value for the `fileno` parameter. Otherwise, you can open the file using the `os.open()` function, which returns a file descriptor directly (the file still needs to be closed when done).

For both the Unix and Windows versions of the constructor, access may be specified as an optional keyword parameter. `access` accepts one of three values: `ACCESS_READ`, `ACCESS_WRITE`, or `ACCESS_COPY` to specify read-only, write-through or copy-on-write memory respectively. `access` can be used on both Unix and Windows. If access is not specified, Windows mmap returns a write-through mapping. The initial memory values for all three access types are taken from the specified file. Assignment to an `ACCESS_READ` memory map raises a `TypeError` exception. Assignment to an `ACCESS_WRITE` memory map affects both memory and the underlying file. Assignment to an `ACCESS_COPY` memory map affects memory but
does not update the underlying file.

*Changed in version 2.5:* To map anonymous memory, -1 should be passed as the fileno along with the length.

*Changed in version 2.6:* mmap.mmap has formerly been a factory function creating mmap objects. Now mmap.mmap is the class itself.

class mmap.mmap(fileno, length[, tagname[, access[, offset]]]])

(*Windows version*) Maps length bytes from the file specified by the file handle fileno, and creates a mmap object. If length is larger than the current size of the file, the file is extended to contain length bytes. If length is 0, the maximum length of the map is the current size of the file, except that if the file is empty Windows raises an exception (you cannot create an empty mapping on Windows).

tagname, if specified and not None, is a string giving a tag name for the mapping. Windows allows you to have many different mappings against the same file. If you specify the name of an existing tag, that tag is opened, otherwise a new tag of this name is created. If this parameter is omitted or None, the mapping is created without a name. Avoiding the use of the tag parameter will assist in keeping your code portable between Unix and Windows.

offset may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the file. offset defaults to 0. offset must be a multiple of the ALLOCATIONGRANULARITY.

class mmap.mmap(fileno, length[, flags[, prot[, access[, offset]]]])

(*Unix version*) Maps length bytes from the file specified by the file descriptor fileno, and returns a mmap object. If length is 0, the
maximum length of the map will be the current size of the file when `mmap` is called.

*flags* specifies the nature of the mapping. `MAP_PRIVATE` creates a private copy-on-write mapping, so changes to the contents of the mmap object will be private to this process, and `MAP_SHARED` creates a mapping that’s shared with all other processes mapping the same areas of the file. The default value is `MAP_SHARED`.

*prot*, if specified, gives the desired memory protection; the two most useful values are `PROT_READ` and `PROT_WRITE`, to specify that the pages may be read or written. *prot* defaults to `PROT_READ | PROT_WRITE`.

*access* may be specified in lieu of *flags* and *prot* as an optional keyword parameter. It is an error to specify both *flags*, *prot* and *access*. See the description of *access* above for information on how to use this parameter.

*offset* may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the file. *offset* defaults to 0. *offset* must be a multiple of the PAGESIZE or ALLOCATIONGRANULARITY.

To ensure validity of the created memory mapping the file specified by the descriptor *fileno* is internally automatically synchronized with physical backing store on Mac OS X and OpenVMS.

This example shows a simple way of using `mmap`:

```python
import mmap

# write a simple example file
with open("hello.txt", "wb") as f:
```

f.write("Hello Python!
")

with open("hello.txt", "r+b") as f:
    # memory-map the file, size 0 means whole file
    map = mmap.mmap(f.fileno(), 0)
    # read content via standard file methods
    print map.readline()  # prints "Hello Python!"
    # read content via slice notation
    print map[:5]  # prints "Hello"
    # update content using slice notation;
    # note that new content must have same size
    map[6:] = " world!"
    # ... and read again using standard file methods
    map.seek(0)
    print map.readline()  # prints "Hello world!"
    # close the map
    map.close()

The next example demonstrates how to create an anonymous map and exchange data between the parent and child processes:

import mmap
import os

map = mmap.mmap(-1, 13)
map.write("Hello world!"

pid = os.fork()
if pid == 0:  # In a child process
    map.seek(0)
    print map.readline()
    map.close()

Memory-mapped file objects support the following methods:

mmap.close()

Close the file. Subsequent calls to other methods of the object
will result in an exception being raised.

mmap.find(string[, start[, end]])
Returns the lowest index in the object where the substring \textit{string} is found, such that \textit{string} is contained in the range \([\text{start}, \text{end}]\). Optional arguments \textit{start} and \textit{end} are interpreted as in slice notation. Returns \texttt{-1} on failure.

\texttt{mmap.flush([offset, size])}

Flushes changes made to the in-memory copy of a file back to disk. Without use of this call there is no guarantee that changes are written back before the object is destroyed. If \textit{offset} and \textit{size} are specified, only changes to the given range of bytes will be flushed to disk; otherwise, the whole extent of the mapping is flushed.

\textbf{(Windows version)} A nonzero value returned indicates success; zero indicates failure.

\textbf{(Unix version)} A zero value is returned to indicate success. An exception is raised when the call failed.

\texttt{mmap.move(dest, src, count)}

Copy the \textit{count} bytes starting at offset \textit{src} to the destination index \textit{dest}. If the \texttt{mmap} was created with \texttt{ACCESS_READ}, then calls to move will raise a \texttt{TypeError} exception.

\texttt{mmap.read(num)}

Return a string containing up to \textit{num} bytes starting from the current file position; the file position is updated to point after the bytes that were returned.

\texttt{mmap.read_byte()} 

Returns a string of length 1 containing the character at the current file position, and advances the file position by 1.

\texttt{mmap.readline()} 

Returns a single line, starting at the current file position and
mmap.resize(newsize)

Resizes the map and the underlying file, if any. If the mmap was created with ACCESS_READ or ACCESS_COPY, resizing the map will raise a TypeError exception.

mmap.rfind(string[, start[, end]])

Returns the highest index in the object where the substring string is found, such that string is contained in the range [start, end]. Optional arguments start and end are interpreted as in slice notation. Returns -1 on failure.

mmap.seek(pos[, whence])

Set the file's current position. whence argument is optional and defaults to os.SEEK_SET or 0 (absolute file positioning); other values are os.SEEK_CUR or 1 (seek relative to the current position) and os.SEEK_END or 2 (seek relative to the file's end).

mmap.size()

Return the length of the file, which can be larger than the size of the memory-mapped area.

mmap.tell()

Returns the current position of the file pointer.

mmap.write(string)

Write the bytes in string into memory at the current position of the file pointer; the file position is updated to point after the bytes that were written. If the mmap was created with ACCESS_READ, then writing to it will raise a TypeError exception.

mmap.write_byte(byte)

Write the single-character string byte into memory at the
current position of the file pointer; the file position is advanced by 1. If the mmap was created with ACCESS_READ, then writing to it will raise a 

```
TypeError
```

exception.
16.8. readline — GNU readline interface

Platforms: Unix

The readline module defines a number of functions to facilitate completion and reading/writing of history files from the Python interpreter. This module can be used directly or via the rlcompleter module. Settings made using this module affect the behaviour of both the interpreter's interactive prompt and the prompts offered by the raw_input() and input() built-in functions.

**Note:** On MacOS X the readline module can be implemented using the libedit library instead of GNU readline.

The configuration file for libedit is different from that of GNU readline. If you programmatically load configuration strings you can check for the text “libedit” in readline.__doc__ to differentiate between GNU readline and libedit.

The readline module defines the following functions:

readline.parse_and_bind(string)
    Parse and execute single line of a readline init file.

readline.get_line_buffer()
    Return the current contents of the line buffer.

readline.insert_text(string)
    Insert text into the command line.

readline.read_init_file([filename])
Parse a readline initialization file. The default filename is the last filename used.

**readline.** `read_history_file([filename])`

Load a readline history file. The default filename is `~/.history`.

**readline.** `write_history_file([filename])`

Save a readline history file. The default filename is `~/.history`.

**readline.** `clear_history()`

Clear the current history. (Note: this function is not available if the installed version of GNU readline doesn't support it.)

*New in version 2.4.*

**readline.** `get_history_length()`

Return the desired length of the history file. Negative values imply unlimited history file size.

**readline.** `set_history_length(length)`

Set the number of lines to save in the history file. `write_history_file()` uses this value to truncate the history file when saving. Negative values imply unlimited history file size.

**readline.** `get_current_history_length()`

Return the number of lines currently in the history. (This is different from `get_history_length()`, which returns the maximum number of lines that will be written to a history file.)

*New in version 2.3.*

**readline.** `get_history_item(index)`

Return the current contents of history item at `index`. 
New in version 2.3.

readline.remove_history_item(pos)
Remove history item specified by its position from the history.

New in version 2.4.

readline.replace_history_item(pos, line)
Replace history item specified by its position with the given line.

New in version 2.4.

readline.redisplay()
Change what's displayed on the screen to reflect the current contents of the line buffer.

New in version 2.3.

readline.set_startup_hook([function])
Set or remove the startup_hook function. If function is specified, it will be used as the new startup_hook function; if omitted or None, any hook function already installed is removed. The startup_hook function is called with no arguments just before readline prints the first prompt.

readline.set_pre_input_hook([function])
Set or remove the pre_input_hook function. If function is specified, it will be used as the new pre_input_hook function; if omitted or None, any hook function already installed is removed. The pre_input_hook function is called with no arguments after the first prompt has been printed and just before readline starts reading input characters.

readline.set_completer([function])
Set or remove the completer function. If \textit{function} is specified, it will be used as the new completer function; if omitted or \texttt{None}, any completer function already installed is removed. The completer function is called as \texttt{function(text, state)}, for \texttt{state} in 0, 1, 2, ..., until it returns a non-string value. It should return the next possible completion starting with \textit{text}.

readline.\texttt{get\_completer()}  
Get the completer function, or \texttt{None} if no completer function has been set.

\textit{New in version 2.3.}

readline.\texttt{get\_completion\_type()}  
Get the type of completion being attempted.

\textit{New in version 2.6.}

readline.\texttt{get\_begidx()}  
Get the beginning index of the readline tab-completion scope.

readline.\texttt{get\_endidx()}  
Get the ending index of the readline tab-completion scope.

readline.\texttt{set\_completer\_delims(string)}  
Set the readline word delimiters for tab-completion.

readline.\texttt{get\_completer\_delims()}  
Get the readline word delimiters for tab-completion.

readline.\texttt{set\_completion\_display\_matches\_hook([function])}  
Set or remove the completion display function. If \texttt{function} is specified, it will be used as the new completion display function; if omitted or \texttt{None}, any completion display function already installed
is removed. The completion display function is called as
\begin{verbatim}
function(substitution, [matches], longest_match_length)
\end{verbatim} once
each time matches need to be displayed.

\emph{New in version 2.6.}

\begin{verbatim}
readline.add_history(line)
\end{verbatim}

Append a line to the history buffer, as if it was the last line typed.

\begin{itemize}
    \item \textbf{See also:}
    \item \textbf{Module \texttt{rlcompleter}}
        Completion of Python identifiers at the interactive prompt.
\end{itemize}
16.8.1. Example

The following example demonstrates how to use the `readline` module’s history reading and writing functions to automatically load and save a history file named `.pyhist` from the user’s home directory. The code below would normally be executed automatically during interactive sessions from the user’s `PYTHONSTARTUP` file.

```python
import os
import readline
histfile = os.path.join(os.path.expanduser("~"), "pyhist")
try:
    readline.read_history_file(histfile)
except IOError:
    pass
import atexit
atexit.register(readline.write_history_file, histfile)
del os, histfile
```

The following example extends the `code.InteractiveConsole` class to support history save/restore.

```python
import code
import readline
import atexit
import os

class HistoryConsole(code.InteractiveConsole):
    def __init__(self, locals=None, filename="<console>",
                 histfile=os.path.expanduser("~/.console-history"),
                 **kwargs):
        code.InteractiveConsole.__init__(self, locals, filename,
                                         **kwargs)

        self.init_history(histfile)

    def init_history(self, histfile):
        readline.parse_and_bind("tab: complete")
        if hasattr(readline, "read_history_file"):
            try:
                readline.read_history_file(histfile)
            except IOError:
                pass
```

atexit.register(self.save_history, histfile)

def save_history(self, histfile):
    readline.write_history_file(histfile)
16. Optional Operating System Services
16.9. rlcompleter — Completion function for GNU readline

The rlcompleter module defines a completion function suitable for the readline module by completing valid Python identifiers and keywords.

When this module is imported on a Unix platform with the readline module available, an instance of the Completer class is automatically created and its complete() method is set as the readline completer.

Example:

```python
>>> import rlcompleter
>>> import readline
>>> readline.parse_and_bind("tab: complete")
```

The rlcompleter module is designed for use with Python's interactive mode. A user can add the following lines to his or her initialization file (identified by the PYTHONSTARTUP environment variable) to get automatic Tab completion:

```python
try:
    import readline
except ImportError:
    print "Module readline not available."
else:
    import rlcompleter
    readline.parse_and_bind("tab: complete")
```
On platforms without `readline`, the `Completer` class defined by this module can still be used for custom purposes.
Completer objects have the following method:

```
Completer.complete(text, state)
```

Return the state of completion for `text`.

If called for `text` that doesn't include a period character (`'.'`), it will complete from names currently defined in `__main__`, `__builtin__` and keywords (as defined by the `keyword` module).

If called for a dotted name, it will try to evaluate anything without obvious side-effects (functions will not be evaluated, but it can generate calls to `__getattr__()` up to the last part, and find matches for the rest via the `dir()` function. Any exception raised during the evaluation of the expression is caught, silenced and `None` is returned.
The modules described in this chapter provide mechanisms for different processes to communicate.

Some modules only work for two processes that are on the same machine, e.g. `signal` and `subprocess`. Other modules support networking protocols that two or more processes can used to communicate across machines.

The list of modules described in this chapter is:

- **17.1. subprocess** — Subprocess management
  - 17.1.1. Using the subprocess Module
    - 17.1.1.1. Convenience Functions
    - 17.1.1.2. Exceptions
    - 17.1.1.3. Security
  - 17.1.2. Popen Objects
  - 17.1.3. Windows Popen Helpers
    - 17.1.3.1. Constants
  - 17.1.4. Replacing Older Functions with the subprocess Module
    - 17.1.4.1. Replacing /bin/sh shell backquote
    - 17.1.4.2. Replacing shell pipeline
    - 17.1.4.3. Replacing `os.system()`
    - 17.1.4.4. Replacing the `os.spawn` family
    - 17.1.4.5. Replacing `os.popen()`, `os.popen2()`, `os.popen3()`
    - 17.1.4.6. Replacing functions from the `popen2` module
  - 17.1.5. Notes
    - 17.1.5.1. Converting an argument sequence to a string
on Windows

- **17.2. socket** — Low-level networking interface
  - 17.2.1. Socket Objects
  - 17.2.2. Example

- **17.3. ssl** — TLS/SSL wrapper for socket objects
  - 17.3.1. Functions, Constants, and Exceptions
  - 17.3.2. SSLSocket Objects
  - 17.3.3. Certificates
  - 17.3.4. Examples
    - 17.3.4.1. Testing for SSL support
    - 17.3.4.2. Client-side operation
    - 17.3.4.3. Server-side operation

- **17.4. signal** — Set handlers for asynchronous events
  - 17.4.1. Example

- **17.5. popen2** — Subprocesses with accessible I/O streams
  - 17.5.1. Popen3 and Popen4 Objects
  - 17.5.2. Flow Control Issues

- **17.6. asyncore** — Asynchronous socket handler
  - 17.6.1. asyncore Example basic HTTP client
  - 17.6.2. asyncore Example basic echo server

- **17.7. asynchat** — Asynchronous socket command/response handler
  - 17.7.1. asynchat - Auxiliary Classes
  - 17.7.2. asynchat Example
The `subprocess` module allows you to spawn new processes, connect to their input/output/error pipes, and obtain their return codes. This module intends to replace several other, older modules and functions, such as:

```
  os.system
  os.spawn*
  os.popen*
  popen2.*
  commands.*
```

Information about how the `subprocess` module can be used to replace these modules and functions can be found in the following sections.

**See also:** [PEP 324](#) – PEP proposing the subprocess module
17.1.1. Using the subprocess Module

This module defines one class called `Popen`:

```
class subprocess. Popen(args, bufsize=0, executable=None, stdin=None, stdout=None, stderr=None, preexec_fn=None, close_fds=False, shell=False, cwd=None, env=None, universal_newlines=False, startupinfo=None, creationflags=0)
```

Arguments are:

- `args` should be a string, or a sequence of program arguments. The program to execute is normally the first item in the `args` sequence or the string if a string is given, but can be explicitly set by using the `executable` argument. When `executable` is given, the first item in the `args` sequence is still treated by most programs as the command name, which can then be different from the actual executable name. On Unix, it becomes the display name for the executing program in utilities such as `ps`.

On Unix, with `shell=False` (default): In this case, the `Popen` class uses `os.execvp()` to execute the child program. `args` should normally be a sequence. If a string is specified for `args`, it will be used as the name or path of the program to execute; this will only work if the program is being given no arguments.

**Note:** `shlex.split()` can be useful when determining the correct tokenization for `args`, especially in complex cases:

```
>>> import shlex, subprocess
>>> command_line = raw_input()
/bin/vikings -input eggs.txt -output "spam spam.txt" -cmd 'echo '$MONEY''
>>> args = shlex.split(command_line)
>>> print args
['/bin/vikings', '-input', 'eggs.txt', '-output', 'spam spam.txt', '-cmd', 'echo '$MONEY''
>>> p = subprocess.Popen(args) # Success!
```
Note in particular that options (such as `-input`) and arguments (such as `eggs.txt`) that are separated by whitespace in the shell go in separate list elements, while arguments that need quoting or backslash escaping when used in the shell (such as filenames containing spaces or the `echo` command shown above) are single list elements.

On Unix, with `shell=True`: If `args` is a string, it specifies the command string to execute through the shell. This means that the string must be formatted exactly as it would be when typed at the shell prompt. This includes, for example, quoting or backslash escaping filenames with spaces in them. If `args` is a sequence, the first item specifies the command string, and any additional items will be treated as additional arguments to the shell itself. That is to say, `Popen` does the equivalent of:

```
Popen(['/bin/sh', '-c', args[0], args[1], ...])
```

**Warning:** Executing shell commands that incorporate unsanitized input from an untrusted source makes a program vulnerable to shell injection, a serious security flaw which can result in arbitrary command execution. For this reason, the use of `shell=True` is **strongly discouraged** in cases where the command string is constructed from external input:

```
>>> from subprocess import call
>>> filename = input("What file would you like to display?
What file would you like to display?
non_existent; rm -rf / #
>>> call("cat " + filename, shell=True) # Uh-oh. This will
```

`shell=False` does not suffer from this vulnerability; the above Note may be helpful in getting code using `shell=False` to work.

On Windows: the `Popen` class uses `CreateProcess()` to execute
the child program, which operates on strings. If \texttt{args} is a sequence, it will be converted to a string in a manner described in \textit{Converting an argument sequence to a string on Windows}.

\texttt{bufsize}, if given, has the same meaning as the corresponding argument to the built-in \texttt{open()} function: 0 means unbuffered, 1 means line buffered, any other positive value means use a buffer of (approximately) that size. A negative \texttt{bufsize} means to use the system default, which usually means fully buffered. The default value for \texttt{bufsize} is 0 (unbuffered).

\textbf{Note:} If you experience performance issues, it is recommended that you try to enable buffering by setting \texttt{bufsize} to either -1 or a large enough positive value (such as 4096).

The \texttt{executable} argument specifies the program to execute. It is very seldom needed: Usually, the program to execute is defined by the \texttt{args} argument. If \texttt{shell=True}, the \texttt{executable} argument specifies which shell to use. On Unix, the default shell is /bin/sh. On Windows, the default shell is specified by the \texttt{COMSPEC} environment variable. The only reason you would need to specify \texttt{shell=True} on Windows is where the command you wish to execute is actually built in to the shell, eg \texttt{dir}, \texttt{copy}. You don’t need \texttt{shell=True} to run a batch file, nor to run a console-based executable.

\texttt{stdin}, \texttt{stdout} and \texttt{stderr} specify the executed programs’ standard input, standard output and standard error file handles, respectively. Valid values are \texttt{PIPE}, an existing file descriptor (a positive integer), an existing file object, and \texttt{None}. \texttt{PIPE} indicates that a new pipe to the child should be created. With \texttt{None}, no redirection will occur; the child’s file handles will be inherited from the parent. Additionally, \texttt{stderr} can be \texttt{STDOUT}, which indicates that the stderr data from the applications should be captured into the
same file handle as for stdout.

If `preexec_fn` is set to a callable object, this object will be called in the child process just before the child is executed. (Unix only)

If `close_fds` is true, all file descriptors except 0, 1 and 2 will be closed before the child process is executed. (Unix only). Or, on Windows, if `close_fds` is true then no handles will be inherited by the child process. Note that on Windows, you cannot set `close_fds` to true and also redirect the standard handles by setting `stdin`, `stdout` or `stderr`.

If `shell` is `True`, the specified command will be executed through the shell.

If `cwd` is not `None`, the child’s current directory will be changed to `cwd` before it is executed. Note that this directory is not considered when searching the executable, so you can’t specify the program’s path relative to `cwd`.

If `env` is not `None`, it must be a mapping that defines the environment variables for the new process; these are used instead of inheriting the current process’ environment, which is the default behavior.

Note: If specified, `env` must provide any variables required for the program to execute. On Windows, in order to run a side-by-side assembly the specified `env` must include a valid `SystemRoot`.

If `universal_newlines` is `True`, the file objects `stdout` and `stderr` are opened as text files, but lines may be terminated by any of `'\n'`, the Unix end-of-line convention, `'\r'`, the old Macintosh convention or `'\r\n'`, the Windows convention. All of these external representations are seen as `'\n'` by the Python
program.

**Note:** This feature is only available if Python is built with universal newline support (the default). Also, the newlines attribute of the file objects `stdout`, `stdin` and `stderr` are not updated by the `communicate()` method.

If given, `startupinfo` will be a `STARTUPINFO` object, which is passed to the underlying `CreateProcess` function. `creationflags`, if given, can be `CREATE_NEW_CONSOLE` or `CREATE_NEW_PROCESS_GROUP`. (Windows only)

`subprocess.PIPE`

Special value that can be used as the `stdin`, `stdout` or `stderr` argument to `Popen` and indicates that a pipe to the standard stream should be opened.

`subprocess.STDOUT`

Special value that can be used as the `stderr` argument to `Popen` and indicates that standard error should go into the same handle as standard output.

### 17.1.1.1. Convenience Functions

This module also defines the following shortcut functions:

`subprocess.call(*popenargs, **kwargs)`

Run command with arguments. Wait for command to complete, then return the `returncode` attribute.

The arguments are the same as for the `Popen` constructor. Example:

```python
>>> retcode = subprocess.call(['ls', '-l'])
```
Warning:  Like `Popen.wait()`, this will deadlock when using `stdout=PIPE` and/or `stderr=PIPE` and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data.

```
subprocess.check_call(*popenargs, **kwargs)
```

Run command with arguments. Wait for command to complete. If the exit code was zero then return, otherwise raise `CalledProcessError`. The `CalledProcessError` object will have the return code in the `returncode` attribute.

The arguments are the same as for the `Popen` constructor. Example:

```python
>>> subprocess.check_call(['ls', '-l'])
0
```

*New in version 2.5.*

Warning:  See the warning for `call()`.

```
subprocess.check_output(*popenargs, **kwargs)
```

Run command with arguments and return its output as a byte string.

If the exit code was non-zero it raises a `CalledProcessError`. The `CalledProcessError` object will have the return code in the `returncode` attribute and output in the `output` attribute.

The arguments are the same as for the `Popen` constructor. Example:

```python
>>> subprocess.check_output(['ls', '-l', '/dev/null'])
'crw-rw-rw- 1 root root 1, 3 Oct 18 2007 /dev/null'
```
The stdout argument is not allowed as it is used internally. To capture standard error in the result, use `stderr=subprocess.STDOUT`:

```python
>>> subprocess.check_output(
...     ["/bin/sh", "-c", "ls non_existent_file; exit 0"],
...     stderr=subprocess.STDOUT)
'ls: non_existent_file: No such file or directory\n'
```

`New in version 2.7.`

## 17.1.1.2. Exceptions

Exceptions raised in the child process, before the new program has started to execute, will be re-raised in the parent. Additionally, the exception object will have one extra attribute called `child_traceback`, which is a string containing traceback information from the child's point of view.

The most common exception raised is `OSError`. This occurs, for example, when trying to execute a non-existent file. Applications should prepare for `OSError` exceptions.

A `ValueError` will be raised if `Popen` is called with invalid arguments.

`check_call()` will raise `CalledProcessError`, if the called process returns a non-zero return code.

## 17.1.1.3. Security

Unlike some other popen functions, this implementation will never call `/bin/sh` implicitly. This means that all characters, including shell metacharacters, can safely be passed to child processes.
17.1.2. Popen Objects

Instances of the Popen class have the following methods:

Popen.poll()

Check if child process has terminated. Set and return returncode attribute.

Popen.wait()

Wait for child process to terminate. Set and return returncode attribute.

**Warning:** This will deadlock when using stdout=PIPE and/or stderr=PIPE and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use communicate() to avoid that.

Popen.communicate(input=None)

Interact with process: Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate. The optional input argument should be a string to be sent to the child process, or None, if no data should be sent to the child.

communicate() returns a tuple (stdoutdata, stderrdata).

Note that if you want to send data to the process’s stdin, you need to create the Popen object with stdin=PIPE. Similarly, to get anything other than None in the result tuple, you need to give stdout=PIPE and/or stderr=PIPE too.

**Note:** The data read is buffered in memory, so do not use this
method if the data size is large or unlimited.

Popen. `send_signal(signal)`

Sends the signal `signal` to the child.

**Note:** On Windows, SIGTERM is an alias for `terminate()`. CTRL_C_EVENT and CTRL_BREAK_EVENT can be sent to processes started with a `creationflags` parameter which includes `CREATE_NEW_PROCESS_GROUP`.

*New in version 2.6.*

Popen. `terminate()`

Stop the child. On Posix OSs the method sends SIGTERM to the child. On Windows the Win32 API function `TerminateProcess()` is called to stop the child.

*New in version 2.6.*

Popen. `kill()`

Kills the child. On Posix OSs the function sends SIGKILL to the child. On Windows `kill()` is an alias for `terminate()`.

*New in version 2.6.*

The following attributes are also available:

**Warning:** Use `communicate()` rather than `.stdin.write`, `.stdout.read` or `.stderr.read` to avoid deadlocks due to any of the other OS pipe buffers filling up and blocking the child process.

Popen. `stdin`

If the `stdin` argument was `PIPE`, this attribute is a file object that provides input to the child process. Otherwise, it is `None`.  

Popen. **stdout**

If the *stdout* argument was **PIPE**, this attribute is a file object that provides output from the child process. Otherwise, it is **None**.

Popen. **stderr**

If the *stderr* argument was **PIPE**, this attribute is a file object that provides error output from the child process. Otherwise, it is **None**.

Popen. **pid**

The process ID of the child process.

Note that if you set the *shell* argument to **True**, this is the process ID of the spawned shell.

Popen. **returncode**

The child return code, set by **poll()** and **wait()** (and indirectly by **communicate()**). A **None** value indicates that the process hasn’t terminated yet.

A negative value `-N` indicates that the child was terminated by signal `N` (Unix only).
17.1.3. Windows Popen Helpers

The **STARTUPINFO** class and following constants are only available on Windows.

```python
class subprocess.STARTUPINFO

Partial support of the Windows STARTUPINFO structure is used for Popen creation.

dwFlags

A bit field that determines whether certain STARTUPINFO members are used when the process creates a window.

```python
si = subprocess.STARTUPINFO()
si.dwFlags = subprocess.STARTF_USESTDHANDLES | subprocess
```

hStdInput

If `dwFlags` specifies `STARTF_USESTDHANDLES`, this member is the standard input handle for the process. If `STARTF_USESTDHANDLES` is not specified, the default for standard input is the keyboard buffer.

hStdOutput

If `dwFlags` specifies `STARTF_USESTDHANDLES`, this member is the standard output handle for the process. Otherwise, this member is ignored and the default for standard output is the console window's buffer.

hStdError

If `dwFlags` specifies `STARTF_USESTDHANDLES`, this member is the standard error handle for the process. Otherwise, this member is ignored and the default for standard error is the console window's buffer.
The `subprocess` module exposes the following constants.

**subprocess.**`STD_INPUT_HANDLE`

The standard input device. Initially, this is the console input buffer, `CONIN$`.

**subprocess.**`STD_OUTPUT_HANDLE`

The standard output device. Initially, this is the active console screen buffer, `CONOUT$`.

**subprocess.**`STD_ERROR_HANDLE`

The standard error device. Initially, this is the active console screen buffer, `CONOUT$`.

**subprocess.**`SW_HIDE`

Hides the window. Another window will be activated.

**subprocess.**`STARTF_USESTDHANDLES`

Specifies that the `STARTUPINFO.hStdInput`, `STARTUPINFO.hStdOutput`, and `STARTUPINFO.hStdError` members contain additional information.

**subprocess.**`STARTF_USESHOWWINDOW`

Specifies that the `STARTUPINFO.wShowWindow` member contains
additional information.

subprocess.**CREATE_NEW_CONSOLE**

The new process has a new console, instead of inheriting its parent’s console (the default).

This flag is always set when `Popen` is created with `shell=True`.

subprocess.**CREATE_NEW_PROCESS_GROUP**

A `Popen` `creationflags` parameter to specify that a new process group will be created. This flag is necessary for using `os.kill()` on the subprocess.

This flag is ignored if `CREATE_NEW_CONSOLE` is specified.
17.1.4. Replacing Older Functions with the subprocess Module

In this section, “a ==> b” means that b can be used as a replacement for a.

**Note:** All functions in this section fail (more or less) silently if the executed program cannot be found; this module raises an `OSError` exception.

In the following examples, we assume that the subprocess module is imported with “from subprocess import *”.

17.1.4.1. Replacing /bin/sh shell backquote

```python
output=`mycmd myarg`
==> output = Popen(['mycmd', 'myarg'], stdout=PIPE).communicate()[0]
```

17.1.4.2. Replacing shell pipeline

```python
output=`dmesg | grep hda`
==> p1 = Popen(['dmesg'], stdout=PIPE)
p2 = Popen(['grep', 'hda'], stdin=p1.stdout, stdout=PIPE)
p1.stdout.close()  # Allow p1 to receive a SIGPIPE if p2 exits.
output = p2.communicate()[0]
```

The `p1.stdout.close()` call after starting the p2 is important in order for p1 to receive a SIGPIPE if p2 exits before p1.

17.1.4.3. Replacing `os.system()`
sts = os.system("mycmd" + " myarg")

==>

p = Popen("mycmd" + " myarg", shell=True)
sts = os.waitpid(p.pid, 0)[1]

Notes:

- Calling the program through the shell is usually not required.
- It’s easier to look at the `returncode` attribute than the exit status.

A more realistic example would look like this:

```
try:
    retcode = call("mycmd" + " myarg", shell=True)
    if retcode < 0:
        print >>sys.stderr, "Child was terminated by signal", -retcode
    else:
        print >>sys.stderr, "Child returned", retcode
except OSError, e:
    print >>sys.stderr, "Execution failed:", e
```

### 17.1.4.4. Replacing the `os.spawn` family

**P_NOWAIT example:**

```
pid = os.spawnlp(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg")

==>
pid = Popen(["/bin/mycmd", "myarg"]).pid
```

**P_WAIT example:**

```
retcode = os.spawnlp(os.P_WAIT, "/bin/mycmd", "mycmd", "myarg")

==>
retcode = call(["/bin/mycmd", "myarg"])
```

**Vector example:**

```
os.spawnvp(os.P_NOWAIT, path, args)
```
Popen([path] + args[1:]

Environment example:

os.spawnlpe(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg", env)  

Popen(["/bin/mycmd", "myarg"], env={"PATH": "/usr/bin"})

17.1.4.5. Replacing os.popen(), os.popen2(), os.popen3()

pipe = os.popen("cmd", 'r', bufsize)  

pipe = Popen("cmd", shell=True, bufsize=bufsize, stdout=PIPE).stdout

pipe = os.popen("cmd", 'w', bufsize)  

pipe = Popen("cmd", shell=True, bufsize=bufsize, stdin=PIPE).stdin

(child_stdin, child_stdout) = os.popen2("cmd", mode, bufsize)  

p = Popen("cmd", shell=True, bufsize=bufsize,  
             stdin=PIPE, stdout=PIPE, close_fds=True)  

(child_stdin, child_stdout) = (p.stdin, p.stdout)

(child_stdin,  
    child_stdout,  
    child_stderr) = os.popen3("cmd", mode, bufsize)  

p = Popen("cmd", shell=True, bufsize=bufsize,  
             stdin=PIPE, stdout=PIPE, stderr=PIPE, close_fds=True)  

(child_stdin,  
    child_stdout,  
    child_stderr) = (p.stdin, p.stdout, p.stderr)

(child_stdin,  
    child_stdout_and_stderr) = os.popen4("cmd", mode,  
                                           bufsize)
On Unix, os.popen2, os.popen3 and os.popen4 also accept a sequence as the command to execute, in which case arguments will be passed directly to the program without shell intervention. This usage can be replaced as follows:

```
(child_stdin, child_stdout) = os.popen2(['/bin/ls', '-l'], mode, bufsize)
```

```python
p = Popen(['/bin/ls', '-l'], bufsize=bufsize, stdin=PIPE, stdout=PIPE)
(child_stdin, child_stdout) = (p.stdin, p.stdout)
```

Return code handling translates as follows:

```
pipe = os.popen("cmd", 'w')
...
rc = pipe.close()
if rc is not None and rc >> 8:
    print "There were some errors"
```

```python
process = Popen("cmd", 'w', shell=True, stdin=PIPE)
...
process.stdin.close()
if process.wait() != 0:
    print "There were some errors"
```

### 17.1.4.6. Replacing functions from the `popen2` module

```
(child_stdout, child_stdin) = popen2.popen2("somestring", bufsize)
```

```python
p = Popen(['"somestring"', shell=True, bufsize=bufsize, stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```
On Unix, `popen2` also accepts a sequence as the command to execute, in which case arguments will be passed directly to the program without shell intervention. This usage can be replaced as follows:

```python
(child_stdout, child_stdin) = popen2.popen2(['mycmd', 'myarg'], mode)
```

```python
p = Popen(['mycmd', 'myarg'], bufsize=bufsize,
           stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```

`popen2.Popen3` and `popen2.Popen4` basically work as `subprocess.Popen`, except that:

- `Popen` raises an exception if the execution fails.
- the `capturestderr` argument is replaced with the `stderr` argument.
- `stdin=PIPE` and `stdout=PIPE` must be specified.
- `popen2` closes all file descriptors by default, but you have to specify `close_fds=True` with `Popen`.
17.1.5. Notes

17.1.5.1. Converting an argument sequence to a string on Windows

On Windows, an *args sequence is converted to a string that can be parsed using the following rules (which correspond to the rules used by the MS C runtime):

1. Arguments are delimited by white space, which is either a space or a tab.
2. A string surrounded by double quotation marks is interpreted as a single argument, regardless of white space contained within. A quoted string can be embedded in an argument.
3. A double quotation mark preceded by a backslash is interpreted as a literal double quotation mark.
4. Backslashes are interpreted literally, unless they immediately precede a double quotation mark.
5. If backslashes immediately precede a double quotation mark, every pair of backslashes is interpreted as a literal backslash. If the number of backslashes is odd, the last backslash escapes the next double quotation mark as described in rule 3.
17.2. socket — Low-level networking interface

This module provides access to the BSD socket interface. It is available on all modern Unix systems, Windows, Mac OS X, BeOS, OS/2, and probably additional platforms.

**Note:** Some behavior may be platform dependent, since calls are made to the operating system socket APIs.

For an introduction to socket programming (in C), see the following papers: An Introductory 4.3BSD Interprocess Communication Tutorial, by Stuart Sechrest and An Advanced 4.3BSD Interprocess Communication Tutorial, by Samuel J. Leffler et al, both in the UNIX Programmer's Manual, Supplementary Documents 1 (sections PS1:7 and PS1:8). The platform-specific reference material for the various socket-related system calls are also a valuable source of information on the details of socket semantics. For Unix, refer to the manual pages; for Windows, see the WinSock (or Winsock 2) specification. For IPv6-ready APIs, readers may want to refer to RFC 3493 titled Basic Socket Interface Extensions for IPv6.

The Python interface is a straightforward transliteration of the Unix system call and library interface for sockets to Python's object-oriented style: the `socket()` function returns a `socket object` whose methods implement the various socket system calls. Parameter types are somewhat higher-level than in the C interface: as with `read()` and `write()` operations on Python files, buffer allocation on receive operations is automatic, and buffer length is implicit on send operations.

Socket addresses are represented as follows: A single string is used
for the **AF_UNIX** address family. A pair `(host, port)` is used for the **AF_INET** address family, where `host` is a string representing either a hostname in Internet domain notation like `daring.cwi.nl` or an IPv4 address like `100.50.200.5`, and `port` is an integral port number. For **AF_INET6** address family, a four-tuple `(host, port, flowinfo, scopeid)` is used, where `flowinfo` and `scopeid` represents `sin6_flowinfo` and `sin6_scope_id` member in `struct sockaddr_in6` in C. For **socket** module methods, `flowinfo` and `scopeid` can be omitted just for backward compatibility. Note, however, omission of `scopeid` can cause problems in manipulating scoped IPv6 addresses. Other address families are currently not supported. The address format required by a particular socket object is automatically selected based on the address family specified when the socket object was created.

For IPv4 addresses, two special forms are accepted instead of a host address: the empty string represents **INADDR_ANY**, and the string `<broadcast>` represents **INADDR_BROADCAST**. The behavior is not available for IPv6 for backward compatibility, therefore, you may want to avoid these if you intend to support IPv6 with your Python programs.

If you use a hostname in the `host` portion of IPv4/v6 socket address, the program may show a nondeterministic behavior, as Python uses the first address returned from the DNS resolution. The socket address will be resolved differently into an actual IPv4/v6 address, depending on the results from DNS resolution and/or the host configuration. For deterministic behavior use a numeric address in `host` portion.

*New in version 2.5:* **AF_NETLINK** sockets are represented as pairs `pid, groups`.

*New in version 2.6:* Linux-only support for TIPC is also available using the **AF_TIPC** address family. TIPC is an open, non-IP based
networked protocol designed for use in clustered computer environments. Addresses are represented by a tuple, and the fields depend on the address type. The general tuple form is (addr_type, v1, v2, v3 [, scope]), where:

- `addr_type` is one of TIPC_ADDR_NAMESEQ, TIPC_ADDR_NAME, or TIPC_ADDR_ID.
- `scope` is one of TIPC_ZONE_SCOPE, TIPC_CLUSTER_SCOPE, and TIPC_NODE_SCOPE.

- If `addr_type` is TIPC_ADDR_NAME, then v1 is the server type, v2 is the port identifier, and v3 should be 0.

  If `addr_type` is TIPC_ADDR_NAMESEQ, then v1 is the server type, v2 is the lower port number, and v3 is the upper port number.

  If `addr_type` is TIPC_ADDR_ID, then v1 is the node, v2 is the reference, and v3 should be set to 0.

All errors raise exceptions. The normal exceptions for invalid argument types and out-of-memory conditions can be raised; errors related to socket or address semantics raise the error `socket.error`.

Non-blocking mode is supported through `setblocking()`. A generalization of this based on timeouts is supported through `settimeout()`.

The module `socket` exports the following constants and functions:

`exception socket.error`

This exception is raised for socket-related errors. The accompanying value is either a string telling what went wrong or a pair (errno, string) representing an error returned by a
system call, similar to the value accompanying os.error. See the module errno, which contains names for the error codes defined by the underlying operating system.

*Changed in version 2.6:* socket.error is now a child class of IOError.

**exception** socket.herror

This exception is raised for address-related errors, i.e. for functions that use h_errno in the C API, including gethostbyname_ex() and gethostbyaddr().

The accompanying value is a pair (h_errno, string) representing an error returned by a library call. string represents the description of h_errno, as returned by the hstrerror() C function.

**exception** socket.gaierror

This exception is raised for address-related errors, for getaddrinfo() and getnameinfo(). The accompanying value is a pair (error, string) representing an error returned by a library call. string represents the description of error, as returned by the gai_strerror() C function. The error value will match one of the EAI_* constants defined in this module.

**exception** socket.timeout

This exception is raised when a timeout occurs on a socket which has had timeouts enabled via a prior call to settimeout(). The accompanying value is a string whose value is currently always “timed out”.

*New in version 2.3.*

socket.AF_UNIX
socket.AF_INET
socket. **AF_INET6**

These constants represent the address (and protocol) families, used for the first argument to `socket()`. If the `AF_UNIX` constant is not defined then this protocol is unsupported.

socket. **SOCK_STREAM**
socket. **SOCK_DGRAM**
socket. **SOCK_RAW**
socket. **SOCK_RDM**
socket. **SOCK_SEQPACKET**

These constants represent the socket types, used for the second argument to `socket()`. (Only `SOCK_STREAM` and `SOCK_DGRAM` appear to be generally useful.)

**SO_***
socket. **SOMAXCONN**
**MSG_***
**SOL_***
**IPPROTO_***
**IPPORT_***
**INADDR_***
**IP_***
**IPV6_***
**EAI_***
**AI_***
**NI_***
**TCP_***

Many constants of these forms, documented in the Unix documentation on sockets and/or the IP protocol, are also defined in the socket module. They are generally used in arguments to the `setsockopt()` and `getsockopt()` methods of socket objects. In most cases, only those symbols that are defined in the Unix header files are defined; for a few symbols, default values are provided.

**SIO_***
**RCVALL_***

Constants for Windows' `WSAIoctl()`. The constants are used as
arguments to the ioctl() method of socket objects.

New in version 2.6.

TIPC_ *

TIPC related constants, matching the ones exported by the C socket API. See the TIPC documentation for more information.

New in version 2.6.

socket. has_ipv6

This constant contains a boolean value which indicates if IPv6 is supported on this platform.

New in version 2.3.

socket. create_connection(address[, timeout[, source_address]])

Convenience function. Connect to address (a 2-tuple (host, port)), and return the socket object. Passing the optional timeout parameter will set the timeout on the socket instance before attempting to connect. If no timeout is supplied, the global default timeout setting returned by getdefaulttimeout() is used.

If supplied, source_address must be a 2-tuple (host, port) for the socket to bind to as its source address before connecting. If host or port are " or 0 respectively the OS default behavior will be used.

New in version 2.6.

Changed in version 2.7: source_address was added.

socket. getaddrinfo(host, port, family=0, socktype=0, proto=0, flags=0)

Translate the host/port argument into a sequence of 5-tuples that
contain all the necessary arguments for creating a socket connected to that service. host is a domain name, a string representation of an IPv4/v6 address or None. port is a string service name such as 'http', a numeric port number or None. By passing None as the value of host and port, you can pass NULL to the underlying C API.

The family, socktype and proto arguments can be optionally specified in order to narrow the list of addresses returned. Passing zero as a value for each of these arguments selects the full range of results. The flags argument can be one or several of the AI_* constants, and will influence how results are computed and returned. For example, AI_NUMERICHOST will disable domain name resolution and will raise an error if host is a domain name.

The function returns a list of 5-tuples with the following structure:

(family, socktype, proto, canonname, sockaddr)

In these tuples, family, socktype, proto are all integers and are meant to be passed to the socket() function. canonname will be a string representing the canonical name of the host if AI_CANONNAME is part of the flags argument; else canonname will be empty. sockaddr is a tuple describing a socket address, whose format depends on the returned family (a (address, port) 2-tuple for AF_INET, a (address, port, flow info, scope id) 4-tuple for AF_INET6), and is meant to be passed to the socket.connect() method.

The following example fetches address information for a hypothetical TCP connection to www.python.org on port 80 (results may differ on your system if IPv6 isn’t enabled):

```python
>>> socket.getaddrinfo("www.python.org", 80, 0, 0, socket.S0...)
```
New in version 2.2.

socket. `getfqdn ([name])`

Return a fully qualified domain name for `name`. If `name` is omitted or empty, it is interpreted as the local host. To find the fully qualified name, the hostname returned by `gethostbyaddr()` is checked, followed by aliases for the host, if available. The first name which includes a period is selected. In case no fully qualified domain name is available, the hostname as returned by `gethostname()` is returned.

New in version 2.0.

socket. `gethostbyname (hostname)`

Translate a host name to IPv4 address format. The IPv4 address is returned as a string, such as `'100.50.200.5'`. If the host name is an IPv4 address itself it is returned unchanged. See `gethostbyname_ex()` for a more complete interface. `gethostbyname()` does not support IPv6 name resolution, and `getaddrinfo()` should be used instead for IPv4/v6 dual stack support.

socket. `gethostbyname_ex (hostname)`

Translate a host name to IPv4 address format, extended interface. Return a triple `(hostname, aliaslist, ipaddrlist)` where `hostname` is the primary host name responding to the given `ip_address`, `aliaslist` is a (possibly empty) list of alternative host names for the same address, and `ipaddrlist` is a list of IPv4 addresses for the same interface on the same host (often but not always a single address). `gethostbyname_ex()` does not support
IPv6 name resolution, and getaddrinfo() should be used instead for IPv4/v6 dual stack support.

socket.gethostname()

Return a string containing the hostname of the machine where the Python interpreter is currently executing.

If you want to know the current machine's IP address, you may want to use gethostbyname(gethostname()). This operation assumes that there is a valid address-to-host mapping for the host, and the assumption does not always hold.

Note: gethostname() doesn't always return the fully qualified domain name; use getfqdn() (see above).

socket.gethostbyaddr(ip_address)

Return a triple (hostname, aliaslist, ipaddrlist) where hostname is the primary host name responding to the given ip_address, aliaslist is a (possibly empty) list of alternative host names for the same address, and ipaddrlist is a list of IPv4/v6 addresses for the same interface on the same host (most likely containing only a single address). To find the fully qualified domain name, use the function getfqdn(). gethostbyaddr() supports both IPv4 and IPv6.

socket.getnameinfo(sockaddr, flags)

Translate a socket address sockaddr into a 2-tuple (host, port). Depending on the settings of flags, the result can contain a fully-qualified domain name or numeric address representation in host. Similarly, port can contain a string port name or a numeric port number.

New in version 2.2.
socket. `getprotobytename(protocolname)`
Translate an Internet protocol name (for example, 'icmp') to a constant suitable for passing as the (optional) third argument to the `socket()` function. This is usually only needed for sockets opened in “raw” mode (SOCK_RAW); for the normal socket modes, the correct protocol is chosen automatically if the protocol is omitted or zero.

socket. `getservbyname(servicename[, protocolname])`  
Translate an Internet service name and protocol name to a port number for that service. The optional protocol name, if given, should be 'tcp' or 'udp', otherwise any protocol will match.

socket. `getservbyport(port[, protocolname])`  
Translate an Internet port number and protocol name to a service name for that service. The optional protocol name, if given, should be 'tcp' or 'udp', otherwise any protocol will match.

socket. `socket([family[, type[, proto]]])`  
Create a new socket using the given address family, socket type and protocol number. The address family should be `AF_INET` (the default), `AF_INET6` or `AF_UNIX`. The socket type should be `SOCK_STREAM` (the default), `SOCK_DGRAM` or perhaps one of the other `sock_` constants. The protocol number is usually zero and may be omitted in that case.

socket. `socketpair([family[, type[, proto]]])`  
Build a pair of connected socket objects using the given address family, socket type, and protocol number. Address family, socket type, and protocol number are as for the `socket()` function above. The default family is `AF_UNIX` if defined on the platform; otherwise, the default is `AF_INET`. Availability: Unix.
New in version 2.4.

socket.`fromfd(fd, family, type[, proto])`
Duplicate the file descriptor `fd` (an integer as returned by a file object's `fileno()` method) and build a socket object from the result. Address family, socket type and protocol number are as for the `socket()` function above. The file descriptor should refer to a socket, but this is not checked — subsequent operations on the object may fail if the file descriptor is invalid. This function is rarely needed, but can be used to get or set socket options on a socket passed to a program as standard input or output (such as a server started by the Unix inet daemon). The socket is assumed to be in blocking mode. Availability: Unix.

socket.`ntohl(x)`
Convert 32-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

socket.` ntohs(x)`
Convert 16-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

socket.` htonl(x)`
Convert 32-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

socket.` htons(x)`
Convert 16-bit positive integers from host to network byte order.
On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

socket.<code>inet_aton(ip_string)</code>
Convert an IPv4 address from dotted-quad string format (for example, ‘123.45.67.89’) to 32-bit packed binary format, as a string four characters in length. This is useful when conversing with a program that uses the standard C library and needs objects of type <code>struct in_addr</code>, which is the C type for the 32-bit packed binary this function returns.

<code>inet_aton()</code> also accepts strings with less than three dots; see the Unix manual page <code>inet(3)</code> for details.

If the IPv4 address string passed to this function is invalid, <code>socket.error</code> will be raised. Note that exactly what is valid depends on the underlying C implementation of <code>inet_aton()</code>.

<code>inet_aton()</code> does not support IPv6, and <code>inet_pton()</code> should be used instead for IPv4/v6 dual stack support.

socket.<code>inet_ntoa(packed_ip)</code>
Convert a 32-bit packed IPv4 address (a string four characters in length) to its standard dotted-quad string representation (for example, ‘123.45.67.89’). This is useful when conversing with a program that uses the standard C library and needs objects of type <code>struct in_addr</code>, which is the C type for the 32-bit packed binary data this function takes as an argument.

If the string passed to this function is not exactly 4 bytes in length, <code>socket.error</code> will be raised. <code>inet_ntoa()</code> does not support IPv6, and <code>inet_ntop()</code> should be used instead for IPv4/v6 dual stack support.
socket.\texttt{inet\_pton}(\textit{address\_family}, \textit{ip\_string})

Convert an IP address from its family-specific string format to a packed, binary format. \texttt{inet\_pton()} is useful when a library or network protocol calls for an object of type \texttt{struct in\_addr} (similar to \texttt{inet\_aton()}) or \texttt{struct in6\_addr}.

Supported values for \textit{address\_family} are currently \texttt{AF\_INET} and \texttt{AF\_INET6}. If the IP address string \textit{ip\_string} is invalid, \texttt{socket.error} will be raised. Note that exactly what is valid depends on both the value of \textit{address\_family} and the underlying implementation of \texttt{inet\_pton()}.

Availability: Unix (maybe not all platforms).

\textit{New in version 2.3.}

socket.\texttt{inet\_ntop}(\textit{address\_family}, \textit{packed\_ip})

Convert a packed IP address (a string of some number of characters) to its standard, family-specific string representation (for example, '7.10.0.5' or '5aef:2b::8') \texttt{inet\_ntop()} is useful when a library or network protocol returns an object of type \texttt{struct in\_addr} (similar to \texttt{inet\_ntoa()}) or \texttt{struct in6\_addr}.

Supported values for \textit{address\_family} are currently \texttt{AF\_INET} and \texttt{AF\_INET6}. If the string \textit{packed\_ip} is not the correct length for the specified address family, \texttt{ValueError} will be raised. A \texttt{socket.error} is raised for errors from the call to \texttt{inet\_ntop()}.

Availability: Unix (maybe not all platforms).

\textit{New in version 2.3.}

socket.\texttt{getdefault\_timeout}()

Return the default timeout in floating seconds for new socket
objects. A value of `None` indicates that new socket objects have no timeout. When the socket module is first imported, the default is `None`.

*New in version 2.3.*

`socket.setdefaulttimeout(timeout)`

Set the default timeout in floating seconds for new socket objects. A value of `None` indicates that new socket objects have no timeout. When the socket module is first imported, the default is `None`.

*New in version 2.3.*

`socket.SocketType`

This is a Python type object that represents the socket object type. It is the same as `type(socket(...))`.

---

**See also:**

**Module** `SocketServer`  
Classes that simplify writing network servers.

**Module** `ssl`  
A TLS/SSL wrapper for socket objects.
17.2.1. Socket Objects

Socket objects have the following methods. Except for `makefile()` these correspond to Unix system calls applicable to sockets.

```python
socket.accept()
```

Accept a connection. The socket must be bound to an address and listening for connections. The return value is a pair `(conn, address)` where `conn` is a new socket object usable to send and receive data on the connection, and `address` is the address bound to the socket on the other end of the connection.

```python
socket.bind(address)
```

Bind the socket to `address`. The socket must not already be bound. (The format of `address` depends on the address family — see above.)

**Note:** This method has historically accepted a pair of parameters for `AF_INET` addresses instead of only a tuple. This was never intentional and is no longer available in Python 2.0 and later.

```python
socket.close()
```

Close the socket. All future operations on the socket object will fail. The remote end will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

**Note:** `close()` releases the resource associated with a connection but does not necessarily close the connection immediately. If you want to close the connection in a timely fashion, call `shutdown()` before `close()`.
socket.connect(address)
Connect to a remote socket at address. (The format of address depends on the address family — see above.)

**Note:** This method has historically accepted a pair of parameters for AF_INET addresses instead of only a tuple. This was never intentional and is no longer available in Python 2.0 and later.

socket.connect_ex(address)
Like connect(address), but return an error indicator instead of raising an exception for errors returned by the C-level connect() call (other problems, such as “host not found,” can still raise exceptions). The error indicator is 0 if the operation succeeded, otherwise the value of the errno variable. This is useful to support, for example, asynchronous connects.

**Note:** This method has historically accepted a pair of parameters for AF_INET addresses instead of only a tuple. This was never intentional and is no longer available in Python 2.0 and later.

socket.fileno()
Return the socket's file descriptor (a small integer). This is useful with select.select().

Under Windows the small integer returned by this method cannot be used where a file descriptor can be used (such as os.fdopen()). Unix does not have this limitation.

socket.getpeername()
Return the remote address to which the socket is connected. This is useful to find out the port number of a remote IPv4/v6 socket,
for instance. (The format of the address returned depends on the address family — see above.) On some systems this function is not supported.

socket.getsockname()

Return the socket's own address. This is useful to find out the port number of an IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.)

socket.getsockopt(level, optname[, buflen])

Return the value of the given socket option (see the Unix man page getsockopt(2)). The needed symbolic constants (so_* etc.) are defined in this module. If buflen is absent, an integer option is assumed and its integer value is returned by the function. If buflen is present, it specifies the maximum length of the buffer used to receive the option in, and this buffer is returned as a string. It is up to the caller to decode the contents of the buffer (see the optional built-in module struct for a way to decode C structures encoded as strings).

socket.ioctl(control, option)

Platform: Windows

The ioctl() method is a limited interface to the WSAIoctl system interface. Please refer to the Win32 documentation for more information.

On other platforms, the generic fcntl.fcntl() and fcntl.ioctl() functions may be used; they accept a socket object as their first argument.

New in version 2.6.

socket.listen(backlog)

Listen for connections made to the socket. The backlog argument
specifies the maximum number of queued connections and should be at least 0; the maximum value is system-dependent (usually 5), the minimum value is forced to 0.

socket.makefile([mode[, bufsize]])
Return a file object associated with the socket. (File objects are described in File Objects.) The file object references a dup()ped version of the socket file descriptor, so the file object and socket object may be closed or garbage-collected independently. The socket must be in blocking mode (it can not have a timeout). The optional mode and bufsize arguments are interpreted the same way as by the built-in file() function.

Note: On Windows, the file-like object created by makefile() cannot be used where a file object with a file descriptor is expected, such as the stream arguments of subprocess.Popen().

socket.recv(bufsize[, flags])
Receive data from the socket. The return value is a string representing the data received. The maximum amount of data to be received at once is specified by bufsize. See the Unix manual page recv(2) for the meaning of the optional argument flags; it defaults to zero.

Note: For best match with hardware and network realities, the value of bufsize should be a relatively small power of 2, for example, 4096.

socket.recvfrom(bufsize[, flags])
Receive data from the socket. The return value is a pair (string, address) where string is a string representing the data received
and *address* is the address of the socket sending the data. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family — see above.)

```c
socket.recvfrom_into(buffer, nbytes, flags]
```
Receive data from the socket, writing it into *buffer* instead of creating a new string. The return value is a pair (nbytes, address) where *nbytes* is the number of bytes received and *address* is the address of the socket sending the data. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family — see above.)

*New in version 2.5.*

```c
socket.recv_into(buffer, nbytes, flags]
```
Receive up to *nbytes* bytes from the socket, storing the data into a buffer rather than creating a new string. If *nbytes* is not specified (or 0), receive up to the size available in the given buffer. Returns the number of bytes received. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero.

*New in version 2.5.*

```c
socket.send(string, flags]
```
Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for *recv()* above. Returns the number of bytes sent. Applications are responsible for checking that all data has been sent; if only some of the data was transmitted, the application needs to attempt delivery of the remaining data.
socket. **sendall**(string[, flags])

Send data to the socket. The socket must be connected to a remote socket. The optional flags argument has the same meaning as for **recv()** above. Unlike **send()**, this method continues to send data from **string** until either all data has been sent or an error occurs. **None** is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully sent.

socket. **sendto**(string[, flags], address)

Send data to the socket. The socket should not be connected to a remote socket, since the destination socket is specified by **address**. The optional flags argument has the same meaning as for **recv()** above. Return the number of bytes sent. (The format of address depends on the address family — see above.)

socket. **setblocking**(flag)

Set blocking or non-blocking mode of the socket: if flag is 0, the socket is set to non-blocking, else to blocking mode. Initially all sockets are in blocking mode. In non-blocking mode, if a **recv()** call doesn’t find any data, or if a **send()** call can’t immediately dispose of the data, a error exception is raised; in blocking mode, the calls block until they can proceed. **s.setblocking(0)** is equivalent to **s.settimeout(0.0)**; **s.setblocking(1)** is equivalent to **s.settimeout(None)**.

socket. **settimeout**(value)

Set a timeout on blocking socket operations. The value argument can be a nonnegative float expressing seconds, or **None**. If a float is given, subsequent socket operations will raise a timeout exception if the timeout period value has elapsed before the operation has completed. Setting a timeout of **None** disables
Timeout mode internally sets the socket in non-blocking mode. The blocking and timeout modes are shared between file descriptors and socket objects that refer to the same network endpoint. A consequence of this is that file objects returned by the `makefile()` method must only be used when the socket is in blocking mode; in timeout or non-blocking mode file operations that cannot be completed immediately will fail.

Note that the `connect()` operation is subject to the timeout setting, and in general it is recommended to call `settimeout()` before calling
connect() or pass a timeout parameter to create_connection(). The system network stack may return a connection timeout error of its own regardless of any Python socket timeout setting.

socket.setsockopt(level, optname, value)

Set the value of the given socket option (see the Unix manual page setsockopt(2)). The needed symbolic constants are defined in the socket module (so_* etc.). The value can be an integer or a string representing a buffer. In the latter case it is up to the caller to ensure that the string contains the proper bits (see the optional built-in module struct for a way to encode C structures as strings).

socket.shutdown(how)

Shut down one or both halves of the connection. If how is SHUT_RD, further receives are disallowed. If how is SHUT_WR, further sends are disallowed. If how is SHUT_RDWR, further sends and receives are disallowed. Depending on the platform, shutting down one half of the connection can also close the opposite half (e.g. on Mac OS X, shutdown(SHUT_WR) does not allow further reads on the other end of the connection).

Note that there are no methods read() or write(); use recv() and send() without flags argument instead.

Socket objects also have these (read-only) attributes that correspond to the values given to the socket constructor.

socket.family

The socket family.

New in version 2.5.

socket.type

The socket type.
New in version 2.5.

socket.proto

The socket protocol.

New in version 2.5.
17.2.2. Example

Here are four minimal example programs using the TCP/IP protocol: a server that echoes all data that it receives back (servicing only one client), and a client using it. Note that a server must perform the sequence `socket(), bind(), listen(), accept()` (possibly repeating the `accept()` to service more than one client), while a client only needs the sequence `socket(), connect()`. Also note that the server does not `send()/recv()` on the socket it is listening on but on the new socket returned by `accept()`.

The first two examples support IPv4 only.

```python
# Echo server program
import socket

HOST = '' # Symbolic name meaning all available interfaces
PORT = 50007 # Arbitrary non-privileged port

s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.bind((HOST, PORT))
s.listen(1)
conn, addr = s.accept()

print 'Connected by', addr
while 1:
    data = conn.recv(1024)
    if not data: break
    conn.send(data)
conn.close()
```

```python
# Echo client program
import socket

HOST = 'daring.cwi.nl' # The remote host
PORT = 50007 # The same port as used by the server

s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.connect((HOST, PORT))
s.send('Hello, world')
data = s.recv(1024)
s.close()
```
The next two examples are identical to the above two, but support both IPv4 and IPv6. The server side will listen to the first address family available (it should listen to both instead). On most of IPv6-ready systems, IPv6 will take precedence and the server may not accept IPv4 traffic. The client side will try to connect to the all addresses returned as a result of the name resolution, and sends traffic to the first one connected successfully.

```python
# Echo server program
import socket
import sys

HOST = None  # Symbolic name meaning all available
PORT = 50007  # Arbitrary non-privileged port
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC,
                               socket.SOCK_STREAM, 0, socket.AI_PASSIVE):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except socket.error, msg:
        s = None
        continue
    try:
        s.bind(sa)
        s.listen(1)
    except socket.error, msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print 'could not open socket'
    sys.exit(1)
conn, addr = s.accept()
print 'Connected by', addr
while 1:
    data = conn.recv(1024)
    if not data: break
    conn.send(data)
conn.close()
```
The last example shows how to write a very simple network sniffer with raw sockets on Windows. The example requires administrator privileges to modify the interface:

```python
import socket

# the public network interface
HOST = socket.gethostbyname(socket.gethostname())

# create a raw socket and bind it to the public interface
s = socket.socket(socket.AF_INET, socket.SOCK_RAW, socket.IPPROTO_IP)
s.bind((HOST, 0))
```
# Include IP headers
s.setsockopt(socket.IPPROTO_IP, socket.IP_HDRINCL, 1)

# receive all packages
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_ON)

# receive a package
print s.recvfrom(65565)

# disabled promiscuous mode
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_OFF)
17.3. `ssl` — TLS/SSL wrapper for socket objects

New in version 2.6.

This module provides access to Transport Layer Security (often known as “Secure Sockets Layer”) encryption and peer authentication facilities for network sockets, both client-side and server-side. This module uses the OpenSSL library. It is available on all modern Unix systems, Windows, Mac OS X, and probably additional platforms, as long as OpenSSL is installed on that platform.

**Note:** Some behavior may be platform dependent, since calls are made to the operating system socket APIs. The installed version of OpenSSL may also cause variations in behavior.

This section documents the objects and functions in the `ssl` module; for more general information about TLS, SSL, and certificates, the reader is referred to the documents in the “See Also” section at the bottom.

This module provides a class, `ssl.SSLSocket`, which is derived from the `socket.socket` type, and provides a socket-like wrapper that also encrypts and decrypts the data going over the socket with SSL. It supports additional `read()` and `write()` methods, along with a method, `getpeercert()`, to retrieve the certificate of the other side of the connection, and a method, `cipher()`, to retrieve the cipher being used for the secure connection.
17.3.1. Functions, Constants, and Exceptions

exception ssl.SSLError

Raised to signal an error from the underlying SSL implementation. This signifies some problem in the higher-level encryption and authentication layer that’s superimposed on the underlying network connection. This error is a subtype of socket.error, which in turn is a subtype of IOError.

ssl.wrap_socket(sock, keyfile=None, certfile=None, server_side=False, cert_reqs=CERT_NONE, ssl_version={see docs}, ca_certs=None, do_handshake_on_connect=True, suppress_ragged_eofs=True, ciphers=None)

Takes an instance sock of socket.socket, and returns an instance of ssl.SSLSocket, a subtype of socket.socket, which wraps the underlying socket in an SSL context. For client-side sockets, the context construction is lazy; if the underlying socket isn’t connected yet, the context construction will be performed after connect() is called on the socket. For server-side sockets, if the socket has no remote peer, it is assumed to be a listening socket, and the server-side SSL wrapping is automatically performed on client connections accepted via the accept() method. wrap_socket() may raise SSLError.

The keyfile and certfile parameters specify optional files which contain a certificate to be used to identify the local side of the connection. See the discussion of Certificates for more information on how the certificate is stored in the certfile.

Often the private key is stored in the same file as the certificate; in this case, only the certfile parameter need be passed. If the
private key is stored in a separate file, both parameters must be used. If the private key is stored in the `certfile`, it should come before the first certificate in the certificate chain:

```
-----BEGIN RSA PRIVATE KEY-----
...
-----END RSA PRIVATE KEY-----
-----BEGIN CERTIFICATE-----
...
-----END CERTIFICATE-----
```

The parameter `server_side` is a boolean which identifies whether server-side or client-side behavior is desired from this socket.

The parameter `cert_reqs` specifies whether a certificate is required from the other side of the connection, and whether it will be validated if provided. It must be one of the three values `CERT_NONE` (certificates ignored), `CERT_OPTIONAL` (not required, but validated if provided), or `CERT_REQUIRED` (required and validated). If the value of this parameter is not `CERT_NONE`, then the `ca_certs` parameter must point to a file of CA certificates.

The `ca_certs` file contains a set of concatenated “certification authority” certificates, which are used to validate certificates passed from the other end of the connection. See the discussion of `Certificates` for more information about how to arrange the certificates in this file.

The parameter `ssl_version` specifies which version of the SSL protocol to use. Typically, the server chooses a particular protocol version, and the client must adapt to the server’s choice. Most of the versions are not interoperable with the other versions. If not specified, for client-side operation, the default SSL version is SSLv3; for server-side operation, SSLv23. These version selections provide the most compatibility with other versions.
Here's a table showing which versions in a client (down the side) can connect to which versions in a server (along the top):

<table>
<thead>
<tr>
<th>client / server</th>
<th>SSLv2</th>
<th>SSLv3</th>
<th>SSLv23</th>
<th>TLSv1</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSLv2</td>
<td>yes</td>
<td>no</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td>SSLv3</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td>SSLv23</td>
<td>yes</td>
<td>no</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td>TLSv1</td>
<td>no</td>
<td>no</td>
<td>yes</td>
<td>yes</td>
</tr>
</tbody>
</table>

**Note:** Which connections succeed will vary depending on the version of OpenSSL. For instance, in some older versions of OpenSSL (such as 0.9.7l on OS X 10.4), an SSLv2 client could not connect to an SSLv23 server. Another example: beginning with OpenSSL 1.0.0, an SSLv23 client will not actually attempt SSLv2 connections unless you explicitly enable SSLv2 ciphers; for example, you might specify "ALL" or "SSLv2" as the *ciphers* parameter to enable them.

The *ciphers* parameter sets the available ciphers for this SSL object. It should be a string in the OpenSSL cipher list format.

The parameter *do_handshake_on_connect* specifies whether to do the SSL handshake automatically after doing a *socket.connect()* method, or whether the application program will call it explicitly, by invoking the *SSLSocket.do_handshake()* method. Calling *SSLSocket.do_handshake()* explicitly gives the program control over the blocking behavior of the socket I/O involved in the handshake.

The parameter *suppress_ragged_eofs* specifies how the *SSLSocket.read()* method should signal unexpected EOF from the other end of the connection. If specified as *True* (the default), it returns a normal EOF in response to unexpected EOF errors raised from the underlying socket; if *False*, it will raise the
exceptions back to the caller.

*Changed in version 2.7:* New optional argument `ciphers`.

**ssl.RAND_status()**

Returns True if the SSL pseudo-random number generator has been seeded with ‘enough’ randomness, and False otherwise. You can use `ssl.RAND_egd()` and `ssl.RAND_add()` to increase the randomness of the pseudo-random number generator.

**ssl.RAND_egd(path)**

If you are running an entropy-gathering daemon (EGD) somewhere, and `path` is the pathname of a socket connection open to it, this will read 256 bytes of randomness from the socket, and add it to the SSL pseudo-random number generator to increase the security of generated secret keys. This is typically only necessary on systems without better sources of randomness.

**ssl.RAND_add(bytes, entropy)**

Mixes the given `bytes` into the SSL pseudo-random number generator. The parameter `entropy` (a float) is a lower bound on the entropy contained in string (so you can always use `0.0`). See [RFC 1750](https://tools.ietf.org/html/rfc1750) for more information on sources of entropy.

**ssl.cert_time_to_seconds(timestring)**

Returns a floating-point value containing a normal seconds-after-the-epoch time value, given the time-string representing the “notBefore” or “notAfter” date from a certificate.

Here's an example:
>>> import ssl
>>> ssl.cert_time_to_seconds("May 9 00:00:00 2007 GMT")
1178694000.0
>>> import time
>>> time.ctime(ssl.cert_time_to_seconds("May 9 00:00:00 2007 GMT"))
'Wed May 9 00:00:00 2007'

ssl.get_server_certificate(addr,
ssl_version=PROTOCOL_SSLv3, ca_certs=None)

Given the address `addr` of an SSL-protected server, as a
`hostname, port-number` pair, fetches the server's certificate, and
returns it as a PEM-encoded string. If `ssl_version` is specified,
uses that version of the SSL protocol to attempt to connect to the
server. If `ca_certs` is specified, it should be a file containing a list
of root certificates, the same format as used for the same
parameter in `wrap_socket()`. The call will attempt to validate the
server certificate against that set of root certificates, and will fail if
the validation attempt fails.

ssl.DER_cert_to_PEM_cert(DER_cert_bytes)

Given a certificate as a DER-encoded blob of bytes, returns a
PEM-encoded string version of the same certificate.

ssl.PEM_cert_to_DER_cert(PEM_cert_string)

Given a certificate as an ASCII PEM string, returns a DER-
encoded sequence of bytes for that same certificate.

ssl.CERT_NONE

Value to pass to the `cert_reqs` parameter to `sslobject()` when
no certificates will be required or validated from the other side of
the socket connection.

ssl.CERT_OPTIONAL

Value to pass to the `cert_reqs` parameter to `sslobject()` when
no certificates will be required from the other side of the socket connection, but if they are provided, will be validated. Note that use of this setting requires a valid certificate validation file also be passed as a value of the ca_certs parameter.

**ssl.CERT_REQUIRED**

Value to pass to the cert_reqs parameter to sslobject() when certificates will be required from the other side of the socket connection. Note that use of this setting requires a valid certificate validation file also be passed as a value of the ca_certs parameter.

**ssl.PROTOCOL_SSLv2**

Selects SSL version 2 as the channel encryption protocol.

This protocol is not available if OpenSSL is compiled with OPENSSL_NO_SSL2 flag.

**Warning:** SSL version 2 is insecure. Its use is highly discouraged.

**ssl.PROTOCOL_SSLv23**

Selects SSL version 2 or 3 as the channel encryption protocol. This is a setting to use with servers for maximum compatibility with the other end of an SSL connection, but it may cause the specific ciphers chosen for the encryption to be of fairly low quality.

**ssl.PROTOCOL_SSLv3**

Selects SSL version 3 as the channel encryption protocol. For clients, this is the maximally compatible SSL variant.

**ssl.PROTOCOL_TLSv1**

Selects TLS version 1 as the channel encryption protocol. This is the most modern version, and probably the best choice for
maximum protection, if both sides can speak it.

**ssl. OPENSSL_VERSION**
The version string of the OpenSSL library loaded by the interpreter:

```
>>> ssl.OPENSSL_VERSION
'OpenSSL 0.9.8k 25 Mar 2009'
```

*New in version 2.7.*

**ssl. OPENSSL_VERSION_INFO**
A tuple of five integers representing version information about the OpenSSL library:

```
>>> ssl.OPENSSL_VERSION_INFO
(0, 9, 8, 11, 15)
```

*New in version 2.7.*

**ssl. OPENSSL_VERSION_NUMBER**
The raw version number of the OpenSSL library, as a single integer:

```
>>> ssl.OPENSSL_VERSION_NUMBER
9470143L
>>> hex(ssl.OPENSSL_VERSION_NUMBER)
'0x9080bfL'
```

*New in version 2.7.*
17.3.2. SSLSocket Objects

**SSLSocket.read([nbytes=1024])**

Reads up to `nbytes` bytes from the SSL-encrypted channel and returns them.

**SSLSocket.write(data)**

Writes the `data` to the other side of the connection, using the SSL channel to encrypt. Returns the number of bytes written.

**SSLSocket.getpeercert(binary_form=False)**

If there is no certificate for the peer on the other end of the connection, returns `None`.

If the parameter `binary_form` is `False`, and a certificate was received from the peer, this method returns a `dict` instance. If the certificate was not validated, the dict is empty. If the certificate was validated, it returns a dict with the keys `subject` (the principal for which the certificate was issued), and `notAfter` (the time after which the certificate should not be trusted). The certificate was already validated, so the `notBefore` and `issuer` fields are not returned. If a certificate contains an instance of the `Subject Alternative Name` extension (see [RFC 3280](https://tools.ietf.org/html/rfc3280)), there will also be a `subjectAltName` key in the dictionary.

The “subject” field is a tuple containing the sequence of relative distinguished names (RDNs) given in the certificate’s data structure for the principal, and each RDN is a sequence of name-value pairs:

```python
{'notAfter': 'Feb 16 16:54:50 2013 GMT',
'subject': (((('countryName', u'US'),),
(('stateOrProvinceName', u'Delaware'),),
```
(('localityName', u'Wilmington'),),
(('organizationName', u'Python Software Foundation'
(('organizationalUnitName', u'SSL'),),
(('commonName', u'somemachine.python.org'),))}

If the binary_form parameter is True , and a certificate was
provided, this method returns the DER-encoded form of the entire
certificate as a sequence of bytes, or None if the peer did not
provide a certificate. This return value is independent of
validation; if validation was required ( CERT_OPTIONAL or
CERT_REQUIRED ), it will have been validated, but if CERT_NONE was
used to establish the connection, the certificate, if present, will
not have been validated.
SSLSocket. cipher ()

Returns a three-value tuple containing the name of the cipher
being used, the version of the SSL protocol that defines its use,
and the number of secret bits being used. If no connection has
been established, returns None .
SSLSocket. do_handshake ()

Perform a TLS/SSL handshake. If this is used with a nonblocking socket, it may raise SSLError with an arg[0] of
SSL_ERROR_WANT_READ or SSL_ERROR_WANT_WRITE , in which case it
must be called again until it completes successfully. For example,
to simulate the behavior of a blocking socket, one might write:
while True:
try:
s.do_handshake()
break
except ssl.SSLError, err:
if err.args[0] == ssl.SSL_ERROR_WANT_READ:
select.select([s], [], [])
elif err.args[0] == ssl.SSL_ERROR_WANT_WRITE:
select.select([], [s], [])
else:


SSLSocket. **unwrap()**

Performs the SSL shutdown handshake, which removes the TLS layer from the underlying socket, and returns the underlying socket object. This can be used to go from encrypted operation over a connection to unencrypted. The socket instance returned should always be used for further communication with the other side of the connection, rather than the original socket instance (which may not function properly after the unwrap).
17.3.3. Certificates

Certificates in general are part of a public-key / private-key system. In this system, each principal, (which may be a machine, or a person, or an organization) is assigned a unique two-part encryption key. One part of the key is public, and is called the public key; the other part is kept secret, and is called the private key. The two parts are related, in that if you encrypt a message with one of the parts, you can decrypt it with the other part, and only with the other part.

A certificate contains information about two principals. It contains the name of a subject, and the subject's public key. It also contains a statement by a second principal, the issuer, that the subject is who he claims to be, and that this is indeed the subject’s public key. The issuer’s statement is signed with the issuer's private key, which only the issuer knows. However, anyone can verify the issuer’s statement by finding the issuer’s public key, decrypting the statement with it, and comparing it to the other information in the certificate. The certificate also contains information about the time period over which it is valid. This is expressed as two fields, called “notBefore” and “notAfter”.

In the Python use of certificates, a client or server can use a certificate to prove who they are. The other side of a network connection can also be required to produce a certificate, and that certificate can be validated to the satisfaction of the client or server that requires such validation. The connection attempt can be set to raise an exception if the validation fails. Validation is done automatically, by the underlying OpenSSL framework; the application need not concern itself with its mechanics. But the application does usually need to provide sets of certificates to allow this process to take place.

Python uses files to contain certificates. They should be formatted as
“PEM” (see RFC 1422), which is a base-64 encoded form wrapped with a header line and a footer line:

```
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

The Python files which contain certificates can contain a sequence of certificates, sometimes called a certificate chain. This chain should start with the specific certificate for the principal who “is” the client or server, and then the certificate for the issuer of that certificate, and then the certificate for the issuer of that certificate, and so on up the chain till you get to a certificate which is self-signed, that is, a certificate which has the same subject and issuer, sometimes called a root certificate. The certificates should just be concatenated together in the certificate file. For example, suppose we had a three certificate chain, from our server certificate to the certificate of the certification authority that signed our server certificate, to the root certificate of the agency which issued the certification authority’s certificate:

```
-----BEGIN CERTIFICATE-----
... (certificate for your server)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the certificate for the CA)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the root certificate for the CA's issuer)...
-----END CERTIFICATE-----
```

If you are going to require validation of the other side of the connection’s certificate, you need to provide a “CA certs” file, filled with the certificate chains for each issuer you are willing to trust. Again, this file just contains these chains concatenated together. For validation, Python will use the first chain it finds in the file which matches.
Some “standard” root certificates are available from various certification authorities: CACert.org, Thawte, Verisign, Positive SSL (used by python.org), Equifax and GeoTrust.

In general, if you are using SSL3 or TLS1, you don’t need to put the full chain in your “CA certs” file; you only need the root certificates, and the remote peer is supposed to furnish the other certificates necessary to chain from its certificate to a root certificate. See RFC 4158 for more discussion of the way in which certification chains can be built.

If you are going to create a server that provides SSL-encrypted connection services, you will need to acquire a certificate for that service. There are many ways of acquiring appropriate certificates, such as buying one from a certification authority. Another common practice is to generate a self-signed certificate. The simplest way to do this is with the OpenSSL package, using something like the following:

```
% openssl req -new -x509 -days 365 -nodes -out cert.pem -keyout
Generating a 1024 bit RSA private key
........+++++
.............................+++++
writing new private key to 'cert.pem'
-----
You are about to be asked to enter information that will be incorporated into your certificate request.
What you are about to enter is what is called a Distinguished Name or DN.
There are quite a few fields but you can leave some blank.
For some fields there will be a default value.
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MyState
Locality Name (eg, city) []:Some City
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Org
Organizational Unit Name (eg, section) []:My Group
Common Name (eg, YOUR name) []:myserver.mygroup.myorganization.com
Email Address []:ops@myserver.mygroup.myorganization.com
%```
The disadvantage of a self-signed certificate is that it is its own root certificate, and no one else will have it in their cache of known (and trusted) root certificates.
17.3.4. Examples

17.3.4.1. Testing for SSL support

To test for the presence of SSL support in a Python installation, user code should use the following idiom:

```python
try:
    import ssl
except ImportError:
    pass
else:
    ... # do something that requires SSL support
```

17.3.4.2. Client-side operation

This example connects to an SSL server, prints the server’s address and certificate, sends some bytes, and reads part of the response:

```python
import socket, ssl, pprint

s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)

# require a certificate from the server
ssl_sock = ssl.wrap_socket(s,
                           ca_certs="/etc/ca_certs_file",
                           cert_reqs=ssl.CERT_REQUIRED)

ssl_sock.connect(('www.verisign.com', 443))

print repr(ssl_sock.getpeername())
print ssl_sock.cipher()
print pprint.pformat(ssl_sock.getpeercert())

# Set a simple HTTP request -- use httplib in actual code.
ssl_sock.write("""GET / HTTP/1.0\r
Host: www.verisign.com\r\n\n""")

# Read a chunk of data. Will not necessarily
```
# read all the data returned by the server.
data = ssl_sock.read()

# note that closing the SSLSocket will also close the underlying socket
ssl_sock.close()

As of September 6, 2007, the certificate printed by this program looked like this:

```json
{
    'notAfter': 'May 8 23:59:59 2009 GMT',
    'subject': {
        'serialNumber': '2497886',
        'countryName': 'US',
        'stateOrProvinceName': 'Delaware',
        'postalCode': '94043',
        'localityName': 'Mountain View',
        'streetAddress': '487 East Middlefield Road',
        'organizationName': 'VeriSign, Inc.',
        'organizationalUnitName': 'Production Security Services',
        'organizationalUnitName': 'Terms of use at www.verisign.com/rpa (c)06',
        'commonName': 'www.verisign.com'
    }
}
```

which is a fairly poorly-formed subject field.

### 17.3.4.3. Server-side operation

For server operation, typically you'd need to have a server certificate, and private key, each in a file. You’d open a socket, bind it to a port, call listen() on it, then start waiting for clients to connect:

```python
import socket, ssl
bindsocket = socket.socket()
bindsocket.bind(('myaddr.mydomain.com', 10023))
bindsocket.listen(5)
```
When one did, you’d call `accept()` on the socket to get the new socket from the other end, and use `wrap_socket()` to create a server-side SSL context for it:

```python
while True:
    newsocket, fromaddr = bindsocket.accept()
    connstream = ssl.wrap_socket(newsocket,
        server_side=True,
        certfile="mycertfile",
        keyfile="mykeyfile",
        ssl_version=ssl.PROTOCOL_TLSv1)
    try:
        deal_with_client(connstream)
    finally:
        connstream.shutdown(socket.SHUT_RDWR)
        connstream.close()
```

Then you’d read data from the `connstream` and do something with it till you are finished with the client (or the client is finished with you):

```python
def deal_with_client(connstream):
    data = connstream.read()
    # null data means the client is finished with us
    while data:
        if not do_something(connstream, data):
            # we'll assume do_something returns False
            # when we're finished with client
            break
        data = connstream.read()
    # finished with client
```

And go back to listening for new client connections.

17. Interprocess Communication and Networking
This module provides mechanisms to use signal handlers in Python. Some general rules for working with signals and their handlers:

- A handler for a particular signal, once set, remains installed until it is explicitly reset (Python emulates the BSD style interface regardless of the underlying implementation), with the exception of the handler for `SIGCHLD`, which follows the underlying implementation.
- There is no way to “block” signals temporarily from critical sections (since this is not supported by all Unix flavors).
- Although Python signal handlers are called asynchronously as far as the Python user is concerned, they can only occur between the “atomic” instructions of the Python interpreter. This means that signals arriving during long calculations implemented purely in C (such as regular expression matches on large bodies of text) may be delayed for an arbitrary amount of time.
- When a signal arrives during an I/O operation, it is possible that the I/O operation raises an exception after the signal handler returns. This is dependent on the underlying Unix system’s semantics regarding interrupted system calls.
- Because the C signal handler always returns, it makes little sense to catch synchronous errors like `SIGFPE` or `SIGSEGV`.
- Python installs a small number of signal handlers by default: `SIGPIPE` is ignored (so write errors on pipes and sockets can be reported as ordinary Python exceptions) and `SIGINT` is translated into a `KeyboardInterrupt` exception. All of these can be overridden.
- Some care must be taken if both signals and threads are used...
in the same program. The fundamental thing to remember in using signals and threads simultaneously is: always perform \texttt{signal()} operations in the main thread of execution. Any thread can perform an \texttt{alarm()}, \texttt{getsignal()}, \texttt{pause()}, \texttt{setitimer()} or \texttt{getitimer()}; only the main thread can set a new signal handler, and the main thread will be the only one to receive signals (this is enforced by the Python \texttt{signal} module, even if the underlying thread implementation supports sending signals to individual threads). This means that signals can't be used as a means of inter-thread communication. Use locks instead.

The variables defined in the \texttt{signal} module are:

\texttt{signal.SIG_DFL}

This is one of two standard signal handling options; it will simply perform the default function for the signal. For example, on most systems the default action for \texttt{SIGQUIT} is to dump core and exit, while the default action for \texttt{SIGCHLD} is to simply ignore it.

\texttt{signal.SIG_IGN}

This is another standard signal handler, which will simply ignore the given signal.

\texttt{SIG*}

All the signal numbers are defined symbolically. For example, the hangup signal is defined as \texttt{signal.SIGHUP}; the variable names are identical to the names used in C programs, as found in \texttt{<signal.h>}. The Unix man page for ‘\texttt{signal()}’ lists the existing signals (on some systems this is \texttt{signal(2)}, on others the list is in \texttt{signal(7)}). Note that not all systems define the same set of signal names; only those names defined by the system are defined by this module.

\texttt{signal.CTRL_C_EVENT}

The signal corresponding to the CTRL+C keystroke event. This
signal can only be used with `os.kill()`.

Availability: Windows.

*New in version 2.7.*

**signal.CTRL_BREAK_EVENT**
The signal corresponding to the CTRL+BREAK keystroke event. This signal can only be used with `os.kill()`.

Availability: Windows.

*New in version 2.7.*

**signal.NSIG**
One more than the number of the highest signal number.

**signal.ITIMER_REAL**
Decrements interval timer in real time, and delivers `SIGALRM` upon expiration.

**signal.ITIMER_VIRTUAL**
Decrements interval timer only when the process is executing, and delivers `SIGVTALRM` upon expiration.

**signal.ITIMER_PROF**
Decrements interval timer both when the process executes and when the system is executing on behalf of the process. Coupled with `ITIMER_VIRTUAL`, this timer is usually used to profile the time spent by the application in user and kernel space. `SIGPROF` is delivered upon expiration.

The `signal` module defines one exception:

**exception signal.ItimerError**
Raised to signal an error from the underlying `setitimer()` or
getitimer() implementation. Expect this error if an invalid interval timer or a negative time is passed to setitimer(). This error is a subtype of IOError.

The signal module defines the following functions:

signal.alarm(time)

If time is non-zero, this function requests that a SIGALRM signal be sent to the process in time seconds. Any previously scheduled alarm is canceled (only one alarm can be scheduled at any time). The returned value is then the number of seconds before any previously set alarm was to have been delivered. If time is zero, no alarm is scheduled, and any scheduled alarm is canceled. If the return value is zero, no alarm is currently scheduled. (See the Unix man page alarm(2).) Availability: Unix.

signal.getsignal(signalnum)

Return the current signal handler for the signal signalnum. The returned value may be a callable Python object, or one of the special values signal.SIG_IGN, signal.SIG_DFL or None. Here, signal.SIG_IGN means that the signal was previously ignored, signal.SIG_DFL means that the default way of handling the signal was previously in use, and None means that the previous signal handler was not installed from Python.

signal.pause()

Cause the process to sleep until a signal is received; the appropriate handler will then be called. Returns nothing. Not on Windows. (See the Unix man page signal(2).)

signal.setitimer(which, seconds[, interval])

Sets given interval timer (one of signal.ITIMER_REAL, signal.ITIMER_VIRTUAL or signal.ITIMER_PROF) specified by
which to fire after seconds (float is accepted, different from alarm() and after that every interval seconds. The interval timer specified by which can be cleared by setting seconds to zero.

When an interval timer fires, a signal is sent to the process. The signal sent is dependent on the timer being used; signal.ITIMER_REAL will deliver SIGALRM, signal.ITIMER_VIRTUAL sends SIGVTALRM, and signal.ITIMER_PROF will deliver SIGPROF.

The old values are returned as a tuple: (delay, interval).

Attempting to pass an invalid interval timer will cause an ItimerError. Availability: Unix.

New in version 2.6.

signal.getitimer(which)

Returns current value of a given interval timer specified by which. Availability: Unix.

New in version 2.6.

signal.set_wakeup_fd(fd)

Set the wakeup fd to fd. When a signal is received, a '\0' byte is written to the fd. This can be used by a library to wakeup a poll or select call, allowing the signal to be fully processed.

The old wakeup fd is returned. fd must be non-blocking. It is up to the library to remove any bytes before calling poll or select again.

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a ValueError exception to be raised.

New in version 2.6.
signal. `siginterrupt(signalnum, flag)`
Change system call restart behaviour: if `flag` is `False`, system calls will be restarted when interrupted by signal `signalnum`, otherwise system calls will be interrupted. Returns nothing. Availability: Unix (see the man page `siginterrupt(3)` for further information).

Note that installing a signal handler with `signal()` will reset the restart behaviour to interruptible by implicitly calling `siginterrupt()` with a true `flag` value for the given signal.

*New in version 2.6.*

signal. `signal(signalnum, handler)`
Set the handler for signal `signalnum` to the function `handler`. `handler` can be a callable Python object taking two arguments (see below), or one of the special values `signal.SIG_IGN` or `signal.SIG_DFL`. The previous signal handler will be returned (see the description of `getsignal()` above). (See the Unix man page `signal(2)`.)

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a `ValueError` exception to be raised.

The `handler` is called with two arguments: the signal number and the current stack frame (`None` or a frame object; for a description of frame objects, see the `description in the type hierarchy` or see the attribute descriptions in the `inspect` module).

On Windows, `signal()` can only be called with `SIGABRT`, `SIGFPE`, `SIGILL`, `SIGINT`, `SIGSEGV`, or `SIGTERM`. A `ValueError` will be raised in any other case.
17.4.1. Example

Here is a minimal example program. It uses the `alarm()` function to limit the time spent waiting to open a file; this is useful if the file is for a serial device that may not be turned on, which would normally cause the `os.open()` to hang indefinitely. The solution is to set a 5-second alarm before opening the file; if the operation takes too long, the alarm signal will be sent, and the handler raises an exception.

```python
import signal, os

def handler(signum, frame):
    print('Signal handler called with signal', signum)
    raise IOError("Couldn't open device!")

# Set the signal handler and a 5-second alarm
signal.signal(signal.SIGALRM, handler)
signal.alarm(5)

# This open() may hang indefinitely
fd = os.open('/dev/ttyS0', os.O_RDWR)

signal.alarm(0)  # Disable the alarm
```

17.5. `popen2` — Subprocesses with accessible I/O streams

*Deprecated since version 2.6:* This module is obsolete. Use the `subprocess` module. Check especially the *Replacing Older Functions with the subprocess Module* section.

This module allows you to spawn processes and connect to their input/output/error pipes and obtain their return codes under Unix and Windows.

The `subprocess` module provides more powerful facilities for spawning new processes and retrieving their results. Using the `subprocess` module is preferable to using the `popen2` module.

The primary interface offered by this module is a trio of factory functions. For each of these, if `bufsize` is specified, it specifies the buffer size for the I/O pipes. `mode`, if provided, should be the string `'b'` or `'t'`; on Windows this is needed to determine whether the file objects should be opened in binary or text mode. The default value for `mode` is `'t'`.

On Unix, `cmd` may be a sequence, in which case arguments will be passed directly to the program without shell intervention (as with `os.spawnv()`). If `cmd` is a string it will be passed to the shell (as with `os.system()`).

The only way to retrieve the return codes for the child processes is by using the `poll()` or `wait()` methods on the `Popen3` and `Popen4` classes; these are only available on Unix. This information is not available when using the `popen2()`, `popen3()`, and `popen4()` functions, or the equivalent functions in the `os` module. (Note that the
tuples returned by the `os` module's functions are in a different order from the ones returned by the `popen2` module.)

```python
popen2. popen2(cmd[, bufsize[, mode]])
Executes `cmd` as a sub-process. Returns the file objects (child_stdout, child_stdin).
```

```python
popen2. popen3(cmd[, bufsize[, mode]])
Executes `cmd` as a sub-process. Returns the file objects (child_stdout, child_stdin, child_stderr).
```

```python
popen2. popen4(cmd[, bufsize[, mode]])
Executes `cmd` as a sub-process. Returns the file objects (child_stdout_and_stderr, child_stdin).
```

*New in version 2.0.*

On Unix, a class defining the objects returned by the factory functions is also available. These are not used for the Windows implementation, and are not available on that platform.

```python
class popen2. Popen3(cmd[, capturestderr[, bufsize]])
This class represents a child process. Normally, `Popen3` instances are created using the `popen2()` and `popen3()` factory functions described above.

If not using one of the helper functions to create `Popen3` objects, the parameter `cmd` is the shell command to execute in a sub-process. The `capturestderr` flag, if true, specifies that the object should capture standard error output of the child process. The default is false. If the `bufsize` parameter is specified, it specifies the size of the I/O buffers to/from the child process.
class popen2. **Popen4**(*cmd[, bufsize]*)

Similar to **Popen3**, but always captures standard error into the same file object as standard output. These are typically created using **popen4**().

*New in version 2.0.*
17.5.1. Popen3 and Popen4 Objects

Instances of the Popen3 and Popen4 classes have the following methods:

Popen3. **poll()**

Returns -1 if child process hasn’t completed yet, or its status code (see wait()) otherwise.

Popen3. **wait()**

Waits for and returns the status code of the child process. The status code encodes both the return code of the process and information about whether it exited using the exit() system call or died due to a signal. Functions to help interpret the status code are defined in the os module; see section Process Management for the W*() family of functions.

The following attributes are also available:

Popen3. **fromchild**

A file object that provides output from the child process. For Popen4 instances, this will provide both the standard output and standard error streams.

Popen3. **tchild**

A file object that provides input to the child process.

Popen3. **childerr**

A file object that provides error output from the child process, if capturestderr was true for the constructor, otherwise None. This will always be None for Popen4 instances.

Popen3. **pid**
The process ID of the child process.
17.5.2. Flow Control Issues

Any time you are working with any form of inter-process communication, control flow needs to be carefully thought out. This remains the case with the file objects provided by this module (or the `os` module equivalents).

When reading output from a child process that writes a lot of data to standard error while the parent is reading from the child's standard output, a deadlock can occur. A similar situation can occur with other combinations of reads and writes. The essential factors are that more than `_PC_PIPE_BUF` bytes are being written by one process in a blocking fashion, while the other process is reading from the first process, also in a blocking fashion.

There are several ways to deal with this situation.

The simplest application change, in many cases, will be to follow this model in the parent process:

```python
import popen2
r, w, e = popen2.popen3('python slave.py')
e.readlines()
r.readlines()
r.close()
e.close()
w.close()
```

with code like this in the child:

```python
import os
import sys

# note that each of these print statements
# writes a single long string
```
In particular, note that `sys.stderr` must be closed after writing all data, or `readlines()` won’t return. Also note that `os.close()` must be used, as `sys.stderr.close()` won’t close `stderr` (otherwise assigning to `sys.stderr` will silently close it, so no further errors can be printed).

Applications which need to support a more general approach should integrate I/O over pipes with their `select()` loops, or use separate threads to read each of the individual files provided by whichever `popen*()` function or `Popen*` class was used.

See also:

Module **subprocess**
Module for spawning and managing subprocesses.
This module provides the basic infrastructure for writing asynchronous socket service clients and servers.

There are only two ways to have a program on a single processor do “more than one thing at a time.” Multi-threaded programming is the simplest and most popular way to do it, but there is another very different technique, that lets you have nearly all the advantages of multi-threading, without actually using multiple threads. It’s really only practical if your program is largely I/O bound. If your program is processor bound, then pre-emptive scheduled threads are probably what you really need. Network servers are rarely processor bound, however.

If your operating system supports the `select()` system call in its I/O library (and nearly all do), then you can use it to juggle multiple communication channels at once; doing other work while your I/O is taking place in the “background.” Although this strategy can seem strange and complex, especially at first, it is in many ways easier to understand and control than multi-threaded programming. The `asyncore` module solves many of the difficult problems for you, making the task of building sophisticated high-performance network servers and clients a snap. For “conversational” applications and protocols the companion `asynchat` module is invaluable.

The basic idea behind both modules is to create one or more network `channels`, instances of class `asyncore.dispatcher` and `asynchat.async_chat`. Creating the channels adds them to a global map, used by the `loop()` function if you do not provide it with your own map.
Once the initial channel(s) is(are) created, calling the `loop()` function activates channel service, which continues until the last channel (including any that have been added to the map during asynchronous service) is closed.

```
asyncore.loop([timeout, use_poll, map, count])
```

Enter a polling loop that terminates after count passes or all open channels have been closed. All arguments are optional. The `count` parameter defaults to None, resulting in the loop terminating only when all channels have been closed. The `timeout` argument sets the timeout parameter for the appropriate `select()` or `poll()` call, measured in seconds; the default is 30 seconds. The `use_poll` parameter, if true, indicates that `poll()` should be used in preference to `select()` (the default is `False`).

The `map` parameter is a dictionary whose items are the channels to watch. As channels are closed they are deleted from their map. If `map` is omitted, a global map is used. Channels (instances of `asyncore.dispatcher`, `asynchat.async_chat` and subclasses thereof) can freely be mixed in the map.

```
class asyncore.dispatcher
```

The `dispatcher` class is a thin wrapper around a low-level socket object. To make it more useful, it has a few methods for event-handling which are called from the asynchronous loop. Otherwise, it can be treated as a normal non-blocking socket object.

The firing of low-level events at certain times or in certain connection states tells the asynchronous loop that certain higher-level events have taken place. For example, if we have asked for a socket to connect to another host, we know that the connection has been made when the socket becomes writable for the first time (at this point you know that you may write to it with the
expectation of success). The implied higher-level events are:

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle_connect()</td>
<td>Implied by the first read or write event</td>
</tr>
<tr>
<td>handle_close()</td>
<td>Implied by a read event with no data available</td>
</tr>
<tr>
<td>handle_accept()</td>
<td>Implied by a read event on a listening socket</td>
</tr>
</tbody>
</table>

During asynchronous processing, each mapped channel's `readable()` and `writable()` methods are used to determine whether the channel's socket should be added to the list of channels `select()`ed or `poll()`ed for read and write events.

Thus, the set of channel events is larger than the basic socket events. The full set of methods that can be overridden in your subclass follows:

**handle_read()**

Called when the asynchronous loop detects that a `read()` call on the channel's socket will succeed.

**handle_write()**

Called when the asynchronous loop detects that a writable socket can be written. Often this method will implement the necessary buffering for performance. For example:

```python
def handle_write(self):
    sent = self.send(self.buffer)
    self.buffer = self.buffer[:sent]
```

**handle_expt()**

Called when there is out of band (OOB) data for a socket connection. This will almost never happen, as OOB is tenuously supported and rarely used.
handle_connect()
Called when the active opener’s socket actually makes a connection. Might send a “welcome” banner, or initiate a protocol negotiation with the remote endpoint, for example.

handle_close()
Called when the socket is closed.

handle_error()
Called when an exception is raised and not otherwise handled. The default version prints a condensed traceback.

handle_accept()
Called on listening channels (passive openers) when a connection can be established with a new remote endpoint that has issued a connect() call for the local endpoint.

readable()
Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which read events can occur. The default method simply returns True, indicating that by default, all channels will be interested in read events.

writable()
Called each time around the asynchronous loop to determine whether a channel’s socket should be added to the list on which write events can occur. The default method simply returns True, indicating that by default, all channels will be interested in write events.

In addition, each channel delegates or extends many of the socket methods. Most of these are nearly identical to their socket partners.

create_socket(family, type)
This is identical to the creation of a normal socket, and will use the same options for creation. Refer to the socket documentation for information on creating sockets.

**connect**(*address*)
As with the normal socket object, *address* is a tuple with the first element the host to connect to, and the second the port number.

**send**(*data*)
Send *data* to the remote end-point of the socket.

**recv**(*buffer_size*)
Read at most *buffer_size* bytes from the socket's remote end-point. An empty string implies that the channel has been closed from the other end.

**listen**(*backlog*)
Listen for connections made to the socket. The *backlog* argument specifies the maximum number of queued connections and should be at least 1; the maximum value is system-dependent (usually 5).

**bind**(*address*)
Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family — refer to the socket documentation for more information.) To mark the socket as re-usable (setting the **SO_REUSEADDR** option), call the dispatcher object’s **set_reuse_addr()** method.

**accept()**
Accept a connection. The socket must be bound to an address and listening for connections. The return value can be either **None** or a pair (**conn**, **address**) where **conn** is a new
socket object usable to send and receive data on the connection, and \textit{address} is the address bound to the socket on the other end of the connection. When \texttt{None} is returned it means the connection didn’t take place, in which case the server should just ignore this event and keep listening for further incoming connections.

\texttt{close()}

Close the socket. All future operations on the socket object will fail. The remote end-point will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

\texttt{class asyncore.dispatcher\_with\_send}

A \texttt{dispatcher} subclass which adds simple buffered output capability, useful for simple clients. For more sophisticated usage use \texttt{asynchat.async\_chat}.

\texttt{class asyncore.file\_dispatcher}

A \texttt{file\_dispatcher} takes a file descriptor or file object along with an optional map argument and wraps it for use with the \texttt{poll()} or \texttt{loop()} functions. If provided a file object or anything with a \texttt{fileno()} method, that method will be called and passed to the \texttt{file\_wrapper} constructor. Availability: UNIX.

\texttt{class asyncore.file\_wrapper}

A \texttt{file\_wrapper} takes an integer file descriptor and calls \texttt{os.dup()} to duplicate the handle so that the original handle may be closed independently of the file\_wrapper. This class implements sufficient methods to emulate a socket for use by the \texttt{file\_dispatcher} class. Availability: UNIX.
Here is a very basic HTTP client that uses the `dispatcher` class to implement its socket handling:

```python
import asyncore, socket

class HTTPClient(asyncore.dispatcher):
    def __init__(self, host, path):
        asyncore.dispatcher.__init__(self)
        self.create_socket(socket.AF_INET, socket.SOCK_STREAM)
        self.connect((host, 80))
        self.buffer = 'GET %s HTTP/1.0\r\n\n' % path

    def handle_connect(self):
        pass

    def handle_close(self):
        self.close()

    def handle_read(self):
        print self.recv(8192)

    def writable(self):
        return (len(self.buffer) > 0)

    def handle_write(self):
        sent = self.send(self.buffer)
        self.buffer = self.buffer[sent:]

client = HTTPClient('www.python.org', '/')
asyncore.loop()
```
Here is a basic echo server that uses the `dispatcher` class to accept connections and dispatches the incoming connections to a handler:

```python
import asyncore
import socket

class EchoHandler(asyncore.dispatcher_with_send):
    def handle_read(self):
        data = self.recv(8192)
        if data:
            self.send(data)

class EchoServer(asyncore.dispatcher):
    def __init__(self, host, port):
        asyncore.dispatcher.__init__(self)
        self.create_socket(socket.AF_INET, socket.SOCK_STREAM)
        self.set_reuse_addr()
        self.bind((host, port))
        self.listen(5)

    def handle_accept(self):
        pair = self.accept()
        if pair is None:
            pass
        else:
            sock, addr = pair
            print 'Incoming connection from %s' % repr(addr)
            handler = EchoHandler(sock)

server = EchoServer('localhost', 8080)
asyncore.loop()
```
17.7. asynchat — Asynchronous socket command/response handler

This module builds on the asyncore infrastructure, simplifying asynchronous clients and servers and making it easier to handle protocols whose elements are terminated by arbitrary strings, or are of variable length. asynchat defines the abstract class async_chat that you subclass, providing implementations of the collect_incoming_data() and found_terminator() methods. It uses the same asynchronous loop as asyncore, and the two types of channel, asyncore.dispatcher and asynchat.async_chat, can freely be mixed in the channel map. Typically an asyncore.dispatcher server channel generates new asynchat.async_chat channel objects as it receives incoming connection requests.

```
class asynchat.async_chat
```

This class is an abstract subclass of asyncore.dispatcher. To make practical use of the code you must subclass async_chat, providing meaningful collect_incoming_data() and found_terminator() methods. The asyncore.dispatcher methods can be used, although not all make sense in a message/response context.

Like asyncore.dispatcher, async_chat defines a set of events that are generated by an analysis of socket conditions after a select() call. Once the polling loop has been started the async_chat object’s methods are called by the event-processing framework with no action on the part of the programmer.

Two class attributes can be modified, to improve performance, or possibly even to conserve memory.
ac_in_buffer_size

The asynchronous input buffer size (default 4096).

ac_out_buffer_size

The asynchronous output buffer size (default 4096).

Unlike asyncore.dispatcher, async_chat allows you to define a first-in-first-out queue (fifo) of producers. A producer need have only one method, more(), which should return data to be transmitted on the channel. The producer indicates exhaustion (i.e. that it contains no more data) by having its more() method return the empty string. At this point the async_chat object removes the producer from the fifo and starts using the next producer, if any. When the producer fifo is empty the handle_write() method does nothing. You use the channel object's set_terminator() method to describe how to recognize the end of, or an important breakpoint in, an incoming transmission from the remote endpoint.

To build a functioning async_chat subclass your input methods collect_incoming_data() and found_terminator() must handle the data that the channel receives asynchronously. The methods are described below.

async_chat.close_when_done()

Pushes a None on to the producer fifo. When this producer is popped off the fifo it causes the channel to be closed.

async_chat.collect_incoming_data(data)

Called with data holding an arbitrary amount of received data. The default method, which must be overridden, raises a NotImplementedError exception.

async_chat.discardBuffers()
In emergencies this method will discard any data held in the input and/or output buffers and the producer fifo.

```python
async_chat.found_terminator()
```

Called when the incoming data stream matches the termination condition set by `set_terminator()`. The default method, which must be overridden, raises a `NotImplementedError` exception. The buffered input data should be available via an instance attribute.

```python
async_chat.get_terminator()
```

Returns the current terminator for the channel.

```python
async_chat.push(data)
```

Pushes data on to the channel's fifo to ensure its transmission. This is all you need to do to have the channel write the data out to the network, although it is possible to use your own producers in more complex schemes to implement encryption and chunking, for example.

```python
async_chat.push_with_producer(producer)
```

Takes a producer object and adds it to the producer fifo associated with the channel. When all currently-pushed producers have been exhausted the channel will consume this producer’s data by calling its `more()` method and send the data to the remote endpoint.

```python
async_chat.set_terminator(term)
```

Sets the terminating condition to be recognized on the channel. `term` may be any of three types of value, corresponding to three different ways to handle incoming protocol data.

<table>
<thead>
<tr>
<th>term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>Will call <code>found_terminator()</code> when the string is found in the input stream</td>
</tr>
<tr>
<td>integer</td>
<td>Will call <code>found_terminator()</code> when the indicated number of characters have been received</td>
</tr>
<tr>
<td>---------</td>
<td>-----------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>None</td>
<td>The channel continues to collect data forever</td>
</tr>
</tbody>
</table>

Note that any data following the terminator will be available for reading by the channel after `found_terminator()` is called.
17.7.1. asynchat - Auxiliary Classes

class asynchat.fifo([list=None])

A **fifo** holding data which has been pushed by the application but not yet popped for writing to the channel. A **fifo** is a list used to hold data and/or producers until they are required. If the *list* argument is provided then it should contain producers or data items to be written to the channel.

**is_empty()**
Returns **True** if and only if the fifo is empty.

**first()**
Returns the least-recently **push()**ed item from the fifo.

**push(data)**
Adds the given data (which may be a string or a producer object) to the producer fifo.

**pop()**
If the fifo is not empty, returns **True, first()**, deleting the popped item. Returns **False, None** for an empty fifo.
17.7.2. asynchat Example

The following partial example shows how HTTP requests can be read with `async_chat`. A web server might create an `http_request_handler` object for each incoming client connection. Notice that initially the channel terminator is set to match the blank line at the end of the HTTP headers, and a flag indicates that the headers are being read.

Once the headers have been read, if the request is of type POST (indicating that further data are present in the input stream) then the `Content-Length:` header is used to set a numeric terminator to read the right amount of data from the channel.

The `handle_request()` method is called once all relevant input has been marshalled, after setting the channel terminator to `None` to ensure that any extraneous data sent by the web client are ignored.

class http_request_handler(asyncchat.async_chat):
    def __init__(self, sock, addr, sessions, log):
        asyncchat.async_chat.__init__(self, sock=sock)
        self.addr = addr
        self.sessions = sessions
        self.ibuffer = []
        self.obuffer = ""
        self.set_terminator("\r\n\r\n")
        self.reading_headers = True
        self.handling = False
        self.cgi_data = None
        self.log = log

    def collect_incoming_data(self, data):
        """Buffer the data""
        self.ibuffer.append(data)

    def found_terminator(self):
        if self.reading_headers:
self.reading_headers = False
self.parse_headers("".join(self.ibuffer))
self.ibuffer = []
if self.op.upper() == "POST":
    clen = self.headers.getheader("content-length")
    self.set_terminator(int(clen))
else:
    self.handleing = True
    self.set_terminator(None)
    self.handle_request()
else:
    self.set_terminator(None)  # browsers sometimes over
self.cgi_data = parse(self.headers, "".join(self.ib
self.handling = True
self.ibuffer = []
self.handle_request()
18. Internet Data Handling

This chapter describes modules which support handling data formats commonly used on the Internet.

- **18.1. email** — An email and MIME handling package
  - 18.1.1. email: Representing an email message
  - 18.1.2. email: Parsing email messages
    - 18.1.2.1. FeedParser API
    - 18.1.2.2. Parser class API
    - 18.1.2.3. Additional notes
  - 18.1.3. email: Generating MIME documents
  - 18.1.4. email: Creating email and MIME objects from scratch
  - 18.1.5. email: Internationalized headers
  - 18.1.6. email: Representing character sets
  - 18.1.7. email: Encoders
  - 18.1.8. email: Exception and Defect classes
  - 18.1.9. email: Miscellaneous utilities
  - 18.1.10. email: Iterators
  - 18.1.11. email: Examples
  - 18.1.12. Package History
  - 18.1.13. Differences from mimelib
- **18.2. json** — JSON encoder and decoder
  - 18.2.1. Basic Usage
  - 18.2.2. Encoders and decoders
- **18.3. mailcap** — Mailcap file handling
- **18.4. mailbox** — Manipulate mailboxes in various formats
  - 18.4.1. Mailbox objects
    - 18.4.1.1. Maildir
    - 18.4.1.2. mbox
18.4.1.3. MH
18.4.1.4. Babyl
18.4.1.5. MMDF

18.4.2. Message objects
  18.4.2.1. MaildirMessage
  18.4.2.2. mboxMessage
  18.4.2.3. MHMessage
  18.4.2.4. BabylMessage
  18.4.2.5. MMDFMessage

18.4.3. Exceptions
18.4.4. Deprecated classes and methods
18.4.5. Examples

18.5. mhlib — Access to MH mailboxes
  18.5.1. MH Objects
  18.5.2. Folder Objects
  18.5.3. Message Objects

18.6. mimetools — Tools for parsing MIME messages
  18.6.1. Additional Methods of Message Objects

18.7. mimetypes — Map filenames to MIME types
  18.7.1. MimeTypes Objects

18.8. MimeWriter — Generic MIME file writer
  18.8.1. MimeWriter Objects

18.9. mimify — MIME processing of mail messages

18.10. multfile — Support for files containing distinct parts
  18.10.1. MultiFile Objects
  18.10.2. MultiFile Example

18.11. rfc822 — Parse RFC 2822 mail headers
  18.11.1. Message Objects
  18.11.2. AddressList Objects

18.12. base64 — RFC 3548: Base16, Base32, Base64 Data Encodings

18.13. binhex — Encode and decode binhex4 files
- 18.13.1. Notes
- 18.14. binascii — Convert between binary and ASCII
- 18.15. quopri — Encode and decode MIME quoted-printable data
- 18.16. uu — Encode and decode uuencode files
18.1. `email` — An email and MIME handling package

*New in version 2.2.*

The `email` package is a library for managing email messages, including MIME and other **RFC 2822**-based message documents. It subsumes most of the functionality in several older standard modules such as `rfc822`, `mimetypes`, `multifile`, and other non-standard packages such as `mimecntl`. It is specifically *not* designed to do any sending of email messages to SMTP (**RFC 2821**), NNTP, or other servers; those are functions of modules such as `smtplib` and `nntplib`. The `email` package attempts to be as RFC-compliant as possible, supporting in addition to **RFC 2822**, such MIME-related RFCs as **RFC 2045**, **RFC 2046**, **RFC 2047**, and **RFC 2231**.

The primary distinguishing feature of the `email` package is that it splits the parsing and generating of email messages from the internal *object model* representation of email. Applications using the `email` package deal primarily with objects; you can add sub-objects to messages, remove sub-objects from messages, completely re-arrange the contents, etc. There is a separate parser and a separate generator which handles the transformation from flat text to the object model, and then back to flat text again. There are also handy subclasses for some common MIME object types, and a few miscellaneous utilities that help with such common tasks as extracting and parsing message field values, creating RFC-compliant dates, etc.

The following sections describe the functionality of the `email` package. The ordering follows a progression that should be common in applications: an email message is read as flat text from a file or
other source, the text is parsed to produce the object structure of the email message, this structure is manipulated, and finally, the object tree is rendered back into flat text.

It is perfectly feasible to create the object structure out of whole cloth — i.e. completely from scratch. From there, a similar progression can be taken as above.

Also included are detailed specifications of all the classes and modules that the email package provides, the exception classes you might encounter while using the email package, some auxiliary utilities, and a few examples. For users of the older mimelib package, or previous versions of the email package, a section on differences and porting is provided.

Contents of the email package documentation:

- 18.1.1. email: Representing an email message
- 18.1.2. email: Parsing email messages
  - 18.1.2.1. FeedParser API
  - 18.1.2.2. Parser class API
  - 18.1.2.3. Additional notes
- 18.1.3. email: Generating MIME documents
- 18.1.4. email: Creating email and MIME objects from scratch
- 18.1.5. email: Internationalized headers
- 18.1.6. email: Representing character sets
- 18.1.7. email: Encoders
- 18.1.8. email: Exception and Defect classes
- 18.1.9. email: Miscellaneous utilities
- 18.1.10. email: Iterators
- 18.1.11. email: Examples

Module `nntplib`
  NNTP protocol client
18.1.12. Package History

This table describes the release history of the email package, corresponding to the version of Python that the package was released with. For purposes of this document, when you see a note about change or added versions, these refer to the Python version the change was made in, not the email package version. This table also describes the Python compatibility of each version of the package.

<table>
<thead>
<tr>
<th>email version</th>
<th>distributed with</th>
<th>compatible with</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.x</td>
<td>Python 2.2.0 to Python 2.2.1</td>
<td><em>no longer supported</em></td>
</tr>
<tr>
<td>2.5</td>
<td>Python 2.2.2+ and Python 2.3</td>
<td>Python 2.1 to 2.5</td>
</tr>
<tr>
<td>3.0</td>
<td>Python 2.4</td>
<td>Python 2.3 to 2.5</td>
</tr>
<tr>
<td>4.0</td>
<td>Python 2.5</td>
<td>Python 2.3 to 2.5</td>
</tr>
</tbody>
</table>

Here are the major differences between email version 4 and version 3:

- All modules have been renamed according to PEP 8 standards. For example, the version 3 module `email.Message` was renamed to `email.message` in version 4.

- A new subpackage `email.mime` was added and all the version 3 `email.MIME*` modules were renamed and situated into the `email.mime` subpackage. For example, the version 3 module `email.MIMEText` was renamed to `email.mime.text`.

   *Note that the version 3 names will continue to work until Python 2.6.*
- The `email.mime.application` module was added, which contains the MIMEApplication class.

- Methods that were deprecated in version 3 have been removed. These include `Generator.__call__()`, `Message.get_type()`, `Message.get_main_type()`, and `Message.get_subtype()`.

- Fixes have been added for RFC 2231 support which can change some of the return types for `Message.get_param()` and friends. Under some circumstances, values which used to return a 3-tuple now return simple strings (specifically, if all extended parameter segments were unencoded, there is no language and charset designation expected, so the return type is now a simple string). Also, %-decoding used to be done for both encoded and unencoded segments; this decoding is now done only for encoded segments.

Here are the major differences between `email` version 3 and version 2:

- The `FeedParser` class was introduced, and the `Parser` class was implemented in terms of the `FeedParser`. All parsing therefore is non-strict, and parsing will make a best effort never to raise an exception. Problems found while parsing messages are stored in the message's `defect` attribute.

- All aspects of the API which raised `DeprecationWarning`s in version 2 have been removed. These include the `_encoder` argument to the `MIMEText` constructor, the `Message.add_payload()` method, the `Utils.dump_address_pair()` function, and the functions `Utils.decode()` and `Utils.encode()`.

- New `DeprecationWarning`s have been added to: `Generator.__call__()`, `Message.get_type()`, `Message.get_main_type()`, and `Message.get_subtype()`, and the `strict`
argument to the `Parser` class. These are expected to be removed in future versions.

- Support for Pythons earlier than 2.3 has been removed.

Here are the differences between `email` version 2 and version 1:

- The `email.Header` and `email.Charset` modules have been added.

- The pickle format for `Message` instances has changed. Since this was never (and still isn't) formally defined, this isn't considered a backward incompatibility. However if your application pickles and unpickles `Message` instances, be aware that in `email` version 2, `Message` instances now have private variables `_charset` and `_default_type`.

- Several methods in the `Message` class have been deprecated, or their signatures changed. Also, many new methods have been added. See the documentation for the `Message` class for details. The changes should be completely backward compatible.

- The object structure has changed in the face of `message/rfc822` content types. In `email` version 1, such a type would be represented by a scalar payload, i.e. the container message's `is_multipart()` returned false, `get_payload()` was not a list object, but a single `Message` instance.

  This structure was inconsistent with the rest of the package, so the object representation for `message/rfc822` content types was changed. In `email` version 2, the container does return `True` from `is_multipart()`, and `get_payload()` returns a list containing a single `Message` item.

  Note that this is one place that backward compatibility could not
be completely maintained. However, if you’re already testing the return type of `get_payload()`, you should be fine. You just need to make sure your code doesn’t do a `set_payload()` with a `Message` instance on a container with a content type of `message/rfc822`.

- The `Parser` constructor’s `strict` argument was added, and its `parse()` and `parsestr()` methods grew a `headersonly` argument. The `strict` flag was also added to functions `email.message_from_file()` and `email.message_from_string()`.

- `Generator.__call__()` is deprecated; use `Generator.flatten()` instead. The `Generator` class has also grown the `clone()` method.

- The `DecodedGenerator` class in the `email.Generator` module was added.

- The intermediate base classes `MIMENonMultipart` and `MIMEMultipart` have been added, and interposed in the class hierarchy for most of the other MIME-related derived classes.

- The `_encoder` argument to the `MIMEText` constructor has been deprecated. Encoding now happens implicitly based on the `_charset` argument.

- The following functions in the `email.Utils` module have been deprecated: `dump_address_pairs()`, `decode()`, and `encode()`. The following functions have been added to the module: `make_msgid()`, `decode_rfc2231()`, `encode_rfc2231()`, and `decode_params()`.

- The non-public function `email.Iterators._structure()` was added.
18.1.13. Differences from mimelib

The email package was originally prototyped as a separate library called mimelib. Changes have been made so that method names are more consistent, and some methods or modules have either been added or removed. The semantics of some of the methods have also changed. For the most part, any functionality available in mimelib is still available in the email package, albeit often in a different way. Backward compatibility between the mimelib package and the email package was not a priority.

Here is a brief description of the differences between the mimelib and the email packages, along with hints on how to port your applications.

Of course, the most visible difference between the two packages is that the package name has been changed to email. In addition, the top-level package has the following differences:

- `messageFromString()` has been renamed to `message_from_string()`.
- `messageFromFile()` has been renamed to `message_from_file()`.

The Message class has the following differences:

- The method `asString()` was renamed to `as_string()`.
- The method `ismultipart()` was renamed to `is_multipart()`.
- The `get_payload()` method has grown a `decode` optional argument.
- The method `getall()` was renamed to `get_all()`.
- The method `addheader()` was renamed to `add_header()`.
- The method `gettype()` was renamed to `get_type()`.
- The method `getmaintype()` was renamed to `get_main_type()`.
- The method `getsubtype()` was renamed to `get_subtype()`.
- The method `getparams()` was renamed to `get_params()`.
  Also, whereas `getparams()` returned a list of strings, `get_params()` returns a list of 2-tuples, effectively the key/value pairs of the parameters, split on the '=' sign.
- The method `getparam()` was renamed to `get_param()`.
- The method `getcharsets()` was renamed to `get_charsets()`.
- The method `getfilename()` was renamed to `get_filename()`.
- The method `getboundary()` was renamed to `get_boundary()`.
- The method `setboundary()` was renamed to `set_boundary()`.
- The method `getdecodedpayload()` was removed. To get similar functionality, pass the value 1 to the `decode` flag of the `get_payload()` method.
- The method `getpayloadastext()` was removed. Similar functionality is supported by the `DecodedGenerator` class in the `email.generator` module.
- The method `getbodyastext()` was removed. You can get similar functionality by creating an iterator with `typed_subpart_iterator()` in the `email.iterators` module.

The `Parser` class has no differences in its public interface. It does have some additional smarts to recognize `message/delivery-status` type messages, which it represents as a `Message` instance containing separate `Message` subparts for each header block in the delivery status notification [1].

The `Generator` class has no differences in its public interface. There is a new class in the `email.generator` module though, called `DecodedGenerator` which provides most of the functionality previously available in the `Message.getpayloadastext()` method.
The following modules and classes have been changed:

- The **MIMEBase** class constructor arguments *major* and *minor* have changed to *maintype* and *subtype* respectively.

- The **Image** class/module has been renamed to **MIMEImage**. The *minor* argument has been renamed to *subtype*.

- The **Text** class/module has been renamed to **MIMEText**. The *minor* argument has been renamed to *subtype*.

- The **MessageRFC822** class/module has been renamed to **MIMEMessage**. Note that an earlier version of **mimelib** called this class/module **RFC822**, but that clashed with the Python standard library module **rfc822** on some case-insensitive file systems.

  Also, the **MIMEMessage** class now represents any kind of MIME message with main type *message*. It takes an optional argument *subtype* which is used to set the MIME subtype. *subtype* defaults to **rfc822**.

**mimelib** provided some utility functions in its *address* and *date* modules. All of these functions have been moved to the **email.utils** module.

The **MsgReader** class/module has been removed. Its functionality is most closely supported in the **body_line_iterator()** function in the **email.iterators** module.

**Footnotes**

[1] Delivery Status Notifications (DSN) are defined in **RFC 1894**.
18.1.1. email: Representing an email message

The central class in the email package is the Message class, imported from the email.message module. It is the base class for the email object model. Message provides the core functionality for setting and querying header fields, and for accessing message bodies.

Conceptually, a Message object consists of headers and payloads. Headers are RFC 2822 style field names and values where the field name and value are separated by a colon. The colon is not part of either the field name or the field value.

Headers are stored and returned in case-preserving form but are matched case-insensitively. There may also be a single envelope header, also known as the Unix-From header or the From_ header. The payload is either a string in the case of simple message objects or a list of Message objects for MIME container documents (e.g. multipart/* and message/rfc822).

Message objects provide a mapping style interface for accessing the message headers, and an explicit interface for accessing both the headers and the payload. It provides convenience methods for generating a flat text representation of the message object tree, for accessing commonly used header parameters, and for recursively walking over the object tree.

Here are the methods of the Message class:

class email.message.Message
    The constructor takes no arguments.

    as_string([unixfrom])
Return the entire message flattened as a string. When optional `unixfrom` is `True`, the envelope header is included in the returned string. `unixfrom` defaults to `False`. Flattening the message may trigger changes to the `Message` if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it mangles lines that begin with `From`. For more flexibility, instantiate a `Generator` instance and use its `flatten()` method directly. For example:

```python
from cStringIO import StringIO
from email.generator import Generator
fp = StringIO()
g = Generator(fp, mangle_from_=False, maxheaderlen=60)
g.flatten(msg)
text = fp.getvalue()
```

`__str__()`
Equivalent to `as_string(unixfrom=True)`.

`is_multipart()`
Return `True` if the message’s payload is a list of sub-`Message` objects, otherwise return `False`. When `is_multipart()` returns `False`, the payload should be a string object.

`set_unixfrom(unixfrom)`
Set the message’s envelope header to `unixfrom`, which should be a string.

`get_unixfrom()`
Return the message’s envelope header. Defaults to `None` if the envelope header was never set.
attach(payload)

Add the given payload to the current payload, which must be None or a list of Message objects before the call. After the call, the payload will always be a list of Message objects. If you want to set the payload to a scalar object (e.g. a string), use set_payload() instead.

get_payload([i[, decode]])

Return the current payload, which will be a list of Message objects when is_multipart() is True, or a string when is_multipart() is False. If the payload is a list and you mutate the list object, you modify the message's payload in place.

With optional argument i, get_payload() will return the i-th element of the payload, counting from zero, if is_multipart() is True. An IndexError will be raised if i is less than 0 or greater than or equal to the number of items in the payload. If the payload is a string (i.e. is_multipart() is False) and i is given, a TypeError is raised.

Optional decode is a flag indicating whether the payload should be decoded or not, according to the Content-Transfer-Encoding header. When True and the message is not a multipart, the payload will be decoded if this header’s value is quoted-printable or base64. If some other encoding is used, or Content-Transfer-Encoding header is missing, or if the payload has bogus base64 data, the payload is returned as-is (undecoded). If the message is a multipart and the decode flag is True, then None is returned. The default for decode is False.

set_payload(payload[, charset])
Set the entire message object's payload to `payload`. It is the client's responsibility to ensure the payload invariants. Optional `charset` sets the message's default character set; see `set_charset()` for details.

*Changed in version 2.2.2: charset argument added.*

```
set_charset(charset)
```

Set the character set of the payload to `charset`, which can either be a `Charset` instance (see `email.charset`), a string naming a character set, or `None`. If it is a string, it will be converted to a `Charset` instance. If `charset` is `None`, the `charset` parameter will be removed from the `Content-Type` header (the message will not be otherwise modified). Anything else will generate a `TypeError`.

If there is no existing `MIME-Version` header one will be added. If there is no existing `Content-Type` header, one will be added with a value of `text/plain`. Whether the `Content-Type` header already exists or not, its `charset` parameter will be set to `charset.output_charset`. If `charset.input_charset` and `charset.output_charset` differ, the payload will be re-encoded to the `output_charset`. If there is no existing `Content-Transfer-Encoding` header, then the payload will be transfer-encoded, if needed, using the specified `Charset`, and a header with the appropriate value will be added. If a `Content-Transfer-Encoding` header already exists, the payload is assumed to already be correctly encoded using that `Content-Transfer-Encoding` and is not modified.

The message will be assumed to be of type `text/*`, with the payload either in unicode or encoded with `charset.input_charset`. It will be encoded or converted to `charset.output_charset` and transfer encoded properly, if
needed, when generating the plain text representation of the message. MIME headers (*MIME-Version*, *Content-Type*, *Content-Transfer-Encoding*) will be added as needed.

*New in version 2.2.2.*

**get_charset()**

Return the *charset* instance associated with the message’s payload.

*New in version 2.2.2.*

The following methods implement a mapping-like interface for accessing the message’s *RFC 2822* headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by *keys()* , but in a *Message* object, headers are always returned in the order they appeared in the original message, or were added to the message later. Any header deleted and then re-added are always appended to the end of the header list.

These semantic differences are intentional and are biased toward maximal convenience.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

**__len__()**

Return the total number of headers, including duplicates.

**__contains__(name)**

Return true if the message object has a field named *name*. 
Matching is done case-insensitively and name should not include the trailing colon. Used for the in operator, e.g.:

```python
if 'message-id' in myMessage:
    print 'Message-ID:', myMessage['message-id']
```

__getitem__(name)

Return the value of the named header field. name should not include the colon field separator. If the header is missing, None is returned; a KeyError is never raised.

Note that if the named field appears more than once in the message's headers, exactly which of those field values will be returned is undefined. Use the get_all() method to get the values of all the extant named headers.

__setitem__(name, val)

Add a header to the message with field name name and value val. The field is appended to the end of the message's existing fields.

Note that this does not overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name name, delete the field first, e.g.:

```python
del msg['subject']
msg['subject'] = 'Python roolz!'
```

__delitem__(name)

Delete all occurrences of the field with name name from the message's headers. No exception is raised if the named field isn’t present in the headers.

has_key(name)

Return true if the message contains a header field named
name, otherwise return false.

keys()
Return a list of all the message’s header field names.

values()
Return a list of all the message’s field values.

items()
Return a list of 2-tuples containing all the message’s field headers and values.

get(name[, failobj])
Return the value of the named header field. This is identical to __getitem__() except that optional failobj is returned if the named header is missing (defaults to None).

Here are some additional useful methods:

get_all(name[, failobj])
Return a list of all the values for the field named name. If there are no such named headers in the message, failobj is returned (defaults to None).

add_header(_name, _value, **_params)
Extended header setting. This method is similar to __setitem__() except that additional header parameters can be provided as keyword arguments. _name is the header field to add and _value is the primary value for the header.

For each item in the keyword argument dictionary _params, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as key="value" unless the value is None, in which case only the
key will be added. If the value contains non-ASCII characters, it must be specified as a three tuple in the format \texttt{(CHARSET, LANGUAGE, VALUE)}, where \texttt{CHARSET} is a string naming the charset to be used to encode the value, \texttt{LANGUAGE} can usually be set to \texttt{None} or the empty string (see \texttt{RFC 2231} for other possibilities), and \texttt{VALUE} is the string value containing non-ASCII code points.

Here’s an example:

```
msg.add_header('Content-Disposition', 'attachment', filename='bud.gif')
```

This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.gif"
```

An example with with non-ASCII characters:

```
msg.add_header('Content-Disposition', 'attachment', filename=('iso-8859-1', '', 'Fußballer.ppt'))
```

Which produces

```
Content-Disposition: attachment; filename*="iso-8859-1''Fu%DFballer.ppt"
```

\texttt{replace_header\_name, \_value)}

Replace a header. Replace the first header found in the message that matches \texttt{\_name}, retaining header order and field name case. If no matching header was found, a \texttt{KeyError} is raised.

\textit{New in version 2.2.2.}

\texttt{get\_content\_type()}
Return the message's content type. The returned string is coerced to lower case of the form `maintype/subtype`. If there was no `Content-Type` header in the message the default type as given by `get_default_type()` will be returned. Since according to RFC 2045, messages always have a default type, `get_content_type()` will always return a value.

RFC 2045 defines a message's default type to be `text/plain` unless it appears inside a `multipart/digest` container, in which case it would be `message/rfc822`. If the `Content-Type` header has an invalid type specification, RFC 2045 mandates that the default type be `text/plain`.

*New in version 2.2.2.*

`get_content_maintype()`
Return the message's main content type. This is the `maintype` part of the string returned by `get_content_type()`.

*New in version 2.2.2.*

`get_content_subtype()`
Return the message's sub-content type. This is the `subtype` part of the string returned by `get_content_type()`.

*New in version 2.2.2.*

`get_default_type()`
Return the default content type. Most messages have a default content type of `text/plain`, except for messages that are subparts of `multipart/digest` containers. Such subparts have a default content type of `message/rfc822`.

*New in version 2.2.2.*
set_default_type(ctype)
Set the default content type. ctype should either be text/plain or message/rfc822, although this is not enforced. The default content type is not stored in the Content-Type header.

New in version 2.2.2.

get_params([failobj[, header[, unquote]]])
Return the message's Content-Type parameters, as a list. The elements of the returned list are 2-tuples of key/value pairs, as split on the '=' sign. The left hand side of the '=' is the key, while the right hand side is the value. If there is no '=' sign in the parameter the value is the empty string, otherwise the value is as described in get_param() and is unquoted if optional unquote is True (the default).

Optional failobj is the object to return if there is no Content-Type header. Optional header is the header to search instead of Content-Type.

Changed in version 2.2.2: unquote argument added.

get_param(param[, failobj[, header[, unquote]]])
Return the value of the Content-Type header's parameter param as a string. If the message has no Content-Type header or if there is no such parameter, then failobj is returned (defaults to None).

Optional header if given, specifies the message header to use instead of Content-Type.

Parameter keys are always compared case insensitively. The return value can either be a string, or a 3-tuple if the parameter was RFC 2231 encoded. When it's a 3-tuple, the
elements of the value are of the form \((\text{CHARSET, LANGUAGE, VALUE})\). Note that both \text{CHARSET} and \text{LANGUAGE} can be \text{None}, in which case you should consider \text{VALUE} to be encoded in the \text{us-ascii} charset. You can usually ignore \text{LANGUAGE}.

If your application doesn’t care whether the parameter was encoded as in \text{RFC 2231}, you can collapse the parameter value by calling \text{email.utils.collapse_rfc2231_value()}, passing in the return value from \text{get_param()}. This will return a suitably decoded Unicode string when the value is a tuple, or the original string unquoted if it isn’t. For example:

```python
rawparam = msg.get_param('foo')
param = email.utils.collapse_rfc2231_value(rawparam)
```

In any case, the parameter value (either the returned string, or the \text{VALUE} item in the 3-tuple) is always unquoted, unless \text{unquote} is set to \text{False}.

\textbf{Changed in version 2.2.2: unquote argument added, and 3-tuple return value possible.}

\texttt{set_param(param, value[, header[, requote[, charset[, language]]]]])}

Set a parameter in the \text{Content-Type} header. If the parameter already exists in the header, its value will be replaced with \text{value}. If the \text{Content-Type} header as not yet been defined for this message, it will be set to \text{text/plain} and the new parameter value will be appended as per \text{RFC 2045}.

Optional \text{header} specifies an alternative header to \text{Content-Type}, and all parameters will be quoted as necessary unless optional \text{requote} is \text{False} (the default is \text{True}).
If optional `charset` is specified, the parameter will be encoded according to RFC 2231. Optional `language` specifies the RFC 2231 language, defaulting to the empty string. Both `charset` and `language` should be strings.

*New in version 2.2.2.*

```python
def del_param(param[, header[, requote]])
```
Remove the given parameter completely from the `Content-Type` header. The header will be re-written in place without the parameter or its value. All values will be quoted as necessary unless `requote` is `False` (the default is `True`). Optional `header` specifies an alternative to `Content-Type`.

*New in version 2.2.2.*

```python
def set_type(type[, header][, requote])
```
Set the main type and subtype for the `Content-Type` header. `type` must be a string in the form `maintype/subtype`, otherwise a `ValueError` is raised.

This method replaces the `Content-Type` header, keeping all the parameters in place. If `requote` is `False`, this leaves the existing header’s quoting as is, otherwise the parameters will be quoted (the default).

An alternative header can be specified in the `header` argument. When the `Content-Type` header is set a `MIME-Version` header is also added.

*New in version 2.2.2.*

```python
def get_filename([failobj])
```
Return the value of the `filename` parameter of the `Content-
**Disposition** header of the message. If the header does not have a `filename` parameter, this method falls back to looking for the `name` parameter on the **Content-Type** header. If neither is found, or the header is missing, then `failobj` is returned. The returned string will always be unquoted as per `email.utils.unquote()`.

**get_boundary**([`failobj`])

Return the value of the `boundary` parameter of the **Content-Type** header of the message, or `failobj` if either the header is missing, or has no `boundary` parameter. The returned string will always be unquoted as per `email.utils.unquote()`.

**set_boundary**(`boundary`)

Set the `boundary` parameter of the **Content-Type** header to `boundary`. **set_boundary()** will always quote `boundary` if necessary. A **HeaderParseError** is raised if the message object has no **Content-Type** header.

Note that using this method is subtly different than deleting the old **Content-Type** header and adding a new one with the new boundary via **add_header()**, because **set_boundary()** preserves the order of the **Content-Type** header in the list of headers. However, it does not preserve any continuation lines which may have been present in the original **Content-Type** header.

**get_content_charset**([`failobj`])

Return the `charset` parameter of the **Content-Type** header, coerced to lower case. If there is no **Content-Type** header, or if that header has no `charset` parameter, `failobj` is returned.

Note that this method differs from **get_charset()** which
returns the `charset` instance for the default encoding of the message body.

*New in version 2.2.2.*

`get_charsets(failobj)`  
Return a list containing the character set names in the message. If the message is a `multipart`, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the `charset` parameter in the `Content-Type` header for the represented subpart. However, if the subpart has no `Content-Type` header, no `charset` parameter, or is not of the `text` main MIME type, then that item in the returned list will be `failobj`.

`walk()`  
The `walk()` method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use `walk()` as the iterator in a `for` loop; each iteration returns the next subpart.

Here's an example that prints the MIME type of every part of a multipart message structure:

```python
global msg  

>>> for part in msg.walk():  
...     print part.get_content_type()  
multipart/report  
text/plain  
message/delivery-status  
text/plain  
text/plain  
message/rfc822  
```
Changed in version 2.5: The previously deprecated methods `get_type()`, `get_main_type()`, and `get_subtype()` were removed.

Message objects can also optionally contain two instance attributes, which can be used when generating the plain text of a MIME message.

**preamble**

The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this text can become visible.

The *preamble* attribute contains this leading extra-armor text for MIME documents. When the **Parser** discovers some text after the headers but before the first boundary string, it assigns this text to the message’s *preamble* attribute. When the **Generator** is writing out the plain text representation of a MIME message, and it finds the message has a *preamble* attribute, it will write this text in the area between the headers and the first boundary. See `email.parser` and `email.generator` for details.

Note that if the message object has no preamble, the *preamble* attribute will be `None`.

**epilogue**

The *epilogue* attribute acts the same way as the *preamble* attribute, except that it contains text that appears between the last boundary and the end of the message.

Changed in version 2.5: You do not need to set the epilogue
to the empty string in order for the `Generator` to print a newline at the end of the file.

**defects**

The `defects` attribute contains a list of all the problems found when parsing this message. See `email.errors` for a detailed description of the possible parsing defects.

*New in version 2.4.*
email — An email and MIME handling package
18.1.2. `email`: Parsing email messages

Message object structures can be created in one of two ways: they can be created from whole cloth by instantiating `Message` objects and stringing them together via `attach()` and `set_payload()` calls, or they can be created by parsing a flat text representation of the email message.

The `email` package provides a standard parser that understands most email document structures, including MIME documents. You can pass the parser a string or a file object, and the parser will return to you the root `Message` instance of the object structure. For simple, non-MIME messages the payload of this root object will likely be a string containing the text of the message. For MIME messages, the root object will return `True` from its `is_multipart()` method, and the subparts can be accessed via the `get_payload()` and `walk()` methods.

There are actually two parser interfaces available for use, the classic `Parser` API and the incremental `FeedParser` API. The classic `Parser` API is fine if you have the entire text of the message in memory as a string, or if the entire message lives in a file on the file system. `FeedParser` is more appropriate for when you’re reading the message from a stream which might block waiting for more input (e.g. reading an email message from a socket). The `FeedParser` can consume and parse the message incrementally, and only returns the root object when you close the parser [1].

Note that the parser can be extended in limited ways, and of course you can implement your own parser completely from scratch. There is no magical connection between the `email` package’s bundled
parser and the Message class, so your custom parser can create message object trees any way it finds necessary.
18.1.2.1. FeedParser API

New in version 2.4.

The **FeedParser**, imported from the `email.feedparser` module, provides an API that is conducive to incremental parsing of email messages, such as would be necessary when reading the text of an email message from a source that can block (e.g. a socket). The **FeedParser** can of course be used to parse an email message fully contained in a string or a file, but the classic **Parser** API may be more convenient for such use cases. The semantics and results of the two parser APIs are identical.

The **FeedParser**'s API is simple; you create an instance, feed it a bunch of text until there's no more to feed it, then close the parser to retrieve the root message object. The **FeedParser** is extremely accurate when parsing standards-compliant messages, and it does a very good job of parsing non-compliant messages, providing information about how a message was deemed broken. It will populate a message object's `defects` attribute with a list of any problems it found in a message. See the `email.errors` module for the list of defects that it can find.

Here is the API for the **FeedParser**:

```python
class email.parser.FeedParser([_factory])

Create a **FeedParser** instance. Optional `_factory` is a no-argument callable that will be called whenever a new message object is needed. It defaults to the `email.message.Message` class.

feed(data)

Feed the **FeedParser** some more data. `data` should be a string
```
containing one or more lines. The lines can be partial and the
FeedParser will stitch such partial lines together properly. The
lines in the string can have any of the common three line
endings, carriage return, newline, or carriage return and
newline (they can even be mixed).

**close()**

Closing a FeedParser completes the parsing of all previously
fed data, and returns the root message object. It is undefined
what happens if you feed more data to a closed FeedParser.
18.1.2.2. Parser class API

The **Parser** class, imported from the `email.parser` module, provides an API that can be used to parse a message when the complete contents of the message are available in a string or file. The `email.parser` module also provides a second class, called **HeaderParser** which can be used if you’re only interested in the headers of the message. **HeaderParser** can be much faster in these situations, since it does not attempt to parse the message body, instead setting the payload to the raw body as a string. **HeaderParser** has the same API as the **Parser** class.

```python
class email.parser.Parser([_class])
```

The constructor for the **Parser** class takes an optional argument `_class`. This must be a callable factory (such as a function or a class), and it is used whenever a sub-message object needs to be created. It defaults to **Message** (see `email.message`). The factory will be called without arguments.

The optional **strict** flag is ignored.

**Deprecated since version 2.4:** Because the **Parser** class is a backward compatible API wrapper around the new-in-Python 2.4 **FeedParser**, all parsing is effectively non-strict. You should simply stop passing a **strict** flag to the **Parser** constructor.

**Changed in version 2.2.2:** The **strict** flag was added.

**Changed in version 2.4:** The **strict** flag was deprecated.

The other public **Parser** methods are:
**parse**(*fp[, headersonly]*)

Read all the data from the file-like object *fp*, parse the resulting text, and return the root message object. *fp* must support both the `readline()` and the `read()` methods on file-like objects.

The text contained in *fp* must be formatted as a block of RFC 2822 style headers and header continuation lines, optionally preceded by a envelope header. The header block is terminated either by the end of the data or by a blank line. Following the header block is the body of the message (which may contain MIME-encoded subparts).

Optional *headersonly* is as with the `parse()` method.

*Changed in version 2.2.2*: The *headersonly* flag was added.

**parsestr**(text[, headersonly])

Similar to the `parse()` method, except it takes a string object instead of a file-like object. Calling this method on a string is exactly equivalent to wrapping text in a `StringIO` instance first and calling `parse()`.

Optional *headersonly* is a flag specifying whether to stop parsing after reading the headers or not. The default is *False*, meaning it parses the entire contents of the file.

*Changed in version 2.2.2*: The *headersonly* flag was added.

Since creating a message object structure from a string or a file object is such a common task, two functions are provided as a convenience. They are available in the top-level `email` package namespace.
email.message_from_string(s[, _class[, strict]])

Return a message object structure from a string. This is exactly equivalent to Parser().parsestr(s). Optional _class and strict are interpreted as with the Parser class constructor.

*Changed in version 2.2.2:* The strict flag was added.

email.message_from_file(fp[, _class[, strict]])

Return a message object structure tree from an open file object. This is exactly equivalent to Parser().parse(fp). Optional _class and strict are interpreted as with the Parser class constructor.

*Changed in version 2.2.2:* The strict flag was added.

Here’s an example of how you might use this at an interactive Python prompt:

```python
>>> import email
>>> msg = email.message_from_string(myString)
```
Here are some notes on the parsing semantics:

- Most non-
  **multipart** type messages are parsed as a single message object with a string payload. These objects will return **False** for **is_multipart()**. Their **get_payload()** method will return a string object.
- All **multipart** type messages will be parsed as a container message object with a list of sub-message objects for their payload. The outer container message will return **True** for **is_multipart()** and their **get_payload()** method will return the list of **Message** subparts.
- Most messages with a content type of **message/*** (e.g. **message/delivery-status** and **message/rfc822**) will also be parsed as container object containing a list payload of length 1. Their **is_multipart()** method will return **True**. The single element in the list payload will be a sub-message object.
- Some non-standards compliant messages may not be internally consistent about their **multipart**-edness. Such messages may have a **Content-Type** header of type **multipart**, but their **is_multipart()** method may return **False**. If such messages were parsed with the **FeedParser**, they will have an instance of the **MultipartInvariantViolationDefect** class in their **defects** attribute list. See **email.errors** for details.

**Footnotes**

[1] As of email package version 3.0, introduced in Python 2.4, the classic **Parser** was re-implemented in terms of the **FeedParser**, so the semantics and results are identical between the two parsers.
One of the most common tasks is to generate the flat text of the email message represented by a message object structure. You will need to do this if you want to send your message via the `smtplib` module or the `nntplib` module, or print the message on the console. Taking a message object structure and producing a flat text document is the job of the `Generator` class.

Again, as with the `email.parser` module, you aren’t limited to the functionality of the bundled generator; you could write one from scratch yourself. However the bundled generator knows how to generate most email in a standards-compliant way, should handle MIME and non-MIME email messages just fine, and is designed so that the transformation from flat text, to a message structure via the `Parser` class, and back to flat text, is idempotent (the input is identical to the output). On the other hand, using the Generator on a `Message` constructed by program may result in changes to the `Message` object as defaults are filled in.

Here are the public methods of the `Generator` class, imported from the `email.generator` module:

```python
class email.generator.Generator(outfp[, mangle_from_, [maxheaderlen]])
```

The constructor for the `Generator` class takes a file-like object called `outfp` for an argument. `outfp` must support the `write()` method and be usable as the output file in a Python extended print statement.
Optional `mangle_from_` is a flag that, when `True`, puts a `>` character in front of any line in the body that starts exactly as `From`, i.e. `From` followed by a space at the beginning of the line. This is the only guaranteed portable way to avoid having such lines be mistaken for a Unix mailbox format envelope header separator (see WHY THE CONTENT-LENGTH FORMAT IS BAD for details). `mangle_from_` defaults to `True`, but you might want to set this to `False` if you are not writing Unix mailbox format files.

Optional `maxheaderlen` specifies the longest length for a non-continued header. When a header line is longer than `maxheaderlen` (in characters, with tabs expanded to 8 spaces), the header will be split as defined in the `Header` class. Set to zero to disable header wrapping. The default is 78, as recommended (but not required) by RFC 2822.

The other public `Generator` methods are:

```python
flatten(msg[, unixfrom])
```

Print the textual representation of the message object structure rooted at `msg` to the output file specified when the `Generator` instance was created. Subparts are visited depth-first and the resulting text will be properly MIME encoded.

Optional `unixfrom` is a flag that forces the printing of the envelope header delimiter before the first RFC 2822 header of the root message object. If the root object has no envelope header, a standard one is crafted. By default, this is set to `False` to inhibit the printing of the envelope delimiter.

Note that for subparts, no envelope header is ever printed.

*New in version 2.2.2.*
clone\((fp)\)
Return an independent clone of this Generator instance with the exact same options.

New in version 2.2.2.

write\((s)\)
Write the string \(s\) to the underlying file object, i.e. \(outfp\) passed to Generator’s constructor. This provides just enough file-like API for Generator instances to be used in extended print statements.

As a convenience, see the methods \texttt{Message.as\_string()}\ and \texttt{str(aMessage)}, a.k.a. \texttt{Message.__str__()}, which simplify the generation of a formatted string representation of a message object. For more detail, see \texttt{email.message}.

The \texttt{email.generator} module also provides a derived class, called \texttt{DecodedGenerator} which is like the \texttt{Generator} base class, except that non-text parts are substituted with a format string representing the part.

\texttt{class email\.generator\.DecodedGenerator\((outfp[, mangle\_from\_[, maxheaderlen[, fmt\]]])\)}

This class, derived from Generator walks through all the subparts of a message. If the subpart is of main type \texttt{text}, then it prints the decoded payload of the subpart. Optional \texttt{mangle\_from\_} and \texttt{maxheaderlen} are as with the \texttt{Generator} base class.

If the subpart is not of main type \texttt{text}, optional \texttt{fmt} is a format string that is used instead of the message payload. \texttt{fmt} is expanded with the following keywords, \texttt{%\(\texttt{keyword}\)s} format:
• **type** – Full MIME type of the non-text part
• **maintype** – Main MIME type of the non-text part
• **subtype** – Sub-MIME type of the non-text part
• **filename** – Filename of the non-text part
• **description** – Description associated with the non-text part
• **encoding** – Content transfer encoding of the non-text part

The default value for *fmt* is **None**, meaning

```asciidoc
[Non-text (%(type)s) part of message omitted, filename %(filename)s]
```

*New in version 2.2.2.*

*Changed in version 2.5:* The previously deprecated method `__call__()` was removed.
18.1.4. **email**: Creating email and MIME objects from scratch

Ordinarily, you get a message object structure by passing a file or some text to a parser, which parses the text and returns the root message object. However you can also build a complete message structure from scratch, or even individual `Message` objects by hand. In fact, you can also take an existing structure and add new `Message` objects, move them around, etc. This makes a very convenient interface for slicing-and-dicing MIME messages.

You can create a new object structure by creating `Message` instances, adding attachments and all the appropriate headers manually. For MIME messages though, the `email` package provides some convenient subclasses to make things easier.

Here are the classes:

```python
class email.mime.base.MIMEBase(_maintype, _subtype, **_params)
Module: email.mime.base
```

This is the base class for all the MIME-specific subclasses of `Message`. Ordinarily you won’t create instances specifically of `MIMEBase`, although you could. `MIMEBase` is provided primarily as a convenient base class for more specific MIME-aware subclasses.

`_maintype` is the `Content-Type` major type (e.g. `text` or `image`), and `_subtype` is the `Content-Type` minor type (e.g. `plain` or `gif`). `_params` is a parameter key/value dictionary and is passed directly to `Message.add_header()`.

The `MIMEBase` class always adds a `Content-Type` header (based on `_maintype`, `_subtype`, and `_params`), and a `MIME-Version`
header (always set to 1.0).

```python
class email.mime.nonmultipart.MIMENonMultipart
Module: email.mime.nonmultipart
```

A subclass of MIMEBase, this is an intermediate base class for MIME messages that are not multipart. The primary purpose of this class is to prevent the use of the `attach()` method, which only makes sense for multipart messages. If `attach()` is called, a MultipartConversionError exception is raised.

*New in version 2.2.2.*

```python
class email.mime.multipart.MIMEMultipart([_subtype[, boundary[, _subparts[, _params]]]]))
Module: email.mime.multipart
```

A subclass of MIMEBase, this is an intermediate base class for MIME messages that are multipart. Optional `_subtype` defaults to mixed, but can be used to specify the subtype of the message. A Content-Type header of multipart/_subtype will be added to the message object. A MIME-Version header will also be added.

Optional `boundary` is the multipart boundary string. When `None` (the default), the boundary is calculated when needed (for example, when the message is serialized).

 `_subparts` is a sequence of initial subparts for the payload. It must be possible to convert this sequence to a list. You can always attach new subparts to the message by using the `Message.attach()` method.

Additional parameters for the Content-Type header are taken from the keyword arguments, or passed into the `_params`
argument, which is a keyword dictionary.

New in version 2.2.2.

class email.mime.application.MIMEApplication(_data[, _subtype[, _encoder[, **_params]]]])
Module: email.mime.application

A subclass of MIMENonMultipart, the MIMEApplication class is used to represent MIME message objects of major type application. _data is a string containing the raw byte data. Optional _subtype specifies the MIME subtype and defaults to octet-stream.

Optional _encoder is a callable (i.e. function) which will perform the actual encoding of the data for transport. This callable takes one argument, which is the MIMEApplication instance. It should use get_payload() and set_payload() to change the payload to encoded form. It should also add any Content-Transfer-Encoding or other headers to the message object as necessary. The default encoding is base64. See the email.encoders module for a list of the built-in encoders.

_params are passed straight through to the base class constructor.

New in version 2.5.

class email.mime.audio.MIMEAudio(_audiodata[, _subtype[, _encoder[, **_params]]]])
Module: email.mime.audio

A subclass of MIMENonMultipart, the MIMEAudio class is used to create MIME message objects of major type audio. _audiodata is
a string containing the raw audio data. If this data can be decoded by the standard Python module `sndhdr`, then the subtype will be automatically included in the *Content-Type* header. Otherwise you can explicitly specify the audio subtype via the `_subtype` parameter. If the minor type could not be guessed and `_subtype` was not given, then `TypeError` is raised.

Optional `_encoder` is a callable (i.e. function) which will perform the actual encoding of the audio data for transport. This callable takes one argument, which is the `MIMEAudio` instance. It should use `get_payload()` and `set_payload()` to change the payload to encoded form. It should also add any `Content-Transfer-Encoding` or other headers to the message object as necessary. The default encoding is base64. See the `email.encoders` module for a list of the built-in encoders.

`_params` are passed straight through to the base class constructor.

```python
class email.mime.image.MIMEImage(_imagedata[, _subtype[, _encoder[, **_params]]]])
```

Module: `email.mime.image`

A subclass of `MIMENonMultipart`, the `MIMEImage` class is used to create MIME message objects of major type `image`. _imagedata is a string containing the raw image data. If this data can be decoded by the standard Python module `imghdr`, then the subtype will be automatically included in the *Content-Type* header. Otherwise you can explicitly specify the image subtype via the `_subtype` parameter. If the minor type could not be guessed and `_subtype` was not given, then `TypeError` is raised.

Optional `_encoder` is a callable (i.e. function) which will perform the actual encoding of the image data for transport. This callable
takes one argument, which is the MIMEImage instance. It should use get_payload() and set_payload() to change the payload to encoded form. It should also add any Content-Transfer-Encoding or other headers to the message object as necessary. The default encoding is base64. See the email.encoders module for a list of the built-in encoders.

_params are passed straight through to the MIMEBase constructor.

class email.mime.message.MIMEMessage(_msg[,_subtype])

Module: email.mime.message

A subclass of MIMENonMultipart, the MIMEMessage class is used to create MIME objects of main type message. _msg is used as the payload, and must be an instance of class Message (or a subclass thereof), otherwise a TypeError is raised.

Optional _subtype sets the subtype of the message; it defaults to rfc822.

class email.mime.text.MIMEText(_text[, _subtype[, _charset]])

Module: email.mime.text

A subclass of MIMENonMultipart, the MIMEText class is used to create MIME objects of major type text. _text is the string for the payload. _subtype is the minor type and defaults to plain. _charset is the character set of the text and is passed as a parameter to the MIMENonMultipart constructor; it defaults to us-ascii. If _text is unicode, it is encoded using the output_charset of _charset, otherwise it is used as-is.

Changed in version 2.4: The previously deprecated _encoding argument has been removed. Content Transfer Encoding now happens implicitly based on the _charset argument.
18.1.5. email: Internationalized headers

RFC 2822 is the base standard that describes the format of email messages. It derives from the older RFC 822 standard which came into widespread use at a time when most email was composed of ASCII characters only. RFC 2822 is a specification written assuming email contains only 7-bit ASCII characters.

Of course, as email has been deployed worldwide, it has become internationalized, such that language specific character sets can now be used in email messages. The base standard still requires email messages to be transferred using only 7-bit ASCII characters, so a slew of RFCs have been written describing how to encode email containing non-ASCII characters into RFC 2822-compliant format. These RFCs include RFC 2045, RFC 2046, RFC 2047, and RFC 2231. The email package supports these standards in its email.header and email.charset modules.

If you want to include non-ASCII characters in your email headers, say in the Subject or To fields, you should use the Header class and assign the field in the Message object to an instance of Header instead of using a string for the header value. Import the Header class from the email.header module. For example:

```python
>>> from email.message import Message
>>> from email.header import Header
>>> msg = Message()
>>> h = Header('p\xf6stal', 'iso-8859-1')
>>> msg['Subject'] = h
>>> print msg.as_string()
Subject: =?iso-8859-1?q?p=F6stal?
```

Notice here how we wanted the Subject field to contain a non-ASCII
character? We did this by creating a `Header` instance and passing in the character set that the byte string was encoded in. When the subsequent `Message` instance was flattened, the `Subject` field was properly RFC 2047 encoded. MIME-aware mail readers would show this header using the embedded ISO-8859-1 character.

*New in version 2.2.2.*

Here is the `Header` class description:

```python
class email.header.Header([s[, charset[, maxlinelen[, header_name[, continuation_ws[, errors]]]]]])
```

Create a MIME-compliant header that can contain strings in different character sets.

Optional `s` is the initial header value. If `None` (the default), the initial header value is not set. You can later append to the header with `append()` method calls. `s` may be a byte string or a Unicode string, but see the `append()` documentation for semantics.

Optional `charset` serves two purposes: it has the same meaning as the `charset` argument to the `append()` method. It also sets the default character set for all subsequent `append()` calls that omit the `charset` argument. If `charset` is not provided in the constructor (the default), the `us-ascii` character set is used both as `s`'s initial charset and as the default for subsequent `append()` calls.

The maximum line length can be specified explicitly via `maxlinelen`. For splitting the first line to a shorter value (to account for the field header which isn't included in `s`, e.g. `Subject`) pass in the name of the field in `header_name`. The default `maxlinelen` is 76, and the default value for `header_name` is `None`, meaning it is not taken into account for the first line of a long, split header.
Optional `continuation_ws` must be **RFC 2822**-compliant folding whitespace, and is usually either a space or a hard tab character. This character will be prepended to continuation lines. `continuation_ws` defaults to a single space character (" ").

Optional `errors` is passed straight through to the `append()` method.

```python
append(s[, charset[, errors]])
```

Append the string `s` to the MIME header.

Optional `charset`, if given, should be a `Charset` instance (see `email.charset`) or the name of a character set, which will be converted to a `Charset` instance. A value of `None` (the default) means that the `charset` given in the constructor is used.

`s` may be a byte string or a Unicode string. If it is a byte string (i.e. `isinstance(s, str)` is true), then `charset` is the encoding of that byte string, and a `UnicodeError` will be raised if the string cannot be decoded with that character set.

If `s` is a Unicode string, then `charset` is a hint specifying the character set of the characters in the string. In this case, when producing an **RFC 2822**-compliant header using **RFC 2047** rules, the Unicode string will be encoded using the following charsets in order: `us-ascii`, the `charset` hint, `utf-8`. The first character set to not provoke a `UnicodeError` is used.

Optional `errors` is passed through to any `unicode()` or `ustr.encode()` call, and defaults to “strict”.

```python
encode([splitchars])
```

Encode a message header into an RFC-compliant format, possibly wrapping long lines and encapsulating non-ASCII
parts in base64 or quoted-printable encodings. Optional 
`splitchars` is a string containing characters to split long ASCII 
lines on, in rough support of RFC 2822's highest level 
syntactic breaks. This doesn’t affect RFC 2047 encoded lines.

The `Header` class also provides a number of methods to support 
standard operators and built-in functions.

```python
__str__(self)

A synonym for `Header.encode()`. Useful for `str(aHeader)`.

__unicode__(self)

A helper for the built-in `unicode()` function. Returns the 
header as a Unicode string.

__eq__(self, other)

This method allows you to compare two `Header` instances for 
equality.

__ne__(self, other)

This method allows you to compare two `Header` instances for 
inequality.
```

The `email.header` module also provides the following convenient 
functions.

```python
email.header.decode_header(header)

Decode a message header value without converting the 
character set. The header value is in `header`.

This function returns a list of `(decoded_string, charset)` pairs 
containing each of the decoded parts of the header. `charset` is 
`None` for non-encoded parts of the header, otherwise a lower case 
string containing the name of the character set specified in the 
encoded string.
Here’s an example:
>>> from email.header import decode_header
[('p\xf6stal', 'iso-8859-1')]

[, maxlinelen[,

email.header. make_header (decoded_seq

header_name[, continuation_ws]]])
Create a Header instance from a sequence of pairs as returned
by decode_header() .
takes a header value string and returns a
sequence of pairs of the format (decoded_string, charset)
where charset is the name of the character set.
decode_header()

This function takes one of those sequence of pairs and returns a
Header instance. Optional maxlinelen, header_name, and
continuation_ws are as in the Header constructor.

18.1. email — An email and MIME handling package
18.1.6. email: Representing character sets

This module provides a class `Charset` for representing character sets and character set conversions in email messages, as well as a character set registry and several convenience methods for manipulating this registry. Instances of `Charset` are used in several other modules within the `email` package.

Import this class from the `email.charset` module.

New in version 2.2.2.

```python
class email.charset.Charset([input_charset])
```

Map character sets to their email properties.

This class provides information about the requirements imposed on email for a specific character set. It also provides convenience routines for converting between character sets, given the availability of the applicable codecs. Given a character set, it will do its best to provide information on how to use that character set in an email message in an RFC-compliant way.

Certain character sets must be encoded with quoted-printable or base64 when used in email headers or bodies. Certain character sets must be converted outright, and are not allowed in email.

Optional `input_charset` is as described below; it is always coerced to lower case. After being alias normalized it is also used as a lookup into the registry of character sets to find out the header encoding, body encoding, and output conversion codec to be used for the character set. For example, if `input_charset` is `iso-8859-1`, then headers and bodies will be encoded using...
quoted-printable and no output conversion codec is necessary. If `input_charset` is `euc-jp`, then headers will be encoded with base64, bodies will not be encoded, but output text will be converted from the `euc-jp` character set to the `iso-2022-jp` character set.

`Charset` instances have the following data attributes:

**input_charset**
The initial character set specified. Common aliases are converted to their official email names (e.g. `latin_1` is converted to `iso-8859-1`). Defaults to 7-bit `us-ascii`.

**header_encoding**
If the character set must be encoded before it can be used in an email header, this attribute will be set to `Charset.QP` (for quoted-printable), `Charset.BASE64` (for base64 encoding), or `Charset.SHORTEST` for the shortest of QP or BASE64 encoding. Otherwise, it will be `None`.

**body_encoding**
Same as `header_encoding`, but describes the encoding for the mail message's body, which indeed may be different than the header encoding. `Charset.SHORTEST` is not allowed for `body_encoding`.

**output_charset**
Some character sets must be converted before they can be used in email headers or bodies. If the `input_charset` is one of them, this attribute will contain the name of the character set output will be converted to. Otherwise, it will be `None`.

**input_codec**
The name of the Python codec used to convert the `input_charset` to Unicode. If no conversion codec is
necessary, this attribute will be `None`.

**output_codec**

The name of the Python codec used to convert Unicode to the `output_charset`. If no conversion codec is necessary, this attribute will have the same value as the `input_codec`.

**Charset** instances also have the following methods:

**get_body_encoding()**

Return the content transfer encoding used for body encoding.

This is either the string `quoted-printable` or `base64` depending on the encoding used, or it is a function, in which case you should call the function with a single argument, the Message object being encoded. The function should then set the `Content-Transfer-Encoding` header itself to whatever is appropriate.

Returns the string `quoted-printable` if `body_encoding` is `QP`, returns the string `base64` if `body_encoding` is `BASE64`, and returns the string `7bit` otherwise.

**convert(s)**

Convert the string `s` from the `input_codec` to the `output_codec`.

**to_splittable(s)**

Convert a possibly multibyte string to a safely splittable format. `s` is the string to split.

Uses the `input_codec` to try and convert the string to Unicode, so it can be safely split on character boundaries (even for multibyte characters).

Returns the string as-is if it isn’t known how to convert `s` to
Unicode with the *input_charset*.

Characters that could not be converted to Unicode will be replaced with the Unicode replacement character 'U+FFFD'.

**from_splitable(ustr[, to_output])**

Convert a splittable string back into an encoded string. *ustr* is a Unicode string to “unsplit”.

This method uses the proper codec to try and convert the string from Unicode back into an encoded format. Return the string as-is if it is not Unicode, or if it could not be converted from Unicode.

Characters that could not be converted from Unicode will be replaced with an appropriate character (usually '?').

If *to_output* is True (the default), uses *output_codec* to convert to an encoded format. If *to_output* is False, it uses *input_codec*.

**get_output_charset()**

Return the output character set.

This is the *output_charset* attribute if that is not None, otherwise it is *input_charset*.

**encoded_header_len()**

Return the length of the encoded header string, properly calculating for quoted-printable or base64 encoding.

**header_encode(s[, convert])**

Header-encode the string *s*.

If *convert* is True, the string will be converted from the input
charset to the output charset automatically. This is not useful for multibyte character sets, which have line length issues (multibyte characters must be split on a character, not a byte boundary); use the higher-level Header class to deal with these issues (see email.header). convert defaults to False.

The type of encoding (base64 or quoted-printable) will be based on the header_encoding attribute.

body_encode(s[, convert])
Body-encode the string s.

If convert is True (the default), the string will be converted from the input charset to output charset automatically. Unlike header_encode(), there are no issues with byte boundaries and multibyte charsets in email bodies, so this is usually pretty safe.

The type of encoding (base64 or quoted-printable) will be based on the body_encoding attribute.

The Charset class also provides a number of methods to support standard operations and built-in functions.

__str__()
Returns input_charset as a string coerced to lower case. __repr__() is an alias for __str__().

__eq__(other)
This method allows you to compare two Charset instances for equality.

__ne__(other)
This method allows you to compare two Charset instances for inequality.
The `email.charset` module also provides the following functions for adding new entries to the global character set, alias, and codec registries:

```python
email.charset.add_charset(charset[, header_enc[, body_enc[, output_charset]]])
```

Add character properties to the global registry.

`charset` is the input character set, and must be the canonical name of a character set.

Optional `header_enc` and `body_enc` is either `Charset.QP` for quoted-printable, `Charset.BASE64` for base64 encoding, `Charset.SHORTEST` for the shortest of quoted-printable or base64 encoding, or `None` for no encoding. `SHORTEST` is only valid for `header_enc`. The default is `None` for no encoding.

Optional `output_charset` is the character set that the output should be in. Conversions will proceed from input charset, to Unicode, to the output charset when the method `Charset.convert()` is called. The default is to output in the same character set as the input.

Both `input_charset` and `output_charset` must have Unicode codec entries in the module's character set-to-codec mapping; use `add_codec()` to add codecs the module does not know about. See the `codecs` module's documentation for more information.

The global character set registry is kept in the module global dictionary `CHARSETS`.

```python
email.charset.add_alias(alias, canonical)
```

Add a character set alias. `alias` is the alias name, e.g. `latin-1`. `canonical` is the character set's canonical name, e.g. `iso-8859-1`.
The global charset alias registry is kept in the module global dictionary `ALIASES`.

```
email.charset.add_codec(charset, codecname)
```

Add a codec that map characters in the given character set to and from Unicode.

*charset* is the canonical name of a character set. *codecname* is the name of a Python codec, as appropriate for the second argument to the `unicode()` built-in, or to the `encode()` method of a Unicode string.
18.1.7. email: Encoders

When creating `Message` objects from scratch, you often need to encode the payloads for transport through compliant mail servers. This is especially true for `image/*` and `text/*` type messages containing binary data.

The `email` package provides some convenient encodings in its `encoders` module. These encoders are actually used by the `MIMEAudio` and `MIMEImage` class constructors to provide default encodings. All encoder functions take exactly one argument, the message object to encode. They usually extract the payload, encode it, and reset the payload to this newly encoded value. They should also set the `Content-Transfer-Encoding` header as appropriate.

Here are the encoding functions provided:

```python
email.encoders.encode_quopri(msg)
```

Encodes the payload into quoted-printable form and sets the `Content-Transfer-Encoding` header to `quoted-printable` [1]. This is a good encoding to use when most of your payload is normal printable data, but contains a few unprintable characters.

```python
email.encoders.encode_base64(msg)
```

Encodes the payload into base64 form and sets the `Content-Transfer-Encoding` header to `base64`. This is a good encoding to use when most of your payload is unprintable data since it is a more compact form than quoted-printable. The drawback of base64 encoding is that it renders the text non-human readable.

```python
email.encoders.encode_7or8bit(msg)
```

This doesn’t actually modify the message’s payload, but it does set the `Content-Transfer-Encoding` header to either `7bit` or `8bit`
as appropriate, based on the payload data.

e-mail.encoders.\texttt{encode\_noop}(msg)

This does nothing; it doesn't even set the \texttt{Content-Transfer-Encoding} header.

Footnotes

[1] Note that encoding with \texttt{encode\_quopri()} also encodes all tabs and space characters in the data.
18.1. **email** — An email and MIME handling package
18.1.8. email: Exception and Defect classes

The following exception classes are defined in the email.errors module:

```python
exception email.errors.MessageError
    This is the base class for all exceptions that the email package can raise. It is derived from the standard Exception class and defines no additional methods.

exception email.errors.MessageParseError
    This is the base class for exceptions raised by the Parser class. It is derived from MessageError.

exception email.errors.HeaderParseError
    Raised under some error conditions when parsing the RFC 2822 headers of a message, this class is derived from MessageParseError. It can be raised from the Parser.parse() or Parser.parsestr() methods.

Situations where it can be raised include finding an envelope header after the first RFC 2822 header of the message, finding a continuation line before the first RFC 2822 header is found, or finding a line in the headers which is neither a header or a continuation line.

exception email.errors.BoundaryError
    Raised under some error conditions when parsing the RFC 2822 headers of a message, this class is derived from MessageParseError. It can be raised from the Parser.parse() or Parser.parsestr() methods.
```
Situations where it can be raised include not being able to find the starting or terminating boundary in a `multipart/*` message when strict parsing is used.

`exception` `email.errors.MultipartConversionError`

Raised when a payload is added to a `Message` object using `add_payload()`, but the payload is already a scalar and the message’s `Content-Type` main type is not either `multipart` or missing. `MultipartConversionError` multiply inherits from `MessageError` and the built-in `TypeError`.

Since `Message.add_payload()` is deprecated, this exception is rarely raised in practice. However the exception may also be raised if the `attach()` method is called on an instance of a class derived from `MIMENonMultipart` (e.g. `MIMEImage`).

Here’s the list of the defects that the `FeedParser` can find while parsing messages. Note that the defects are added to the message where the problem was found, so for example, if a message nested inside a `multipart/alternative` had a malformed header, that nested message object would have a defect, but the containing messages would not.

All defect classes are subclassed from `email.errors.MessageDefect`, but this class is *not* an exception!

`New in version 2.4`: All the defect classes were added.

- `NoBoundaryInMultipartDefect` – A message claimed to be a multipart, but had no `boundary` parameter.
- `StartBoundaryNotFoundDefect` – The start boundary claimed in the `Content-Type` header was never found.
- `FirstHeaderLineIsContinuationDefect` – The message had a continuation line as its first header line.
- **MisplacedEnvelopeHeaderDefect** - A “Unix From” header was found in the middle of a header block.
- **MalformedHeaderDefect** – A header was found that was missing a colon, or was otherwise malformed.
- **MultipartInvariantViolationDefect** – A message claimed to be a *multipart*, but no subparts were found. Note that when a message has this defect, its `is_multipart()` method may return false even though its content type claims to be *multipart*. 
18.1.9. email: Miscellaneous utilities

There are several useful utilities provided in the `email.utils` module:

```python
email.utils.quote(str)
```
Return a new string with backslashes in `str` replaced by two backslashes, and double quotes replaced by backslash-double quote.

```python
email.utils.unquote(str)
```
Return a new string which is an unquoted version of `str`. If `str` ends and begins with double quotes, they are stripped off. Likewise if `str` ends and begins with angle brackets, they are stripped off.

```python
email.utils.parseaddr(address)
```
Parse address – which should be the value of some address-containing field such as `To` or `Cc` – into its constituent `realname` and `email address` parts. Returns a tuple of that information, unless the parse fails, in which case a 2-tuple of ('', '') is returned.

```python
email.utils.formataddr(pair)
```
The inverse of `parseaddr()`, this takes a 2-tuple of the form (realname, email_address) and returns the string value suitable for a `To` or `Cc` header. If the first element of `pair` is false, then the second element is returned unmodified.

```python
email.utils.getaddresses(fieldvalues)
```
This method returns a list of 2-tuples of the form returned by `parseaddr()`. `fieldvalues` is a sequence of header field values as might be returned by `Message.get_all()`. Here's a simple example that gets all the recipients of a message:
from email.utils import getaddresses

tos = msg.get_all('to', [])
ccs = msg.get_all('cc', [])
resent_tos = msg.get_all('resent-to', [])
resent_ccs = msg.get_all('resent-cc', [])
all_recipients = getaddresses(tos + ccs + resent_tos + resent_ccs)

email.utils.parsedate(date)
Attempts to parse a date according to the rules in RFC 2822. However, some mailers don't follow that format as specified, so parsedate() tries to guess correctly in such cases. date is a string containing an RFC 2822 date, such as "Mon, 20 Nov 1995 19:12:08 -0500". If it succeeds in parsing the date, parsedate() returns a 9-tuple that can be passed directly to time.mktime(); otherwise None will be returned. Note that indexes 6, 7, and 8 of the result tuple are not usable.

email.utils.parsedate_tz(date)
Performs the same function as parsedate(), but returns either None or a 10-tuple; the first 9 elements make up a tuple that can be passed directly to time.mktime(), and the tenth is the offset of the date's timezone from UTC (which is the official term for Greenwich Mean Time) [1]. If the input string has no timezone, the last element of the tuple returned is None. Note that indexes 6, 7, and 8 of the result tuple are not usable.

email.utils.mktime_tz(tuple)
Turn a 10-tuple as returned by parsedate_tz() into a UTC timestamp. If the timezone item in the tuple is None, assume local time. Minor deficiency: mktime_tz() interprets the first 8 elements of tuple as a local time and then compensates for the timezone difference. This may yield a slight error around changes in daylight savings time, though not worth worrying about for
common use.

```python
email.utils.formatdate([timeval[, localtime][, usegmt]])
```

Returns a date string as per **RFC 2822**, e.g.:

```
Fri, 09 Nov 2001 01:08:47 -0000
```

Optional `timeval` if given is a floating point time value as accepted by `time.gmtime()` and `time.localtime()`, otherwise the current time is used.

Optional `localtime` is a flag that when `True`, interprets `timeval`, and returns a date relative to the local timezone instead of UTC, properly taking daylight savings time into account. The default is `False` meaning UTC is used.

Optional `usegmt` is a flag that when `True`, outputs a date string with the timezone as an ascii string `GMT`, rather than a numeric `-0000`. This is needed for some protocols (such as HTTP). This only applies when `localtime` is `False`. The default is `False`.

*New in version 2.4.*

```python
email.utils.make_msgid([idstring])
```

Returns a string suitable for an **RFC 2822**-compliant *Message-ID* header. Optional `idstring` if given, is a string used to strengthen the uniqueness of the message id.

```python
email.utils.decode_rfc2231(s)
```

Decode the string `s` according to **RFC 2231**.

```python
email.utils.encode_rfc2231(s[, charset[, language]])
```

Encode the string `s` according to **RFC 2231**. Optional `charset` and `language`, if given is the character set name and language name.
to use. If neither is given, s is returned as-is. If charset is given but language is not, the string is encoded using the empty string for language.

```python
email.utils.collapse_rfc2231_value(value[, errors[, fallback_charset]])
```

When a header parameter is encoded in RFC 2231 format, `Message.get_param()` may return a 3-tuple containing the character set, language, and value. `collapse_rfc2231_value()` turns this into a unicode string. Optional `errors` is passed to the `errors` argument of the built-in `unicode()` function; it defaults to `replace`. Optional `fallback_charset` specifies the character set to use if the one in the RFC 2231 header is not known by Python; it defaults to `us-ascii`.

For convenience, if the `value` passed to `collapse_rfc2231_value()` is not a tuple, it should be a string and it is returned unquoted.

```python
email.utils.decode_params(params)
```

Decode parameters list according to RFC 2231. `params` is a sequence of 2-tuples containing elements of the form `(content-type, string-value)`.

*Changed in version 2.4:* The `dump_address_pair()` function has been removed; use `formataddr()` instead.

*Changed in version 2.4:* The `decode()` function has been removed; use the `Header.decode_header()` method instead.

*Changed in version 2.4:* The `encode()` function has been removed; use the `Header.encode()` method instead.
Footnotes

[1] Note that the sign of the timezone offset is the opposite of the sign of the `time.timezone` variable for the same timezone; the latter variable follows the POSIX standard while this module follows RFC 2822.
Iterating over a message object tree is fairly easy with the `Message.walk()` method. The `email.iterators` module provides some useful higher level iterations over message object trees.

**email.iterators.body_line_iterator**

This iterates over all the payloads in all the subparts of `msg`, returning the string payloads line-by-line. It skips over all the subpart headers, and it skips over any subpart with a payload that isn’t a Python string. This is somewhat equivalent to reading the flat text representation of the message from a file using `readline()`, skipping over all the intervening headers.

Optional `decode` is passed through to `Message.get_payload()`.

**email.iterators.typed_subpart_iterator**

This iterates over all the subparts of `msg`, returning only those subparts that match the MIME type specified by `maintype` and `subtype`.

Note that `subtype` is optional; if omitted, then subpart MIME type matching is done only with the main type. `maintype` is optional too; it defaults to `text`.

Thus, by default `typed_subpart_iterator()` returns each subpart that has a MIME type of `text/*`.

The following function has been added as a useful debugging tool. It should not be considered part of the supported public interface for the package.
email.iterators._structure(msg[, fp[, level]])

Prints an indented representation of the content types of the message object structure. For example:

```python
>>> msg = email.message_from_file(somefile)
>>> _structure(msg)
multipart/mixed
text/plain
text/plain
multipart/digest
  message/rfc822
text/plain
  message/rfc822
text/plain
  message/rfc822
text/plain
  message/rfc822
text/plain
  text/plain
  text/plain
```

Optional `fp` is a file-like object to print the output to. It must be suitable for Python’s extended print statement. `level` is used internally.
18.1.11. email: Examples

Here are a few examples of how to use the email package to read, write, and send simple email messages, as well as more complex MIME messages.

First, let's see how to create and send a simple text message:

```python
# Import smtplib for the actual sending function
import smtplib

# Import the email modules we'll need
from email.mime.text import MIMEText

# Open a plain text file for reading. For this example, assume
# the text file contains only ASCII characters.
fp = open('textfile', 'rb')
# Create a text/plain message
msg = MIMEText(fp.read())
fp.close()

# me == the sender's email address
# you == the recipient's email address
msg['Subject'] = 'The contents of %s' % textfile
msg['From'] = me
msg['To'] = you

# Send the message via our own SMTP server, but don't include the
# envelope header.
s = smtplib.SMTP('localhost')
s.sendmail(me, [you], msg.as_string())
s.quit()
```

And parsing RFC822 headers can easily be done by the parse(filename) or parsestr(message_as_string) methods of the Parser() class:

```python
# Import the email modules we'll need
from email.parser import Parser
```
# If the e-mail headers are in a file, uncomment this line:
#headers = Parser().parse(open(messagefile, 'r'))

# Or for parsing headers in a string, use:
headers = Parser().parsestr('From: <user@example.com>
  To: <someone_else@example.com>
  Subject: Test message
  
  Body would go here
')

# Now the header items can be accessed as a dictionary:
print 'To: %s' % headers['to']
print 'From: %s' % headers['from']
print 'Subject: %s' % headers['subject']

Here's an example of how to send a MIME message containing a bunch of family pictures that may be residing in a directory:

# Import smtplib for the actual sending function
import smtplib

# Here are the email package modules we'll need
from email.mime.image import MIMEImage
from email.mime.multipart import MIMEMultipart

COMMASPACE = ', '

# Create the container (outer) email message.
msg = MIMEMultipart()
msg['Subject'] = 'Our family reunion'
# me == the sender's email address
# family == the list of all recipients' email addresses
msg['From'] = me
msg['To'] = COMMASPACE.join(family)
msg.preamble = 'Our family reunion'

# Assume we know that the image files are all in PNG format
for file in pngfiles:
    # Open the files in binary mode. Let the MIMEImage class a
guess the specific image type.
    fp = open(file, 'rb')
    img = MIMEImage(fp.read())
    fp.close()
    msg.attach(img)
Here's an example of how to send the entire contents of a directory as an email message:

```python
#!/usr/bin/env python

"""Send the contents of a directory as a MIME message."""

import os
import sys
import smtplib
# For guessing MIME type based on file name extension
import mimetypes

from optparse import OptionParser
from email import encoders
from email.message import Message
from email.mime.audio import MIMEAudio
from email.mime.base import MIMEBase
from email.mime.image import MIMEImage
from email.mime.multipart import MIMEMultipart
from email.mime.text import MIMEText

COMMASPACE = ',

def main():
    parser = OptionParser(usage="""
    Send the contents of a directory as a MIME message.

    Usage: %prog [options]

    Unless the -o option is given, the email is sent by forwarding SMTP server, which then does the normal delivery process. Your machine must be running an SMTP server.
    """
    parser.add_option('-d', '--directory',
                      type='string', action='store',
                      help="""Mail the contents of the specified directory as a MIME message. Only the regular files in the directory are included."
                      
                      If the -o option is specified, the specified string will be sent as the message.
                      
                      You can use Python's built-in sendmail function for this.
                      
                      
                      The -o option can be used to specify a different SMTP server to use.
                      
                      
                      You can use Python's built-in sendmail function for this.
                      
                      Use the -h option to get more information.
                      """
    parser.add_option('-o', '--smtp',
                      type='string', action='store',
                      help="""Specify the SMTP server to use."
                      
                      If the -o option is specified, the specified string will be sent as the message.
                      
                      You can use Python's built-in sendmail function for this.
                      
                      Use the -h option to get more information.
                      """

    # Send the email via our own SMTP server.
    s = smtplib.SMTP('localhost')
    s.sendmail(me, family, msg.as_string())
    s.quit()
```
msg = MIMEImage(fp.read(), _subtype=subtype)
fp.close()

elif maintype == 'audio':
    fp = open(path, 'rb')
    msg = MIMEAudio(fp.read(), _subtype=subtype)
    fp.close()
else:
    fp = open(path, 'rb')
    msg = MIMEBase(maintype, subtype)
    msg.set_payload(fp.read())
    fp.close()

    # Encode the payload using Base64
    # Set the filename parameter
    msg.add_header('Content-Disposition', 'attachment', filename=outer)
    outer.attach(msg)

    # Now send or store the message
    composed = outer.as_string()

if opts.output:
    fp = open(opts.output, 'w')
    fp.write(composed)
    fp.close()
else:
    s = smtplib.SMTP('localhost')
    s.sendmail(opts.sender, opts.recipients, composed)
    s.quit()

if __name__ == '__main__':
    main()
def main():
    parser = OptionParser(usage="Unpack a MIME message into a directory of files.
Usage: %prog [options] msgfile
"
    parser.add_option('-d', '--directory',
                      type='string', action='store',
                      help="Unpack the MIME message into the directory, which will be created if it do
                      exist.""
    )
    opts, args = parser.parse_args()
    if not opts.directory:
        parser.print_help()
        sys.exit(1)

    try:
        msgfile = args[0]
    except IndexError:
        parser.print_help()
        sys.exit(1)

    try:
        os.mkdir(opts.directory)
    except OSError, e:
        # Ignore directory exists error
        if e.errno != errno.EEXIST:
            raise

    fp = open(msgfile)
    msg = email.message_from_file(fp)
    fp.close()

    counter = 1
    for part in msg.walk():
        # multipart/* are just containers
        if part.get_content_maintype() == 'multipart':
            continue

        # Applications should really sanitize the given filename
        # email message can't be used to overwrite important file
        filename = part.get_filename()
        if not filename:
            ext = mimetypes.guess_extension(part.get_content_type())
            if not ext:
                # Use a generic bag-of-bits extension
Here's an example of how to create an HTML message with an alternative plain text version: [2]

```python
#!/usr/bin/env python

import smtplib
from email.mime.multipart import MIMEMultipart
from email.mime.text import MIMEText

# me == my email address
# you == recipient's email address
me = "my@email.com"
you = "your@email.com"

msg = MIMEMultipart('alternative')
msg['Subject'] = "Link"
msg['From'] = me
msg['To'] = you

text = "Hi!
How are you?
Here is the link you wanted:
http://www.python.org"

html = """"
<html>
  <head></head>
  <body>
    <p>Hi!<br>
       How are you?<br>
       Here is the <a href="http://www.python.org">link</a> you
    </p>
  </body>
</html>

"""
```
Record the MIME types of both parts - text/plain and text/html.

```python
part1 = MIMEText(text, 'plain')
part2 = MIMEText(html, 'html')
```

Attach parts into message container.

According to RFC 2046, the last part of a multipart message, the HTML message, is best and preferred.

```python
msg.attach(part1)
msg.attach(part2)
```

Send the message via local SMTP server.

```python
s = smtplib.SMTP('localhost')
s.sendmail(me, you, msg.as_string())
s.quit()
```

Footnotes

[1] Thanks to Matthew Dixon Cowles for the original inspiration and examples.

18.2. json — JSON encoder and decoder

New in version 2.6.

JSON (JavaScript Object Notation) is a subset of JavaScript syntax (ECMA-262 3rd edition) used as a lightweight data interchange format.

json exposes an API familiar to users of the standard library marshal and pickle modules.

Encoding basic Python object hierarchies:

```python
>>> import json
>>> json.dumps(['foo', {'bar': ('baz', None, 1.0, 2)}])
'["foo", {"bar": ["baz", null, 1.0, 2]}]
>>> print json.dumps("\"foo\bar\"")
"foo\bar"
>>> print json.dumps(u'\u1234')
'\u1234'
>>> print json.dumps('\\')
'\'
>>> print json.dumps({'c': 0, 'b': 0, 'a': 0}, sort_keys=True)
{'a': 0, 'b': 0, 'c': 0}
>>> from StringIO import StringIO
>>> io = StringIO()
>>> json.dump(['streaming API'], io)
>>> io.getvalue()
'"streaming API"
```

Compact encoding:

```python
>>> import json
>>> json.dumps([1,2,3,{'4': 5, '6': 7}], separators=(',',':')
'[1,2,3,{"4":5,"6":7}]'
```

Pretty printing:

```python
>>> import json
>>> json.dumps([1,2,3,{'4': 5, '6': 7}], separators=(',',':')
'[1,2,3,{"4":5,"6":7}]'
```
Decoding JSON:

```python
>>> import json
>>> json.loads('["foo", {"bar":["baz", null, 1.0, 2]}]
[u'foo', {u'bar': [u'baz', None, 1.0, 2]}]
>>> json.loads('"foo\nbar")
u'foo\08ar
>>> from StringIO import StringIO
>>> io = StringIO('"streaming API"')
>>> json.load(io)
[u'streaming API']
```

Specializing JSON object decoding:

```python
>>> import json
>>> def as_complex(dct):
...     if '__complex__' in dct:
...         return complex(dct['real'], dct['imag'])
...     return dct
...
>>> json.loads('{"__complex__": true, "real": 1, "imag": 2}', object_hook=as_complex)
(1+2j)
>>> import decimal
>>> json.loads('1.1', parse_float=decimal.Decimal)
Decimal('1.1')
```

Extending JSONEncoder:

```python
>>> import json
>>> class ComplexEncoder(json.JSONEncoder):
...     def default(self, obj):
...         if isinstance(obj, complex):
...             return [obj.real, obj.imag]
...         return json.JSONEncoder.default(self, obj)
...```
>>> dumps(2 + 1j, cls=ComplexEncoder)
'2.0, 1.0]
>>> ComplexEncoder().encode(2 + 1j)
'2.0, 1.0]
>>> list(ComplexEncoder().iterencode(2 + 1j))
'['2.0, ',', ',', '1.0', ',']'

Using json.tool from the shell to validate and pretty-print:

$ echo '{"json":"obj"}' | python -mjson.tool
{
    "json": "obj"
}
$ echo '{1.2:3.4}' | python -mjson.tool
Expecting property name: line 1 column 2 (char 2)

**Note:** The JSON produced by this module’s default settings is a subset of YAML, so it may be used as a serializer for that as well.
18.2.1. Basic Usage

```python
json.dump(obj, fp[, skipkeys[, ensure_ascii[, check_circular[, allow_nan[, cls[, indent[, separators[, encoding[, default[, **kw]]]]]]]]]])
```

Serialize `obj` as a JSON formatted stream to `fp` (a `write()`-supporting file-like object).

If `skipkeys` is `True` (default: `False`), then dict keys that are not of a basic type (`str`, `unicode`, `int`, `long`, `float`, `bool`, `None`) will be skipped instead of raising a `TypeError`.

If `ensure_ascii` is `False` (default: `True`), then some chunks written to `fp` may be `unicode` instances, subject to normal Python `str` to `unicode` coercion rules. Unless `fp.write()` explicitly understands `unicode` (as in `codecs.getwriter()`) this is likely to cause an error.

If `check_circular` is `False` (default: `True`), then the circular reference check for container types will be skipped and a circular reference will result in an `OverflowError` (or worse).

If `allow_nan` is `False` (default: `True`), then it will be a `ValueError` to serialize out of range `float` values (`nan`, `inf`, `-inf`) in strict compliance of the JSON specification, instead of using the JavaScript equivalents (`NaN`, `Infinity`, `-Infinity`).

If `indent` is a non-negative integer, then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0, or negative, will only insert newlines. `None` (the default) selects the most compact representation.

If `separators` is an `(item_separator, dict_separator)` tuple, then
it will be used instead of the default (',', ':') separators. ('', ', ', ':') is the most compact JSON representation.

`encoding` is the character encoding for str instances, default is UTF-8.

`default(obj)` is a function that should return a serializable version of `obj` or raise `TypeError`. The default simply raises `TypeError`.

To use a custom `JSONEncoder` subclass (e.g. one that overrides the `default()` method to serialize additional types), specify it with the `cls` kwarg; otherwise `JSONEncoder` is used.

**Note:** Unlike `pickle` and `marshal`, JSON is not a framed protocol so trying to serialize more objects with repeated calls to `dump()` and the same `fp` will result in an invalid JSON file.

```python
json.dumps(obj[, skipkeys[, ensure_ascii[, check_circular[, allow_nan[, cls[, indent[, separators[, encoding[, default[, **kw]]]]]]]]]]
```

Serialize `obj` to a JSON formatted `str`.

If `ensure_ascii` is False, then the return value will be a `unicode` instance. The other arguments have the same meaning as in `dump()`.

```python
json.load(fp[, encoding[, cls[, object_hook[, parse_float[, parse_int[, parse_constant[, object_pairs_hook[, **kw]]]]]]]]
```

Deserializes `fp` (a `.read()`-supporting file-like object containing a JSON document) to a Python object.

If the contents of `fp` are encoded with an ASCII based encoding.
other than UTF-8 (e.g. latin-1), then an appropriate encoding name must be specified. Encodings that are not ASCII based (such as UCS-2) are not allowed, and should be wrapped with codecs.getreader(encoding)(fp), or simply decoded to a unicode object and passed to loads().

object_hook is an optional function that will be called with the result of any object literal decoded (a dict). The return value of object_hook will be used instead of the dict. This feature can be used to implement custom decoders (e.g. JSON-RPC class hinting).

object_pairs_hook is an optional function that will be called with the result of any object literal decoded with an ordered list of pairs. The return value of object_pairs_hook will be used instead of the dict. This feature can be used to implement custom decoders that rely on the order that the key and value pairs are decoded (for example, collections.OrderedDict() will remember the order of insertion). If object_hook is also defined, the object_pairs_hook takes priority.

Changed in version 2.7: Added support for object_pairs_hook.

parse_float, if specified, will be called with the string of every JSON float to be decoded. By default, this is equivalent to float(num_str). This can be used to use another datatype or parser for JSON floats (e.g. decimal.Decimal).

parse_int, if specified, will be called with the string of every JSON int to be decoded. By default, this is equivalent to int(num_str). This can be used to use another datatype or parser for JSON integers (e.g. float).

parse_constant, if specified, will be called with one of the
following strings: '-Infinity', 'Infinity', 'NaN', 'null', 'true', 'false'. This can be used to raise an exception if invalid JSON numbers are encountered.

To use a custom JSONDecoder subclass, specify it with the cls kwarg; otherwise JSONDecoder is used. Additional keyword arguments will be passed to the constructor of the class.

```python
json.loads(s[, encoding[, cls[, object_hook[, parse_float[, parse_int[, parse_constant[, object_pairs_hook[, **kw]]]]]]]])
```

Deserialize s (a str or unicode instance containing a JSON document) to a Python object.

If s is a str instance and is encoded with an ASCII based encoding other than UTF-8 (e.g. latin-1), then an appropriate encoding name must be specified. Encodings that are not ASCII based (such as UCS-2) are not allowed and should be decoded to unicode first.

The other arguments have the same meaning as in load().
18.2.2. Encoders and decoders

```python
class json.JSONDecoder([encoding[, object_hook[, parse_float[, parse_int[, parse_constant[, strict[, object_pairs_hook]]]]]]])
```

Simple JSON decoder.

Performs the following translations in decoding by default:

<table>
<thead>
<tr>
<th>JSON</th>
<th>Python</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>dict</td>
</tr>
<tr>
<td>array</td>
<td>list</td>
</tr>
<tr>
<td>string</td>
<td>unicode</td>
</tr>
<tr>
<td>number (int)</td>
<td>int, long</td>
</tr>
<tr>
<td>number (real)</td>
<td>float</td>
</tr>
<tr>
<td>true</td>
<td>True</td>
</tr>
<tr>
<td>false</td>
<td>False</td>
</tr>
<tr>
<td>null</td>
<td>None</td>
</tr>
</tbody>
</table>

It also understands NaN, Infinity, and -Infinity as their corresponding float values, which is outside the JSON spec.

`encoding` determines the encoding used to interpret any str objects decoded by this instance (UTF-8 by default). It has no effect when decoding unicode objects.

Note that currently only encodings that are a superset of ASCII work, strings of other encodings should be passed in as unicode.

`object_hook`, if specified, will be called with the result of every JSON object decoded and its return value will be used in place of the given dict. This can be used to provide custom deserializations (e.g. to support JSON-RPC class hinting).
object_pairs_hook, if specified will be called with the result of every JSON object decoded with an ordered list of pairs. The return value of object_pairs_hook will be used instead of the dict. This feature can be used to implement custom decoders that rely on the order that the key and value pairs are decoded (for example, collections.OrderedDict() will remember the order of insertion). If object_hook is also defined, the object_pairs_hook takes priority.

Changed in version 2.7: Added support for object_pairs_hook.

parse_float, if specified, will be called with the string of every JSON float to be decoded. By default, this is equivalent to float(num_str). This can be used to use another datatype or parser for JSON floats (e.g. decimal.Decimal).

parse_int, if specified, will be called with the string of every JSON int to be decoded. By default, this is equivalent to int(num_str). This can be used to use another datatype or parser for JSON integers (e.g. float).

parse_constant, if specified, will be called with one of the following strings: '-Infinity', 'Infinity', 'NaN', 'null', 'true', 'false'. This can be used to raise an exception if invalid JSON numbers are encountered.

If strict is False (True is the default), then control characters will be allowed inside strings. Control characters in this context are those with character codes in the 0-31 range, including \	 (tab), \n, \r and \0.

decode(s)

Return the Python representation of s (a str or unicode instance containing a JSON document)
raw_decode(s)

Decode a JSON document from s (a str or unicode beginning with a JSON document) and return a 2-tuple of the Python representation and the index in s where the document ended.

This can be used to decode a JSON document from a string that may have extraneous data at the end.

class json. JSONEncoder([skipkeys[0], ensure_ascii[1], check_circular[2], allow_nan[3], sort_keys[4], indent[5], separators[6], encoding[7], default[8]])

Extensible JSON encoder for Python data structures.

Supports the following objects and types by default:

<table>
<thead>
<tr>
<th>Python</th>
<th>JSON</th>
</tr>
</thead>
<tbody>
<tr>
<td>dict</td>
<td>object</td>
</tr>
<tr>
<td>list, tuple</td>
<td>array</td>
</tr>
<tr>
<td>str, unicode</td>
<td>string</td>
</tr>
<tr>
<td>int, long, float</td>
<td>number</td>
</tr>
<tr>
<td>True</td>
<td>true</td>
</tr>
<tr>
<td>False</td>
<td>false</td>
</tr>
<tr>
<td>None</td>
<td>null</td>
</tr>
</tbody>
</table>

To extend this to recognize other objects, subclass and implement a default() method with another method that returns a serializable object for o if possible, otherwise it should call the superclass implementation (to raise TypeError).

If skipkeys is False (the default), then it is a TypeError to attempt encoding of keys that are not str, int, long, float or None. If skipkeys is True, such items are simply skipped.

If ensure_ascii is True (the default), the output is guaranteed to
be str objects with all incoming unicode characters escaped. If ensure_ascii is False, the output will be a unicode object.

If check_circular is True (the default), then lists, dicts, and custom encoded objects will be checked for circular references during encoding to prevent an infinite recursion (which would cause an OverflowError). Otherwise, no such check takes place.

If allow_nan is True (the default), then NaN, Infinity, and -Infinity will be encoded as such. This behavior is not JSON specification compliant, but is consistent with most JavaScript based encoders and decoders. Otherwise, it will be a ValueError to encode such floats.

If sort_keys is True (default False), then the output of dictionaries will be sorted by key; this is useful for regression tests to ensure that JSON serializations can be compared on a day-to-day basis.

If indent is a non-negative integer (it is None by default), then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0 will only insert newlines. None is the most compact representation.

If specified, separators should be an (item_separator, key_separator) tuple. The default is (',', ':'). To get the most compact JSON representation, you should specify (',', ':') to eliminate whitespace.

If specified, default is a function that gets called for objects that can’t otherwise be serialized. It should return a JSON encodable version of the object or raise a TypeError.

If encoding is not None, then all input strings will be transformed into unicode using that encoding prior to JSON-encoding. The
default is UTF-8.

**default(o)**

Implement this method in a subclass such that it returns a serializable object for `o`, or calls the base implementation (to raise a `TypeError`).

For example, to support arbitrary iterators, you could implement `default` like this:

```python
def default(self, o):
    try:
        iterable = iter(o)
    except TypeError:
        pass
    else:
        return list(iterable)
    return JSONEncoder.default(self, o)
```

**encode(o)**

Return a JSON string representation of a Python data structure, `o`. For example:

```python
>>> JSONEncoder().encode({"foo": ["bar", "baz"]})
'{"foo": ["bar", "baz"]}'
```

**iterencode(o)**

Encode the given object, `o`, and yield each string representation as available. For example:

```python
for chunk in JSONEncoder().iterencode(bigobject):
    mysocket.write(chunk)
```
Mailcap files are used to configure how MIME-aware applications such as mail readers and Web browsers react to files with different MIME types. (The name “mailcap” is derived from the phrase “mail capability”.) For example, a mailcap file might contain a line like `video/mpeg; xmpeg %s`. Then, if the user encounters an email message or Web document with the MIME type `video/mpeg`, `%s` will be replaced by a filename (usually one belonging to a temporary file) and the `xmpeg` program can be automatically started to view the file.

The mailcap format is documented in RFC 1524, “A User Agent Configuration Mechanism For Multimedia Mail Format Information,” but is not an Internet standard. However, mailcap files are supported on most Unix systems.

```
mailcap.findmatch(caps, MIMEtype[, key[, filename[, plist]]])
```

Return a 2-tuple; the first element is a string containing the command line to be executed (which can be passed to `os.system()`), and the second element is the mailcap entry for a given MIME type. If no matching MIME type can be found, `(None, None)` is returned.

`key` is the name of the field desired, which represents the type of activity to be performed; the default value is ‘view’, since in the most common case you simply want to view the body of the MIME-typed data. Other possible values might be ‘compose’ and ‘edit’, if you wanted to create a new body of the given MIME type or alter the existing body data. See RFC 1524 for a complete list of these fields.
*filename* is the filename to be substituted for *%s* in the command line; the default value is '*/dev/null*' which is almost certainly not what you want, so usually you'll override it by specifying a filename.

*plist* can be a list containing named parameters; the default value is simply an empty list. Each entry in the list must be a string containing the parameter name, an equals sign ('='), and the parameter’s value. Mailcap entries can contain named parameters like *%{foo}* , which will be replaced by the value of the parameter named ‘foo’. For example, if the command line *showpartial %{id} %{number} %{total}* was in a mailcap file, and *plist* was set to ['id=1', 'number=2', 'total=3'], the resulting command line would be 'showpartial 1 2 3'.

In a mailcap file, the “test” field can optionally be specified to test some external condition (such as the machine architecture, or the window system in use) to determine whether or not the mailcap line applies. *findmatch()* will automatically check such conditions and skip the entry if the check fails.

**mailcap.getcaps()**

Returns a dictionary mapping MIME types to a list of mailcap file entries. This dictionary must be passed to the *findmatch()* function. An entry is stored as a list of dictionaries, but it shouldn’t be necessary to know the details of this representation.

The information is derived from all of the mailcap files found on the system. Settings in the user’s mailcap file $HOME/.mailcap will override settings in the system mailcap files /etc/mailcap, /usr/etc/mailcap, and /usr/local/etc/mailcap.

An example usage:
>>> import mailcap
>>> d=mailcap.getcaps()
>>> mailcap.findmatch(d, 'video/mpeg', filename='/tmp/tmp1223')
('xmpeg /tmp/tmp1223', {'view': 'xmpeg %s'})
The Python Standard Library » 18. Internet Data Handling
This module defines two classes, `Mailbox` and `Message`, for accessing and manipulating on-disk mailboxes and the messages they contain. `Mailbox` offers a dictionary-like mapping from keys to messages. `Message` extends the `email.Message` module's `Message` class with format-specific state and behavior. Supported mailbox formats are Maildir, mbox, MH, Babyl, and MMDF.

**See also:**

**Module** email
- Represent and manipulate messages.
18.4.1. Mailbox objects

class mailbox.Mailbox

A mailbox, which may be inspected and modified.

The Mailbox class defines an interface and is not intended to be instantiated. Instead, format-specific subclasses should inherit from Mailbox and your code should instantiate a particular subclass.

The Mailbox interface is dictionary-like, with small keys corresponding to messages. Keys are issued by the Mailbox instance with which they will be used and are only meaningful to that Mailbox instance. A key continues to identify a message even if the corresponding message is modified, such as by replacing it with another message.

Messages may be added to a Mailbox instance using the set-like method add() and removed using a del statement or the set-like methods remove() and discard().

Mailbox interface semantics differ from dictionary semantics in some noteworthy ways. Each time a message is requested, a new representation (typically a Message instance) is generated based upon the current state of the mailbox. Similarly, when a message is added to a Mailbox instance, the provided message representation’s contents are copied. In neither case is a reference to the message representation kept by the Mailbox instance.

The default Mailbox iterator iterates over message representations, not keys as the default dictionary iterator does.
Moreover, modification of a mailbox during iteration is safe and well-defined. Messages added to the mailbox after an iterator is created will not be seen by the iterator. Messages removed from the mailbox before the iterator yields them will be silently skipped, though using a key from an iterator may result in a `KeyError` exception if the corresponding message is subsequently removed.

**Warning:** Be very cautious when modifying mailboxes that might be simultaneously changed by some other process. The safest mailbox format to use for such tasks is Maildir; try to avoid using single-file formats such as mbox for concurrent writing. If you’re modifying a mailbox, you *must* lock it by calling the `lock()` and `unlock()` methods *before* reading any messages in the file or making any changes by adding or deleting a message. Failing to lock the mailbox runs the risk of losing messages or corrupting the entire mailbox.

Mailbox instances have the following methods:

`add(message)`

Add `message` to the mailbox and return the key that has been assigned to it.

Parameter `message` may be a `Message` instance, an `email.Message.Message` instance, a string, or a file-like object (which should be open in text mode). If `message` is an instance of the appropriate format-specific `Message` subclass (e.g., if it’s an `mboxMessage` instance and this is an `mbox` instance), its format-specific information is used. Otherwise, reasonable defaults for format-specific information are used.

`remove(key)`

`__delitem__(key)`
**discard(key)**

Delete the message corresponding to *key* from the mailbox.

If no such message exists, a *KeyError* exception is raised if the method was called as `remove()` or `__delitem__()`, but no exception is raised if the method was called as `discard()`. The behavior of `discard()` may be preferred if the underlying mailbox format supports concurrent modification by other processes.

**__setitem__(key, message)**

Replace the message corresponding to *key* with *message*. Raise a *KeyError* exception if no message already corresponds to *key*.

As with `add()`, parameter *message* may be a Message instance, an `email.Message.Message` instance, a string, or a file-like object (which should be open in text mode). If *message* is an instance of the appropriate format-specific `Message` subclass (e.g., if it’s an `mboxMessage` instance and this is an `mbox` instance), its format-specific information is used. Otherwise, the format-specific information of the message that currently corresponds to *key* is left unchanged.

**iterkeys()**

**keys()**

Return an iterator over all keys if called as `iterkeys()` or return a list of keys if called as `keys()`.

**itervalues()**

**__iter__()**

**values()**

Return an iterator over representations of all messages if
called as `itervalues()` or `__iter__()` or return a list of such representations if called as `values()`. The messages are represented as instances of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

**Note:** The behavior of `__iter__()` is unlike that of dictionaries, which iterate over keys.

`iteritems()`

`items()`

Return an iterator over `(key, message)` pairs, where `key` is a key and `message` is a message representation, if called as `iteritems()` or return a list of such pairs if called as `items()`. The messages are represented as instances of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

`get(key[, default=None])`

`__getitem__(key)`

Return a representation of the message corresponding to `key`. If no such message exists, `default` is returned if the method was called as `get()` and a `KeyError` exception is raised if the method was called as `__getitem__()`. The message is represented as an instance of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

`get_message(key)`

Return a representation of the message corresponding to `key` as an instance of the appropriate format-specific `Message` subclass, or raise a `KeyError` exception if no such message
exists.

get_string(key)
Return a string representation of the message corresponding to key, or raise a KeyError exception if no such message exists.

get_file(key)
Return a file-like representation of the message corresponding to key, or raise a KeyError exception if no such message exists. The file-like object behaves as if open in binary mode. This file should be closed once it is no longer needed.

Note: Unlike other representations of messages, file-like representations are not necessarily independent of the Mailbox instance that created them or of the underlying mailbox. More specific documentation is provided by each subclass.

has_key(key)
__contains__(key)
Return True if key corresponds to a message, False otherwise.

__len__()
Return a count of messages in the mailbox.

clear()
Delete all messages from the mailbox.

pop(key[, default])
Return a representation of the message corresponding to key and delete the message. If no such message exists, return default if it was supplied or else raise a KeyError exception.
The message is represented as an instance of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

**popitem()**
Return an arbitrary `(key, message)` pair, where `key` is a key and `message` is a message representation, and delete the corresponding message. If the mailbox is empty, raise a `KeyError` exception. The message is represented as an instance of the appropriate format-specific `Message` subclass unless a custom message factory was specified when the `Mailbox` instance was initialized.

**update(arg)**
Parameter `arg` should be a `key-to-message` mapping or an iterable of `(key, message)` pairs. Updates the mailbox so that, for each given `key` and `message`, the message corresponding to `key` is set to `message` as if by using `__setitem__()`. As with `__setitem__()`, each `key` must already correspond to a message in the mailbox or else a `KeyError` exception will be raised, so in general it is incorrect for `arg` to be a `Mailbox` instance.

**Note:** Unlike with dictionaries, keyword arguments are not supported.

**flush()**
Write any pending changes to the filesystem. For some `Mailbox` subclasses, changes are always written immediately and `flush()` does nothing, but you should still make a habit of calling this method.

**lock()**
Acquire an exclusive advisory lock on the mailbox so that other processes know not to modify it. An `External Clash Error` is raised if the lock is not available. The particular locking mechanisms used depend upon the mailbox format. You should *always* lock the mailbox before making any modifications to its contents.

```python
unlock()
```
Release the lock on the mailbox, if any.

```python
close()
```
Flush the mailbox, unlock it if necessary, and close any open files. For some `Mailbox` subclasses, this method does nothing.

### 18.4.1.1. Maildir

```python
class mailbox.Maildir(dirname[, factory=rfc822.Message[, create=True]])
```
A subclass of `Mailbox` for mailboxes in Maildir format. Parameter `factory` is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If `factory` is `None`, `MaildirMessage` is used as the default message representation. If `create` is `True`, the mailbox is created if it does not exist.

It is for historical reasons that `factory` defaults to `rfc822.Message` and that `dirname` is named as such rather than `path`. For a `Maildir` instance that behaves like instances of other `Mailbox` subclasses, set `factory` to `None`.

Maildir is a directory-based mailbox format invented for the qmail mail transfer agent and now widely supported by other programs.
Messages in a Maildir mailbox are stored in separate files within a common directory structure. This design allows Maildir mailboxes to be accessed and modified by multiple unrelated programs without data corruption, so file locking is unnecessary.

Maildir mailboxes contain three subdirectories, namely: tmp, new, and cur. Messages are created momentarily in the tmp subdirectory and then moved to the new subdirectory to finalize delivery. A mail user agent may subsequently move the message to the cur subdirectory and store information about the state of the message in a special “info” section appended to its file name.

Folders of the style introduced by the Courier mail transfer agent are also supported. Any subdirectory of the main mailbox is considered a folder if ‘.’ is the first character in its name. Folder names are represented by Maildir without the leading ‘.’. Each folder is itself a Maildir mailbox but should not contain other folders. Instead, a logical nesting is indicated using ‘.’ to delimit levels, e.g., “Archived.2005.07”.

**Note:** The Maildir specification requires the use of a colon (‘:’) in certain message file names. However, some operating systems do not permit this character in file names. If you wish to use a Maildir-like format on such an operating system, you should specify another character to use instead. The exclamation point (‘!’) is a popular choice. For example:

```python
import mailbox
mailbox.Maildir.colon = '!
```

The colon attribute may also be set on a per-instance basis.

Maildir instances have all of the methods of Mailbox in addition to the following:
**list_folders()**

Return a list of the names of all folders.

**get_folder(folder)**

Return a Maildir instance representing the folder whose name is *folder*. A NoSuchMailboxError exception is raised if the folder does not exist.

**add_folder(folder)**

Create a folder whose name is *folder* and return a Maildir instance representing it.

**remove_folder(folder)**

Delete the folder whose name is *folder*. If the folder contains any messages, a NotEmptyError exception will be raised and the folder will not be deleted.

**clean()**

Delete temporary files from the mailbox that have not been accessed in the last 36 hours. The Maildir specification says that mail-reading programs should do this occasionally.

Some Mailbox methods implemented by Maildir deserve special remarks:

**add(message)**

**__setitem__**(key, message)

**update(arg)**

**Warning:** These methods generate unique file names based upon the current process ID. When using multiple threads, undetected name clashes may occur and cause corruption of the mailbox unless threads are coordinated to avoid using these methods to manipulate the same mailbox simultaneously.
flush()
    All changes to Maildir mailboxes are immediately applied, so this method does nothing.

lock()
unlock()
    Maildir mailboxes do not support (or require) locking, so these methods do nothing.

close()
    Maildir instances do not keep any open files and the underlying mailboxes do not support locking, so this method does nothing.

get_file(key)
    Depending upon the host platform, it may not be possible to modify or remove the underlying message while the returned file remains open.

maildir man page from Courier
    Another specification of the format. Describes a common extension for supporting folders.

18.4.1.2. mbox

class mailbox.mbox(path[, factory=None[, create=True]])
A subclass of `Mailbox` for mailboxes in mbox format. Parameter `factory` is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If `factory` is `None`, `mboxMessage` is used as the default message representation. If `create` is `True`, the mailbox is created if it does not exist.

The mbox format is the classic format for storing mail on Unix systems. All messages in an mbox mailbox are stored in a single file with the beginning of each message indicated by a line whose first five characters are “From “.

Several variations of the mbox format exist to address perceived shortcomings in the original. In the interest of compatibility, `mbox` implements the original format, which is sometimes referred to as `mboxo`. This means that the `Content-Length` header, if present, is ignored and that any occurrences of “From ” at the beginning of a line in a message body are transformed to “>From ” when storing the message, although occurrences of “>From ” are not transformed to “From ” when reading the message.

Some `Mailbox` methods implemented by `mbox` deserve special remarks:

`get_file(key)`
Using the file after calling `flush()` or `close()` on the `mbox` instance may yield unpredictable results or raise an exception.

`lock()`
`unlock()`
Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls.

An argument for using the original mbox format rather than a variation.

**“mbox” is a family of several mutually incompatible mailbox formats**
A history of mbox variations.

### 18.4.1.3. MH

```python
class mailbox.MH(path[, factory=None[, create=True]])
```

A subclass of `Mailbox` for mailboxes in MH format. Parameter `factory` is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If `factory` is `None`, `MHMessage` is used as the default message representation. If `create` is `True`, the mailbox is created if it does not exist.

MH is a directory-based mailbox format invented for the MH Message Handling System, a mail user agent. Each message in an MH mailbox resides in its own file. An MH mailbox may contain other MH mailboxes (called folders) in addition to messages. Folders may be nested indefinitely. MH mailboxes also support `sequences`, which are named lists used to logically group messages without moving them to sub-folders. Sequences are defined in a file called `.mh_sequences` in each folder.
The **MH** class manipulates MH mailboxes, but it does not attempt to emulate all of **mh**'s behaviors. In particular, it does not modify and is not affected by the `context` or `.mh_profile` files that are used by **mh** to store its state and configuration.

**MH** instances have all of the methods of **Mailbox** in addition to the following:

**list_folders()**
Return a list of the names of all folders.

**get_folder(folder)**
Return an **MH** instance representing the folder whose name is `folder`. A **NoSuchMailboxError** exception is raised if the folder does not exist.

**add_folder(folder)**
Create a folder whose name is `folder` and return an **MH** instance representing it.

**remove_folder(folder)**
Delete the folder whose name is `folder`. If the folder contains any messages, a **NotEmptyError** exception will be raised and the folder will not be deleted.

**get_sequences()**
Return a dictionary of sequence names mapped to key lists. If there are no sequences, the empty dictionary is returned.

**set_sequences(sequences)**
Re-define the sequences that exist in the mailbox based upon `sequences`, a dictionary of names mapped to key lists, like returned by `get_sequences()`.

**pack()**
Rename messages in the mailbox as necessary to eliminate gaps in numbering. Entries in the sequences list are updated correspondingly.

**Note:** Already-issued keys are invalidated by this operation and should not be subsequently used.

Some **Mailbox** methods implemented by **MH** deserve special remarks:

- `remove(key)`
- `__delitem__(key)`
- `discard(key)`

  These methods immediately delete the message. The MH convention of marking a message for deletion by prepending a comma to its name is not used.

- `lock()`
- `unlock()`

  Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls. For MH mailboxes, locking the mailbox means locking the `.mh_sequences` file and, only for the duration of any operations that affect them, locking individual message files.

- `get_file(key)`

  Depending upon the host platform, it may not be possible to remove the underlying message while the returned file remains open.

- `flush()`

  All changes to MH mailboxes are immediately applied, so this method does nothing.

- `close()`
MH instances do not keep any open files, so this method is equivalent to `unlock()`.

A GPL-licensed book on **mh** and **nmh**, with some information on the mailbox format.

### 18.4.1.4. Babyl

```python
class mailbox. Babyl(path[, factory=None[, create=True]]]
```
A subclass of Mailbox for mailboxes in Babyl format. Parameter `factory` is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If `factory` is `None`, BabylMessage is used as the default message representation. If `create` is `True`, the mailbox is created if it does not exist.

Babyl is a single-file mailbox format used by the Rmail mail user agent included with Emacs. The beginning of a message is indicated by a line containing the two characters Control-Underscore (`\037`) and Control-L (`\014`). The end of a message is indicated by the start of the next message or, in the case of the last message, a line containing a Control-Underscore (`\037`) character.

Messages in a Babyl mailbox have two sets of headers, original headers and so-called visible headers. Visible headers are typically a subset of the original headers that have been reformatted or abridged to be more attractive. Each message in a
Babyl mailbox also has an accompanying list of *labels*, or short strings that record extra information about the message, and a list of all user-defined labels found in the mailbox is kept in the Babyl options section.

*Babyl* instances have all of the methods of *Mailbox* in addition to the following:

**get_labels()**
Return a list of the names of all user-defined labels used in the mailbox.

**Note:** The actual messages are inspected to determine which labels exist in the mailbox rather than consulting the list of labels in the Babyl options section, but the Babyl section is updated whenever the mailbox is modified.

Some *Mailbox* methods implemented by *Babyl* deserve special remarks:

**get_file(key)**
In Babyl mailboxes, the headers of a message are not stored contiguously with the body of the message. To generate a file-like representation, the headers and body are copied together into a *StringIO* instance (from the *StringIO* module), which has an API identical to that of a file. As a result, the file-like object is truly independent of the underlying mailbox but does not save memory compared to a string representation.

**lock()**
**unlock()**
Three locking mechanisms are used—dot locking and, if available, the *flock()* and *lockf()* system calls.
class mailbox.MMDF(path[, factory=None[, create=True]])

A subclass of Mailbox for mailboxes in MMDF format. Parameter factory is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If factory is None, MMDFMessage is used as the default message representation. If create is True, the mailbox is created if it does not exist.

MMDF is a single-file mailbox format invented for the Multichannel Memorandum Distribution Facility, a mail transfer agent. Each message is in the same form as an mbox message but is bracketed before and after by lines containing four Control-A (\001) characters. As with the mbox format, the beginning of each message is indicated by a line whose first five characters are “From “, but additional occurrences of “From ” are not transformed to “>From ” when storing messages because the extra message separator lines prevent mistaking such occurrences for the starts of subsequent messages.

Some Mailbox methods implemented by MMDF deserve special remarks:

get_file(key)
Using the file after calling `flush()` or `close()` on the MMDF instance may yield unpredictable results or raise an exception.

`lock()`
`unlock()`

Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls.

See also:

**mmdf man page from tin**

A specification of MMDF format from the documentation of tin, a newsreader.

**MMDF**

A Wikipedia article describing the Multichannel Memorandum Distribution Facility.
18.4.2. Message objects

class mailbox.Message([message])

If message is omitted, the new instance is created in a default, empty state. If message is an email.Message.Message instance, its contents are copied; furthermore, any format-specific information is converted insofar as possible if message is a Message instance. If message is a string or a file, it should contain an RFC 2822-compliant message, which is read and parsed.

The format-specific state and behaviors offered by subclasses vary, but in general it is only the properties that are not specific to a particular mailbox that are supported (although presumably the properties are specific to a particular mailbox format). For example, file offsets for single-file mailbox formats and file names for directory-based mailbox formats are not retained, because they are only applicable to the original mailbox. But state such as whether a message has been read by the user or marked as important is retained, because it applies to the message itself.

There is no requirement that Message instances be used to represent messages retrieved using Mailbox instances. In some situations, the time and memory required to generate Message representations might not not acceptable. For such situations, Mailbox instances also offer string and file-like representations, and a custom message factory may be specified when a Mailbox instance is initialized.

18.4.2.1. MaildirMessage
A message with Maildir-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

Typically, a mail user agent application moves all of the messages in the `new` subdirectory to the `cur` subdirectory after the first time the user opens and closes the mailbox, recording that the messages are old whether or not they’ve actually been read. Each message in `cur` has an “info” section added to its file name to store information about its state. (Some mail readers may also add an “info” section to messages in `new`.) The “info” section may take one of two forms: it may contain “2,” followed by a list of standardized flags (e.g., “2,FR”) or it may contain “1,” followed by so-called experimental information. Standard flags for Maildir messages are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Draft</td>
<td>Under composition</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>P</td>
<td>Passed</td>
<td>Forwarded, resent, or bounced</td>
</tr>
<tr>
<td>R</td>
<td>Replied</td>
<td>Replied to</td>
</tr>
<tr>
<td>S</td>
<td>Seen</td>
<td>Read</td>
</tr>
<tr>
<td>T</td>
<td>Trashed</td>
<td>Marked for subsequent deletion</td>
</tr>
</tbody>
</table>

`MaildirMessage` instances offer the following methods:

**get_subdir()**

Return either “new” (if the message should be stored in the `new` subdirectory) or “cur” (if the message should be stored in the `cur` subdirectory).

**Note:** A message is typically moved from `new` to `cur` after its mailbox has been accessed, whether or not the message
is has been read. A message msg has been read if "s" in
msg.get_flags() is True.

set_subdir(subdir)
Set the subdirectory the message should be stored in.
Parameter subdir must be either “new” or “cur”.

get_flags()
Return a string specifying the flags that are currently set. If the
message complies with the standard Maildir format, the result
is the concatenation in alphabetical order of zero or one
occurrence of each of 'D', 'F', 'P', 'R', 'S', and 'T'. The
empty string is returned if no flags are set or if “info” contains
experimental semantics.

set_flags(flags)
Set the flags specified by flags and unset all others.

add_flag(flag)
Set the flag(s) specified by flag without changing other flags.
To add more than one flag at a time, flag may be a string of
more than one character. The current “info” is overwritten
whether or not it contains experimental information rather than
flags.

remove_flag(flag)
Unset the flag(s) specified by flag without changing other
flags. To remove more than one flag at a time, flag maybe a
string of more than one character. If “info” contains
experimental information rather than flags, the current “info” is
not modified.

get_date()
Return the delivery date of the message as a floating-point
number representing seconds since the epoch.
**set_date(date)**

Set the delivery date of the message to *date*, a floating-point number representing seconds since the epoch.

**get_info()**

Return a string containing the “info” for a message. This is useful for accessing and modifying “info” that is experimental (i.e., not a list of flags).

**set_info(info)**

Set “info” to *info*, which should be a string.

When a *MaildirMessage* instance is created based upon an *mboxMessage* or *MMDFMessage* instance, the *Status* and *X-Status* headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage or MMDFMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>O flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>R flag</td>
<td>A flag</td>
</tr>
<tr>
<td>S flag</td>
<td>R flag</td>
</tr>
<tr>
<td>T flag</td>
<td>D flag</td>
</tr>
</tbody>
</table>

When a *MaildirMessage* instance is created based upon an *MHMessage* instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>“cur” subdirectory and S flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>R flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When a *MaildirMessage* instance is created based upon a *BabylMessage* instance, the following conversions take place:
### Resulting state

<table>
<thead>
<tr>
<th>Baby1Message state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“cur” subdirectory</td>
</tr>
<tr>
<td>“cur” subdirectory and S flag</td>
</tr>
<tr>
<td>P flag</td>
</tr>
<tr>
<td>R flag</td>
</tr>
<tr>
<td>T flag</td>
</tr>
</tbody>
</table>

| 18.4.2.2. *mboxMessage* |

*class* mailbox. *mboxMessage*(*[message]*)

A message with mbox-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

Messages in an mbox mailbox are stored together in a single file. The sender's envelope address and the time of delivery are typically stored in a line beginning with “From ” that is used to indicate the start of a message, though there is considerable variation in the exact format of this data among mbox implementations. Flags that indicate the state of the message, such as whether it has been read or marked as important, are typically stored in *Status* and *X-Status* headers.

Conventional flags for mbox messages are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Read</td>
<td>Read</td>
</tr>
<tr>
<td>O</td>
<td>Old</td>
<td>Previously detected by MUA</td>
</tr>
<tr>
<td>D</td>
<td>Deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>A</td>
<td>Answered</td>
<td>Replied to</td>
</tr>
</tbody>
</table>

The “R” and “O” flags are stored in the *Status* header, and the “D”, “F”, and “A” flags are stored in the *X-Status* header. The flags and headers typically appear in the order mentioned.
mboxMessage instances offer the following methods:

**get_from**

Return a string representing the “From ” line that marks the start of the message in an mbox mailbox. The leading “From ” and the trailing newline are excluded.

**set_from**(from_[, time_=None])

Set the “From ” line to from_, which should be specified without a leading “From ” or trailing newline. For convenience, time_ may be specified and will be formatted appropriately and appended to from_. If time_ is specified, it should be a struct_time instance, a tuple suitable for passing to time.strftime(), or True (to use time.gmtime()).

**get_flags**

Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of ‘R’, ‘O’, ‘D’, ‘F’, and ‘A’.

**set_flags**(flags)

Set the flags specified by flags and unset all others. Parameter flags should be the concatenation in any order of zero or more occurrences of each of ‘R’, ‘O’, ‘D’, ‘F’, and ‘A’.

**add_flag**(flag)

Set the flag(s) specified by flag without changing other flags. To add more than one flag at a time, flag may be a string of more than one character.

**remove_flag**(flag)

Unset the flag(s) specified by flag without changing other flags. To remove more than one flag at a time, flag maybe a
string of more than one character.

When an `mboxMessage` instance is created based upon a `MaildirMessage` instance, a “From ” line is generated based upon the `MaildirMessage` instance's delivery date, and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>S flag</td>
</tr>
<tr>
<td>O flag</td>
<td>“cur” subdirectory</td>
</tr>
<tr>
<td>D flag</td>
<td>T flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>A flag</td>
<td>R flag</td>
</tr>
</tbody>
</table>

When an `mboxMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>A flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When an `mboxMessage` instance is created based upon a `BabylMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” label</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>D flag</td>
<td>“deleted” label</td>
</tr>
<tr>
<td>A flag</td>
<td>“answered” label</td>
</tr>
</tbody>
</table>

When a `Message` instance is created based upon an `MMDFMessage` instance, the “From ” line is copied and all flags directly correspond:
### 18.4.2.3. **MHMessage**

```python
class mailbox.MHMessage([message])
```

A message with MH-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

MH messages do not support marks or flags in the traditional sense, but they do support sequences, which are logical groupings of arbitrary messages. Some mail reading programs (although not the standard `mh` and `nmh`) use sequences in much the same way flags are used with other formats, as follows:

<table>
<thead>
<tr>
<th>Sequence</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>unseen</td>
<td>Not read, but previously detected by MUA</td>
</tr>
<tr>
<td>replied</td>
<td>Replied to</td>
</tr>
<tr>
<td>flagged</td>
<td>Marked as important</td>
</tr>
</tbody>
</table>

`MHMessage` instances offer the following methods:

- **get_sequences()**
  Return a list of the names of sequences that include this message.

- **set_sequences(sequences)**
  Set the list of sequences that include this message.

- **add_sequence(sequence)**
Add sequence to the list of sequences that include this message.

\texttt{remove\_sequence(sequence)}

Remove sequence from the list of sequences that include this message.

When an \texttt{MHMessage} instance is created based upon a \texttt{MaildirMessage} instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>no S flag</td>
</tr>
<tr>
<td>“replied” sequence</td>
<td>R flag</td>
</tr>
<tr>
<td>“flagged” sequence</td>
<td>F flag</td>
</tr>
</tbody>
</table>

When an \texttt{MHMessage} instance is created based upon an \texttt{mboxMessage} or \texttt{MMDFMessage} instance, the \textit{Status} and \textit{X-Status} headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>\texttt{mboxMessage or MMDFMessage state}</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>no R flag</td>
</tr>
<tr>
<td>“replied” sequence</td>
<td>A flag</td>
</tr>
<tr>
<td>“flagged” sequence</td>
<td>F flag</td>
</tr>
</tbody>
</table>

When an \texttt{MHMessage} instance is created based upon a \texttt{BabylMessage} instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” sequence</td>
<td>“unseen” label</td>
</tr>
<tr>
<td>“replied” sequence</td>
<td>“answered” label</td>
</tr>
</tbody>
</table>

\textbf{18.4.2.4. BabylMessage}

\texttt{class mailbox.BabylMessage([message])}
A message with Babyl-specific behaviors. Parameter \textit{message} has the same meaning as with the \texttt{Message} constructor.

Certain message labels, called \textit{attributes}, are defined by convention to have special meanings. The attributes are as follows:

<table>
<thead>
<tr>
<th>Label</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>unseen</td>
<td>Not read, but previously detected by MUA</td>
</tr>
<tr>
<td>deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>filed</td>
<td>Copied to another file or mailbox</td>
</tr>
<tr>
<td>answered</td>
<td>Replied to</td>
</tr>
<tr>
<td>forwarded</td>
<td>Forwarded</td>
</tr>
<tr>
<td>edited</td>
<td>Modified by the user</td>
</tr>
<tr>
<td>resent</td>
<td>Resent</td>
</tr>
</tbody>
</table>

By default, Rmail displays only visible headers. The \texttt{BabylMessage} class, though, uses the original headers because they are more complete. Visible headers may be accessed explicitly if desired.

\texttt{BabylMessage} instances offer the following methods:

\begin{Verbatim}
\texttt{get\_labels()}  \\
    Return a list of labels on the message.
\end{Verbatim}

\begin{Verbatim}
\texttt{set\_labels(labels)}  \\
    Set the list of labels on the message to \textit{labels}.
\end{Verbatim}

\begin{Verbatim}
\texttt{add\_label(label)}  \\
    Add \textit{label} to the list of labels on the message.
\end{Verbatim}

\begin{Verbatim}
\texttt{remove\_label(label)}  \\
    Remove \textit{label} from the list of labels on the message.
\end{Verbatim}

\begin{Verbatim}
\texttt{get\_visible()}  \\
\end{Verbatim}
Return an `Message` instance whose headers are the message's visible headers and whose body is empty.

**set_visible**(visible)

Set the message's visible headers to be the same as the headers in `message`. Parameter `visible` should be a `Message` instance, an `email.Message.Message` instance, a string, or a file-like object (which should be open in text mode).

**update_visible()**

When a `BabylMessage` instance's original headers are modified, the visible headers are not automatically modified to correspond. This method updates the visible headers as follows: each visible header with a corresponding original header is set to the value of the original header, each visible header without a corresponding original header is removed, and any of `Date`, `From`, `Reply-To`, `To`, `CC`, and `Subject` that are present in the original headers but not the visible headers are added to the visible headers.

When a `BabylMessage` instance is created based upon a `MaildirMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” label</td>
<td>no S flag</td>
</tr>
<tr>
<td>“deleted” label</td>
<td>T flag</td>
</tr>
<tr>
<td>“answered” label</td>
<td>R flag</td>
</tr>
<tr>
<td>“forwarded” label</td>
<td>P flag</td>
</tr>
</tbody>
</table>

When a `BabylMessage` instance is created based upon an `mboxMessage` or `MMDFMessage` instance, the `Status` and `X-Status` headers are omitted and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th><code>mboxMessage</code> or <code>MMDFMessage</code> state</th>
</tr>
</thead>
</table>

When a `BabylMessage` instance is created based upon an `MHMessage` instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>“unseen” label</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>“answered” label</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

### 18.4.2.5. MMDFMessage

```
class mailbox.MMDFMessage([message])
```

A message with MMDF-specific behaviors. Parameter `message` has the same meaning as with the `Message` constructor.

As with message in an mbox mailbox, MMDF messages are stored with the sender’s address and the delivery date in an initial line beginning with “From “. Likewise, flags that indicate the state of the message are typically stored in `Status` and `X-Status` headers.

Conventional flags for MMDF messages are identical to those of mbox message and are as follows:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Meaning</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td>Read</td>
<td>Read</td>
</tr>
<tr>
<td>O</td>
<td>Old</td>
<td>Previously detected by MUA</td>
</tr>
<tr>
<td>D</td>
<td>Deleted</td>
<td>Marked for subsequent deletion</td>
</tr>
<tr>
<td>F</td>
<td>Flagged</td>
<td>Marked as important</td>
</tr>
<tr>
<td>A</td>
<td>Answered</td>
<td>Replied to</td>
</tr>
</tbody>
</table>

The “R” and “O” flags are stored in the `Status` header, and the
“D”, “F”, and “A” flags are stored in the X-Status header. The flags and headers typically appear in the order mentioned.

**MMDF**Message instances offer the following methods, which are identical to those offered by **mbox**Message:

**get_from()**
Return a string representing the “From ” line that marks the start of the message in an mbox mailbox. The leading “From ” and the trailing newline are excluded.

**set_from(from_, time_=None)**
Set the “From ” line to from_, which should be specified without a leading “From ” or trailing newline. For convenience, time_ may be specified and will be formatted appropriately and appended to from_. If time_ is specified, it should be a struct_time instance, a tuple suitable for passing to time.strftime(), or True (to use time.gmtime()).

**get_flags()**
Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of 'R', 'O', 'D', 'F', and 'A'.

**set_flags(flags)**
Set the flags specified by flags and unset all others. Parameter flags should be the concatenation in any order of zero or more occurrences of each of 'R', 'O', 'D', 'F', and 'A'.

**add_flag(flag)**
Set the flag(s) specified by flag without changing other flags. To add more than one flag at a time, flag may be a string of
more than one character.

```
remove_flag(flag)
```

Unset the flag(s) specified by flag without changing other flags. To remove more than one flag at a time, flag maybe a string of more than one character.

When an **MMDFMessage** instance is created based upon a **MaildirMessage** instance, a “From ” line is generated based upon the **MaildirMessage** instance’s delivery date, and the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MaildirMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>S flag</td>
</tr>
<tr>
<td>O flag</td>
<td>“cur” subdirectory</td>
</tr>
<tr>
<td>D flag</td>
<td>T flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>A flag</td>
<td>R flag</td>
</tr>
</tbody>
</table>

When an **MMDFMessage** instance is created based upon an **MHMessage** instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>MHMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” sequence</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” sequence</td>
</tr>
<tr>
<td>F flag</td>
<td>“flagged” sequence</td>
</tr>
<tr>
<td>A flag</td>
<td>“replied” sequence</td>
</tr>
</tbody>
</table>

When an **MMDFMessage** instance is created based upon a **BabylMessage** instance, the following conversions take place:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>BabylMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag and O flag</td>
<td>no “unseen” label</td>
</tr>
<tr>
<td>O flag</td>
<td>“unseen” label</td>
</tr>
</tbody>
</table>
When an `MMDFMessage` instance is created based upon an `mboxMessage` instance, the “From ” line is copied and all flags directly correspond:

<table>
<thead>
<tr>
<th>Resulting state</th>
<th>mboxMessage state</th>
</tr>
</thead>
<tbody>
<tr>
<td>R flag</td>
<td>R flag</td>
</tr>
<tr>
<td>O flag</td>
<td>O flag</td>
</tr>
<tr>
<td>D flag</td>
<td>D flag</td>
</tr>
<tr>
<td>F flag</td>
<td>F flag</td>
</tr>
<tr>
<td>A flag</td>
<td>A flag</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>D flag</th>
<th>“deleted” label</th>
</tr>
</thead>
<tbody>
<tr>
<td>A flag</td>
<td>“answered” label</td>
</tr>
</tbody>
</table>
18.4.3. Exceptions

The following exception classes are defined in the mailbox module:

```plaintext
exception mailbox.Error
    The based class for all other module-specific exceptions.

exception mailbox.NoSuchMailboxError
    Raised when a mailbox is expected but is not found, such as when instantiating a Mailbox subclass with a path that does not exist (and with the create parameter set to False), or when opening a folder that does not exist.

exception mailbox.NotEmptyError
    Raised when a mailbox is not empty but is expected to be, such as when deleting a folder that contains messages.

exception mailbox.ExternalClashError
    Raised when some mailbox-related condition beyond the control of the program causes it to be unable to proceed, such as when failing to acquire a lock that another program already holds a lock, or when a uniquely-generated file name already exists.

exception mailbox.FormatError
    Raised when the data in a file cannot be parsed, such as when an MH instance attempts to read a corrupted mh_sequences file.
```
18.4.4. Deprecated classes and methods

*Deprecated since version 2.6.*

Older versions of the `mailbox` module do not support modification of mailboxes, such as adding or removing message, and do not provide classes to represent format-specific message properties. For backward compatibility, the older mailbox classes are still available, but the newer classes should be used in preference to them. The old classes will be removed in Python 3.0.

Older mailbox objects support only iteration and provide a single public method:

```python
oldmailbox.next()
```

Return the next message in the mailbox, created with the optional `factory` argument passed into the mailbox object’s constructor. By default this is an `rfc822.Message` object (see the `rfc822` module). Depending on the mailbox implementation the `fp` attribute of this object may be a true file object or a class instance simulating a file object, taking care of things like message boundaries if multiple mail messages are contained in a single file, etc. If no more messages are available, this method returns `None`.

Most of the older mailbox classes have names that differ from the current mailbox class names, except for `Maildir`. For this reason, the new `Maildir` class defines a `next()` method and its constructor differs slightly from those of the other new mailbox classes.

The older mailbox classes whose names are not the same as their newer counterparts are as follows:

```python
class mailbox.UnixMailbox(fp[, factory])
```
Access to a classic Unix-style mailbox, where all messages are contained in a single file and separated by `From` (a.k.a. `From_`) lines. The file object `fp` points to the mailbox file. The optional `factory` parameter is a callable that should create new message objects. `factory` is called with one argument, `fp` by the `next()` method of the mailbox object. The default is the `rfc822.Message` class (see the `rfc822` module – and the note below).

**Note:** For reasons of this module’s internal implementation, you will probably want to open the `fp` object in binary mode. This is especially important on Windows.

For maximum portability, messages in a Unix-style mailbox are separated by any line that begins exactly with the string `From` (note the trailing space) if preceded by exactly two newlines. Because of the wide-range of variations in practice, nothing else on the `From_` line should be considered. However, the current implementation doesn’t check for the leading two newlines. This is usually fine for most applications.

The `UnixMailbox` class implements a more strict version of `From_` line checking, using a regular expression that usually correctly matched `From_` delimiters. It considers delimiter line to be separated by `From name time` lines. For maximum portability, use the `PortableUnixMailbox` class instead. This class is identical to `UnixMailbox` except that individual messages are separated by only `From` lines.

```python
class mailbox. PortableUnixMailbox(fp[, factory])
```

A less-strict version of `UnixMailbox`, which considers only the `From` at the beginning of the line separating messages. The “name time” portion of the From line is ignored, to protect against some variations that are observed in practice. This works since
lines in the message which begin with 'From' are quoted by mail handling software at delivery-time.

```python
class mailbox. MmdfMailbox(fp[, factory])
Access an MMDF-style mailbox, where all messages are contained in a single file and separated by lines consisting of 4 control-A characters. The file object fp points to the mailbox file. Optional factory is as with the UnixMailbox class.
```

```python
class mailbox. MHMailbox(dirname[, factory])
Access an MH mailbox, a directory with each message in a separate file with a numeric name. The name of the mailbox directory is passed in dirname. factory is as with the UnixMailbox class.
```

```python
class mailbox. BabylMailbox(fp[, factory])
Access a Babyl mailbox, which is similar to an MMDF mailbox. In Babyl format, each message has two sets of headers, the original headers and the visible headers. The original headers appear before a line containing only '*** EOOH ***' (End-Of-Original-Headers) and the visible headers appear after the EOOH line. Babyl-compliant mail readers will show you only the visible headers, and BabylMailbox objects will return messages containing only the visible headers. You'll have to do your own parsing of the mailbox file to get at the original headers. Mail messages start with the EOOH line and end with a line containing only '\037\014'. factory is as with the UnixMailbox class.
```

If you wish to use the older mailbox classes with the email module rather than the deprecated rfc822 module, you can do so as follows:

```python
import email
import email.Errors
import mailbox
```
def msgfactory(fp):
    try:
        return email.message_from_file(fp)
    except email.Errors.MessageParseError:
        # Don't return None since that will
        # stop the mailbox iterator
        return ''

mbox = mailbox.UnixMailbox(fp, msgfactory)

Alternatively, if you know your mailbox contains only well-formed MIME messages, you can simplify this to:

```python
import email
import mailbox

mbox = mailbox.UnixMailbox(fp, email.message_from_file)
```
18.4.5. Examples

A simple example of printing the subjects of all messages in a mailbox that seem interesting:

```python
import mailbox
for message in mailbox.mbox('~/mbox):
    subject = message['subject']  # Could possibly be None
    if subject and 'python' in subject.lower():
        print subject
```

To copy all mail from a Babyl mailbox to an MH mailbox, converting all of the format-specific information that can be converted:

```python
import mailbox
destination = mailbox.MH('~/Mail')
destination.lock()
for message in mailbox.Babyl('~/RMAIL'):
    destination.add(mailbox.MHMessage(message))
destination.flush()
destination.unlock()
```

This example sorts mail from several mailing lists into different mailboxes, being careful to avoid mail corruption due to concurrent modification by other programs, mail loss due to interruption of the program, or premature termination due to malformed messages in the mailbox:

```python
import mailbox
import email.Errors

list_names = ('python-list', 'python-dev', 'python-bugs')

boxes = dict((name, mailbox.mbox('~/email/%s' % name)) for name
             inbox = mailbox.Maildir('~/Maildir', factory=None)

for key in inbox.iterkeys():
    try:
```
message = inbox[key]
except email.Errors.MessageParseError:
    continue  # The message is malformed. Just

for name in list_names:
    list_id = message['list-id']
    if list_id and name in list_id:
        # Get mailbox to use
        box = boxes[name]

        # Write copy to disk before removing original.
        # If there's a crash, you might duplicate a message
        # that's better than losing a message completely.
        box.lock()
        box.add(message)
        box.flush()
        box.unlock()

        # Remove original message
        inbox.lock()
        inbox.discard(key)
        inbox.flush()
        inbox.unlock()
        break  # Found destination, so stop looking

for box in boxes.itervalues():
    box.close()
The `mhlib` module provides a Python interface to MH folders and their contents.

The module contains three basic classes, `MH`, which represents a particular collection of folders, `Folder`, which represents a single folder, and `Message`, which represents a single message.

```python
class mhlib.MH([path[, profile]])
    MH represents a collection of MH folders.

class mhlib.Folder(mh, name)
    The Folder class represents a single folder and its messages.

class mhlib.Message(folder, number[, name])
    Message objects represent individual messages in a folder. The Message class is derived from `mimetools.Message`.
```
18.5.1. MH Objects

MH instances have the following methods:

MH. `error(format[, ...])`
Print an error message – can be overridden.

MH. `getprofile(key)`
Return a profile entry (None if not set).

MH. `getpath()`
Return the mailbox pathname.

MH. `getcontext()`
Return the current folder name.

MH. `setcontext(name)`
Set the current folder name.

MH. `listfolders()`
Return a list of top-level folders.

MH. `listallfolders()`
Return a list of all folders.

MH. `listsubfolders(name)`
Return a list of direct subfolders of the given folder.

MH. `listallsubfolders(name)`
Return a list of all subfolders of the given folder.

MH. `makefolder(name)`
Create a new folder.
MH. `deletefolder(name)`
    Delete a folder – must have no subfolders.

MH. `openfolder(name)`
    Return a new open folder object.
18.5.2. Folder Objects

Folder instances represent open folders and have the following methods:

Folder. `error(format[, ...])`
Print an error message – can be overridden.

Folder. `getfullname()`
Return the folder’s full pathname.

Folder. `getsequencesfilename()`
Return the full pathname of the folder’s sequences file.

Folder. `getmessagefilename(n)`
Return the full pathname of message n of the folder.

Folder. `listmessages()`
Return a list of messages in the folder (as numbers).

Folder. `getcurrent()`
Return the current message number.

Folder. `setcurrent(n)`
Set the current message number to n.

Folder. `parsesequence(seq)`
Parse msgs syntax into list of messages.

Folder. `getlast()`
Get last message, or 0 if no messages are in the folder.

Folder. `setlast(n)`
Set last message (internal use only).

Folder. **getsequences()**
Return dictionary of sequences in folder. The sequence names are used as keys, and the values are the lists of message numbers in the sequences.

Folder. **putsequences(dict)**
Return dictionary of sequences in folder name: list.

Folder. **removemessages(list)**
Remove messages in list from folder.

Folder. **refilemessages(list, tofolder)**
Move messages in list to other folder.

Folder. **movemessage(n, tofolder, ton)**
Move one message to a given destination in another folder.

Folder. **copymessage(n, tofolder, ton)**
Copy one message to a given destination in another folder.
18.5.3. Message Objects

The `Message` class adds one method to those of `mimetools.Message`:

```
Message.openmessage(n)
```

Return a new open message object (costs a file descriptor).
18.6. mimetools — Tools for parsing MIME messages

*Deprecated since version 2.3:* The `email` package should be used in preference to the `mimetools` module. This module is present only to maintain backward compatibility, and it has been removed in 3.x.

This module defines a subclass of the `rfc822` module's `Message` class and a number of utility functions that are useful for the manipulation for MIME multipart or encoded message.

It defines the following items:

```python
class mimetools.Message(fp[, seekable])
```

Return a new instance of the `Message` class. This is a subclass of the `rfc822.Message` class, with some additional methods (see below). The `seekable` argument has the same meaning as for `rfc822.Message`.

```python
mimetools.choose_boundary()
```

Return a unique string that has a high likelihood of being usable as a part boundary. The string has the form `hostipaddr.uid.pid.timestamp.random`.

```python
mimetools.decode(input, output, encoding)
```

Read data encoded using the allowed MIME `encoding` from open file object `input` and write the decoded data to open file object `output`. Valid values for `encoding` include `base64`, `quoted-printable`, `uuencode`, `x-uuencode`, `uue`, `x-uue`, `7bit`, and `8bit`. Decoding messages encoded in `7bit` or `8bit` has no effect. The input is simply copied to the output.
mimetools. **encode**(input, output, encoding)

Read data from open file object input and write it encoded using the allowed MIME encoding to open file object output. Valid values for encoding are the same as for decode().

mimetools. **copyliteral**(input, output)

Read lines from open file input until EOF and write them to open file output.

mimetools. **copybinary**(input, output)

Read blocks until EOF from open file input and write them to open file output. The block size is currently fixed at 8192.

**See also:**

**Module email**

Comprehensive email handling package; supersedes the mimetools module.

**Module rfc822**

Provides the base class for mimetools.Message.

**Module multifile**

Support for reading files which contain distinct parts, such as MIME data.

http://faqs.cs.uu.nl/na-dir/mail/mime-faq/.html

The MIME Frequently Asked Questions document. For an overview of MIME, see the answer to question 1.1 in Part 1 of this document.
18.6.1. Additional Methods of Message Objects

The `Message` class defines the following methods in addition to the `rfc822.Message` methods:

**Message.getplist()**

Return the parameter list of the `Content-Type` header. This is a list of strings. For parameters of the form `key=value`, `key` is converted to lower case but `value` is not. For example, if the message contains the header `Content-type: text/html; spam=1; Spam=2; Spam` then `getplist()` will return the Python list `['spam=1', 'spam=2', 'Spam']`.

**Message.getparam(name)**

Return the `value` of the first parameter (as returned by `getplist()`) of the form `name=value` for the given `name`. If `value` is surrounded by quotes of the form `<...>` or `"..."`, these are removed.

**Message.getencoding()**

Return the encoding specified in the `Content-Transfer-Encoding` message header. If no such header exists, return `'7bit'`. The encoding is converted to lower case.

**Message.gettype()**

Return the message type (of the form `type/subtype`) as specified in the `Content-Type` header. If no such header exists, return `'text/plain'`. The type is converted to lower case.

**Message.getmaintype()**
Return the main type as specified in the `Content-Type` header. If no such header exists, return 'text'. The main type is converted to lower case.

**Message.** `getsubtype()`

Return the subtype as specified in the `Content-Type` header. If no such header exists, return 'plain'. The subtype is converted to lower case.
18.7. mimetypes — Map filenames to MIME types

The `mimetypes` module converts between a filename or URL and the MIME type associated with the filename extension. Conversions are provided from filename to MIME type and from MIME type to filename extension; encodings are not supported for the latter conversion.

The module provides one class and a number of convenience functions. The functions are the normal interface to this module, but some applications may be interested in the class as well.

The functions described below provide the primary interface for this module. If the module has not been initialized, they will call `init()` if they rely on the information `init()` sets up.

```python
mimetypes.guess_type(filename[, strict])
```

Guess the type of a file based on its filename or URL, given by `filename`. The return value is a tuple `(type, encoding)` where `type` is `None` if the type can’t be guessed (missing or unknown suffix) or a string of the form `'type/subtype'`, usable for a MIME `content-type` header.

`encoding` is `None` for no encoding or the name of the program used to encode (e.g. `compress` or `gzip`). The encoding is suitable for use as a `Content-Encoding` header, not as a `Content-Transfer-Encoding` header. The mappings are table driven. Encoding suffixes are case sensitive; type suffixes are first tried case sensitively, then case insensitively.

Optional `strict` is a flag specifying whether the list of known MIME
types is limited to only the official types registered with IANA are recognized. When strict is true (the default), only the IANA types are supported; when strict is false, some additional non-standard but commonly used MIME types are also recognized.

mimetypes.\texttt{guess\_all\_extensions(type[, strict])}

Guess the extensions for a file based on its MIME type, given by type. The return value is a list of strings giving all possible filename extensions, including the leading dot (\texttt{'.'}). The extensions are not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type type by \texttt{guess\_type()}. Optional strict has the same meaning as with the \texttt{guess\_type()} function.

mimetypes.\texttt{guess\_extension(type[, strict])}

Guess the extension for a file based on its MIME type, given by type. The return value is a string giving a filename extension, including the leading dot (\texttt{'.'}). The extension is not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type type by \texttt{guess\_type()}. If no extension can be guessed for type, \texttt{None} is returned. Optional strict has the same meaning as with the \texttt{guess\_type()} function.

Some additional functions and data items are available for controlling the behavior of the module.

mimetypes.\texttt{init([files])}

Initialize the internal data structures. If given, files must be a sequence of file names which should be used to augment the default type map. If omitted, the file names to use are taken from
knownfiles; on Windows, the current registry settings are loaded. Each file named in files or knownfiles takes precedence over those named before it. Calling init() repeatedly is allowed.

Changed in version 2.7: Previously, Windows registry settings were ignored.

mimetypes.read_mime_types(filename)
Load the type map given in the file filename, if it exists. The type map is returned as a dictionary mapping filename extensions, including the leading dot ('.'), to strings of the form 'type/subtype'. If the file filename does not exist or cannot be read, None is returned.

mimetypes.add_type(type, ext[, strict])
Add a mapping from the mimetype type to the extension ext. When the extension is already known, the new type will replace the old one. When the type is already known the extension will be added to the list of known extensions.

When strict is True (the default), the mapping will added to the official MIME types, otherwise to the non-standard ones.

mimetypes.inited
Flag indicating whether or not the global data structures have been initialized. This is set to true by init().

mimetypes.knownfiles
List of type map file names commonly installed. These files are typically named mime.types and are installed in different locations by different packages.

mimetypes.suffix_map
Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type
are indicated by the same extension. For example, the .tgz extension is mapped to .tar.gz to allow the encoding and type to be recognized separately.

mimetypes.**encodings_map**
Dictionary mapping filename extensions to encoding types.

mimetypes.**types_map**
Dictionary mapping filename extensions to MIME types.

mimetypes.**common_types**
Dictionary mapping filename extensions to non-standard, but commonly found MIME types.

The **MimeTypes** class may be useful for applications which may want more than one MIME-type database:

```python
class mimetypes.MimeTypes([filenames])
```

This class represents a MIME-types database. By default, it provides access to the same database as the rest of this module. The initial database is a copy of that provided by the module, and may be extended by loading additional `mime.types`-style files into the database using the `read()` or `readfp()` methods. The mapping dictionaries may also be cleared before loading additional data if the default data is not desired.

The optional `filenames` parameter can be used to cause additional files to be loaded “on top” of the default database.

*New in version 2.2.*

An example usage of the module:

```python
>>> import mimetypes
>>> mimetypes.init()
>>> mimetypes.knownfiles
```
['/etc/mime.types', '/etc/httpd/mime.types', ... ]

>>> mimetypes.suffix_map['.tgz']
'.tar.gz'

>>> mimetypes.encodings_map['.gz']
'gzip'

>>> mimetypes.types_map['.tgz']
'application/x-tar-gz'
18.7.1. MimeTypes Objects

**MimeTypes** instances provide an interface which is very like that of the **mimetypes** module.

**MimeTypes.suffix_map**

Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately. This is initially a copy of the global `suffix_map` defined in the module.

**MimeTypes.encodings_map**

Dictionary mapping filename extensions to encoding types. This is initially a copy of the global `encodings_map` defined in the module.

**MimeTypes.types_map**

Dictionary mapping filename extensions to MIME types. This is initially a copy of the global `types_map` defined in the module.

**MimeTypes.common_types**

Dictionary mapping filename extensions to non-standard, but commonly found MIME types. This is initially a copy of the global `common_types` defined in the module.

**MimeTypes.guess_extension**(type[, strict])

Similar to the `guess_extension()` function, using the tables stored as part of the object.

**MimeTypes.guess_all_extensions**(type[, strict])

Similar to the `guess_all_extensions()` function, using the tables
stored as part of the object.

MimeTypes. **guess_type(url[, strict])**
Similar to the **guess_type()** function, using the tables stored as part of the object.

MimeTypes. **read(path)**
Load MIME information from a file named *path*. This uses **readfp()** to parse the file.

MimeTypes. **readfp(file)**
Load MIME type information from an open file. The file must have the format of the standard **mime.types** files.

MimeTypes. **read_windows_registry()**
Load MIME type information from the Windows registry. Availability: Windows.

*New in version 2.7.*
18.8. MimeWriter — Generic MIME file writer

*Deprecated since version 2.3:* The `email` package should be used in preference to the `MimeWriter` module. This module is present only to maintain backward compatibility.

This module defines the class `MimeWriter`. The `MimeWriter` class implements a basic formatter for creating MIME multi-part files. It doesn't seek around the output file nor does it use large amounts of buffer space. You must write the parts out in the order that they should occur in the final file. `MimeWriter` does buffer the headers you add, allowing you to rearrange their order.

```python
class MimeWriter

MimeWriter(fp)
```

Return a new instance of the `MimeWriter` class. The only argument passed, `fp`, is a file object to be used for writing. Note that a `StringIO` object could also be used.
18.8.1. MimeWriter Objects

MimeWriter instances have the following methods:

MimeWriter.addheader(key, value[, prefix])
Add a header line to the MIME message. The key is the name of the header, where the value obviously provides the value of the header. The optional argument prefix determines where the header is inserted; \(0\) means append at the end, \(1\) is insert at the start. The default is to append.

MimeWriter.flushheaders()
Causes all headers accumulated so far to be written out (and forgotten). This is useful if you don’t need a body part at all, e.g. for a subpart of type message/rfc822 that’s (mis)used to store some header-like information.

MimeWriter.startbody(ctype[, plist[, prefix]])
Returns a file-like object which can be used to write to the body of the message. The content-type is set to the provided ctype, and the optional parameter plist provides additional parameters for the content-type declaration. prefix functions as in addheader() except that the default is to insert at the start.

MimeWriter.startmultipartbody(subtype[, boundary[, plist[, prefix]]])
Returns a file-like object which can be used to write to the body of the message. Additionally, this method initializes the multi-part code, where subtype provides the multipart subtype, boundary may provide a user-defined boundary specification, and plist provides optional parameters for the subtype. prefix functions as in startbody(). Subparts should be created using nextpart().
MimeWriter.nextpart()

Returns a new instance of MimeWriter which represents an individual part in a multipart message. This may be used to write the part as well as used for creating recursively complex multipart messages. The message must first be initialized with startmultipartbody() before using nextpart().

MimeWriter.lastpart()

This is used to designate the last part of a multipart message, and should always be used when writing multipart messages.
The Python Standard Library » 18. Internet Data Handling »
18.9. mimify — MIME processing of mail messages

Deprecated since version 2.3: The email package should be used in preference to the mimify module. This module is present only to maintain backward compatibility.

The mimify module defines two functions to convert mail messages to and from MIME format. The mail message can be either a simple message or a so-called multipart message. Each part is treated separately. Mimifying (a part of) a message entails encoding the message as quoted-printable if it contains any characters that cannot be represented using 7-bit ASCII. Unmimifying (a part of) a message entails undoing the quoted-printable encoding. Mimify and unmimify are especially useful when a message has to be edited before being sent. Typical use would be:

```
unmimify message
edit message
mimify message
send message
```

The modules defines the following user-callable functions and user-settable variables:

```
mimify.mimify(infile, outfile)
```

Copy the message in `infile` to `outfile`, converting parts to quoted-printable and adding MIME mail headers when necessary. `infile` and `outfile` can be file objects (actually, any object that has a `readline()` method (for `infile`) or a `write()` method (for `outfile`)) or strings naming the files. If `infile` and `outfile` are both strings, they may have the same value.
mimify.unmimify(infile, outfile[, decode_base64])

Copy the message in infile to outfile, decoding all quoted-printable parts. infile and outfile can be file objects (actually, any object that has a readline() method (for infile) or a write() method (for outfile)) or strings naming the files. If infile and outfile are both strings, they may have the same value. If the decode_base64 argument is provided and tests true, any parts that are coded in the base64 encoding are decoded as well.

mimify.mime_decode_header(line)

Return a decoded version of the encoded header line in line. This only supports the ISO 8859-1 charset (Latin-1).

mimify.mime_encode_header(line)

Return a MIME-encoded version of the header line in line.

mimify.MAXLEN

By default, a part will be encoded as quoted-printable when it contains any non-ASCII characters (characters with the 8th bit set), or if there are any lines longer than MAXLEN characters (default value 200).

mimify.CHARSET

When not specified in the mail headers, a character set must be filled in. The string used is stored in CHARSET, and the default value is ISO-8859-1 (also known as Latin1 (latin-one)).

This module can also be used from the command line. Usage is as follows:

mimify.py -e [-l length] [infile [outfile]]
mimify.py -d [-b] [infile [outfile]]

to encode (mimify) and decode (unmimify) respectively. infile defaults to standard input, outfile defaults to standard output. The
same file can be specified for input and output.

If the `-I` option is given when encoding, if there are any lines longer than the specified `length`, the containing part will be encoded.

If the `-b` option is given when decoding, any base64 parts will be decoded as well.

**See also:**

**Module** quopri

Encode and decode MIME quoted-printable files.
18.10. `multifile` — Support for files containing distinct parts

*Deprecated since version 2.5:* The `email` package should be used in preference to the `multifile` module. This module is present only to maintain backward compatibility.

The `MultiFile` object enables you to treat sections of a text file as file-like input objects, with `''` being returned by `readline()` when a given delimiter pattern is encountered. The defaults of this class are designed to make it useful for parsing MIME multipart messages, but by subclassing it and overriding methods it can be easily adapted for more general use.

```python
class multifile.MultiFile(fp[, seekable])

Create a multi-file. You must instantiate this class with an input object argument for the `MultiFile` instance to get lines from, such as a file object returned by `open()`.

`MultiFile` only ever looks at the input object’s `readline()`, `seek()` and `tell()` methods, and the latter two are only needed if you want random access to the individual MIME parts. To use `MultiFile` on a non-seekable stream object, set the optional `seekable` argument to false; this will prevent using the input object’s `seek()` and `tell()` methods.
```

It will be useful to know that in `MultiFile`’s view of the world, text is composed of three kinds of lines: data, section-dividers, and end-markers. MultiFile is designed to support parsing of messages that may have multiple nested message parts, each with its own pattern for section-divider and end-marker lines.
See also:

**Module email**

Comprehensive email handling package; supersedes the **multifile** module.
18.10.1. MultiFile Objects

A MultiFile instance has the following methods:

MultiFile.\texttt{readline}($str$)

Read a line. If the line is data (not a section-divider or end-marker or real EOF) return it. If the line matches the most-recently-stacked boundary, return '' and set self.last to 1 or 0 according as the match is or is not an end-marker. If the line matches any other stacked boundary, raise an error. On encountering end-of-file on the underlying stream object, the method raises Error unless all boundaries have been popped.

MultiFile.\texttt{readlines}($str$)

Return all lines remaining in this part as a list of strings.

MultiFile.\texttt{read}()

Read all lines, up to the next section. Return them as a single (multiline) string. Note that this doesn’t take a size argument!

MultiFile.\texttt{seek}($pos[, whence]$)

Seek. Seek indices are relative to the start of the current section. The pos and whence arguments are interpreted as for a file seek.

MultiFile.\texttt{tell}()

Return the file position relative to the start of the current section.

MultiFile.\texttt{next}()

Skip lines to the next section (that is, read lines until a section-divider or end-marker has been consumed). Return true if there is such a section, false if an end-marker is seen. Re-enable the most-recently-pushed boundary.
MultiFile.is_data(str)
Return true if str is data and false if it might be a section boundary. As written, it tests for a prefix other than '---' at start of line (which all MIME boundaries have) but it is declared so it can be overridden in derived classes.

Note that this test is used intended as a fast guard for the real boundary tests; if it always returns false it will merely slow processing, not cause it to fail.

MultiFile.push(str)
Push a boundary string. When a decorated version of this boundary is found as an input line, it will be interpreted as a section-divider or end-marker (depending on the decoration, see RFC 2045). All subsequent reads will return the empty string to indicate end-of-file, until a call to pop() removes the boundary a or next() call reenables it.

It is possible to push more than one boundary. Encountering the most-recently-pushed boundary will return EOF; encountering any other boundary will raise an error.

MultiFile.pop()
Pop a section boundary. This boundary will no longer be interpreted as EOF.

MultiFile.section_divider(str)
Turn a boundary into a section-divider line. By default, this method prepends '---' (which MIME section boundaries have) but it is declared so it can be overridden in derived classes. This method need not append LF or CR-LF, as comparison with the result ignores trailing whitespace.

MultiFile.end_marker(str)
Turn a boundary string into an end-marker line. By default, this method prepends ‘--‘ and appends ‘--‘ (like a MIME-multipart end-of-message marker) but it is declared so it can be overridden in derived classes. This method need not append LF or CR-LF, as comparison with the result ignores trailing whitespace.

Finally, **MultiFile** instances have two public instance variables:

**MultiFile. level**
- Nesting depth of the current part.

**MultiFile. last**
- True if the last end-of-file was for an end-of-message marker.
import mimetools
import multifile
import StringIO

def extract_mime_part_matching(stream, mimetype):
    """Return the first element in a multipart MIME message on matching mimetype."""

    msg = mimetools.Message(stream)
    msgtype = msg.gettype()
    params = msg.getplist()

    data = StringIO.StringIO()
    if msgtype[:10] == "multipart/"
        file = multifile.MultiFile(stream)
        file.push(msg.getparam("boundary"))
        while file.next():
            submsg = mimetools.Message(file)
            try:
                data = StringIO.StringIO()
                mimetools.decode(file, data, submsg.getencoding)
            except ValueError:
                continue
            if submsg.gettype() == mimetype:
                break
        file.pop()
    return data.getvalue()
18.11. rfc822 — Parse RFC 2822 mail headers

*Deprecated since version 2.3:* The `email` package should be used in preference to the `rfc822` module. This module is present only to maintain backward compatibility, and has been removed in 3.0.

This module defines a class, `Message`, which represents an “email message” as defined by the Internet standard RFC 2822. [1] Such messages consist of a collection of message headers, and a message body. This module also defines a helper class `AddressList` for parsing RFC 2822 addresses. Please refer to the RFC for information on the specific syntax of RFC 2822 messages.

The `mailbox` module provides classes to read mailboxes produced by various end-user mail programs.

```python
class rfc822.Message(file[, seekable])
```

A `Message` instance is instantiated with an input object as parameter. Message relies only on the input object having a `readline()` method; in particular, ordinary file objects qualify. Instantiation reads headers from the input object up to a delimiter line (normally a blank line) and stores them in the instance. The message body, following the headers, is not consumed.

This class can work with any input object that supports a `readline()` method. If the input object has seek and tell capability, the `rewindbody()` method will work; also, illegal lines will be pushed back onto the input stream. If the input object lacks seek but has an `unread()` method that can push back a line of input, `Message` will use that to push back illegal lines. Thus this
class can be used to parse messages coming from a buffered stream.

The optional *seekable* argument is provided as a workaround for certain stdio libraries in which *tell()* discards buffered data before discovering that the *lseek()* system call doesn’t work. For maximum portability, you should set the seekable argument to zero to prevent that initial *tell()* when passing in an unseekable object such as a file object created from a socket object.

Input lines as read from the file may either be terminated by CR-LF or by a single linefeed; a terminating CR-LF is replaced by a single linefeed before the line is stored.

All header matching is done independent of upper or lower case; e.g. `m['From']`, `m['from']` and `m['FROM']` all yield the same result.

class rfc822.AddressList(field)
   You may instantiate the AddressList helper class using a single string parameter, a comma-separated list of RFC 2822 addresses to be parsed. (The parameter *None* yields an empty list.)

class rfc822.quote(str)
   Return a new string with backslashes in *str* replaced by two backslashes and double quotes replaced by backslash-double quote.

class rfc822.unquote(str)
   Return a new string which is an unquoted version of *str*. If *str* ends and begins with double quotes, they are stripped off. Likewise if *str* ends and begins with angle brackets, they are stripped off.

class rfc822.parseaddr(address)
Parse *address*, which should be the value of some address-containing field such as *To* or *Cc*, into its constituent “realname” and “email address” parts. Returns a tuple of that information, unless the parse fails, in which case a 2-tuple `(None, None)` is returned.

**rfc822. dump_address_pair(pair)**

The inverse of `parseaddr()`, this takes a 2-tuple of the form `(realname, email_address)` and returns the string value suitable for a *To* or *Cc* header. If the first element of `pair` is false, then the second element is returned unmodified.

**rfc822. parsedate(date)**

Attempts to parse a date according to the rules in [RFC 2822](https://tools.ietf.org/html/rfc2822). However, some mailers don’t follow that format as specified, so `parsedate()` tries to guess correctly in such cases. *date* is a string containing an [RFC 2822](https://tools.ietf.org/html/rfc2822) date, such as `'Mon, 20 Nov 1995 19:12:08 -0500'`. If it succeeds in parsing the date, `parsedate()` returns a 9-tuple that can be passed directly to `time.mktime()`; otherwise `None` will be returned. Note that indexes 6, 7, and 8 of the result tuple are not usable.

**rfc822. parsedate_tz(date)**

Performs the same function as `parsedate()`, but returns either `None` or a 10-tuple; the first 9 elements make up a tuple that can be passed directly to `time.mktime()`, and the tenth is the offset of the date’s timezone from UTC (which is the official term for Greenwich Mean Time). (Note that the sign of the timezone offset is the opposite of the sign of the `time.timezone` variable for the same timezone; the latter variable follows the POSIX standard while this module follows [RFC 2822](https://tools.ietf.org/html/rfc2822).) If the input string has no timezone, the last element of the tuple returned is `None`. Note that indexes 6, 7, and 8 of the result tuple are not usable.
**rfc822.mktime_tz(tuple)**

Turn a 10-tuple as returned by `parsedate_tz()` into a UTC timestamp. If the timezone item in the tuple is `None`, assume local time. Minor deficiency: this first interprets the first 8 elements as a local time and then compensates for the timezone difference; this may yield a slight error around daylight savings time switch dates. Not enough to worry about for common use.

---

**See also:**

Classes to read various mailbox formats produced by end-user mail programs.

**Module mimetools**

Subclass of `rfc822.Message` that handles MIME encoded messages.
18.11.1. Message Objects

A `Message` instance has the following methods:

Message. **rewindbody()**

Seek to the start of the message body. This only works if the file object is seekable.

Message. **isheader(line)**

Returns a line's canonicalized fieldname (the dictionary key that will be used to index it) if the line is a legal RFC 2822 header; otherwise returns `None` (implying that parsing should stop here and the line be pushed back on the input stream). It is sometimes useful to override this method in a subclass.

Message. **islast(line)**

Return `true` if the given line is a delimiter on which Message should stop. The delimiter line is consumed, and the file object's read location positioned immediately after it. By default this method just checks that the line is blank, but you can override it in a subclass.

Message. **iscomment(line)**

Return `True` if the given line should be ignored entirely, just skipped. By default this is a stub that always returns `False`, but you can override it in a subclass.

Message. **getallmatchingheaders(name)**

Return a list of lines consisting of all headers matching `name`, if any. Each physical line, whether it is a continuation line or not, is a separate list item. Return the empty list if no header matches `name`.
Message. **getfirstmatchingheader**(name)

Return a list of lines comprising the first header matching name, and its continuation line(s), if any. Return None if there is no header matching name.

Message. **getrawheader**(name)

Return a single string consisting of the text after the colon in the first header matching name. This includes leading whitespace, the trailing linefeed, and internal linefeeds and whitespace if there any continuation line(s) were present. Return None if there is no header matching name.

Message. **getheader**(name[, default])

Return a single string consisting of the last header matching name, but strip leading and trailing whitespace. Internal whitespace is not stripped. The optional default argument can be used to specify a different default to be returned when there is no header matching name; it defaults to None. This is the preferred way to get parsed headers.

Message. **get**(name[, default])

An alias for getheader(), to make the interface more compatible with regular dictionaries.

Message. **getaddr**(name)

Return a pair (full name, email address) parsed from the string returned by getheader(name). If no header matching name exists, return (None, None); otherwise both the full name and the address are (possibly empty) strings.

Example: If *m*’s first From header contains the string 'jack@cwi.nl (Jack Jansen)', then m.getaddr('From') will yield the pair ('Jack Jansen', 'jack@cwi.nl'). If the header contained
instead, it would yield the exact same result.

Message. **getaddrlist(name)**

This is similar to **getaddr(list)**, but parses a header containing a list of email addresses (e.g. a To header) and returns a list of (full name, email address) pairs (even if there was only one address in the header). If there is no header matching name, return an empty list.

If multiple headers exist that match the named header (e.g. if there are several Cc headers), all are parsed for addresses. Any continuation lines the named headers contain are also parsed.

Message. **getdate(name)**

Retrieve a header using **getheader()** and parse it into a 9-tuple compatible with **time.mktime();** note that fields 6, 7, and 8 are not usable. If there is no header matching name, or it is unparsable, return None.

Date parsing appears to be a black art, and not all mailers adhere to the standard. While it has been tested and found correct on a large collection of email from many sources, it is still possible that this function may occasionally yield an incorrect result.

Message. **getdate_tz(name)**

Retrieve a header using **getheader()** and parse it into a 10-tuple; the first 9 elements will make a tuple compatible with **time.mktime()**, and the 10th is a number giving the offset of the date's timezone from UTC. Note that fields 6, 7, and 8 are not usable. Similarly to **getdate()**, if there is no header matching name, or it is unparsable, return None.

Message instances also support a limited mapping interface. In
particular: m[name] is like m.getheader(name) but raises KeyError if there is no matching header; and len(m), m.get(name[, default]), name in m, m.keys(), m.values() m.items(), and m.setdefault(name[, default]) act as expected, with the one difference that setdefault() uses an empty string as the default value. Message instances also support the mapping writable interface m[name] = value and del m[name]. Message objects do not support the clear(), copy(), popitem(), or update() methods of the mapping interface. (Support for get() and setdefault() was only added in Python 2.2.)

Finally, Message instances have some public instance variables:

Message.headers
A list containing the entire set of header lines, in the order in which they were read (except that setitem calls may disturb this order). Each line contains a trailing newline. The blank line terminating the headers is not contained in the list.

Message.fp
The file or file-like object passed at instantiation time. This can be used to read the message content.

Message.unixfrom
The Unix From line, if the message had one, or an empty string. This is needed to regenerate the message in some contexts, such as an mbox-style mailbox file.
18.11.2. AddressList Objects

An `AddressList` instance has the following methods:

`AddressList.__len__()`

Return the number of addresses in the address list.

`AddressList.__str__()`

Return a canonicalized string representation of the address list. Addresses are rendered in “name” `<host@domain>` form, comma-separated.

`AddressList.__add__(alist)`

Return a new `AddressList` instance that contains all addresses in both `AddressList` operands, with duplicates removed (set union).

`AddressList.__iadd__(alist)`

In-place version of `__add__()`; turns this `AddressList` instance into the union of itself and the right-hand instance, `alist`.

`AddressList.__sub__(alist)`

Return a new `AddressList` instance that contains every address in the left-hand `AddressList` operand that is not present in the right-hand address operand (set difference).

`AddressList.__isub__(alist)`

In-place version of `__sub__()`, removing addresses in this list which are also in `alist`.

Finally, `AddressList` instances have one public instance variable:

`AddressList.addresslist`

A list of tuple string pairs, one per address. In each member, the
first is the canonicalized name part, the second is the actual route-address ('@'-separated username-host.domain pair).

Footnotes

This module originally conformed to RFC 822, hence the name. Since then, RFC 2822 has been released as an update to RFC 822. This module should be considered RFC 2822-conformant, especially in cases where the syntax or semantics have changed since RFC 822.
This module provides data encoding and decoding as specified in RFC 3548. This standard defines the Base16, Base32, and Base64 algorithms for encoding and decoding arbitrary binary strings into text strings that can be safely sent by email, used as parts of URLs, or included as part of an HTTP POST request. The encoding algorithm is not the same as the uuencode program.

There are two interfaces provided by this module. The modern interface supports encoding and decoding string objects using all three alphabets. The legacy interface provides for encoding and decoding to and from file-like objects as well as strings, but only using the Base64 standard alphabet.

The modern interface, which was introduced in Python 2.4, provides:

```python
base64.b64encode(s[, altchars])
```

Encode a string use Base64.

`s` is the string to encode. Optional `altchars` must be a string of at least length 2 (additional characters are ignored) which specifies an alternative alphabet for the `+` and `/` characters. This allows an application to e.g. generate URL or filesystem safe Base64 strings. The default is `None`, for which the standard Base64 alphabet is used.

The encoded string is returned.

```python
base64.b64decode(s[, altchars])
```
Decode a Base64 encoded string.

`s` is the string to decode. Optional `altchars` must be a string of at least length 2 (additional characters are ignored) which specifies the alternative alphabet used instead of the `+` and `/` characters.

The decoded string is returned. A `TypeError` is raised if `s` were incorrectly padded or if there are non-alphabet characters present in the string.

```
base64.standard_b64encode(s)
```

Encode string `s` using the standard Base64 alphabet.

```
base64.standard_b64decode(s)
```

Decode string `s` using the standard Base64 alphabet.

```
base64.urlsafe_b64encode(s)
```

Encode string `s` using a URL-safe alphabet, which substitutes `-` instead of `+` and `_` instead of `/` in the standard Base64 alphabet. The result can still contain `=`.

```
base64.urlsafe_b64decode(s)
```

Decode string `s` using a URL-safe alphabet, which substitutes `-` instead of `+` and `_` instead of `/` in the standard Base64 alphabet.

```
base64.b32encode(s)
```

Encode a string using Base32. `s` is the string to encode. The encoded string is returned.

```
base64.b32decode(s[, casefold[, map01]])
```

Decode a Base32 encoded string.

`s` is the string to decode. Optional `casefold` is a flag specifying whether a lowercase alphabet is acceptable as input. For security
purposes, the default is `False`.

**RFC 3548** allows for optional mapping of the digit 0 (zero) to the letter O (oh), and for optional mapping of the digit 1 (one) to either the letter I (eye) or letter L (el). The optional argument `map01` when not `None`, specifies which letter the digit 1 should be mapped to (when `map01` is not `None`, the digit 0 is always mapped to the letter O). For security purposes the default is `None`, so that 0 and 1 are not allowed in the input.

The decoded string is returned. A `TypeError` is raised if `s` were incorrectly padded or if there are non-alphabet characters present in the string.

**base64.** `b16encode(s)`

Encode a string using Base16.

`s` is the string to encode. The encoded string is returned.

**base64.** `b16decode(s[, casefold])`

Decode a Base16 encoded string.

`s` is the string to decode. Optional `casefold` is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is `False`.

The decoded string is returned. A `TypeError` is raised if `s` were incorrectly padded or if there are non-alphabet characters present in the string.

The legacy interface:

**base64.** `decode(input, output)`

Decode the contents of the `input` file and write the resulting binary data to the `output` file. `input` and `output` must either be file objects
or objects that mimic the file object interface. `input` will be read until `input.read()` returns an empty string.

**base64. `decodestring(s)`**

Decode the string `s`, which must contain one or more lines of base64 encoded data, and return a string containing the resulting binary data.

**base64. `encode(input, output)`**

Encode the contents of the `input` file and write the resulting base64 encoded data to the `output` file. `input` and `output` must either be file objects or objects that mimic the file object interface. `input` will be read until `input.read()` returns an empty string. `encode()` returns the encoded data plus a trailing newline character (`'\n'`).

**base64. `encodestring(s)`**

Encode the string `s`, which can contain arbitrary binary data, and return a string containing one or more lines of base64-encoded data. `encodestring()` returns a string containing one or more lines of base64-encoded data always including an extra trailing newline (`'\n'`).

An example usage of the module:

```python
>>> import base64
>>> encoded = base64.b64encode('data to be encoded')
>>> encoded
'ZGF0YSB0byBiZSBlbmNvZGVk'
>>> data = base64.b64decode(encoded)
>>> data
'data to be encoded'
```

**See also:**

**Module** [binascii](http://docs.python.org/library/binascii.html)
Support module containing ASCII-to-binary and binary-to-ASCII conversions.

**RFC 1521 - MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies**

Section 5.2, “Base64 Content-Transfer-Encoding,” provides the definition of the base64 encoding.
18.13. `binhex` — Encode and decode binhex4 files

This module encodes and decodes files in binhex4 format, a format allowing representation of Macintosh files in ASCII. On the Macintosh, both forks of a file and the finder information are encoded (or decoded), on other platforms only the data fork is handled.

**Note:** In Python 3.x, special Macintosh support has been removed.

The `binhex` module defines the following functions:

```python
binhex.binhex(input, output)
```

Convert a binary file with filename `input` to binhex file `output`. The `output` parameter can either be a filename or a file-like object (any object supporting a `write()` and `close()` method).

```python
binhex.hexbin(input[, output])
```

Decode a binhex file `input`. `input` may be a filename or a file-like object supporting `read()` and `close()` methods. The resulting file is written to a file named `output`, unless the argument is omitted in which case the output filename is read from the binhex file.

The following exception is also defined:

```python
exception binhex.Error
```

Exception raised when something can’t be encoded using the binhex format (for example, a filename is too long to fit in the filename field), or when input is not properly encoded binhex data.
See also:

**Module binascii**
Support module containing ASCII-to-binary and binary-to-ASCII conversions.
18.13.1. Notes

There is an alternative, more powerful interface to the coder and decoder, see the source for details.

If you code or decode textfiles on non-Macintosh platforms they will still use the old Macintosh newline convention (carriage-return as end of line).

As of this writing, `hexbin()` appears to not work in all cases.
18.14. binascii — Convert between binary and ASCII

The `binascii` module contains a number of methods to convert between binary and various ASCII-encoded binary representations. Normally, you will not use these functions directly but use wrapper modules like `uu`, `base64`, or `binhex` instead. The `binascii` module contains low-level functions written in C for greater speed that are used by the higher-level modules.

The `binascii` module defines the following functions:

- **`binascii.a2b_uu(string)`**
  Convert a single line of uuencoded data back to binary and return the binary data. Lines normally contain 45 (binary) bytes, except for the last line. Line data may be followed by whitespace.

- **`binascii.b2a_uu(data)`**
  Convert binary data to a line of ASCII characters, the return value is the converted line, including a newline char. The length of `data` should be at most 45.

- **`binascii.a2b_base64(string)`**
  Convert a block of base64 data back to binary and return the binary data. More than one line may be passed at a time.

- **`binascii.b2a_base64(data)`**
  Convert binary data to a line of ASCII characters in base64 coding. The return value is the converted line, including a newline char. The length of `data` should be at most 57 to adhere to the base64 standard.

- **`binascii.a2b_qp(string[, header])`**
Convert a block of quoted-printable data back to binary and return the binary data. More than one line may be passed at a time. If the optional argument header is present and true, underscores will be decoded as spaces.

```
binascii.b2a_qp(data[, quotetabs, istext, header])
```

Convert binary data to a line(s) of ASCII characters in quoted-printable encoding. The return value is the converted line(s). If the optional argument quotetabs is present and true, all tabs and spaces will be encoded. If the optional argument istext is present and true, newlines are not encoded but trailing whitespace will be encoded. If the optional argument header is present and true, spaces will be encoded as underscores per RFC1522. If the optional argument header is present and false, newline characters will be encoded as well; otherwise linefeed conversion might corrupt the binary data stream.

```
binascii.a2b_hqx(string)
```

Convert binhex4 formatted ASCII data to binary, without doing RLE-decompression. The string should contain a complete number of binary bytes, or (in case of the last portion of the binhex4 data) have the remaining bits zero.

```
binascii.rledecode_hqx(data)
```

Perform RLE-decompression on the data, as per the binhex4 standard. The algorithm uses \( \text{\texttt{0x90}} \) after a byte as a repeat indicator, followed by a count. A count of \( \text{\texttt{0}} \) specifies a byte value of \( \text{\texttt{0x90}} \). The routine returns the decompressed data, unless data input data ends in an orphaned repeat indicator, in which case the Incomplete exception is raised.

```
binascii.rlecode_hqx(data)
```

Perform binhex4 style RLE-compression on data and return the result.
binascii.b2a_hqx(data)

Perform hexbin4 binary-to-ASCII translation and return the resulting string. The argument should already be RLE-coded, and have a length divisible by 3 (except possibly the last fragment).

binascii.crc_hqx(data, crc)

Compute the binhex4 crc value of data, starting with an initial crc and returning the result.

binascii.crc32(data[, crc])

Compute CRC-32, the 32-bit checksum of data, starting with an initial crc. This is consistent with the ZIP file checksum. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm. Use as follows:

```python
print binascii.crc32("hello world")
# Or, in two pieces:
crc = binascii.crc32("hello")
crc = binascii.crc32(" world", crc) & 0xffffffff
print 'crc32 = 0x%08x' % crc
```

**Note:** To generate the same numeric value across all Python versions and platforms use crc32(data) & 0xffffffff. If you are only using the checksum in packed binary format this is not necessary as the return value is the correct 32bit binary representation regardless of sign.

*Changed in version 2.6:* The return value is in the range [-2**31, 2**31-1] regardless of platform. In the past the value would be signed on some platforms and unsigned on others. Use & 0xffffffff on the value if you want it to match 3.0 behavior.

*Changed in version 3.0:* The return value is unsigned and in the range [0, 2**32-1] regardless of platform.
binascii.\texttt{b2a\_hex}(\textit{data})
binascii.\texttt{hexlify}(\textit{data})

Return the hexadecimal representation of the binary \textit{data}. Every byte of \textit{data} is converted into the corresponding 2-digit hex representation. The resulting string is therefore twice as long as the length of \textit{data}.

binascii.\texttt{a2b\_hex}(\textit{hexstr})
binascii.\texttt{unhexlify}(\textit{hexstr})

Return the binary data represented by the hexadecimal string \textit{hexstr}. This function is the inverse of \texttt{b2a\_hex()}. \textit{hexstr} must contain an even number of hexadecimal digits (which can be upper or lower case), otherwise a \texttt{TypeError} is raised.

\textit{exception} binascii.\texttt{Error}

Exception raised on errors. These are usually programming errors.

\textit{exception} binascii.\texttt{Incomplete}

Exception raised on incomplete data. These are usually not programming errors, but may be handled by reading a little more data and trying again.

\textbf{See also:}

\textbf{Module} \texttt{base64}

Support for base64 encoding used in MIME email messages.

\textbf{Module} \texttt{binhex}

Support for the binhex format used on the Macintosh.

\textbf{Module} \texttt{uu}

Support for UU encoding used on Unix.

\textbf{Module} \texttt{quopri}

Support for quoted-printable encoding used in MIME email
messages.
18.15. quopri — Encode and decode MIME quoted-printable data

This module performs quoted-printable transport encoding and decoding, as defined in RFC 1521: “MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies”. The quoted-printable encoding is designed for data where there are relatively few nonprintable characters; the base64 encoding scheme available via the base64 module is more compact if there are many such characters, as when sending a graphics file.

See also: Latest version of the quopri module Python source code

quopri.decode(input, output[, header])

Decode the contents of the input file and write the resulting decoded binary data to the output file. input and output must either be file objects or objects that mimic the file object interface. input will be read until input.readline() returns an empty string. If the optional argument header is present and true, underscore will be decoded as space. This is used to decode “Q”-encoded headers as described in RFC 1522: “MIME (Multipurpose Internet Mail Extensions) Part Two: Message Header Extensions for Non-ASCII Text”.

quopri.encode(input, output, quotetabs)

Encode the contents of the input file and write the resulting quoted-printable data to the output file. input and output must either be file objects or objects that mimic the file object interface. input will be read until input.readline() returns an empty string. quotetabs is a flag which controls whether to encode embedded
spaces and tabs; when true it encodes such embedded whitespace, and when false it leaves them unencoded. Note that spaces and tabs appearing at the end of lines are always encoded, as per RFC 1521.

quopri.**decodestring***(\[s, header])
Like `decode()`, except that it accepts a source string and returns the corresponding decoded string.

quopri.**encodestring***(\[s, quotetabs])
Like `encode()`, except that it accepts a source string and returns the corresponding encoded string. `quotetabs` is optional (defaulting to 0), and is passed straight through to `encode()`.

See also:

**Module* mimify**
General utilities for processing of MIME messages.

**Module* base64**
Encode and decode MIME base64 data
This module encodes and decodes files in uuencode format, allowing arbitrary binary data to be transferred over ASCII-only connections. Wherever a file argument is expected, the methods accept a file-like object. For backwards compatibility, a string containing a pathname is also accepted, and the corresponding file will be opened for reading and writing; the pathname `-` is understood to mean the standard input or output. However, this interface is deprecated; it’s better for the caller to open the file itself, and be sure that, when required, the mode is `'rb'` or `'wb'` on Windows.

This code was contributed by Lance Ellinghouse, and modified by Jack Jansen.

See also: Latest version of the uu module Python source code

The `uu` module defines the following functions:

`uu.encode(in_file, out_file[, name[, mode]])`

Uuencode file `in_file` into file `out_file`. The uuencoded file will have the header specifying `name` and `mode` as the defaults for the results of decoding the file. The default defaults are taken from `in_file`, or `-` and `0666` respectively.

`uu.decode(in_file[, out_file[, mode[, quiet]]])`

This call decodes uuencoded file `in_file` placing the result on file `out_file`. If `out_file` is a pathname, `mode` is used to set the permission bits if the file must be created. Defaults for `out_file` and `mode` are taken from the uuencode header. However, if the
file specified in the header already exists, a \texttt{uu.Error} is raised.

\texttt{decode()} may print a warning to standard error if the input was produced by an incorrect uuencoder and Python could recover from that error. Setting \texttt{quiet} to a true value silences this warning.

\textit{exception} \texttt{uu.Error}

Subclass of \texttt{Exception}, this can be raised by \texttt{uu.decode()} under various situations, such as described above, but also including a badly formatted header, or truncated input file.

\textbf{Module \texttt{binascii}}

Support module containing ASCII-to-binary and binary-to-ASCII conversions.
19. Structured Markup Processing Tools

Python supports a variety of modules to work with various forms of structured data markup. This includes modules to work with the Standard Generalized Markup Language (SGML) and the Hypertext Markup Language (HTML), and several interfaces for working with the Extensible Markup Language (XML).

It is important to note that modules in the xml package require that there be at least one SAX-compliant XML parser available. Starting with Python 2.3, the Expat parser is included with Python, so the xml.parsers.expat module will always be available. You may still want to be aware of the PyXML add-on package; that package provides an extended set of XML libraries for Python.

The documentation for the xml.dom and xml.sax packages are the definition of the Python bindings for the DOM and SAX interfaces.

19.1. HTMLParser — Simple HTML and XHTML parser

**Note:** The `HTMLParser` module has been renamed to `html.parser` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

*New in version 2.2.*

This module defines a class `HTMLParser` which serves as the basis for parsing text files formatted in HTML (HyperText Mark-up Language) and XHTML. Unlike the parser in `htmllib`, this parser is not based on the SGML parser in `sgmllib`.

```python
class HTMLParser

    The `HTMLParser` class is instantiated without arguments.

    An `HTMLParser` instance is fed HTML data and calls handler functions when tags begin and end. The `HTMLParser` class is meant to be overridden by the user to provide a desired behavior.

    Unlike the parser in `htmllib`, this parser does not check that end tags match start tags or call the end-tag handler for elements which are closed implicitly by closing an outer element.

An exception is defined as well:

```exception

    Exception raised by the `HTMLParser` class when it encounters an error while parsing. This exception provides three attributes: `msg` is a brief message explaining the error, `lineno` is the number of the line on which the broken construct was detected, and `offset`
is the number of characters into the line at which the construct starts.

**HTMLParser** instances have the following methods:

**HTMLParser. reset()**
Reset the instance. Loses all unprocessed data. This is called implicitly at instantiation time.

**HTMLParser. feed(data)**
Feed some text to the parser. It is processed insofar as it consists of complete elements; incomplete data is buffered until more data is fed or close() is called.

**HTMLParser. close()**
Force processing of all buffered data as if it were followed by an end-of-file mark. This method may be redefined by a derived class to define additional processing at the end of the input, but the redefined version should always call the **HTMLParser** base class method close().

**HTMLParser. getpos()**
Return current line number and offset.

**HTMLParser. get_starttag_text()**
Return the text of the most recently opened start tag. This should not normally be needed for structured processing, but may be useful in dealing with HTML “as deployed” or for re-generating input with minimal changes (whitespace between attributes can be preserved, etc.).

**HTMLParser. handle_starttag(tag, attrs)**
This method is called to handle the start of a tag. It is intended to be overridden by a derived class; the base class implementation
does nothing.

The tag argument is the name of the tag converted to lower case. The attrs argument is a list of \((\text{name}, \text{value})\) pairs containing the attributes found inside the tag’s `<>` brackets. The name will be translated to lower case, and quotes in the value have been removed, and character and entity references have been replaced. For instance, for the tag `<A HREF="http://www.cwi.nl/">`, this method would be called as `handle_starttag('a', [('href', 'http://www.cwi.nl/')])`.

*Changed in version 2.6:* All entity references from `htmlentitydefs` are now replaced in the attribute values.

**HTMLParser. \texttt{handle_startendtag}**(tag, attrs)

Similar to `handle_starttag()`, but called when the parser encounters an XHTML-style empty tag (<a .../>). This method may be overridden by subclasses which require this particular lexical information; the default implementation simple calls `handle_starttag()` and `handle_endtag()`.

**HTMLParser. \texttt{handle_endtag}**(tag)

This method is called to handle the end tag of an element. It is intended to be overridden by a derived class; the base class implementation does nothing. The tag argument is the name of the tag converted to lower case.

**HTMLParser. \texttt{handle_data}**(data)

This method is called to process arbitrary data. It is intended to be overridden by a derived class; the base class implementation does nothing.

**HTMLParser. \texttt{handle_charref}**(name)

This method is called to process a character reference of the
form &ref;: It is intended to be overridden by a derived class; the base class implementation does nothing.

**HTMLParser**. `handle_entityref(name)`

This method is called to process a general entity reference of the form &name; where `name` is an general entity reference. It is intended to be overridden by a derived class; the base class implementation does nothing.

**HTMLParser**. `handle_comment(data)`

This method is called when a comment is encountered. The `comment` argument is a string containing the text between the -- and -- delimiters, but not the delimiters themselves. For example, the comment <!--text--> will cause this method to be called with the argument 'text'. It is intended to be overridden by a derived class; the base class implementation does nothing.

**HTMLParser**. `handle_decl(decl)`

Method called when an SGML `doctype` declaration is read by the parser. The `decl` parameter will be the entire contents of the declaration inside the <!...> markup. It is intended to be overridden by a derived class; the base class implementation does nothing.

**HTMLParser**. `unknown_decl(data)`

Method called when an unrecognized SGML declaration is read by the parser. The `data` parameter will be the entire contents of the declaration inside the <!...> markup. It is sometimes useful to be overridden by a derived class; the base class implementation throws an `HTMLParseError`.

**HTMLParser**. `handle_pi(data)`

Method called when a processing instruction is encountered. The
The `data` parameter will contain the entire processing instruction. For example, for the processing instruction `<?proc color='red'>`, this method would be called as `handle_pi("proc color='red'")`. It is intended to be overridden by a derived class; the base class implementation does nothing.

**Note:** The `HTMLParser` class uses the SGML syntactic rules for processing instructions. An XHTML processing instruction using the trailing `'? '` will cause the `'? '` to be included in `data`. 
As a basic example, below is a very basic HTML parser that uses the `HTMLParser` class to print out tags as they are encountered:

```python
from HTMLParser import HTMLParser

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print "Encountered the beginning of a %s tag" % tag

    def handle_endtag(self):
        print "Encountered the end of a %s tag" % tag
```
19.2. sgmllib — Simple SGML parser

*Deprecated since version 2.6:* The `sgmllib` module has been removed in Python 3.0.

This module defines a class `SGMLParser` which serves as the basis for parsing text files formatted in SGML (Standard Generalized Markup Language). In fact, it does not provide a full SGML parser — it only parses SGML insofar as it is used by HTML, and the module only exists as a base for the `htmllib` module. Another HTML parser which supports XHTML and offers a somewhat different interface is available in the `HTMLParser` module.

```python
class sgmllib.SGMLParser

The `SGMLParser` class is instantiated without arguments. The parser is hardcoded to recognize the following constructs:

- Opening and closing tags of the form `<tag attr="value" ...>` and `</tag>`, respectively.
- Numeric character references of the form `&#name;`.
- Entity references of the form `&name;`.
- SGML comments of the form `<![--text-->]`. Note that spaces, tabs, and newlines are allowed between the trailing `>` and the immediately preceding `--`. 

A single exception is defined as well:

```python
exception sgmllib.SGMLParseError

Exception raised by the `SGMLParser` class when it encounters an error while parsing.
```
New in version 2.1.

SGMLParser instances have the following methods:

SGMLParser.**reset()**
Reset the instance. Loses all unprocessed data. This is called implicitly at instantiation time.

SGMLParser.**setnomoretags()**
Stop processing tags. Treat all following input as literal input (CDATA). (This is only provided so the HTML tag `<PLAINTEXT>` can be implemented.)

SGMLParser.**setliteral()**
Enter literal mode (CDATA mode).

SGMLParser.**feed(data)**
Feed some text to the parser. It is processed insofar as it consists of complete elements; incomplete data is buffered until more data is fed or **close()** is called.

SGMLParser.**close()**
Force processing of all buffered data as if it were followed by an end-of-file mark. This method may be redefined by a derived class to define additional processing at the end of the input, but the redefined version should always call **close()**.

SGMLParser.**get_starttag_text()**
Return the text of the most recently opened start tag. This should not normally be needed for structured processing, but may be useful in dealing with HTML “as deployed” or for re-generating input with minimal changes (whitespace between attributes can be preserved, etc.).

SGMLParser.**handle_starttag(tag, method, attributes)**
This method is called to handle start tags for which either a `start_tag()` or `do_tag()` method has been defined. The `tag` argument is the name of the tag converted to lower case, and the `method` argument is the bound method which should be used to support semantic interpretation of the start tag. The `attributes` argument is a list of `(name, value)` pairs containing the attributes found inside the tag’s `<>` brackets.

The `name` has been translated to lower case. Double quotes and backslashes in the `value` have been interpreted, as well as known character references and known entity references terminated by a semicolon (normally, entity references can be terminated by any non-alphanumerical character, but this would break the very common case of `<A HREF="url?spam=1&eggs=2">` when `eggs` is a valid entity name).

For instance, for the tag `<A HREF="http://www.cwi.nl/">`, this method would be called as `unknown_starttag('a', [('href', 'http://www.cwi.nl/')])`. The base implementation simply calls `method` with `attributes` as the only argument.

New in version 2.5: Handling of entity and character references within attribute values.

`SGMLParser.handle_endtag(tag, method)`

This method is called to handle endtags for which an `end_tag()` method has been defined. The `tag` argument is the name of the tag converted to lower case, and the `method` argument is the bound method which should be used to support semantic interpretation of the end tag. If no `end_tag()` method is defined for the closing element, this handler is not called. The base implementation simply calls `method`.

`SGMLParser.handle_data(data)`
This method is called to process arbitrary data. It is intended to be overridden by a derived class; the base class implementation does nothing.

SGMLParser.handle_charref(ref)

This method is called to process a character reference of the form &ref;. The base implementation uses convert_charref() to convert the reference to a string. If that method returns a string, it is passed to handle_data(), otherwise unknown_charref(ref) is called to handle the error.

*Changed in version 2.5:* Use convert_charref() instead of hard-coding the conversion.

SGMLParser.convert_charref(ref)

Convert a character reference to a string, or None. ref is the reference passed in as a string. In the base implementation, ref must be a decimal number in the range 0-255. It converts the code point found using the convert_codepoint() method. If ref is invalid or out of range, this method returns None. This method is called by the default handle_charref() implementation and by the attribute value parser.

*New in version 2.5.*

SGMLParser.convert_codepoint(codepoint)

Convert a codepoint to a str value. Encodings can be handled here if appropriate, though the rest of sgmllib is oblivious on this matter.

*New in version 2.5.*

SGMLParser.handle_entityref(ref)

This method is called to process a general entity reference of the
form &ref; where ref is an general entity reference. It converts ref by passing it to convert_entityref(). If a translation is returned, it calls the method handle_data() with the translation; otherwise, it calls the method unknown_entityref(ref). The default entitydefs defines translations for &amp;, &apos, &gt;, &lt;, and &quot;.

Changed in version 2.5: Use convert_entityref() instead of hard-coding the conversion.

SGMLParser.convert_entityref(ref)
Convert a named entity reference to a str value, or None. The resulting value will not be parsed. ref will be only the name of the entity. The default implementation looks for ref in the instance (or class) variable entitydefs which should be a mapping from entity names to corresponding translations. If no translation is available for ref, this method returns None. This method is called by the default handle_entityref() implementation and by the attribute value parser.

New in version 2.5.

SGMLParser.handle_comment(comment)
This method is called when a comment is encountered. The comment argument is a string containing the text between the <!-- and --> delimiters, but not the delimiters themselves. For example, the comment <!--text--> will cause this method to be called with the argument 'text'. The default method does nothing.

SGMLParser.handle_decl(data)
Method called when an SGML declaration is read by the parser. In practice, the DOCTYPE declaration is the only thing observed in
HTML, but the parser does not discriminate among different (or broken) declarations. Internal subsets in a \texttt{DOCTYPE} declaration are not supported. The \texttt{data} parameter will be the entire contents of the declaration inside the \texttt{<!...>} markup. The default implementation does nothing.

\texttt{SGMLParser.report_unbalanced(tag)}
This method is called when an end tag is found which does not correspond to any open element.

\texttt{SGMLParser.unknown_starttag(tag, attributes)}
This method is called to process an unknown start tag. It is intended to be overridden by a derived class; the base class implementation does nothing.

\texttt{SGMLParser.unknown_endtag(tag)}
This method is called to process an unknown end tag. It is intended to be overridden by a derived class; the base class implementation does nothing.

\texttt{SGMLParser.unknown_charref(ref)}
This method is called to process unresolvable numeric character references. Refer to \texttt{handle_charref()} to determine what is handled by default. It is intended to be overridden by a derived class; the base class implementation does nothing.

\texttt{SGMLParser.unknown_entityref(ref)}
This method is called to process an unknown entity reference. It is intended to be overridden by a derived class; the base class implementation does nothing.

Apart from overriding or extending the methods listed above, derived classes may also define methods of the following form to define processing of specific tags. Tag names in the input stream are case
independent; the tag occurring in method names must be in lower case:

SGMLParser.`start_tag(attributes)`
This method is called to process an opening tag tag. It has preference over `do_tag()`. The attributes argument has the same meaning as described for `handle_starttag()` above.

SGMLParser.`do_tag(attributes)`
This method is called to process an opening tag tag for which no `start_tag()` method is defined. The attributes argument has the same meaning as described for `handle_starttag()` above.

SGMLParser.`end_tag()`
This method is called to process a closing tag tag.

Note that the parser maintains a stack of open elements for which no end tag has been found yet. Only tags processed by `start_tag()` are pushed on this stack. Definition of an `end_tag()` method is optional for these tags. For tags processed by `do_tag()` or by `unknown_tag()`, no `end_tag()` method must be defined; if defined, it will not be used. If both `start_tag()` and `do_tag()` methods exist for a tag, the `start_tag()` method takes precedence.
19.3. htmllib — A parser for HTML documents

*Deprecated since version 2.6:* The htmllib module has been removed in Python 3.0.

This module defines a class which can serve as a base for parsing text files formatted in the HyperText Mark-up Language (HTML). The class is not directly concerned with I/O — it must be provided with input in string form via a method, and makes calls to methods of a “formatter” object in order to produce output. The HTMLParser class is designed to be used as a base class for other classes in order to add functionality, and allows most of its methods to be extended or overridden. In turn, this class is derived from and extends the SGMLParser class defined in module sgmllib. The HTMLParser implementation supports the HTML 2.0 language as described in RFC 1866. Two implementations of formatter objects are provided in the formatter module; refer to the documentation for that module for information on the formatter interface.

The following is a summary of the interface defined by sgmllib.SGMLParser:

- The interface to feed data to an instance is through the `feed()` method, which takes a string argument. This can be called with as little or as much text at a time as desired; `p.feed(a); p.feed(b)` has the same effect as `p.feed(a+b)`. When the data contains complete HTML markup constructs, these are processed immediately; incomplete constructs are saved in a buffer. To force processing of all unprocessed data, call the `close()` method.
For example, to parse the entire contents of a file, use:

```python
parser.feed(open('myfile.html').read())
parser.close()
```

- The interface to define semantics for HTML tags is very simple: derive a class and define methods called `start_tag()`, `end_tag()`, or `do_tag()`. The parser will call these at appropriate moments: `start_tag()` or `do_tag()` is called when an opening tag of the form `<tag ...>` is encountered; `end_tag()` is called when a closing tag of the form `<tag>` is encountered. If an opening tag requires a corresponding closing tag, like `<H1> ...</H1>`, the class should define the `start_tag()` method; if a tag requires no closing tag, like `<P>`, the class should define the `do_tag()` method.

The module defines a parser class and an exception:

```python
class htmllib.HTMLParser(formatter)
    This is the basic HTML parser class. It supports all entity names required by the XHTML 1.0 Recommendation (http://www.w3.org/TR/xhtml1). It also defines handlers for all HTML 2.0 and many HTML 3.0 and 3.2 elements.
```

```python
exception htmllib.HTMLParseError
    Exception raised by the HTMLParser class when it encounters an error while parsing.
```

*New in version 2.4.*

See also:

```python
Module formatter
    Interface definition for transforming an abstract flow of formatting events into specific output events on writer objects.
```
Module **HTMLParser**
Alternate HTML parser that offers a slightly lower-level view of the input, but is designed to work with XHTML, and does not implement some of the SGML syntax not used in “HTML as deployed” and which isn’t legal for XHTML.

Module **htmlentitydefs**
Definition of replacement text for XHTML 1.0 entities.

Module **sgmllib**
Base class for **HTMLParser**.
19.3.1. HTMLParser Objects

In addition to tag methods, the **HTMLParser** class provides some additional methods and instance variables for use within tag methods.

**HTMLParser.formatter**

This is the formatter instance associated with the parser.

**HTMLParser.nofill**

Boolean flag which should be true when whitespace should not be collapsed, or false when it should be. In general, this should only be true when character data is to be treated as “preformatted” text, as within a `<PRE>` element. The default value is false. This affects the operation of `handle_data()` and `save_end()`.

**HTMLParser.anchor_bgn(href, name, type)**

This method is called at the start of an anchor region. The arguments correspond to the attributes of the `<A>` tag with the same names. The default implementation maintains a list of hyperlinks (defined by the `HREF` attribute for `<A>` tags) within the document. The list of hyperlinks is available as the data attribute `anchorlist`.

**HTMLParser.anchor_end()**

This method is called at the end of an anchor region. The default implementation adds a textual footnote marker using an index into the list of hyperlinks created by `anchor_bgn()`.

**HTMLParser.handle_image(source, alt[, ismap[, align[, width[, height]]]]))**
This method is called to handle images. The default implementation simply passes the \textit{alt} value to the \texttt{handle_data()} method.

\texttt{HTMLParser.save\_bgn()}

Begins saving character data in a buffer instead of sending it to the formatter object. Retrieve the stored data via \texttt{save\_end()}. Use of the \texttt{save\_bgn() / save\_end()} pair may not be nested.

\texttt{HTMLParser.save\_end()}

Ends buffering character data and returns all data saved since the preceding call to \texttt{save\_bgn()}. If the \texttt{nofill} flag is false, whitespace is collapsed to single spaces. A call to this method without a preceding call to \texttt{save\_bgn()} will raise a \texttt{TypeError} exception.
19.4. htmlentitydefs — Definitions of HTML general entities

**Note:** The `htmlentitydefs` module has been renamed to `html.entities` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

This module defines three dictionaries, `name2codepoint`, `codepoint2name`, and `entitydefs`. `entitydefs` is used by the `httplib` module to provide the `entitydefs` member of the `HTMLParser` class. The definition provided here contains all the entities defined by XHTML 1.0 that can be handled using simple textual substitution in the Latin-1 character set (ISO-8859-1).

`htmlentitydefs.entitydefs`  
A dictionary mapping XHTML 1.0 entity definitions to their replacement text in ISO Latin-1.

`htmlentitydefs.name2codepoint`  
A dictionary that maps HTML entity names to the Unicode codepoints.

*New in version 2.3.*

`htmlentitydefs.codepoint2name`  
A dictionary that maps Unicode codepoints to HTML entity names.

*New in version 2.3.*
19.5. xml.parsers.expat — Fast XML parsing using Expat

New in version 2.0.

The xml.parsers.expat module is a Python interface to the Expat non-validating XML parser. The module provides a single extension type, xmlparser, that represents the current state of an XML parser. After an xmlparser object has been created, various attributes of the object can be set to handler functions. When an XML document is then fed to the parser, the handler functions are called for the character data and markup in the XML document.

This module uses the pyexpat module to provide access to the Expat parser. Direct use of the pyexpat module is deprecated.

This module provides one exception and one type object:

exception xml.parsers.expat.ExpatError
  The exception raised when Expat reports an error. See section ExpatError Exceptions for more information on interpreting Expat errors.

exception xml.parsers.expat.error
  Alias for ExpatError.

xml.parsers.expat.XMLParserType
  The type of the return values from the ParserCreate() function.

The xml.parsers.expat module contains two functions:

xml.parsers.expat.ErrorString(errno)
  Returns an explanatory string for a given error number errno.
xml.parsers.expat.ParserCreate([encoding], namespace_separator))

Creates and returns a new xmlparser object. encoding, if specified, must be a string naming the encoding used by the XML data. Expat doesn’t support as many encodings as Python does, and its repertoire of encodings can’t be extended; it supports UTF-8, UTF-16, ISO-8859-1 (Latin1), and ASCII. If encoding [1] is given it will override the implicit or explicit encoding of the document.

Expat can optionally do XML namespace processing for you, enabled by providing a value for namespace_separator. The value must be a one-character string; a ValueError will be raised if the string has an illegal length (None is considered the same as omission). When namespace processing is enabled, element type names and attribute names that belong to a namespace will be expanded. The element name passed to the element handlers StartElementHandler and EndElementHandler will be the concatenation of the namespace URI, the namespace separator character, and the local part of the name. If the namespace separator is a zero byte (chr(0)) then the namespace URI and the local part will be concatenated without any separator.

For example, if namespace_separator is set to a space character (' ') and the following document is parsed:

```xml
<?xml version="1.0"?>
<root xmlns = "http://default-namespace.org/
     xmlns:py = "http://www.python.org/ns/">
  <py:elem1 />
  <elem2 xmlns="" />
</root>
```

StartElementHandler will receive the following strings for each element:
See also:

The Expat XML Parser
   Home page of the Expat project.
19.5.1. XMLParser Objects

xmlparser objects have the following methods:

xmlparser.Parse(data[, isfinal])
   Parses the contents of the string data, calling the appropriate handler functions to process the parsed data. isfinal must be true on the final call to this method. data can be the empty string at any time.

xmlparser.ParseFile(file)
   Parse XML data reading from the object file. file only needs to provide the read(nbytes) method, returning the empty string when there's no more data.

xmlparser.SetBase(base)
   Sets the base to be used for resolving relative URIs in system identifiers in declarations. Resolving relative identifiers is left to the application: this value will be passed through as the base argument to the ExternalEntityRefHandler(), NotationDeclHandler(), and UnparsedEntityDeclHandler() functions.

xmlparser.GetBase()
   Returns a string containing the base set by a previous call to SetBase(), or None if SetBase() hasn't been called.

xmlparser.GetInputContext()
   Returns the input data that generated the current event as a string. The data is in the encoding of the entity which contains the text. When called while an event handler is not active, the return value is None.
New in version 2.1.

*xmlparser.* **ExternalEntityParserCreate**(context[, encoding])
Create a “child” parser which can be used to parse an external parsed entity referred to by content parsed by the parent parser. The *context* parameter should be the string passed to the **ExternalEntityRefHandler** handler function, described below. The child parser is created with the *ordered_attributes*, *returns_unicode* and *specified_attributes* set to the values of this parser.

*xmlparser.* **SetParamEntityParsing**(flag)
Control parsing of parameter entities (including the external DTD subset). Possible *flag* values are *XML_PARAM_ENTITY_PARSING_NEVER*, *XML_PARAM_ENTITY_PARSING_UNLESS_STANDALONE* and *XML_PARAM_ENTITY_PARSING_ALWAYS*. Return true if setting the flag was successful.

*xmlparser.* **UseForeignDTD**(flag)
Calling this with a true value for *flag* (the default) will cause Expat to call the **ExternalEntityRefHandler** with *None* for all arguments to allow an alternate DTD to be loaded. If the document does not contain a document type declaration, the **ExternalEntityRefHandler** will still be called, but the **StartDoctypeDeclHandler** and **EndDoctypeDeclHandler** will not be called.

Passing a false value for *flag* will cancel a previous call that passed a true value, but otherwise has no effect.

This method can only be called before the **Parse**() or **ParseFile**() methods are called; calling it after either of those
have been called causes :blue:`ExpatError` to be raised with the :blue:`code` attribute :blue:`set` to :blue:`errors.XML_ERROR_CANT_CHANGE_FEATURE_ONCE_PARSING`.

*New in version 2.3.*

XMLParser objects have the following attributes:

**XMLParser.buffer_size**

The size of the buffer used when :blue:`buffer_text` is true. A new buffer size can be set by assigning a new integer value to this attribute. When the size is changed, the buffer will be flushed.

*New in version 2.3.*

*Changed in version 2.6:* The buffer size can now be changed.

**XMLParser.buffer_text**

Setting this to true causes the XMLParser object to buffer textual content returned by Expat to avoid multiple calls to the :blue:`CharacterDataHandler()` callback whenever possible. This can improve performance substantially since Expat normally breaks character data into chunks at every line ending. This attribute is false by default, and may be changed at any time.

*New in version 2.3.*

**XMLParser.buffer_used**

If :blue:`buffer_text` is enabled, the number of bytes stored in the buffer. These bytes represent UTF-8 encoded text. This attribute has no meaningful interpretation when :blue:`buffer_text` is false.

*New in version 2.3.*

**XMLParser.ordered_attributes**

Setting this attribute to a non-zero integer causes the attributes to
be reported as a list rather than a dictionary. The attributes are presented in the order found in the document text. For each attribute, two list entries are presented: the attribute name and the attribute value. (Older versions of this module also used this format.) By default, this attribute is false; it may be changed at any time.

**New in version 2.1.**

**xmlparser.returns_unicode**

If this attribute is set to a non-zero integer, the handler functions will be passed Unicode strings. If `returns_unicode` is `False`, 8-bit strings containing UTF-8 encoded data will be passed to the handlers. This is `True` by default when Python is built with Unicode support.

**Changed in version 1.6:** Can be changed at any time to affect the result type.

**xmlparser.specified_attributes**

If set to a non-zero integer, the parser will report only those attributes which were specified in the document instance and not those which were derived from attribute declarations. Applications which set this need to be especially careful to use what additional information is available from the declarations as needed to comply with the standards for the behavior of XML processors. By default, this attribute is false; it may be changed at any time.

**New in version 2.1.**

The following attributes contain values relating to the most recent error encountered by an `xmlparser` object, and will only have correct values once a call to `Parse()` or `ParseFile()` has raised a `xml.parsers.expat.ExpatError` exception.
xmlparser. **ErrorByteIndex**

Byte index at which an error occurred.

xmlparser. **ErrorCode**

Numeric code specifying the problem. This value can be passed to the `ErrorString()` function, or compared to one of the constants defined in the `errors` object.

xmlparser. **ErrorColumnNumber**

Column number at which an error occurred.

xmlparser. **ErrorLineNumber**

Line number at which an error occurred.

The following attributes contain values relating to the current parse location in an `xmlparser` object. During a callback reporting a parse event they indicate the location of the first of the sequence of characters that generated the event. When called outside of a callback, the position indicated will be just past the last parse event (regardless of whether there was an associated callback).

*New in version 2.4.*

xmlparser. **CurrentByteIndex**

Current byte index in the parser input.

xmlparser. **CurrentColumnNumber**

Current column number in the parser input.

xmlparser. **CurrentLineNumber**

Current line number in the parser input.

Here is the list of handlers that can be set. To set a handler on an `xmlparser` object `o`, use `o.handlername = func`. `handlername` must be taken from the following list, and `func` must be a callable object accepting the correct number of arguments. The arguments are all
strings, unless otherwise stated.

xmlparser. **XmlDeclHandler***(version, encoding, standalone)**

Called when the XML declaration is parsed. The XML declaration is the (optional) declaration of the applicable version of the XML recommendation, the encoding of the document text, and an optional “standalone” declaration. `version` and `encoding` will be strings of the type dictated by the `returns_unicode` attribute, and `standalone` will be 1 if the document is declared standalone, 0 if it is declared not to be standalone, or -1 if the standalone clause was omitted. This is only available with Expat version 1.95.0 or newer.

*New in version 2.1.*

xmlparser. **StartDoctypeDeclHandler***(doctypeName, systemId, publicId, has_internal_subset)**

Called when Expat begins parsing the document type declaration (**<!DOCTYPE ...**). The `doctypeName` is provided exactly as presented. The `systemId` and `publicId` parameters give the system and public identifiers if specified, or `None` if omitted. `has_internal_subset` will be true if the document contains and internal document declaration subset. This requires Expat version 1.2 or newer.

xmlparser. **EndDoctypeDeclHandler**()

Called when Expat is done parsing the document type declaration. This requires Expat version 1.2 or newer.

xmlparser. **ElementDeclHandler**(name, model)**

Called once for each element type declaration. `name` is the name of the element type, and `model` is a representation of the content model.
xmlparser. **AttlistDeclHandler**(elname, attname, type, default, required)

Called for each declared attribute for an element type. If an attribute list declaration declares three attributes, this handler is called three times, once for each attribute. *elname* is the name of the element to which the declaration applies and *attname* is the name of the attribute declared. The attribute type is a string passed as *type*; the possible values are 'CDATA', 'ID', 'IDREF', ...

*default* gives the default value for the attribute used when the attribute is not specified by the document instance, or *None* if there is no default value (#IMPLIED values). If the attribute is required to be given in the document instance, *required* will be true. This requires Expat version 1.95.0 or newer.

xmlparser. **StartElementHandler**(name, attributes)

Called for the start of every element. *name* is a string containing the element name, and *attributes* is a dictionary mapping attribute names to their values.

xmlparser. **EndElementHandler**(name)

Called for the end of every element.

xmlparser. **ProcessingInstructionHandler**(target, data)

Called for every processing instruction.

xmlparser. **CharacterDataHandler**(data)

Called for character data. This will be called for normal character data, CDATA marked content, and ignorable whitespace. Applications which must distinguish these cases can use the **StartCdataSectionHandler**, **EndCdataSectionHandler**, and **ElementDeclHandler** callbacks to collect the required information.

xmlparser. **UnparsedEntityDeclHandler**(entityName, base, systemId, publicId, notationName)
Called for unparsed (NDATA) entity declarations. This is only present for version 1.2 of the Expat library; for more recent versions, use `EntityDeclHandler` instead. (The underlying function in the Expat library has been declared obsolete.)

```
xmlparser.EntityDeclHandler(entityName, is_parameter_entity, value, base, systemId, publicId, notationName)
```

Called for all entity declarations. For parameter and internal entities, `value` will be a string giving the declared contents of the entity; this will be `None` for external entities. The `notationName` parameter will be `None` for parsed entities, and the name of the notation for unparsed entities. `is_parameter_entity` will be true if the entity is a parameter entity or false for general entities (most applications only need to be concerned with general entities). This is only available starting with version 1.95.0 of the Expat library.

*New in version 2.1.*

```
xmlparser.NotationDeclHandler(notationName, base, systemId, publicId)
```

Called for notation declarations. `notationName`, `base`, and `systemId`, and `publicId` are strings if given. If the public identifier is omitted, `publicId` will be `None`.

```
xmlparser.StartNamespaceDeclHandler(prefix, uri)
```

Called when an element contains a namespace declaration. Namespace declarations are processed before the `StartElementHandler` is called for the element on which declarations are placed.

```
xmlparser.EndNamespaceDeclHandler(prefix)
```

Called when the closing tag is reached for an element that contained a namespace declaration. This is called once for each
namespace declaration on the element in the reverse of the order for which the `StartNamespaceDeclHandler` was called to indicate the start of each namespace declaration’s scope. Calls to this handler are made after the corresponding `EndElementHandler` for the end of the element.

```xml
xmlparser.CommentHandler(data)
```
Called for comments. `data` is the text of the comment, excluding the leading ‘<!–‘ and trailing ‘–>‘.

```xml
xmlparser.StartCdataSectionHandler()
```
Called at the start of a CDATA section. This and `EndCdataSectionHandler` are needed to be able to identify the syntactical start and end for CDATA sections.

```xml
xmlparser.EndCdataSectionHandler()
```
Called at the end of a CDATA section.

```xml
xmlparser.DefaultHandler(data)
```
Called for any characters in the XML document for which no applicable handler has been specified. This means characters that are part of a construct which could be reported, but for which no handler has been supplied.

```xml
xmlparser.DefaultHandlerExpand(data)
```
This is the same as the `DefaultHandler()`, but doesn’t inhibit expansion of internal entities. The entity reference will not be passed to the default handler.

```xml
xmlparser.NotStandaloneHandler()
```
Called if the XML document hasn’t been declared as being a standalone document. This happens when there is an external subset or a reference to a parameter entity, but the XML declaration does not set standalone to `yes` in an XML declaration.
If this handler returns 0, then the parser will raise an `XML_ERROR_NOT_STANDALONE` error. If this handler is not set, no exception is raised by the parser for this condition.

`xmlparser.ExternalEntityRefHandler(context, base, systemId, publicId)`

Called for references to external entities. `base` is the current base, as set by a previous call to `SetBase()`. The public and system identifiers, `systemId` and `publicId`, are strings if given; if the public identifier is not given, `publicId` will be `None`. The `context` value is opaque and should only be used as described below.

For external entities to be parsed, this handler must be implemented. It is responsible for creating the sub-parser using `ExternalEntityParserCreate(context)`, initializing it with the appropriate callbacks, and parsing the entity. This handler should return an integer; if it returns 0, the parser will raise an `XML_ERROR_EXTERNAL_ENTITY_HANDLING` error, otherwise parsing will continue.

If this handler is not provided, external entities are reported by the `DefaultHandler` callback, if provided.
19.5.2. ExpatError Exceptions

ExpatError exceptions have a number of interesting attributes:

ExpatError.code
Expat’s internal error number for the specific error. This will match one of the constants defined in the errors object from this module.

*New in version 2.1.*

ExpatError.lineno
Line number on which the error was detected. The first line is numbered 1.

*New in version 2.1.*

ExpatError.offset
Character offset into the line where the error occurred. The first column is numbered 0.

*New in version 2.1.*
The following program defines three handlers that just print out their arguments.

```python
import xml.parsers.expat

# 3 handler functions
def start_element(name, attrs):
    print 'Start element:', name, attrs

def end_element(name):
    print 'End element:', name

def char_data(data):
    print 'Character data:', repr(data)

p = xml.parsers.expat.ParserCreate()
p.StartElementHandler = start_element
p.EndElementHandler = end_element
p.CharacterDataHandler = char_data

p.Parse("""<?xml version="1.0"?>
<parent id="top"><child1 name="paul">Text goes here</child1>
<child2 name="fred">More text</child2>
</parent>""", 1)
```

The output from this program is:

```
Start element: parent {'id': 'top'}
Start element: child1 {'name': 'paul'}
Character data: 'Text goes here'
End element: child1
Character data: '\n'
Start element: child2 {'name': 'fred'}
Character data: 'More text'
End element: child2
Character data: '\n'
End element: parent
```
19.5.4. Content Model Descriptions

Content modules are described using nested tuples. Each tuple contains four values: the type, the quantifier, the name, and a tuple of children. Children are simply additional content module descriptions.

The values of the first two fields are constants defined in the model object of the `xml.parsers.expat` module. These constants can be collected in two groups: the model type group and the quantifier group.

The constants in the model type group are:

- `xml.parsers.expat.XML_CTYPE_ANY`
  The element named by the model name was declared to have a content model of ANY.

- `xml.parsers.expat.XML_CTYPE_CHOICE`
  The named element allows a choice from a number of options; this is used for content models such as `(A | B | C)`.

- `xml.parsers.expat.XML_CTYPE_EMPTY`
  Elements which are declared to be EMPTY have this model type.

- `xml.parsers.expat.XML_CTYPE_MIXED`

- `xml.parsers.expat.XML_CTYPE_NAME`

- `xml.parsers.expat.XML_CTYPE_SEQ`
  Models which represent a series of models which follow one after the other are indicated with this model type. This is used for models such as `(A, B, C)`.

The constants in the quantifier group are:
No modifier is given, so it can appear exactly once, as for A.

The model is optional: it can appear once or not at all, as for A?.

The model must occur one or more times (like A+).

The model must occur zero or more times, as for A*.
19.5.5. Expat error constants

The following constants are provided in the `errors` object of the `xml.parsers.expat` module. These constants are useful in interpreting some of the attributes of the `ExpatError` exception objects raised when an error has occurred.

The `errors` object has the following attributes:

- `xml.parsers.expat.XML_ERROR_ASYNC_ENTITY`
- `xml.parsers.expat.XML_ERROR_ATTRIBUTE_EXTERNAL_ENTITY_REF`
  - An entity reference in an attribute value referred to an external entity instead of an internal entity.
- `xml.parsers.expat.XML_ERROR_BAD_CHAR_REF`
  - A character reference referred to a character which is illegal in XML (for example, character \&\theta;, or '\&\#89;').
- `xml.parsers.expat.XML_ERROR_BINARY_ENTITY_REF`
  - An entity reference referred to an entity which was declared with a notation, so cannot be parsed.
- `xml.parsers.expat.XML_ERROR_DUPLICATE_ATTRIBUTE`
  - An attribute was used more than once in a start tag.
- `xml.parsers.expat.XML_ERROR_INCORRECT_ENCODING`
- `xml.parsers.expat.XML_ERROR_INVALID_TOKEN`
  - Raised when an input byte could not properly be assigned to a character; for example, a NUL byte (value \&\theta;) in a UTF-8 input stream.
- `xml.parsers.expat.XML_ERROR_JUNK_AFTER_DOC_ELEMENT`
  - Something other than whitespace occurred after the document
element.

xml.parsers.expat.XML_ERROR_MISPLACED_XML_PI
  An XML declaration was found somewhere other than the start of the input data.

xml.parsers.expat.XML_ERROR_NO_ELEMENTS
  The document contains no elements (XML requires all documents to contain exactly one top-level element).

xml.parsers.expat.XML_ERROR_NO_MEMORY
  Expat was not able to allocate memory internally.

xml.parsers.expat.XML_ERROR_PARAM_ENTITY_REF
  A parameter entity reference was found where it was not allowed.

xml.parsers.expat.XML_ERROR_PARTIAL_CHAR
  An incomplete character was found in the input.

xml.parsers.expat.XML_ERROR_RECURSIVE_ENTITY_REF
  An entity reference contained another reference to the same entity; possibly via a different name, and possibly indirectly.

xml.parsers.expat.XML_ERROR_SYNTAX
  Some unspecified syntax error was encountered.

xml.parsers.expat.XML_ERROR_TAG_MISMATCH
  An end tag did not match the innermost open start tag.

xml.parsers.expat.XML_ERROR_UNCLOSED_TOKEN
  Some token (such as a start tag) was not closed before the end of the stream or the next token was encountered.

xml.parsers.expat.XML_ERROR_UNDEFINED_ENTITY
  A reference was made to a entity which was not defined.

xml.parsers.expat.XML_ERROR_UNKNOWN_ENCODING
  The document encoding is not supported by Expat.
xml.parsers.expat.XMLElement

A CDATA marked section was not closed.

xml.parsers.expat.XML_ERROR_EXTERNAL_ENTITY_HANDLING

The parser determined that the document was not “standalone” though it declared itself to be in the XML declaration, and the NotStandaloneHandler was set and returned 0.

xml.parsers.expat.XML_ERROR_FEATURE_REQUIRES_XML_DTD

An operation was requested that requires DTD support to be compiled in, but Expat was configured without DTD support. This should never be reported by a standard build of the xml.parsers.expat module.

xml.parsers.expat.XML_ERROR_CANT_CHANGE_FEATURE_ONCE_PARSING

A behavioral change was requested after parsing started that can only be changed before parsing has started. This is (currently) only raised by UseForeignDTD().

xml.parsers.expat.XML_ERROR_UNBOUND_PREFIX

An undeclared prefix was found when namespace processing was enabled.

xml.parsers.expat.XML_ERROR_UNDECLARING_PREFIX

The document attempted to remove the namespace declaration associated with a prefix.

xml.parsers.expat.XML_ERROR_INCOMPLETE_PE

A parameter entity contained incomplete markup.
The document contained no document element at all.

xml.parsers.expat.XML_ERROR_TEXT_DECL
There was an error parsing a text declaration in an external entity.

xml.parsers.expat.XML_ERROR_PUBLICID
Characters were found in the public id that are not allowed.

xml.parsers.expat.XML_ERROR_SUSPENDED
The requested operation was made on a suspended parser, but isn't allowed. This includes attempts to provide additional input or to stop the parser.

xml.parsers.expat.XML_ERROR_NOT_SUSPENDED
An attempt to resume the parser was made when the parser had not been suspended.

xml.parsers.expat.XML_ERROR_ABORTED
This should not be reported to Python applications.

xml.parsers.expat.XML_ERROR_FINISHED
The requested operation was made on a parser which was finished parsing input, but isn't allowed. This includes attempts to provide additional input or to stop the parser.

xml.parsers.expat.XML_ERROR_SUSPEND_PE

Footnotes

The encoding string included in XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not. See http://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and http://www.iana.org/assignments/character-sets.

19.6. `xml.dom` — The Document Object Model API

*New in version 2.0.*

The Document Object Model, or “DOM,” is a cross-language API from the World Wide Web Consortium (W3C) for accessing and modifying XML documents. A DOM implementation presents an XML document as a tree structure, or allows client code to build such a structure from scratch. It then gives access to the structure through a set of objects which provided well-known interfaces.

The DOM is extremely useful for random-access applications. SAX only allows you a view of one bit of the document at a time. If you are looking at one SAX element, you have no access to another. If you are looking at a text node, you have no access to a containing element. When you write a SAX application, you need to keep track of your program’s position in the document somewhere in your own code. SAX does not do it for you. Also, if you need to look ahead in the XML document, you are just out of luck.

Some applications are simply impossible in an event driven model with no access to a tree. Of course you could build some sort of tree yourself in SAX events, but the DOM allows you to avoid writing that code. The DOM is a standard tree representation for XML data.

The Document Object Model is being defined by the W3C in stages, or “levels” in their terminology. The Python mapping of the API is substantially based on the DOM Level 2 recommendation.

DOM applications typically start by parsing some XML into a DOM. How this is accomplished is not covered at all by DOM Level 1, and Level 2 provides only limited improvements: There is a
DOMImplementation object class which provides access to Document creation methods, but no way to access an XML reader/parser/Document builder in an implementation-independent way. There is also no well-defined way to access these methods without an existing Document object. In Python, each DOM implementation will provide a function getDOMImplementation(). DOM Level 3 adds a Load/Store specification, which defines an interface to the reader, but this is not yet available in the Python standard library.

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification; this portion of the reference manual describes the interpretation of the specification in Python.

The specification provided by the W3C defines the DOM API for Java, ECMAScript, and OMG IDL. The Python mapping defined here is based in large part on the IDL version of the specification, but strict compliance is not required (though implementations are free to support the strict mapping from IDL). See section Conformance for a detailed discussion of mapping requirements.

See also:

**Document Object Model (DOM) Level 2 Specification**
The W3C recommendation upon which the Python DOM API is based.

**Document Object Model (DOM) Level 1 Specification**
The W3C recommendation for the DOM supported by xml.dom.minidom.

**Python Language Mapping Specification**
This specifies the mapping from OMG IDL to Python.
19.6.1. Module Contents

The `xml.dom` contains the following functions:

`xml.dom.registerDOMImplementation(name, factory)`

Register the `factory` function with the name `name`. The factory function should return an object which implements the `DOMImplementation` interface. The factory function can return the same object every time, or a new one for each call, as appropriate for the specific implementation (e.g. if that implementation supports some customization).

`xml.dom.getDOMImplementation([name[, features]])`:

Return a suitable DOM implementation. The `name` is either well-known, the module name of a DOM implementation, or `None`. If it is not `None`, imports the corresponding module and returns a `DOMImplementation` object if the import succeeds. If no name is given, and if the environment variable `PYTHON_DOM` is set, this variable is used to find the implementation.

If name is not given, this examines the available implementations to find one with the required feature set. If no implementation can be found, raise an `ImportError`. The features list must be a sequence of `(feature, version)` pairs which are passed to the `hasFeature()` method on available `DOMImplementation` objects.

Some convenience constants are also provided:

`xml.dom.EMPTY_NAMESPACE`

The value used to indicate that no namespace is associated with a node in the DOM. This is typically found as the `namespaceURI` of a node, or used as the `namespaceURI` parameter to a
namespaces-specific method.

New in version 2.2.

The namespace URI associated with the reserved prefix `xml`, as defined by Namespaces in XML (section 4).

New in version 2.2.

The namespace URI for namespace declarations, as defined by Document Object Model (DOM) Level 2 Core Specification (section 1.1.8).

New in version 2.2.

The URI of the XHTML namespace as defined by XHTML 1.0: The Extensible HyperText Markup Language (section 3.1.1).

New in version 2.2.

In addition, `xml.dom` contains a base `Node` class and the DOM exception classes. The `Node` class provided by this module does not implement any of the methods or attributes defined by the DOM specification; concrete DOM implementations must provide those. The `Node` class provided as part of this module does provide the constants used for the `nodeType` attribute on concrete `Node` objects; they are located within the class rather than at the module level to conform with the DOM specifications.
19.6.2. Objects in the DOM

The definitive documentation for the DOM is the DOM specification from the W3C.

Note that DOM attributes may also be manipulated as nodes instead of as simple strings. It is fairly rare that you must do this, however, so this usage is not yet documented.

<table>

</table>
An additional section describes the exceptions defined for working with the DOM in Python.

### 19.6.2.1. DOMImplementation Objects

The **DOMImplementation** interface provides a way for applications to determine the availability of particular features in the DOM they are using. DOM Level 2 added the ability to create new **Document** and **DocumentType** objects using the **DOMImplementation** as well.

**DOMImplementation**.hasFeature(feature, version)

Return true if the feature identified by the pair of strings feature and version is implemented.

**DOMImplementation**.createDocument(namespaceUri, qualifiedName, doctype)

Return a new **Document** object (the root of the DOM), with a child **Element** object having the given namespaceUri and qualifiedName. The doctype must be a **DocumentType** object created by createDocumentType(), or None. In the Python DOM API, the first two arguments can also be None in order to indicate that no **Element** child is to be created.

**DOMImplementation**.createDocumentType(qualifiedName, publicId, systemId)

Return a new **DocumentType** object that encapsulates the given qualifiedName, publicId, and systemId strings, representing the
information contained in an XML document type declaration.

19.6.2.2. Node Objects

All of the components of an XML document are subclasses of Node.

Node. **nodeType**
An integer representing the node type. Symbolic constants for the types are on the Node object: ELEMENT_NODE, ATTRIBUTE_NODE, TEXT_NODE, CDATA_SECTION_NODE, ENTITY_NODE, PROCESSING_INSTRUCTION_NODE, COMMENT_NODE, DOCUMENT_NODE, DOCUMENT_TYPE_NODE, NOTATION_NODE. This is a read-only attribute.

Node. **parentNode**
The parent of the current node, or None for the document node. The value is always a Node object or None. For Element nodes, this will be the parent element, except for the root element, in which case it will be the Document object. For Attr nodes, this is always None. This is a read-only attribute.

Node. **attributes**
A NamedNodeMap of attribute objects. Only elements have actual values for this; others provide None for this attribute. This is a read-only attribute.

Node. **previousSibling**
The node that immediately precedes this one with the same parent. For instance the element with an end-tag that comes just before the self element's start-tag. Of course, XML documents are made up of more than just elements so the previous sibling could be text, a comment, or something else. If this node is the first child of the parent, this attribute will be None. This is a read-only attribute.
Node. **nextSibling**
The node that immediately follows this one with the same parent. See also **previousSibling**. If this is the last child of the parent, this attribute will be **None**. This is a read-only attribute.

Node. **childNodes**
A list of nodes contained within this node. This is a read-only attribute.

Node. **firstChild**
The first child of the node, if there are any, or **None**. This is a read-only attribute.

Node. **lastChild**
The last child of the node, if there are any, or **None**. This is a read-only attribute.

Node. **localName**
The part of the `tagName` following the colon if there is one, else the entire `tagName`. The value is a string.

Node. **prefix**
The part of the `tagName` preceding the colon if there is one, else the empty string. The value is a string, or **None**

Node. **namespaceURI**
The namespace associated with the element name. This will be a string or **None**. This is a read-only attribute.

Node. **nodeName**
This has a different meaning for each node type; see the DOM specification for details. You can always get the information you would get here from another property such as the `tagName` property for elements or the `name` property for attributes. For all node types, the value of this attribute will be either a string or
Node. **nodeValue**
This has a different meaning for each node type; see the DOM specification for details. The situation is similar to that with **nodeName**. The value is a string or None.

Node. **hasAttributes()**
Returns true if the node has any attributes.

Node. **hasChildNodes()**
Returns true if the node has any child nodes.

Node. **isSameNode(other)**
Returns true if other refers to the same node as this node. This is especially useful for DOM implementations which use any sort of proxy architecture (because more than one object can refer to the same node).

**Note:** This is based on a proposed DOM Level 3 API which is still in the “working draft” stage, but this particular interface appears uncontroversial. Changes from the W3C will not necessarily affect this method in the Python DOM interface (though any new W3C API for this would also be supported).

Node. **appendChild(newChild)**
Add a new child node to this node at the end of the list of children, returning newChild. If the node was already in in the tree, it is removed first.

Node. **insertBefore(newChild, refChild)**
Insert a new child node before an existing child. It must be the case that refChild is a child of this node; if not, ValueError is raised. newChild is returned. If refChild is None, it inserts
newChild at the end of the children’s list.

Node. **removeChild**(oldChild)

Remove a child node. oldChild must be a child of this node; if not, **ValueError** is raised. oldChild is returned on success. If oldChild will not be used further, its **unlink()** method should be called.

Node. **replaceChild**(newChild, oldChild)

Replace an existing node with a new node. It must be the case that oldChild is a child of this node; if not, **ValueError** is raised.

Node. **normalize**()

Join adjacent text nodes so that all stretches of text are stored as single Text instances. This simplifies processing text from a DOM tree for many applications.

*New in version 2.1.*

Node. **cloneNode**(deep)

Clone this node. Setting deep means to clone all child nodes as well. This returns the clone.

### 19.6.2.3. NodeList Objects

A NodeList represents a sequence of nodes. These objects are used in two ways in the DOM Core recommendation: the Element objects provides one as its list of child nodes, and the getElementsByTagName() and getElementsByTagNameNS() methods of Node return objects with this interface to represent query results.

The DOM Level 2 recommendation defines one method and one attribute for these objects:

NodeList. **item**(i)
Return the \(i\)'th item from the sequence, if there is one, or \textbf{None}. The index \(i\) is not allowed to be less than zero or greater than or equal to the length of the sequence.

**NodeList**. \texttt{length}

The number of nodes in the sequence.

In addition, the Python DOM interface requires that some additional support is provided to allow \texttt{NodeList} objects to be used as Python sequences. All \texttt{NodeList} implementations must include support for \texttt{__len__()} and \texttt{__getitem__()}; this allows iteration over the \texttt{NodeList} in \texttt{for} statements and proper support for the \texttt{len()} built-in function.

If a DOM implementation supports modification of the document, the \texttt{NodeList} implementation must also support the \texttt{__setitem__()} and \texttt{__delitem__()} methods.

### 19.6.2.4. DocumentType Objects

Information about the notations and entities declared by a document (including the external subset if the parser uses it and can provide the information) is available from a \texttt{DocumentType} object. The \texttt{DocumentType} for a document is available from the \texttt{Document} object’s \texttt{doctype} attribute; if there is no \texttt{DOCTYPE} declaration for the document, the document’s \texttt{doctype} attribute will be set to \textbf{None} instead of an instance of this interface.

\texttt{DocumentType} is a specialization of \texttt{Node}, and adds the following attributes:

**DocumentType**. \texttt{publicId}

The public identifier for the external subset of the document type definition. This will be a string or \textbf{None}. 
**DocumentType.** **systemId**

The system identifier for the external subset of the document type definition. This will be a URI as a string, or None.

**DocumentType.** **internalSubset**

A string giving the complete internal subset from the document. This does not include the brackets which enclose the subset. If the document has no internal subset, this should be None.

**DocumentType.** **name**

The name of the root element as given in the DOCTYPE declaration, if present.

**DocumentType.** **entities**

This is a NamedNodeMap giving the definitions of external entities. For entity names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be None if the information is not provided by the parser, or if no entities are defined.

**DocumentType.** **notations**

This is a NamedNodeMap giving the definitions of notations. For notation names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be None if the information is not provided by the parser, or if no notations are defined.

---

### 19.6.2.5. Document Objects

A **Document** represents an entire XML document, including its constituent elements, attributes, processing instructions, comments etc. Remember that it inherits properties from **Node**.

**Document.** **documentElement**

The one and only root element of the document.
Document.**createElement**(tagName)
Create and return a new element node. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as `insertBefore()` or `appendChild()`.

Document.**createElementNS**(namespaceURI, tagName)
Create and return a new element with a namespace. The tagName may have a prefix. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as `insertBefore()` or `appendChild()`.

Document.**createTextNode**(data)
Create and return a text node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

Document.**createComment**(data)
Create and return a comment node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

Document.**createProcessingInstruction**(target, data)
Create and return a processing instruction node containing the target and data passed as parameters. As with the other creation methods, this one does not insert the node into the tree.

Document.**createAttribute**(name)
Create and return an attribute node. This method does not associate the attribute node with any particular element. You must use `setAttributeNode()` on the appropriate `Element` object to use the newly created attribute instance.
Document. **createAttributeNS** *(namespaceURI, qualifiedName)*

Create and return an attribute node with a namespace. The *tagName* may have a prefix. This method does not associate the attribute node with any particular element. You must use **setAttributeNode()** on the appropriate **Element** object to use the newly created attribute instance.

Document. **getElementsByTagName** *(tagName)*

Search for all descendants (direct children, children's children, etc.) with a particular element type name.

Document. **getElementsByTagNameNS** *(namespaceURI, localName)*

Search for all descendants (direct children, children's children, etc.) with a particular namespace URI and localname. The localname is the part of the namespace after the prefix.

### 19.6.2.6. Element Objects

**Element** is a subclass of **Node**, so inherits all the attributes of that class.

**Element**. **tagName**

The element type name. In a namespace-using document it may have colons in it. The value is a string.

**Element**. **getElementsByTagName** *(tagName)*

Same as equivalent method in the **Document** class.

**Element**. **getElementsByTagNameNS** *(namespaceURI, localName)*

Same as equivalent method in the **Document** class.

**Element**. **hasAttribute** *(name)*

Returns true if the element has an attribute named by *name*. 
Element. **hasAttributeNS**(namespaceURI, localName)
    Returns true if the element has an attribute named by namespaceURI and localName.

Element. **getAttribute**(name)
    Return the value of the attribute named by name as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

Element. **getAttributeNode**(attrname)
    Return the Attr node for the attribute named by attrname.

Element. **getAttributeNS**(namespaceURI, localName)
    Return the value of the attribute named by namespaceURI and localName as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

Element. **getAttributeNodeNS**(namespaceURI, localName)
    Return an attribute value as a node, given a namespaceURI and localName.

Element. **removeAttribute**(name)
    Remove an attribute by name. If there is no matching attribute, a NotFoundErr is raised.

Element. **removeAttributeNode**(oldAttr)
    Remove and return oldAttr from the attribute list, if present. If oldAttr is not present, NotFoundErr is raised.

Element. **removeAttributeNS**(namespaceURI, localName)
    Remove an attribute by name. Note that it uses a localName, not a qname. No exception is raised if there is no matching attribute.

Element. **setAttribute**(name, value)
Set an attribute value from a string.

**Element. `setAttributeNode(newAttr)`**

Add a new attribute node to the element, replacing an existing attribute if necessary if the `name` attribute matches. If a replacement occurs, the old attribute node will be returned. If `newAttr` is already in use, `InuseAttributeErr` will be raised.

**Element. `setAttributeNodeNS(newAttr)`**

Add a new attribute node to the element, replacing an existing attribute if necessary if the `namespaceURI` and `localName` attributes match. If a replacement occurs, the old attribute node will be returned. If `newAttr` is already in use, `InuseAttributeErr` will be raised.

**Element. `setAttributeNS(namespaceURI, qname, value)`**

Set an attribute value from a string, given a `namespaceURI` and a `qname`. Note that a qname is the whole attribute name. This is different than above.

### 19.6.2.7. Attr Objects

`Attr` inherits from `Node`, so inherits all its attributes.

**Attr. `name`**

The attribute name. In a namespace-using document it may include a colon.

**Attr. `localName`**

The part of the name following the colon if there is one, else the entire name. This is a read-only attribute.

**Attr. `prefix`**

The part of the name preceding the colon if there is one, else the empty string.
**Attr. value**
The text value of the attribute. This is a synonym for the `nodeValue` attribute.

### 19.6.2.8. NamedNodeMap Objects

`NamedNodeMap` does *not* inherit from `Node`.

**NamedNodeMap.length**
The length of the attribute list.

**NamedNodeMap.item(index)**
Return an attribute with a particular index. The order you get the attributes in is arbitrary but will be consistent for the life of a DOM. Each item is an attribute node. Get its value with the `value` attribute.

There are also experimental methods that give this class more mapping behavior. You can use them or you can use the standardized `getAttribute*()` family of methods on the `Element` objects.

### 19.6.2.9. Comment Objects

`Comment` represents a comment in the XML document. It is a subclass of `Node`, but cannot have child nodes.

**Comment.data**
The content of the comment as a string. The attribute contains all characters between the leading `<!--` and trailing `-->`, but does not include them.

### 19.6.2.10. Text and CDATASection Objects
The **Text** interface represents text in the XML document. If the parser and DOM implementation support the DOM's XML extension, portions of the text enclosed in CDATA marked sections are stored in **CDATASection** objects. These two interfaces are identical, but provide different values for the `nodeType` attribute.

These interfaces extend the **Node** interface. They cannot have child nodes.

**Text.data**

The content of the text node as a string.

**Note:** The use of a **CDATASection** node does not indicate that the node represents a complete CDATA marked section, only that the content of the node was part of a CDATA section. A single CDATA section may be represented by more than one node in the document tree. There is no way to determine whether two adjacent **CDATASection** nodes represent different CDATA marked sections.

### 19.6.2.11. ProcessingInstruction Objects

Represents a processing instruction in the XML document; this inherits from the **Node** interface and cannot have child nodes.

**ProcessingInstruction.target**

The content of the processing instruction up to the first whitespace character. This is a read-only attribute.

**ProcessingInstruction.data**

The content of the processing instruction following the first whitespace character.

### 19.6.2.12. Exceptions
New in version 2.1.

The DOM Level 2 recommendation defines a single exception, DOMException, and a number of constants that allow applications to determine what sort of error occurred. DOMException instances carry a code attribute that provides the appropriate value for the specific exception.

The Python DOM interface provides the constants, but also expands the set of exceptions so that a specific exception exists for each of the exception codes defined by the DOM. The implementations must raise the appropriate specific exception, each of which carries the appropriate value for the code attribute.

exception xml.dom.DOMException
    Base exception class used for all specific DOM exceptions. This exception class cannot be directly instantiated.

exception xml.dom.DomStringSizeErr
    Raised when a specified range of text does not fit into a string. This is not known to be used in the Python DOM implementations, but may be received from DOM implementations not written in Python.

exception xml.dom.HierarchyRequestErr
    Raised when an attempt is made to insert a node where the node type is not allowed.

exception xml.dom.IndexSizeErr
    Raised when an index or size parameter to a method is negative or exceeds the allowed values.

exception xml.dom.InuseAttributeErr
    Raised when an attempt is made to insert an Attr node that is already present elsewhere in the document.
exception xml.dom.**InvalidAccessErr**
Raised if a parameter or an operation is not supported on the underlying object.

exception xml.dom.**InvalidCharacterErr**
This exception is raised when a string parameter contains a character that is not permitted in the context it's being used in by the XML 1.0 recommendation. For example, attempting to create an `Element` node with a space in the element type name will cause this error to be raised.

exception xml.dom.**InvalidModificationErr**
Raised when an attempt is made to modify the type of a node.

exception xml.dom.**InvalidStateErr**
Raised when an attempt is made to use an object that is not defined or is no longer usable.

exception xml.dom.**NamespaceErr**
If an attempt is made to change any object in a way that is not permitted with regard to the Namespaces in XML recommendation, this exception is raised.

exception xml.dom.**NotFoundError**
Exception when a node does not exist in the referenced context. For example, `NamedNodeMap.removeNamedItem()` will raise this if the node passed in does not exist in the map.

exception xml.dom.**NotSupportedErr**
Raised when the implementation does not support the requested type of object or operation.

exception xml.dom.**NoDataAllowedErr**
This is raised if data is specified for a node which does not support data.
**exception** xml.dom.**NoModificationAllowedErr**

Raised on attempts to modify an object where modifications are not allowed (such as for read-only nodes).

**exception** xml.dom.**SyntaxErr**

Raised when an invalid or illegal string is specified.

**exception** xml.dom.**WrongDocumentErr**

Raised when a node is inserted in a different document than it currently belongs to, and the implementation does not support migrating the node from one document to the other.

The exception codes defined in the DOM recommendation map to the exceptions described above according to this table:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOMSTRING_SIZE_ERR</td>
<td>DomstringSizeErr</td>
</tr>
<tr>
<td>HIERARCHY_REQUEST_ERR</td>
<td>HierarchyRequestErr</td>
</tr>
<tr>
<td>INDEX_SIZE_ERR</td>
<td>IndexSizeErr</td>
</tr>
<tr>
<td>INUSE_ATTRIBUTE_ERR</td>
<td>InuseAttributeErr</td>
</tr>
<tr>
<td>INVALID_ACCESS_ERR</td>
<td>InvalidAccessErr</td>
</tr>
<tr>
<td>INVALID_CHARACTER_ERR</td>
<td>InvalidCharacterErr</td>
</tr>
<tr>
<td>INVALID_MODIFICATION_ERR</td>
<td>InvalidModificationErr</td>
</tr>
<tr>
<td>INVALID_STATE_ERR</td>
<td>InvalidStateErr</td>
</tr>
<tr>
<td>NAMESPACE_ERR</td>
<td>NamespaceErr</td>

</tr>
<tr>
<td>SYNTAX_ERR</td>
<td>SyntaxErr</td>
</tr>
<tr>
<td>WRONG_DOCUMENT_ERR</td>
<td>WrongDocumentErr</td>
</tr>
</tbody>
</table>
19.6.3. Conformance

This section describes the conformance requirements and relationships between the Python DOM API, the W3C DOM recommendations, and the OMG IDL mapping for Python.

19.6.3.1. Type Mapping

The primitive IDL types used in the DOM specification are mapped to Python types according to the following table.

<table>
<thead>
<tr>
<th>IDL Type</th>
<th>Python Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>IntegerType (with a value of 0 or 1)</td>
</tr>
<tr>
<td>int</td>
<td>IntegerType</td>
</tr>
<tr>
<td>long int</td>
<td>IntegerType</td>
</tr>
<tr>
<td>unsigned int</td>
<td>IntegerType</td>
</tr>
</tbody>
</table>

Additionally, the DOMString defined in the recommendation is mapped to a Python string or Unicode string. Applications should be able to handle Unicode whenever a string is returned from the DOM.

The IDL null value is mapped to None, which may be accepted or provided by the implementation whenever null is allowed by the API.

19.6.3.2. Accessor Methods

The mapping from OMG IDL to Python defines accessor functions for IDL attribute declarations in much the way the Java mapping does. Mapping the IDL declarations

```python
readonly attribute string someValue;
attribute string anotherValue;
```
yields three accessor functions: a “get” method for `someValue` (_get_someValue()), and “get” and “set” methods for `anotherValue` (_get_anotherValue() and _set_anotherValue()). The mapping, in particular, does not require that the IDL attributes are accessible as normal Python attributes: `object.someValue` is not required to work, and may raise an `AttributeError`.

The Python DOM API, however, does require that normal attribute access work. This means that the typical surrogates generated by Python IDL compilers are not likely to work, and wrapper objects may be needed on the client if the DOM objects are accessed via CORBA. While this does require some additional consideration for CORBA DOM clients, the implementers with experience using DOM over CORBA from Python do not consider this a problem. Attributes that are declared `readonly` may not restrict write access in all DOM implementations.

In the Python DOM API, accessor functions are not required. If provided, they should take the form defined by the Python IDL mapping, but these methods are considered unnecessary since the attributes are accessible directly from Python. “Set” accessors should never be provided for `readonly` attributes.

The IDL definitions do not fully embody the requirements of the W3C DOM API, such as the notion of certain objects, such as the return value of `getElementsByTagName()`, being “live”. The Python DOM API does not require implementations to enforce such requirements.
19.7. `xml.dom.minidom` — Lightweight DOM implementation

New in version 2.0.

`xml.dom.minidom` is a light-weight implementation of the Document Object Model interface. It is intended to be simpler than the full DOM and also significantly smaller.

DOM applications typically start by parsing some XML into a DOM. With `xml.dom.minidom`, this is done through the parse functions:

```python
from xml.dom.minidom import parse, parseString

dom1 = parse('c:\temp\mydata.xml')  # parse an XML file by name

datasource = open('c:\temp\mydata.xml')
dom2 = parse(datasource)  # parse an open file

dom3 = parseString('<myxml>Some data<empty/> some more data</myxml>')
```

The `parse()` function can take either a filename or an open file object.

`xml.dom.minidom.parse(filename_or_file[, parser[, bufsize]])`

Return a `Document` from the given input. `filename_or_file` may be either a file name, or a file-like object. `parser`, if given, must be a SAX2 parser object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the `parseString()` function instead:
xml.dom.minidom.parseString(string[, parser])

Return a Document that represents the string. This method creates a StringIO object for the string and passes that on to parse().

Both functions return a Document object representing the content of the document.

What the parse() and parseString() functions do is connect an XML parser with a “DOM builder” that can accept parse events from any SAX parser and convert them into a DOM tree. The name of the functions are perhaps misleading, but are easy to grasp when learning the interfaces. The parsing of the document will be completed before these functions return; it’s simply that these functions do not provide a parser implementation themselves.

You can also create a Document by calling a method on a “DOM Implementation” object. You can get this object either by calling the getDOMImplementation() function in the xml.dom package or the xml.dom.minidom module. Using the implementation from the xml.dom.minidom module will always return a Document instance from the minidom implementation, while the version from xml.dom may provide an alternate implementation (this is likely if you have the PyXML package installed). Once you have a Document, you can add child nodes to it to populate the DOM:

```python
from xml.dom.minidom import getDOMImplementation
impl = getDOMImplementation()
newdoc = impl.createDocument(None, "some_tag", None)
top_element = newdoc.documentElement
text = newdoc.createTextNode('Some textual content.')
top_element.appendChild(text)
```

Once you have a DOM document object, you can access the parts of
your XML document through its properties and methods. These properties are defined in the DOM specification. The main property of the document object is the `documentElement` property. It gives you the main element in the XML document: the one that holds all others. Here is an example program:

```python
dom3 = parseString("<myxml>Some data</myxml>")
assert dom3.documentElement.tagName == "myxml"
```

When you are finished with a DOM tree, you may optionally call the `unlink()` method to encourage early cleanup of the now-unneeded objects. `unlink()` is a `xml.dom.minidom`-specific extension to the DOM API that renders the node and its descendants are essentially useless. Otherwise, Python’s garbage collector will eventually take care of the objects in the tree.

**See also:**

**Document Object Model (DOM) Level 1 Specification**

The W3C recommendation for the DOM supported by `xml.dom.minidom`.
The definition of the DOM API for Python is given as part of the `xml.dom` module documentation. This section lists the differences between the API and `xml.dom.minidom`.

**Node. `unlink()`**

Break internal references within the DOM so that it will be garbage collected on versions of Python without cyclic GC. Even when cyclic GC is available, using this can make large amounts of memory available sooner, so calling this on DOM objects as soon as they are no longer needed is good practice. This only needs to be called on the Document object, but may be called on child nodes to discard children of that node.

**Node. `writexml()`**

Write XML to the writer object. The writer should have a `write()` method which matches that of the file object interface. The `indent` parameter is the indentation of the current node. The `addindent` parameter is the incremental indentation to use for subnodes of the current one. The `newl` parameter specifies the string to use to terminate newlines.

For the Document node, an additional keyword argument `encoding` can be used to specify the encoding field of the XML header.

*Changed in version 2.1:* The optional keyword parameters `indent`, `addindent`, and `newl` were added to support pretty output.

*Changed in version 2.3:* For the Document node, an additional keyword argument `encoding` can be used to specify the encoding field of the XML header.
Node. `toxml([encoding])`

Return the XML that the DOM represents as a string.

With no argument, the XML header does not specify an encoding, and the result is Unicode string if the default encoding cannot represent all characters in the document. Encoding this string in an encoding other than UTF-8 is likely incorrect, since UTF-8 is the default encoding of XML.

With an explicit `encoding` [1] argument, the result is a byte string in the specified encoding. It is recommended that this argument is always specified. To avoid `UnicodeError` exceptions in case of unrepresentable text data, the encoding argument should be specified as “utf-8”.

*Changed in version 2.3:* the `encoding` argument was introduced; see `writexml()`.

Node. `toprettyxml([indent='', [newl='', [encoding='']]])`

Return a pretty-printed version of the document. `indent` specifies the indentation string and defaults to a tabulator; `newl` specifies the string emitted at the end of each line and defaults to \n.

*New in version 2.1.*

*Changed in version 2.3:* the encoding argument was introduced; see `writexml()`.

The following standard DOM methods have special considerations with `xml.dom.minidom`:

Node. `cloneNode(deep)`

Although this method was present in the version of `xml.dom.minidom` packaged with Python 2.0, it was seriously
broken. This has been corrected for subsequent releases.
19.7.2. DOM Example

This example program is a fairly realistic example of a simple program. In this particular case, we do not take much advantage of the flexibility of the DOM.

```python
import xml.dom.minidom

document = """
<slideshow>
<title>Demo slideshow</title>
<slide><title>Slide title</title>
<point>This is a demo</point>
<point>Of a program for processing slides</point>
</slide>

<slide><title>Another demo slide</title>
<point>It is important</point>
<point>To have more than</point>
<point>one slide</point>
</slide>
""

dom = xml.dom.minidom.parseString(document)

def getText(nodelist):
    rc = []
    for node in nodelist:
        if node.nodeType == node.TEXT_NODE:
            rc.append(node.data)
    return ''.join(rc)

def handleSlideshow(slideshow):
    print "<html>
    handleSlideshowTitle(slideshow.getElementsByTagName("title")
    slides = slideshow.getElementsByTagName("slide")
    handleToc(slides)
    handleSlides(slides)
    print "</html>"

def handleSlides(slides):
    for slide in slides:
```
def handleSlide(slide):
    handleSlideTitle(slide.getElementsByTagName("title")[0])
    handlePoints(slide.getElementsByTagName("point"))

def handleSlideshowTitle(title):
    print "<title>%s</title>" % getText(title.childNodes)

def handleSlideTitle(title):
    print "<h2>%s</h2>" % getText(title.childNodes)

def handlePoints(points):
    print "<ul>
    for point in points:
        handlePoint(point)
    print "</ul>"

def handlePoint(point):
    print "<li>%s</li>" % getText(point.childNodes)

def handleToc(slides):
    for slide in slides:
        title = slide.getElementsByTagName("title")[0]
        print "<p>%s</p>" % getText(title.childNodes)

handleSlideshow(dom)
19.7.3. minidom and the DOM standard

The `xml.dom.minidom` module is essentially a DOM 1.0-compatible DOM with some DOM 2 features (primarily namespace features).

Usage of the DOM interface in Python is straight-forward. The following mapping rules apply:

- Interfaces are accessed through instance objects. Applications should not instantiate the classes themselves; they should use the creator functions available on the `Document` object. Derived interfaces support all operations (and attributes) from the base interfaces, plus any new operations.
- Operations are used as methods. Since the DOM uses only `in` parameters, the arguments are passed in normal order (from left to right). There are no optional arguments. `void` operations return `None`.
- IDL attributes map to instance attributes. For compatibility with the OMG IDL language mapping for Python, an attribute `foo` can also be accessed through accessor methods `_get_foo()` and `_set_foo()`. `readonly` attributes must not be changed; this is not enforced at runtime.
- The types `short`, `int`, `unsigned int`, `unsigned long`, `long`, and `boolean` all map to Python integer objects.
- The type `DOMString` maps to Python strings. `xml.dom.minidom` supports either byte or Unicode strings, but will normally produce Unicode strings. Values of type `DOMString` may also be `None` where allowed to have the IDL `null` value by the DOM specification from the W3C.
- `const` declarations map to variables in their respective scope (e.g. `xml.dom.minidom.Node.PROCESSING_INSTRUCTION_NODE`); they must not be changed.
- **DOMException** is currently not supported in `xml.dom.minidom`. Instead, `xml.dom.minidom` uses standard Python exceptions such as **TypeError** and **AttributeError**.

- **NodeList** objects are implemented using Python’s built-in list type. Starting with Python 2.2, these objects provide the interface defined in the DOM specification, but with earlier versions of Python they do not support the official API. They are, however, much more “Pythonic” than the interface defined in the W3C recommendations.

The following interfaces have no implementation in `xml.dom.minidom`:

- **DOMTimeStamp**
- **DocumentType** (added in Python 2.1)
- **DOMImplementation** (added in Python 2.1)
- **CharacterData**
- **CDATASection**
- **Notation**
- **Entity**
- **EntityReference**
- **DocumentFragment**

Most of these reflect information in the XML document that is not of general utility to most DOM users.

**Footnotes**

The encoding string included in XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not. See [http://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl](http://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl) and [http://www.iana.org/assignments/character-sets](http://www.iana.org/assignments/character-sets).
19.8. xml.dom.pulldom — Support for building partial DOM trees

New in version 2.0.

xml.dom.pulldom allows building only selected portions of a Document Object Model representation of a document from SAX events.

class xml.dom.pulldom.PullDOM([documentFactory])
    xml.sax.handler.ContentHandler implementation that ...

class xml.dom.pulldom.DOMEventStream(stream, parser, bufsize)
    ...

class xml.dom.pulldom.SAX2DOM([documentFactory])
    xml.sax.handler.ContentHandler implementation that ...

xml.dom.pulldom.parse(stream_or_string[, parser[, bufsize]])
    ...

xml.dom.pulldom.parseString(string[, parser])
    ...

xml.dom.pulldom.default_bufsize
    Default value for the bufsize parameter to parse().

    Changed in version 2.1: The value of this variable can be changed before calling parse() and the new value will take effect.
19.8.1. DOMEventStream Objects

DOMEventStream.\texttt{getEvent}() 
...

DOMEventStream.\texttt{expandNode}(node) 
...

DOMEventStream.\texttt{reset}() 
...
19.9. xml.sax — Support for SAX2 parsers

New in version 2.0.

The xml.sax package provides a number of modules which implement the Simple API for XML (SAX) interface for Python. The package itself provides the SAX exceptions and the convenience functions which will be most used by users of the SAX API.

The convenience functions are:

xml.sax.make_parser([parser_list])

Create and return a SAX XMLReader object. The first parser found will be used. If parser_list is provided, it must be a sequence of strings which name modules that have a function named create_parser(). Modules listed in parser_list will be used before modules in the default list of parsers.

xml.sax.parse(filename_or_stream, handler[, error_handler])

Create a SAX parser and use it to parse a document. The document, passed in as filename_or_stream, can be a filename or a file object. The handler parameter needs to be a SAX ContentHandler instance. If error_handler is given, it must be a SAX ErrorHandler instance; if omitted, SAXParseException will be raised on all errors. There is no return value; all work must be done by the handler passed in.

xml.sax.parseString(string, handler[, error_handler])

Similar to parse(), but parses from a buffer string received as a parameter.
A typical SAX application uses three kinds of objects: readers, handlers and input sources. “Reader” in this context is another term for parser, i.e. some piece of code that reads the bytes or characters from the input source, and produces a sequence of events. The events then get distributed to the handler objects, i.e. the reader invokes a method on the handler. A SAX application must therefore obtain a reader object, create or open the input sources, create the handlers, and connect these objects all together. As the final step of preparation, the reader is called to parse the input. During parsing, methods on the handler objects are called based on structural and syntactic events from the input data.

For these objects, only the interfaces are relevant; they are normally not instantiated by the application itself. Since Python does not have an explicit notion of interface, they are formally introduced as classes, but applications may use implementations which do not inherit from the provided classes. The InputSource, Locator, Attributes, AttributesNS, and XMLReader interfaces are defined in the module xml.sax.xmlreader. The handler interfaces are defined in xml.sax.handler. For convenience, InputSource (which is often instantiated directly) and the handler classes are also available from xml.sax. These interfaces are described below.

In addition to these classes, xml.sax provides the following exception classes.

```python
exception xml.sax.SAXException(msg[, exception])
```
Encapsulate an XML error or warning. This class can contain basic error or warning information from either the XML parser or the application: it can be subclassed to provide additional functionality or to add localization. Note that although the handlers defined in the ErrorHandler interface receive instances of this exception, it is not required to actually raise the exception — it is also useful as a container for information.
When instantiated, `msg` should be a human-readable description of the error. The optional `exception` parameter, if given, should be `None` or an exception that was caught by the parsing code and is being passed along as information.

This is the base class for the other SAX exception classes.

```python
exception xml.sax.SAXParseException(msg, exception, locator)
```
Subclass of `SAXException` raised on parse errors. Instances of this class are passed to the methods of the SAX `ErrorHandler` interface to provide information about the parse error. This class supports the SAX `Locator` interface as well as the `SAXException` interface.

```python
exception xml.sax.SAXNotRecognizedException(msg, exception)
```
Subclass of `SAXException` raised when a SAX `XMLReader` is confronted with an unrecognized feature or property. SAX applications and extensions may use this class for similar purposes.

```python
exception xml.sax.SAXNotSupportedException(msg, exception)
```
Subclass of `SAXException` raised when a SAX `XMLReader` is asked to enable a feature that is not supported, or to set a property to a value that the implementation does not support. SAX applications and extensions may use this class for similar purposes.

**SAX: The Simple API for XML**
This site is the focal point for the definition of the SAX API. It provides a Java implementation and online documentation. Links to implementations and historical information are also available.

**Module** `xml.sax.handler`
Definitions of the interfaces for application-provided objects.

**Module** `xml.sax.saxutils`
Convenience functions for use in SAX applications.

**Module** `xml.sax.xmlreader`
Definitions of the interfaces for parser-provided objects.
19.9.1. SAXException Objects

The `SAXException` exception class supports the following methods:

SAXException. `getMessage()`
   Return a human-readable message describing the error condition.

SAXException. `getException()`
   Return an encapsulated exception object, or `None`. 
The SAX API defines four kinds of handlers: content handlers, DTD handlers, error handlers, and entity resolvers. Applications normally only need to implement those interfaces whose events they are interested in; they can implement the interfaces in a single object or in multiple objects. Handler implementations should inherit from the base classes provided in the module `xml.sax.handler`, so that all methods get default implementations.

**class xml.sax.handler.ContentHandler**

This is the main callback interface in SAX, and the one most important to applications. The order of events in this interface mirrors the order of the information in the document.

**class xml.sax.handler.DTDHandler**

Handle DTD events.

This interface specifies only those DTD events required for basic parsing (unparsed entities and attributes).

**class xml.sax.handler.EntityResolver**

Basic interface for resolving entities. If you create an object implementing this interface, then register the object with your Parser, the parser will call the method in your object to resolve all external entities.

**class xml.sax.handler.ErrorHandler**

Interface used by the parser to present error and warning messages to the application. The methods of this object control whether errors are immediately converted to exceptions or are
handled in some other way.

In addition to these classes, `xml.sax.handler` provides symbolic constants for the feature and property names.

`xml.sax.handler.feature_namespaces`

- **value**: "http://xml.org/sax/features/namespaces"
- true: Perform Namespace processing.
- false: Optionally do not perform Namespace processing (implies namespace-prefixes; default).
- access: (parsing) read-only; (not parsing) read/write

`xml.sax.handler.feature_namespace_prefixes`

- **value**: "http://xml.org/sax/features/namespace-prefixes"
- true: Report the original prefixed names and attributes used for Namespace declarations.
- false: Do not report attributes used for Namespace declarations, and optionally do not report original prefixed names (default).
- access: (parsing) read-only; (not parsing) read/write

`xml.sax.handler.feature_string_interning`

- **value**: "http://xml.org/sax/features/string-interning"
- true: All element names, prefixes, attribute names, Namespace URIs, and local names are interned using the built-in intern function.
- false: Names are not necessarily interned, although they may be (default).
- access: (parsing) read-only; (not parsing) read/write

`xml.sax.handler.feature_validation`

- **value**: "http://xml.org/sax/features/validation"
- true: Report all validation errors (implies external-general-entities and external-parameter-entities).
- false: Do not report validation errors.
- access: (parsing) read-only; (not parsing) read/write
xml.sax.handler.feature_external_ges
value: "http://xml.org/sax/features/external-general-entities"
true: Include all external general (text) entities.
false: Do not include external general entities.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_external_pes
value: "http://xml.org/sax/features/external-parameter-entities"
true: Include all external parameter entities, including the external DTD subset.
false: Do not include any external parameter entities, even the external DTD subset.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.all_features
List of all features.

xml.sax.handler.property_lexical_handler
value: "http://xml.org/sax/properties/lexical-handler"
data type: xml.sax.sax2lib.LexicalHandler (not supported in Python 2)
description: An optional extension handler for lexical events like comments.
access: read/write

xml.sax.handler.property_declaration_handler
value: "http://xml.org/sax/properties/declaration-handler"
data type: xml.sax.sax2lib.DeclHandler (not supported in Python 2)
description: An optional extension handler for DTD-related events other than notations and unparsed entities.
access: read/write
xml.sax.handler.\property\_dom\_node

value: \"http://xml.org/sax/properties/dom-node\"

data type: org.w3c.dom.Node (not supported in Python 2)
description: When parsing, the current DOM node being visited if this is a DOM iterator; when not parsing, the root DOM node for iteration.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.\property\_xml\_string

value: \"http://xml.org/sax/properties/xml-string\"

data type: String
description: The literal string of characters that was the source for the current event.
access: read-only

xml.sax.handler.all\_properties

List of all known property names.
Users are expected to subclass `ContentHandler` to support their application. The following methods are called by the parser on the appropriate events in the input document:

**ContentHandler. `setDocumentLocator(locator)`**

Called by the parser to give the application a locator for locating the origin of document events.

SAX parsers are strongly encouraged (though not absolutely required) to supply a locator: if it does so, it must supply the locator to the application by invoking this method before invoking any of the other methods in the DocumentHandler interface.

The locator allows the application to determine the end position of any document-related event, even if the parser is not reporting an error. Typically, the application will use this information for reporting its own errors (such as character content that does not match an application's business rules). The information returned by the locator is probably not sufficient for use with a search engine.

Note that the locator will return correct information only during the invocation of the events in this interface. The application should not attempt to use it at any other time.

**ContentHandler. `startDocument()`**

Receive notification of the beginning of a document.

The SAX parser will invoke this method only once, before any other methods in this interface or in DTDHandler (except for `setDocumentLocator()`).
**ContentHandler**. `endDocument()`  
Receive notification of the end of a document.

The SAX parser will invoke this method only once, and it will be the last method invoked during the parse. The parser shall not invoke this method until it has either abandoned parsing (because of an unrecoverable error) or reached the end of input.

**ContentHandler**. `startPrefixMapping(prefix, uri)`  
Begin the scope of a prefix-URI Namespace mapping.

The information from this event is not necessary for normal Namespace processing: the SAX XML reader will automatically replace prefixes for element and attribute names when the `feature_namespaces` feature is enabled (the default).

There are cases, however, when applications need to use prefixes in character data or in attribute values, where they cannot safely be expanded automatically; the `startPrefixMapping()` and `endPrefixMapping()` events supply the information to the application to expand prefixes in those contexts itself, if necessary.

Note that `startPrefixMapping()` and `endPrefixMapping()` events are not guaranteed to be properly nested relative to each-other: all `startPrefixMapping()` events will occur before the corresponding `startElement()` event, and all `endPrefixMapping()` events will occur after the corresponding `endElement()` event, but their order is not guaranteed.

**ContentHandler**. `endPrefixMapping(prefix)`  
End the scope of a prefix-URI mapping.

See `startPrefixMapping()` for details. This event will always
occur after the corresponding `endElement()` event, but the order of `endPrefixMapping()` events is not otherwise guaranteed.

**ContentHandler. `startElement(name, attrs)`**

Signals the start of an element in non-namespace mode.

The `name` parameter contains the raw XML 1.0 name of the element type as a string and the `attrs` parameter holds an object of the `Attributes` interface (see *The Attributes Interface*) containing the attributes of the element. The object passed as `attrs` may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the `copy()` method of the `attrs` object.

**ContentHandler. `endElement(name)`**

Signals the end of an element in non-namespace mode.

The `name` parameter contains the name of the element type, just as with the `startElement()` event.

**ContentHandler. `startElementNS(name, qname, attrs)`**

Signals the start of an element in namespace mode.

The `name` parameter contains the name of the element type as a `tuple`, the `qname` parameter contains the raw XML 1.0 name used in the source document, and the `attrs` parameter holds an instance of the `AttributesNS` interface (see *The AttributesNS Interface*) containing the attributes of the element. If no namespace is associated with the element, the `uri` component of `name` will be `None`. The object passed as `attrs` may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the `copy()` method of the `attrs` object.
Parsers may set the *qname* parameter to *None*, unless the `feature_namespace_prefixes` feature is activated.

**ContentHandler. endElementNS(name, qname)**

Signals the end of an element in namespace mode.

The *name* parameter contains the name of the element type, just as with the `startElementNS()` method, likewise the *qname* parameter.

**ContentHandler. characters(content)**

Receive notification of character data.

The Parser will call this method to report each chunk of character data. SAX parsers may return all contiguous character data in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity so that the Locator provides useful information.

*content* may be a Unicode string or a byte string; the *expat* reader module produces always Unicode strings.

**Note:** The earlier SAX 1 interface provided by the Python XML Special Interest Group used a more Java-like interface for this method. Since most parsers used from Python did not take advantage of the older interface, the simpler signature was chosen to replace it. To convert old code to the new interface, use *content* instead of slicing content with the old *offset* and *length* parameters.

**ContentHandler. ignorableWhitespace(whitespace)**

Receive notification of ignorable whitespace in element content.

Validating Parsers must use this method to report each chunk of
ignorable whitespace (see the W3C XML 1.0 recommendation, section 2.10): non-validating parsers may also use this method if they are capable of parsing and using content models.

SAX parsers may return all contiguous whitespace in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity, so that the Locator provides useful information.

**ContentHandler**. `processingInstruction(target, data)`

Receive notification of a processing instruction.

The Parser will invoke this method once for each processing instruction found: note that processing instructions may occur before or after the main document element.

A SAX parser should never report an XML declaration (XML 1.0, section 2.8) or a text declaration (XML 1.0, section 4.3.1) using this method.

**ContentHandler**. `skippedEntity(name)`

Receive notification of a skipped entity.

The Parser will invoke this method once for each entity skipped. Non-validating processors may skip entities if they have not seen the declarations (because, for example, the entity was declared in an external DTD subset). All processors may skip external entities, depending on the values of the `feature_external_ges` and the `feature_external_pes` properties.
19.10.2. DTDHandler Objects

**DTDHandler** instances provide the following methods:

**DTDHandler.notationDecl**\((name, publicId, systemId)\)
Handle a notation declaration event.

**DTDHandler.unparsedEntityDecl**\((name, publicId, systemId, ndata)\)
Handle an unparsed entity declaration event.
19.10.3. EntityResolver Objects

EntityResolver. **resolveEntity**(publicId, systemId)

Resolve the system identifier of an entity and return either the system identifier to read from as a string, or an InputSource to read from. The default implementation returns `systemId`.
19.10.4. ErrorHandler Objects

Objects with this interface are used to receive error and warning information from the `XMLReader`. If you create an object that implements this interface, then register the object with your `XMLReader`, the parser will call the methods in your object to report all warnings and errors. There are three levels of errors available: warnings, (possibly) recoverable errors, and unrecoverable errors. All methods take a `SAXParseException` as the only parameter. Errors and warnings may be converted to an exception by raising the passed-in exception object.

```python
ErrorHandler.error(exception)
```

Called when the parser encounters a recoverable error. If this method does not raise an exception, parsing may continue, but further document information should not be expected by the application. Allowing the parser to continue may allow additional errors to be discovered in the input document.

```python
ErrorHandler.fatalError(exception)
```

Called when the parser encounters an error it cannot recover from; parsing is expected to terminate when this method returns.

```python
ErrorHandler.warning(exception)
```

Called when the parser presents minor warning information to the application. Parsing is expected to continue when this method returns, and document information will continue to be passed to the application. Raising an exception in this method will cause parsing to end.
19.11. `xml.sax.saxutils` — SAX Utilities

*New in version 2.0.*

The module `xml.sax.saxutils` contains a number of classes and functions that are commonly useful when creating SAX applications, either in direct use, or as base classes.

```python
xml.sax.saxutils.escape(data[, entities])
```

Escape `&`, `<`, and `>` in a string of data.

You can escape other strings of data by passing a dictionary as the optional `entities` parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. The characters `&`, `<` and `>` are always escaped, even if `entities` is provided.

```python
xml.sax.saxutils.unescape(data[, entities])
```

Unescape `&amp;`, `&lt;`, and `&gt;` in a string of data.

You can unescape other strings of data by passing a dictionary as the optional `entities` parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. `&amp;`, `&lt;`, and `&gt;` are always unescaped, even if `entities` is provided.

*New in version 2.3.*

```python
xml.sax.saxutils.quoteattr(data[, entities])
```

Similar to `escape()`, but also prepares `data` to be used as an attribute value. The return value is a quoted version of `data` with
any additional required replacements. \texttt{quoteattr()} will select a quote character based on the content of \textit{data}, attempting to avoid encoding any quote characters in the string. If both single- and double-quote characters are already in \textit{data}, the double-quote characters will be encoded and \textit{data} will be wrapped in double-quotes. The resulting string can be used directly as an attribute value:

\begin{verbatim}
>>> print "<element attr=%s"> % quoteattr("ab ' cd " ef")
<element attr="ab ' cd &quot; ef">
\end{verbatim}

This function is useful when generating attribute values for HTML or any SGML using the reference concrete syntax.

\textit{New in version 2.2.}

\begin{verbatim}
class xml.sax.saxutils.XMLGenerator([out[, encoding]])
This class implements the ContentHandler interface by writing SAX events back into an XML document. In other words, using an XMLGenerator as the content handler will reproduce the original document being parsed. \textit{out} should be a file-like object which will default to \texttt{sys.stdout}. \textit{encoding} is the encoding of the output stream which defaults to 'iso-8859-1'.

class xml.sax.saxutils.XMLFilterBase(base)
This class is designed to sit between an XMLReader and the client application’s event handlers. By default, it does nothing but pass requests up to the reader and events on to the handlers unmodified, but subclasses can override specific methods to modify the event stream or the configuration requests as they pass through.

xml.sax.saxutils.prepare_input_source(source[, base])
This function takes an input source and an optional base URL
and returns a fully resolved `InputSource` object ready for reading. The input source can be given as a string, a file-like object, or an `InputSource` object; parsers will use this function to implement the polymorphic `source` argument to their `parse()` method.
SAX parsers implement the `XMLReader` interface. They are implemented in a Python module, which must provide a function `create_parser()`. This function is invoked by `xml.sax.make_parser()` with no arguments to create a new parser object.

```python
class xml.sax.xmlreader.XMLReader
    Base class which can be inherited by SAX parsers.
```

```python
class xml.sax.xmlreader.IncrementalParser
    In some cases, it is desirable not to parse an input source at once, but to feed chunks of the document as they get available. Note that the reader will normally not read the entire file, but read it in chunks as well; still `parse()` won't return until the entire document is processed. So these interfaces should be used if the blocking behaviour of `parse()` is not desirable.

    When the parser is instantiated it is ready to begin accepting data from the feed method immediately. After parsing has been finished with a call to close the reset method must be called to make the parser ready to accept new data, either from feed or using the parse method.

    Note that these methods must not be called during parsing, that is, after parse has been called and before it returns.

    By default, the class also implements the parse method of the XMLReader interface using the feed, close and reset methods of the IncrementalParser interface as a convenience to SAX 2.0
driver writers.

class xml.sax.xmlreader.Locator

Interface for associating a SAX event with a document location. A locator object will return valid results only during calls to DocumentHandler methods; at any other time, the results are unpredictable. If information is not available, methods may return None.

class xml.sax.xmlreader.InputSource([systemId])

Encapsulation of the information needed by the XMLReader to read entities.

This class may include information about the public identifier, system identifier, byte stream (possibly with character encoding information) and/or the character stream of an entity.

Applications will create objects of this class for use in the XMLReader.parse() method and for returning from EntityResolver.resolveEntity.

An InputSource belongs to the application, the XMLReader is not allowed to modify InputSource objects passed to it from the application, although it may make copies and modify those.

class xml.sax.xmlreader.AttributesImpl(attrs)

This is an implementation of the Attributes interface (see section The Attributes Interface). This is a dictionary-like object which represents the element attributes in a startElement() call. In addition to the most useful dictionary operations, it supports a number of other methods as described by the interface. Objects of this class should be instantiated by readers; attrs must be a dictionary-like object containing a mapping from attribute names to attribute values.
class xml.sax.xmlreader.AttributesNSImpl(attr, qnames)

Namespace-aware variant of AttributesImpl, which will be passed to startElementNS(). It is derived from AttributesImpl, but understands attribute names as two-tuples of namespaceURI and localname. In addition, it provides a number of methods expecting qualified names as they appear in the original document. This class implements the AttributesNS interface (see section The AttributesNS Interface).
19.12.1. XMLReader Objects

The XMLReader interface supports the following methods:

`XMLReader.parse(source)`

Process an input source, producing SAX events. The `source` object can be a system identifier (a string identifying the input source – typically a file name or an URL), a file-like object, or an `InputSource` object. When `parse()` returns, the input is completely processed, and the parser object can be discarded or reset. As a limitation, the current implementation only accepts byte streams; processing of character streams is for further study.

`XMLReader.getContentHandler()`

Return the current `ContentHandler`.

`XMLReader.setContentHandler(handler)`

Set the current `ContentHandler`. If no `ContentHandler` is set, content events will be discarded.

`XMLReader.getDTDHandler()`

Return the current `DTDHandler`.

`XMLReader.setDTDHandler(handler)`

Set the current `DTDHandler`. If no `DTDHandler` is set, DTD events will be discarded.

`XMLReader.getEntityResolver()`

Return the current `EntityResolver`.

`XMLReader.setEntityResolver(handler)`

Set the current `EntityResolver`. If no `EntityResolver` is set,
attempts to resolve an external entity will result in opening the system identifier for the entity, and fail if it is not available.

`XMLReader.getErrorHandler()`  
Return the current `ErrorHandler`.

`XMLReader.setErrorHandler(handler)`  
Set the current error handler. If no `ErrorHandler` is set, errors will be raised as exceptions, and warnings will be printed.

`XMLReader.setLocale(locale)`  
Allow an application to set the locale for errors and warnings.

SAX parsers are not required to provide localization for errors and warnings; if they cannot support the requested locale, however, they must raise a SAX exception. Applications may request a locale change in the middle of a parse.

`XMLReader.getFeature(featurename)`  
Return the current setting for feature `featurename`. If the feature is not recognized, `SAXNotRecognizedException` is raised. The well-known featurenames are listed in the module `xml.sax.handler`.

`XMLReader.setFeature(featurename, value)`  
Set the `featurename` to `value`. If the feature is not recognized, `SAXNotRecognizedException` is raised. If the feature or its setting is not supported by the parser, `SAXNotSupportedException` is raised.

`XMLReader.getProperty(propertyname)`  
Return the current setting for property `propertyname`. If the property is not recognized, a `SAXNotRecognizedException` is raised. The well-known propertynames are listed in the module `xml.sax.handler`. 
XMLReader. **setProperty**(propertyname, value)

Set the *propertyname* to *value*. If the property is not recognized, *SAXNotRecognizedException* is raised. If the property or its setting is not supported by the parser, *SAXNotSupportedException* is raised.
19.12.2. IncrementalParser Objects

Instances of IncrementalParser offer the following additional methods:

IncrementalParser. **feed(data)**
Process a chunk of data.

IncrementalParser. **close()**
Assume the end of the document. That will check well-formedness conditions that can be checked only at the end, invoke handlers, and may clean up resources allocated during parsing.

IncrementalParser. **reset()**
This method is called after close has been called to reset the parser so that it is ready to parse new documents. The results of calling parse or feed after close without calling reset are undefined.
19.12.3. Locator Objects

Instances of `Locator` provide these methods:

- **Locator. `getColumnNumber()`**
  Return the column number where the current event ends.

- **Locator. `getLineNumber()`**
  Return the line number where the current event ends.

- **Locator. `getPublicId()`**
  Return the public identifier for the current event.

- **Locator. `getSystemId()`**
  Return the system identifier for the current event.
19.12.4. InputSource Objects

InputSource.setPublicId(id)
Sets the public identifier of this InputSource.

InputSource.getPublicId()
Returns the public identifier of this InputSource.

InputSource.setSystemId(id)
Sets the system identifier of this InputSource.

InputSource.getSystemId()
Returns the system identifier of this InputSource.

InputSource.setEncoding(encoding)
Sets the character encoding of this InputSource.

   The encoding must be a string acceptable for an XML encoding declaration (see section 4.3.3 of the XML recommendation).

   The encoding attribute of the InputSource is ignored if the InputSource also contains a character stream.

InputSource.getEncoding()
Get the character encoding of this InputSource.

InputSource.setByteStream(bytefile)
Set the byte stream (a Python file-like object which does not perform byte-to-character conversion) for this input source.

   The SAX parser will ignore this if there is also a character stream specified, but it will use a byte stream in preference to opening a URI connection itself.
If the application knows the character encoding of the byte stream, it should set it with the `setEncoding` method.

**InputSource**. `getBytesStream()`  
Get the byte stream for this input source.

The `getEncoding` method will return the character encoding for this byte stream, or None if unknown.

**InputSource**. `setCharacterStream(charfile)`  
Set the character stream for this input source. (The stream must be a Python 1.6 Unicode-wrapped file-like that performs conversion to Unicode strings.)

If there is a character stream specified, the SAX parser will ignore any byte stream and will not attempt to open a URI connection to the system identifier.

**InputSource**. `getCharacterStream()`  
Get the character stream for this input source.
19.12.5. The Attributes Interface

Attributes objects implement a portion of the mapping protocol, including the methods copy(), get(), has_key(), items(), keys(), and values(). The following methods are also provided:

Attributes. `getLength()`
    Return the number of attributes.

Attributes. `getNames()`
    Return the names of the attributes.

Attributes. `getType(name)`
    Returns the type of the attribute `name`, which is normally 'CDATA'.

Attributes. `getValue(name)`
    Return the value of attribute `name`. 
19.12.6. The AttributesNS Interface

This interface is a subtype of the Attributes interface (see section *The Attributes Interface*). All methods supported by that interface are also available on AttributesNS objects.

The following methods are also available:

AttributesNS.\texttt{getValueByQName(name)}

Return the value for a qualified name.

AttributesNS.\texttt{getNameByQName(name)}

Return the (namespace, localname) pair for a qualified name.

AttributesNS.\texttt{getQNameByName(name)}

Return the qualified name for a (namespace, localname) pair.

AttributesNS.\texttt{getQNames()}

Return the qualified names of all attributes.
New in version 2.5.

The **Element** type is a flexible container object, designed to store hierarchical data structures in memory. The type can be described as a cross between a list and a dictionary.

Each element has a number of properties associated with it:

- a tag which is a string identifying what kind of data this element represents (the element type, in other words).
- a number of attributes, stored in a Python dictionary.
- a text string.
- an optional tail string.
- a number of child elements, stored in a Python sequence

To create an element instance, use the **Element** constructor or the **SubElement()** factory function.

The **ElementTree** class can be used to wrap an element structure, and convert it from and to XML.

A C implementation of this API is available as **xml.etree.cElementTree**.

See [http://effbot.org/zone/element-index.htm](http://effbot.org/zone/element-index.htm) for tutorials and links to other docs. Fredrik Lundh’s page is also the location of the development version of the xml.etree.ElementTree.

*Changed in version 2.7:* The ElementTree API is updated to 1.3. For more information, see **Introducing ElementTree 1.3**.
19.13.1. Functions

xml.etree.ElementTree.Comment(text=None)
Comment element factory. This factory function creates a special element that will be serialized as an XML comment by the standard serializer. The comment string can be either a bytestring or a Unicode string. text is a string containing the comment string. Returns an element instance representing a comment.

xml.etree.ElementTree.dump(elem)
Writes an element tree or element structure to sys.stdout. This function should be used for debugging only.

The exact output format is implementation dependent. In this version, it's written as an ordinary XML file.

elem is an element tree or an individual element.

xml.etree.ElementTree.fromstring(text)
Parses an XML section from a string constant. Same as XML(). text is a string containing XML data. Returns an Element instance.

xml.etree.ElementTree.fromstringlist(sequence, parser=None)
Parses an XML document from a sequence of string fragments. sequence is a list or other sequence containing XML data fragments. parser is an optional parser instance. If not given, the standard XMLParser parser is used. Returns an Element instance.

New in version 2.7.

xml.etree.ElementTree.iselement(element)
Checks if an object appears to be a valid element object. element is an element instance. Returns a true value if this is an element
xml.etree.ElementTree. **iterparse**(*source*, *events=None*, *parser=None*)

Parses an XML section into an element tree incrementally, and reports what's going on to the user. *source* is a filename or file object containing XML data. *events* is a list of events to report back. If omitted, only “end” events are reported. *parser* is an optional parser instance. If not given, the standard XMLParser parser is used. Returns an *iterator* providing (*event*, *elem*) pairs.

**Note:** *iterparse()* only guarantees that it has seen the “>” character of a starting tag when it emits a “start” event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present. If you need a fully populated element, look for “end” events instead.

xml.etree.ElementTree. **parse**(*source*, *parser=None*)

Parses an XML section into an element tree. *source* is a filename or file object containing XML data. *parser* is an optional parser instance. If not given, the standard XMLParser parser is used. Returns an *ElementTree* instance.

xml.etree.ElementTree. **ProcessingInstruction**(*target*,
*text=None*)

PI element factory. This factory function creates a special element that will be serialized as an XML processing instruction. *target* is a string containing the PI target. *text* is a string containing the PI contents, if given. Returns an element instance, representing a processing instruction.
xml.etree.ElementTree.register_namespace(prefix, uri)

Registers a namespace prefix. The registry is global, and any existing mapping for either the given prefix or the namespace URI will be removed. prefix is a namespace prefix. uri is a namespace uri. Tags and attributes in this namespace will be serialized with the given prefix, if at all possible.

New in version 2.7.

xml.etree.ElementTree.SubElement(parent, tag, attrib={}, **extra)

Subelement factory. This function creates an element instance, and appends it to an existing element.

The element name, attribute names, and attribute values can be either bytestings or Unicode strings. parent is the parent element. tag is the subelement name. attrib is an optional dictionary, containing element attributes. extra contains additional attributes, given as keyword arguments. Returns an element instance.

xml.etree.ElementTree.tostring(element, encoding="us-ascii", method="xml")

Generates a string representation of an XML element, including all subelements. element is an Element instance. encoding [1] is the output encoding (default is US-ASCII). method is either "xml", "html" or "text" (default is "xml"). Returns an encoded string containing the XML data.

xml.etree.ElementTree.tostringlist(element, encoding="us-ascii", method="xml")

Generates a string representation of an XML element, including all subelements. element is an Element instance. encoding [1] is the output encoding (default is US-ASCII). method is either "xml", "html" or "text" (default is "xml"). Returns a list of
encoded strings containing the XML data. It does not guarantee any specific sequence, except that 
"".join(tostringlist(element)) == tostring(element).

New in version 2.7.

xml.etree.ElementTree.XML(text, parser=None)

Parses an XML section from a string constant. This function can be used to embed “XML literals” in Python code. text is a string containing XML data. parser is an optional parser instance. If not given, the standard XMLParser parser is used. Returns an Element instance.

xml.etree.ElementTree.XMLID(text, parser=None)

Parses an XML section from a string constant, and also returns a dictionary which maps from element id:s to elements. text is a string containing XML data. parser is an optional parser instance. If not given, the standard XMLParser parser is used. Returns a tuple containing an Element instance and a dictionary.
19.13.2. Element Objects

class xml.etree.ElementTree.Element(tag, attrib={}, **extra)

Element class. This class defines the Element interface, and provides a reference implementation of this interface.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. tag is the element name. attrib is an optional dictionary, containing element attributes. extra contains additional attributes, given as keyword arguments.

tag
A string identifying what kind of data this element represents (the element type, in other words).

text
The text attribute can be used to hold additional data associated with the element. As the name implies this attribute is usually a string but may be any application-specific object. If the element is created from an XML file the attribute will contain any text found between the element tags.

tail
The tail attribute can be used to hold additional data associated with the element. This attribute is usually a string but may be any application-specific object. If the element is created from an XML file the attribute will contain any text found after the element’s end tag and before the next tag.

attrib
A dictionary containing the element’s attributes. Note that while the attrib value is always a real mutable Python dictionary, an ElementTree implementation may choose to use another internal representation, and create the dictionary only if someone asks for it. To take advantage of such
implementations, use the dictionary methods below whenever possible.

The following dictionary-like methods work on the element attributes.

clear()
Resets an element. This function removes all subelements, clears all attributes, and sets the text and tail attributes to None.

get(key, default=None)
Gets the element attribute named key.

Returns the attribute value, or default if the attribute was not found.

items()
Returns the element attributes as a sequence of (name, value) pairs. The attributes are returned in an arbitrary order.

keys()
Returns the elements attribute names as a list. The names are returned in an arbitrary order.

set(key, value)
Set the attribute key on the element to value.

The following methods work on the element's children (subelements).

append(subelement)
Adds the element subelement to the end of this elements internal list of subelements.

extend(subelements)
Appends subelements from a sequence object with zero or
more elements. Raises :exc:`AssertionError` if a subelement is not a valid object.

New in version 2.7.

**find**(match)

Finds the first subelement matching *match*. *match* may be a tag name or path. Returns an element instance or :const:`None`.

**findall**(match)

Finds all matching subelements, by tag name or path. Returns a list containing all matching elements in document order.

**findtext**(match, default=None)

Finds text for the first subelement matching *match*. *match* may be a tag name or path. Returns the text content of the first matching element, or *default* if no element was found. Note that if the matching element has no text content an empty string is returned.

**getchildren**( )

.. deprecated:: 2.7

    Use :func:`list(elem)` or iteration.

**getiterator**(tag=None)

.. deprecated:: 2.7

**insert**(index, element)

Inserts a subelement at the given position in this element.

**iter**(tag=None)

Creates a tree :mod:`iterator` with the current element as the root. The iterator iterates over this element and all elements below it, in document (depth first) order. If *tag* is not :const:`None` or `'*'`, only
elements whose tag equals tag are returned from the iterator. If the tree structure is modified during iteration, the result is undefined.

**iterfind**(match)
Finds all matching subelements, by tag name or path. Returns an iterable yielding all matching elements in document order.

*New in version 2.7.*

**itertext()**
Creates a text iterator. The iterator loops over this element and all subelements, in document order, and returns all inner text.

*New in version 2.7.*

**makeelement**(tag, attrib)
Creates a new element object of the same type as this element. Do not call this method, use the `SubElement()` factory function instead.

**remove**(subelement)
Removes subelement from the element. Unlike the find* methods this method compares elements based on the instance identity, not on tag value or contents.

`Element` objects also support the following sequence type methods for working with subelements: `__delitem__()`, `__getitem__()`, `__setitem__()`, `__len__()`. Caution: Elements with no subelements will test as `False`. This behavior will change in future versions. Use specific `len(elem)` or `elem is None` test instead.
element = root.find('foo')

if not element:  # careful!
    print "element not found, or element has no subelements"

if element is None:
    print "element not found"
19.13.3. ElementTree Objects

class xml.etree.ElementTree.**ElementTree**(element=None, file=None)

ElementTree wrapper class. This class represents an entire element hierarchy, and adds some extra support for serialization to and from standard XML.

*element* is the root element. The tree is initialized with the contents of the XML *file* if given.

**_setroot**(element)

Replaces the root element for this tree. This discards the current contents of the tree, and replaces it with the given element. Use with care. *element* is an element instance.

**find**(match)

Finds the first toplevel element matching *match*. *match* may be a tag name or path. Same as getroot().find(match). Returns the first matching element, or *None* if no element was found.

**findall**(match)

Finds all matching subelements, by tag name or path. Same as getroot().findall(match). *match* may be a tag name or path. Returns a list containing all matching elements, in document order.

**findtext**(match, default=None)

Finds the element text for the first toplevel element with given tag. Same as getroot().findtext(match). *match* may be a tag name or path. *default* is the value to return if the element was not found. Returns the text content of the first matching element, or the default value no element was found. Note that
if the element is found, but has no text content, this method returns an empty string.

getiterator(tag=None)

Deprecated since version 2.7: Use method ElementTree.iter() instead.

getroot()

Returns the root element for this tree.

iter(tag=None)

Creates and returns a tree iterator for the root element. The iterator loops over all elements in this tree, in section order. tag is the tag to look for (default is to return all elements)

iterfind(match)

Finds all matching subelements, by tag name or path. Same as getroot().iterfind(match). Returns an iterable yielding all matching elements in document order.

New in version 2.7.

parse(source, parser=None)

Loads an external XML section into this element tree. source is a file name or file object. parser is an optional parser instance. If not given, the standard XMLParser parser is used. Returns the section root element.

write(file, encoding="us-ascii", xml_declaration=None, method="xml")

Writes the element tree to a file, as XML. file is a file name, or a file object opened for writing. encoding [1] is the output encoding (default is US-ASCII). xml_declaration controls if an XML declaration should be added to the file. Use False for never, True for always, None for only if not US-ASCII or UTF-
8 (default is None). method is either "xml", "html" or "text" (default is "xml"). Returns an encoded string.

This is the XML file that is going to be manipulated:

```xml
<html>
  <head>
    <title>Example page</title>
  </head>
  <body>
    <p>Moved to <a href="http://example.org/">example.org</a> or <a href="http://example.com/">example.com</a>.</p>
  </body>
</html>
```

Example of changing the attribute “target” of every link in first paragraph:

```python
>>> from xml.etree.ElementTree import ElementTree
>>> tree = ElementTree()
>>> tree.parse("index.xhtml")
<Element 'html' at 0xb77e6fac>
>>> p = tree.find("body/p")  # Finds first occurrence of tag
>>> p
<Element 'p' at 0xb77ec26c>
>>> links = list(p.iter("a"))  # Returns list of all links
>>> links
[<Element 'a' at 0xb77ec2ac>, <Element 'a' at 0xb77ec1cc>]
>>> for i in links:  # Iterates through all found links
...     i.attrib["target"] = "blank"
>>> tree.write("output.xhtml")
```
19.13.4. QName Objects

```python
class xml.etree.ElementTree.QName(text_or_uri, tag=None)
```

QName wrapper. This can be used to wrap a QName attribute value, in order to get proper namespace handling on output. `text_or_uri` is a string containing the QName value, in the form `{uri}local`, or, if the tag argument is given, the URI part of a QName. If `tag` is given, the first argument is interpreted as an URI, and this argument is interpreted as a local name. QName instances are opaque.
19.13.5. TreeBuilder Objects

```python
class xml.etree.ElementTree.TreeBuilder(element_factory=None)
```

Generic element structure builder. This builder converts a sequence of start, data, and end method calls to a well-formed element structure. You can use this class to build an element structure using a custom XML parser, or a parser for some other XML-like format. The `element_factory` is called to create new `Element` instances when given.

```python
close()
```

Flushes the builder buffers, and returns the toplevel document element. Returns an `Element` instance.

```python
data(data)
```

Adds text to the current element. `data` is a string. This should be either a bytestring, or a Unicode string.

```python
data(tag)
```

Closes the current element. `tag` is the element name. Returns the closed element.

```python
start(tag, attrs)
```

Opens a new element. `tag` is the element name. `attrs` is a dictionary containing element attributes. Returns the opened element.

In addition, a custom `TreeBuilder` object can provide the following method:

```python
doctype(name, pubid, system)
```

Handles a doctype declaration. `name` is the doctype name. `pubid` is the public identifier. `system` is the system identifier. This method does not exist on the default `TreeBuilder` class.
New in version 2.7.
19.13.6. XMLParser Objects

class xml.etree.ElementTree.XMLParser(html=0, target=None, encoding=None)

Element structure builder for XML source data, based on the expat parser. html are predefined HTML entities. This flag is not supported by the current implementation. target is the target object. If omitted, the builder uses an instance of the standard TreeBuilder class. encoding [1] is optional. If given, the value overrides the encoding specified in the XML file.

close()

Finishes feeding data to the parser. Returns an element structure.

doctype(name, pubid, system)

Deprecated since version 2.7: Define the TreeBuilder.doctype() method on a custom TreeBuilder target.

feed(data)

Feeds data to the parser. data is encoded data.

XMLParser.feed() calls target's start() method for each opening tag, its end() method for each closing tag, and data is processed by method data(). XMLParser.close() calls target's method close(). XMLParser can be used not only for building a tree structure. This is an example of counting the maximum depth of an XML file:

```python
>>> from xml.etree.ElementTree import XMLParser
>>> class MaxDepth:
...     maxDepth = 0
...     depth = 0
... # The target object of XMLParser
```
... def start(self, tag, attrib):  # Called for each opening tag.
    self.depth += 1
    if self.depth > self.maxDepth:
        self.maxDepth = self.depth
... def end(self, tag):  # Called for each closing tag.
    self.depth -= 1
... def data(self, data):
    pass  # We do not need to do anything with data.
... def close(self):  # Called when all data has been parsed.
    return self.maxDepth

>>> target = MaxDepth()
>>> parser = XMLParser(target=target)
>>> exampleXml = ""

... <a>
    ...
    <b>
        ...
        <b>
            ...
            <c>
                ...
                <d>
                    ...
                    </d>
            ...
            </c>
        ...
        </b>
    ...
    </a>"

>>> parser.feed(exampleXml)
>>> parser.close()
4

Footnotes

The encoding string included in XML output should conform to the appropriate standards. For example, “UTF-8” is valid, but “UTF8” is not. See http://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and http://www.iana.org/assignments/character-sets.
20. Internet Protocols and Support

The modules described in this chapter implement Internet protocols and support for related technology. They are all implemented in Python. Most of these modules require the presence of the system-dependent module `socket`, which is currently supported on most popular platforms. Here is an overview:

- **20.1. `webbrowser`** — Convenient Web-browser controller
  - 20.1.1. Browser Controller Objects
- **20.2. `cgi`** — Common Gateway Interface support
  - 20.2.1. Introduction
  - 20.2.2. Using the `cgi` module
  - 20.2.3. Higher Level Interface
  - 20.2.4. Old classes
  - 20.2.5. Functions
  - 20.2.6. Caring about security
  - 20.2.7. Installing your CGI script on a Unix system
  - 20.2.8. Testing your CGI script
  - 20.2.9. Debugging CGI scripts
  - 20.2.10. Common problems and solutions
- **20.3. `cgitb`** — Traceback manager for CGI scripts
- **20.4. `wsgiref`** — WSGI Utilities and Reference Implementation
  - 20.4.1. `wsgiref.util` — WSGI environment utilities
  - 20.4.2. `wsgiref.headers` — WSGI response header tools
  - 20.4.3. `wsgiref.simple_server` — a simple WSGI HTTP server
  - 20.4.4. `wsgiref.validate` — WSGI conformance checker
  - 20.4.5. `wsgiref.handlers` — server/gateway base classes
  - 20.4.6. Examples
- **20.5. `urllib`** — Open arbitrary resources by URL
  - 20.5.1. High-level interface
• 20.5.2. Utility functions
• 20.5.3. URL Opener objects
• 20.5.4. urllib Restrictions
• 20.5.5. Examples

• 20.6. urllib2 — extensible library for opening URLs
  • 20.6.1. Request Objects
  • 20.6.2. OpenerDirector Objects
  • 20.6.3. BaseHandler Objects
  • 20.6.4. HTTPRedirectHandler Objects
  • 20.6.5. HTTPCookieProcessor Objects
  • 20.6.6. ProxyHandler Objects
  • 20.6.7. HTTPPasswordMgr Objects
  • 20.6.8. AbstractBasicAuthHandler Objects
  • 20.6.9. HTTPBasicAuthHandler Objects
  • 20.6.10. ProxyBasicAuthHandler Objects
  • 20.6.11. AbstractDigestAuthHandler Objects
  • 20.6.12. HTTPDigestAuthHandler Objects
  • 20.6.13. ProxyDigestAuthHandler Objects
  • 20.6.14. HTTPHandler Objects
  • 20.6.15. HTTPSHandler Objects
  • 20.6.16. FileHandler Objects
  • 20.6.17. FTPHandler Objects
  • 20.6.18. CacheFTPHandler Objects
  • 20.6.19. UnknownHandler Objects
  • 20.6.20. HTTPErrorProcessor Objects
  • 20.6.21. Examples

• 20.7. httplib — HTTP protocol client
  • 20.7.1. HTTPConnection Objects
  • 20.7.2. HTTPResponse Objects
  • 20.7.3. Examples

• 20.8. ftplib — FTP protocol client
  • 20.8.1. FTP Objects
  • 20.8.2. FTP_TLS Objects

• 20.9. poplib — POP3 protocol client
- 20.9.1. POP3 Objects
- 20.9.2. POP3 Example
- 20.10. imaplib — IMAP4 protocol client
  - 20.10.1. IMAP4 Objects
  - 20.10.2. IMAP4 Example
- 20.11. nntplib — NNTP protocol client
  - 20.11.1. NNTP Objects
- 20.12. smtplib — SMTP protocol client
  - 20.12.1. SMTP Objects
  - 20.12.2. SMTP Example
- 20.13. smtpd — SMTP Server
  - 20.13.1. SMTPServer Objects
  - 20.13.2. DebuggingServer Objects
  - 20.13.3. PureProxy Objects
  - 20.13.4. MailmanProxy Objects
- 20.14. telnetlib — Telnet client
  - 20.14.1. Telnet Objects
  - 20.14.2. Telnet Example
- 20.15. uuid — UUID objects according to RFC 4122
  - 20.15.1. Example
- 20.16. urlparse — Parse URLs into components
  - 20.16.1. Results of urlparse() and urlsplit()
- 20.17. SocketServer — A framework for network servers
  - 20.17.1. Server Creation Notes
  - 20.17.2. Server Objects
  - 20.17.3. RequestHandler Objects
  - 20.17.4. Examples
    - 20.17.4.1. SocketServer.TCPServer Example
    - 20.17.4.2. SocketServer.UDPServer Example
    - 20.17.4.3. Asynchronous Mixins
- 20.18. BaseHTTPServer — Basic HTTP server
  - 20.18.1. More examples
- 20.19. SimpleHTTPServer — Simple HTTP request handler
- 20.20. **CGIHTTPServer** — CGI-capable HTTP request handler
- 20.21. **cookielib** — Cookie handling for HTTP clients
  - 20.21.2. FileCookieJar subclasses and co-operation with web browsers
  - 20.21.3. CookiePolicy Objects
  - 20.21.4. DefaultCookiePolicy Objects
  - 20.21.5. Cookie Objects
  - 20.21.6. Examples
- 20.22. **Cookie** — HTTP state management
  - 20.22.1. Cookie Objects
  - 20.22.2. Morsel Objects
  - 20.22.3. Example
- 20.23. **xmlrpclib** — XML-RPC client access
  - 20.23.1. ServerProxy Objects
  - 20.23.2. Boolean Objects
  - 20.23.3. DateTime Objects
  - 20.23.4. Binary Objects
  - 20.23.5. Fault Objects
  - 20.23.6. ProtocolError Objects
  - 20.23.7. MultiCall Objects
  - 20.23.8. Convenience Functions
  - 20.23.9. Example of Client Usage
  - 20.23.10. Example of Client and Server Usage
- 20.24. **SimpleXMLRPCServer** — Basic XML-RPC server
  - 20.24.1. SimpleXMLRPCServer Objects
    - 20.24.1.1. SimpleXMLRPCServer Example
  - 20.24.2. CGIXMLRPCRequestHandler
- 20.25. **DocXMLRPCServer** — Self-documenting XML-RPC server
  - 20.25.1. DocXMLRPCServer Objects
  - 20.25.2. DocCGIXMLRPCRequestHandler
20.1. webbrowser — Convenient Web-browser controller

The webbrowser module provides a high-level interface to allow displaying Web-based documents to users. Under most circumstances, simply calling the open() function from this module will do the right thing.

Under Unix, graphical browsers are preferred under X11, but text-mode browsers will be used if graphical browsers are not available or an X11 display isn’t available. If text-mode browsers are used, the calling process will block until the user exits the browser.

If the environment variable BROWSER exists, it is interpreted to override the platform default list of browsers, as a os.pathsep-separated list of browsers to try in order. When the value of a list part contains the string %s, then it is interpreted as a literal browser command line to be used with the argument URL substituted for %s; if the part does not contain %s, it is simply interpreted as the name of the browser to launch. [1]

For non-Unix platforms, or when a remote browser is available on Unix, the controlling process will not wait for the user to finish with the browser, but allow the remote browser to maintain its own windows on the display. If remote browsers are not available on Unix, the controlling process will launch a new browser and wait.

The script webbrowser can be used as a command-line interface for the module. It accepts an URL as the argument. It accepts the following optional parameters: -n opens the URL in a new browser window, if possible; -t opens the URL in a new browser page (“tab”). The options are, naturally, mutually exclusive.
The following exception is defined:

```python
exception webbrowser.Error
    Exception raised when a browser control error occurs.
```

The following functions are defined:

```python
webbrowser.open(url[, new=0[, autoraise=True]])
    Display url using the default browser. If new is 0, the url is opened in the same browser window if possible. If new is 1, a new browser window is opened if possible. If new is 2, a new browser page ("tab") is opened if possible. If autoraise is True, the window is raised if possible (note that under many window managers this will occur regardless of the setting of this variable).
```

Note that on some platforms, trying to open a filename using this function, may work and start the operating system's associated program. However, this is neither supported nor portable.

*Changed in version 2.5: new can now be 2.*

```python
webbrowser.open_new(url)
    Open url in a new window of the default browser, if possible, otherwise, open url in the only browser window.
```

```python
webbrowser.open_new_tab(url)
    Open url in a new page ("tab") of the default browser, if possible, otherwise equivalent to open_new().
```

*New in version 2.5.*

```python
webbrowser.get([name])
    Return a controller object for the browser type name. If name is empty, return a controller for a default browser appropriate to the caller's environment.
```
webbrowser.register(name, constructor[, instance])

Register the browser type name. Once a browser type is registered, the get() function can return a controller for that browser type. If instance is not provided, or is None, constructor will be called without parameters to create an instance when needed. If instance is provided, constructor will never be called, and may be None.

This entry point is only useful if you plan to either set the BROWSER variable or call get() with a nonempty argument matching the name of a handler you declare.

A number of browser types are predefined. This table gives the type names that may be passed to the get() function and the corresponding instantiations for the controller classes, all defined in this module.

<table>
<thead>

<tr>
<td>'elinks'</td>
<td>Elinks('elinks')</td>
<td></td>
</tr>
<tr>
<td>'lynx'</td>
<td>GenericBrowser('lynx')</td>
<td></td>
</tr>
</tbody>
</table>
Notes:

1. “Konqueror” is the file manager for the KDE desktop environment for Unix, and only makes sense to use if KDE is running. Some way of reliably detecting KDE would be nice; the KDEDIR variable is not sufficient. Note also that the name “kfm” is used even when using the konqueror command with KDE 2 — the implementation selects the best strategy for running Konqueror.
2. Only on Windows platforms.
3. Only on Mac OS platforms; requires the standard MacPython ic module.
4. Only on Mac OS X platform.

Here are some simple examples:

```python
url = 'http://www.python.org/'

# Open URL in a new tab, if a browser window is already open.
webbrowser.open_new_tab(url + 'doc/')

# Open URL in new window, raising the window if possible.
webbrowser.open_new(url)
```
Browser controllers provide these methods which parallel three of the module-level convenience functions:

```
controller.open(url[, new=0[, autoraise=True]])
```

Display `url` using the browser handled by this controller. If `new` is 1, a new browser window is opened if possible. If `new` is 2, a new browser page (“tab”) is opened if possible.

```
controller.open_new(url)
```

Open `url` in a new window of the browser handled by this controller, if possible, otherwise, open `url` in the only browser window. Alias `open_new()`.

```
controller.open_new_tab(url)
```

Open `url` in a new page (“tab”) of the browser handled by this controller, if possible, otherwise equivalent to `open_new()`.

*New in version 2.5.*

Footnotes

[1] Executables named here without a full path will be searched in the directories given in the `PATH` environment variable.
20. Internet Protocols and Support
20.2. cgi — Common Gateway Interface support

Support module for Common Gateway Interface (CGI) scripts.

This module defines a number of utilities for use by CGI scripts written in Python.
A CGI script is invoked by an HTTP server, usually to process user input submitted through an HTML `<FORM>` or `<ISINDEX>` element.

Most often, CGI scripts live in the server’s special `cgi-bin` directory. The HTTP server places all sorts of information about the request (such as the client’s hostname, the requested URL, the query string, and lots of other goodies) in the script’s shell environment, executes the script, and sends the script’s output back to the client.

The script’s input is connected to the client too, and sometimes the form data is read this way; at other times the form data is passed via the “query string” part of the URL. This module is intended to take care of the different cases and provide a simpler interface to the Python script. It also provides a number of utilities that help in debugging scripts, and the latest addition is support for file uploads from a form (if your browser supports it).

The output of a CGI script should consist of two sections, separated by a blank line. The first section contains a number of headers, telling the client what kind of data is following. Python code to generate a minimal header section looks like this:

```python
print "Content-Type: text/html" # HTML is following
print "# blank line, end of header"
```

The second section is usually HTML, which allows the client software to display nicely formatted text with header, in-line images, etc. Here’s Python code that prints a simple piece of HTML:

```python
print "<TITLE>CGI script output</TITLE>"
print "<H1>This is my first CGI script</H1>"
print "Hello, world!"
```
20.2.2. Using the cgi module

Begin by writing `import cgi`. Do not use `from cgi import *` — the module defines all sorts of names for its own use or for backward compatibility that you don’t want in your namespace.

When you write a new script, consider adding these lines:

```python
import cgitb
cgitb.enable()
```

This activates a special exception handler that will display detailed reports in the Web browser if any errors occur. If you’d rather not show the guts of your program to users of your script, you can have the reports saved to files instead, with code like this:

```python
import cgitb
cgitb.enable(display=0, logdir="/tmp")
```

It’s very helpful to use this feature during script development. The reports produced by `cgitb` provide information that can save you a lot of time in tracking down bugs. You can always remove the `cgitb` line later when you have tested your script and are confident that it works correctly.

To get at submitted form data, it’s best to use the `FieldStorage` class. The other classes defined in this module are provided mostly for backward compatibility. Instantiate it exactly once, without arguments. This reads the form contents from standard input or the environment (depending on the value of various environment variables set according to the CGI standard). Since it may consume standard input, it should be instantiated only once.

The `FieldStorage` instance can be indexed like a Python dictionary. It
allows membership testing with the `in` operator, and also supports the standard dictionary method `keys()` and the built-in function `len()`. Form fields containing empty strings are ignored and do not appear in the dictionary; to keep such values, provide a true value for the optional `keep_blank_values` keyword parameter when creating the `FieldStorage` instance.

For instance, the following code (which assumes that the `Content-Type` header and blank line have already been printed) checks that the fields `name` and `addr` are both set to a non-empty string:

```python
form = cgi.FieldStorage()
if "name" not in form or "addr" not in form:
    print "<H1>Error</H1>"
    print "Please fill in the name and addr fields."
    return

print "<p>name: ", form["name"].value
print "<p>addr: ", form["addr"].value
...
```

Here the fields, accessed through `form[key]`, are themselves instances of `FieldStorage` (or `MiniFieldStorage`, depending on the form encoding). The `value` attribute of the instance yields the string value of the field. The `getvalue()` method returns this string value directly; it also accepts an optional second argument as a default to return if the requested key is not present.

If the submitted form data contains more than one field with the same name, the object retrieved by `form[key]` is not a `FieldStorage` or `MiniFieldStorage` instance but a list of such instances. Similarly, in this situation, `form.getvalue(key)` would return a list of strings. If you expect this possibility (when your HTML form contains multiple fields with the same name), use the `getlist()` function, which always returns a list of values (so that you do not need to special-case the single item case). For example, this code concatenates any
number of username fields, separated by commas:

```python
value = form.getlist("username")
usernames = ",".join(value)
```

If a field represents an uploaded file, accessing the value via the `value` attribute or the `getvalue()` method reads the entire file in memory as a string. This may not be what you want. You can test for an uploaded file by testing either the `filename` attribute or the `file` attribute. You can then read the data at leisure from the `file` attribute:

```python
fileitem = form["userfile"]
if fileitem.file:
    # It's an uploaded file; count lines
    linecount = 0
    while 1:
        line = fileitem.file.readline()
        if not line: break
        linecount = linecount + 1
```

If an error is encountered when obtaining the contents of an uploaded file (for example, when the user interrupts the form submission by clicking on a Back or Cancel button) the `done` attribute of the object for the field will be set to the value `-1`.

The file upload draft standard entertains the possibility of uploading multiple files from one field (using a recursive `multipart/*` encoding). When this occurs, the item will be a dictionary-like `FieldStorage` item. This can be determined by testing its `type` attribute, which should be `multipart/form-data` (or perhaps another MIME type matching `multipart/*`). In this case, it can be iterated over recursively just like the top-level form object.

When a form is submitted in the “old” format (as the query string or as a single data part of type `application/x-www-form-urlencoded`), the
items will actually be instances of the class MiniFieldStorage. In this case, the list, file, and filename attributes are always None.

A form submitted via POST that also has a query string will contain both FieldStorage and MiniFieldStorage items.
20.2.3. Higher Level Interface

New in version 2.2.

The previous section explains how to read CGI form data using the FieldStorage class. This section describes a higher level interface which was added to this class to allow one to do it in a more readable and intuitive way. The interface doesn't make the techniques described in previous sections obsolete — they are still useful to process file uploads efficiently, for example.

The interface consists of two simple methods. Using the methods you can process form data in a generic way, without the need to worry whether only one or more values were posted under one name.

In the previous section, you learned to write following code anytime you expected a user to post more than one value under one name:

```python
item = form.getvalue("item")
if isinstance(item, list):
    # The user is requesting more than one item.
else:
    # The user is requesting only one item.
```

This situation is common for example when a form contains a group of multiple checkboxes with the same name:

```html
<input type="checkbox" name="item" value="1" />
<input type="checkbox" name="item" value="2" />
```

In most situations, however, there's only one form control with a particular name in a form and then you expect and need only one value associated with this name. So you write a script containing for example this code:
user = form.getvalue("user").upper()

The problem with the code is that you should never expect that a client will provide valid input to your scripts. For example, if a curious user appends another `user=foo` pair to the query string, then the script would crash, because in this situation the `form.getvalue("user")` method call returns a list instead of a string. Calling the `upper()` method on a list is not valid (since lists do not have a method of this name) and results in an `AttributeError` exception.

Therefore, the appropriate way to read form data values was to always use the code which checks whether the obtained value is a single value or a list of values. That's annoying and leads to less readable scripts.

A more convenient approach is to use the methods `getfirst()` and `getlist()` provided by this higher level interface.

FieldStorage. `getfirst(name[, default])`

This method always returns only one value associated with form field `name`. The method returns only the first value in case that more values were posted under such name. Please note that the order in which the values are received may vary from browser to browser and should not be counted on. [1] If no such form field or value exists then the method returns the value specified by the optional parameter `default`. This parameter defaults to `None` if not specified.

FieldStorage. `getlist(name)`

This method always returns a list of values associated with form field `name`. The method returns an empty list if no such form field or value exists for `name`. It returns a list consisting of one item if only one such value exists.
Using these methods you can write nice compact code:

```python
import cgi
form = cgi.FieldStorage()
user = form.getfirst("user", "").upper()  # This way it's safe
for item in form.getlist("item"):
    do_something(item)
```
20.2.4. Old classes

Deprecation since version 2.6.

*SvFormContentDict* stores single value form content as dictionary; it assumes each field name occurs in the form only once.

*FormContentDict* stores multiple value form content as a dictionary (the form items are lists of values). Useful if your form contains multiple fields with the same name.

Other classes (*FormContent*, *InterpFormContentDict*) are present for backwards compatibility with really old applications only.
20.2.5. Functions

These are useful if you want more control, or if you want to employ some of the algorithms implemented in this module in other circumstances.

```python
cgi.parse(fp[, keep_blank_values[, strict_parsing]])
```
Parse a query in the environment or from a file (the file defaults to `sys.stdin`). The `keep_blank_values` and `strict_parsing` parameters are passed to `urlparse.parse_qs()` unchanged.

```python
cgi.parse_qs(qs[, keep_blank_values[, strict_parsing]])
```
This function is deprecated in this module. Use `urlparse.parse_qs()` instead. It is maintained here only for backward compatibility.

```python
cgi.parse_qsl(qs[, keep_blank_values[, strict_parsing]])
```
This function is deprecated in this module. Use `urlparse.parse_qsl()` instead. It is maintained here only for backward compatibility.

```python
cgi.parse_multipart(fp, pdict)
```
Parse input of type `multipart/form-data` (for file uploads). Arguments are `fp` for the input file and `pdict` for a dictionary containing other parameters in the `Content-Type` header.

Returns a dictionary just like `urlparse.parse_qs()` keys are the field names, each value is a list of values for that field. This is easy to use but not much good if you are expecting megabytes to be uploaded — in that case, use the `FieldStorage` class instead which is much more flexible.
Note that this does not parse nested multipart parts — use `FieldStorage` for that.

cgi.**parse_header**(string)
Parse a MIME header (such as `Content-Type`) into a main value and a dictionary of parameters.

cgi.**test**()
Robust test CGI script, usable as main program. Writes minimal HTTP headers and formats all information provided to the script in HTML form.

cgi.**print_environ**()
Format the shell environment in HTML.

cgi.**print_form**(form)
Format a form in HTML.

cgi.**print_directory**()
Format the current directory in HTML.

cgi.**print_environ_usage**()
Print a list of useful (used by CGI) environment variables in HTML.

cgi.**escape**(s[, quote])
Convert the characters `&`, `<` and `>` in string s to HTML-safe sequences. Use this if you need to display text that might contain such characters in HTML. If the optional flag `quote` is true, the quotation mark character (`"`) is also translated; this helps for inclusion in an HTML attribute value delimited by double quotes, as in `<a href="...">`. Note that single quotes are never translated.
If the value to be quoted might include single- or double-quote characters, or both, consider using the `quoteattr()` function in the `xml.sax.saxutils` module instead.
20.2.6. Caring about security

There's one important rule: if you invoke an external program (via the `os.system()` or `os.popen()` functions, or others with similar functionality), make very sure you don't pass arbitrary strings received from the client to the shell. This is a well-known security hole whereby clever hackers anywhere on the Web can exploit a gullible CGI script to invoke arbitrary shell commands. Even parts of the URL or field names cannot be trusted, since the request doesn't have to come from your form!

To be on the safe side, if you must pass a string gotten from a form to a shell command, you should make sure the string contains only alphanumeric characters, dashes, underscores, and periods.
20.2.7. Installing your CGI script on a Unix system

Read the documentation for your HTTP server and check with your local system administrator to find the directory where CGI scripts should be installed; usually this is in a directory `cgi-bin` in the server tree.

Make sure that your script is readable and executable by “others”; the Unix file mode should be `0755` octal (use `chmod 0755 filename`). Make sure that the first line of the script contains `#!` starting in column 1 followed by the pathname of the Python interpreter, for instance:

```
#!/usr/local/bin/python
```

Make sure the Python interpreter exists and is executable by “others”.

Make sure that any files your script needs to read or write are readable or writable, respectively, by “others” — their mode should be `0644` for readable and `0666` for writable. This is because, for security reasons, the HTTP server executes your script as user “nobody”, without any special privileges. It can only read (write, execute) files that everybody can read (write, execute). The current directory at execution time is also different (it is usually the server’s `cgi-bin` directory) and the set of environment variables is also different from what you get when you log in. In particular, don’t count on the shell’s search path for executables (PATH) or the Python module search path (PYTHONPATH) to be set to anything interesting.

If you need to load modules from a directory which is not on Python’s
default module search path, you can change the path in your script, before importing other modules. For example:

```python
import sys
sys.path.insert(0, "usr/home/joe/lib/python")
sys.path.insert(0, "usr/local/lib/python")
```

(This way, the directory inserted last will be searched first!)

Instructions for non-Unix systems will vary; check your HTTP server’s documentation (it will usually have a section on CGI scripts).
20.2.8. Testing your CGI script

Unfortunately, a CGI script will generally not run when you try it from the command line, and a script that works perfectly from the command line may fail mysteriously when run from the server. There’s one reason why you should still test your script from the command line: if it contains a syntax error, the Python interpreter won’t execute it at all, and the HTTP server will most likely send a cryptic error to the client.

Assuming your script has no syntax errors, yet it does not work, you have no choice but to read the next section.
20.2.9. Debugging CGI scripts

First of all, check for trivial installation errors — reading the section above on installing your CGI script carefully can save you a lot of time. If you wonder whether you have understood the installation procedure correctly, try installing a copy of this module file (cgi.py) as a CGI script. When invoked as a script, the file will dump its environment and the contents of the form in HTML form. Give it the right mode etc, and send it a request. If it’s installed in the standard cgi-bin directory, it should be possible to send it a request by entering a URL into your browser of the form:

http://yourhostname/cgi-bin/cgi.py?name=Joe+Blow&addr=At+Home

If this gives an error of type 404, the server cannot find the script — perhaps you need to install it in a different directory. If it gives another error, there’s an installation problem that you should fix before trying to go any further. If you get a nicely formatted listing of the environment and form content (in this example, the fields should be listed as “addr” with value “At Home” and “name” with value “Joe Blow”), the cgi.py script has been installed correctly. If you follow the same procedure for your own script, you should now be able to debug it.

The next step could be to call the cgi module’s test() function from your script: replace its main code with the single statement

cgi.test()

This should produce the same results as those gotten from installing the cgi.py file itself.

When an ordinary Python script raises an unhandled exception (for
whatever reason: of a typo in a module name, a file that can’t be opened, etc.), the Python interpreter prints a nice traceback and exits. While the Python interpreter will still do this when your CGI script raises an exception, most likely the traceback will end up in one of the HTTP server’s log files, or be discarded altogether.

Fortunately, once you have managed to get your script to execute some code, you can easily send tracebacks to the Web browser using the cgitb module. If you haven’t done so already, just add the lines:

```python
import cgitb

cgitb.enable()
```

to the top of your script. Then try running it again; when a problem occurs, you should see a detailed report that will likely make apparent the cause of the crash.

If you suspect that there may be a problem in importing the cgitb module, you can use an even more robust approach (which only uses built-in modules):

```python
import sys
sys.stderr = sys.stdout
print "Content-Type: text/plain"
print ...
...your code here...
```

This relies on the Python interpreter to print the traceback. The content type of the output is set to plain text, which disables all HTML processing. If your script works, the raw HTML will be displayed by your client. If it raises an exception, most likely after the first two lines have been printed, a traceback will be displayed. Because no HTML interpretation is going on, the traceback will be readable.
20.2.10. Common problems and solutions

- Most HTTP servers buffer the output from CGI scripts until the script is completed. This means that it is not possible to display a progress report on the client's display while the script is running.
- Check the installation instructions above.
- Check the HTTP server's log files. (`tail -f logfile` in a separate window may be useful!)
- Always check a script for syntax errors first, by doing something like `python script.py`.
- If your script does not have any syntax errors, try adding `import cgitb; cgitb.enable()` to the top of the script.
- When invoking external programs, make sure they can be found. Usually, this means using absolute path names — `PATH` is usually not set to a very useful value in a CGI script.
- When reading or writing external files, make sure they can be read or written by the userid under which your CGI script will be running: this is typically the userid under which the web server is running, or some explicitly specified userid for a web server's `suexec` feature.
- Don't try to give a CGI script a set-uid mode. This doesn't work on most systems, and is a security liability as well.

Footnotes

[1] Note that some recent versions of the HTML specification do state what order the field values should be supplied in, but knowing whether a request was received from a conforming browser, or even from a browser at all, is tedious and error-prone.
20.3. cgitb — Traceback manager for CGI scripts

New in version 2.2.

The cgitb module provides a special exception handler for Python scripts. (Its name is a bit misleading. It was originally designed to display extensive traceback information in HTML for CGI scripts. It was later generalized to also display this information in plain text.) After this module is activated, if an uncaught exception occurs, a detailed, formatted report will be displayed. The report includes a traceback showing excerpts of the source code for each level, as well as the values of the arguments and local variables to currently running functions, to help you debug the problem. Optionally, you can save this information to a file instead of sending it to the browser.

To enable this feature, simply add this to the top of your CGI script:

```python
import cgitb
cgitb.enable()
```

The options to the `enable()` function control whether the report is displayed in the browser and whether the report is logged to a file for later analysis.

```python
cgitb.enable([display[, logdir[, context[, format]]]])
```

This function causes the cgitb module to take over the interpreter’s default handling for exceptions by setting the value of `sys.excepthook`.

The optional argument `display` defaults to `1` and can be set to `0` to suppress sending the traceback to the browser. If the
argument `logdir` is present, the traceback reports are written to files. The value of `logdir` should be a directory where these files will be placed. The optional argument `context` is the number of lines of context to display around the current line of source code in the traceback; this defaults to 5. If the optional argument `format` is "html", the output is formatted as HTML. Any other value forces plain text output. The default value is "html".

cgitb.handler([info])
This function handles an exception using the default settings (that is, show a report in the browser, but don’t log to a file). This can be used when you’ve caught an exception and want to report it using cgitb. The optional `info` argument should be a 3-tuple containing an exception type, exception value, and traceback object, exactly like the tuple returned by `sys.exc_info()`. If the `info` argument is not supplied, the current exception is obtained from `sys.exc_info()`.
20.4. wsgiref — WSGI Utilities and Reference Implementation

New in version 2.5.

The Web Server Gateway Interface (WSGI) is a standard interface between web server software and web applications written in Python. Having a standard interface makes it easy to use an application that supports WSGI with a number of different web servers.

Only authors of web servers and programming frameworks need to know every detail and corner case of the WSGI design. You don’t need to understand every detail of WSGI just to install a WSGI application or to write a web application using an existing framework.

wsgiref is a reference implementation of the WSGI specification that can be used to add WSGI support to a web server or framework. It provides utilities for manipulating WSGI environment variables and response headers, base classes for implementing WSGI servers, a demo HTTP server that serves WSGI applications, and a validation tool that checks WSGI servers and applications for conformance to the WSGI specification (PEP 333).

See http://www.wsgi.org for more information about WSGI, and links to tutorials and other resources.
This module provides a variety of utility functions for working with WSGI environments. A WSGI environment is a dictionary containing HTTP request variables as described in PEP 333. All of the functions taking an environ parameter expect a WSGI-compliant dictionary to be supplied; please see PEP 333 for a detailed specification.

**wsgiref.util.guess_scheme(environ)**
Return a guess for whether wsgi.url_scheme should be “http” or “https”, by checking for a HTTPS environment variable in the environ dictionary. The return value is a string.

This function is useful when creating a gateway that wraps CGI or a CGI-like protocol such as FastCGI. Typically, servers providing such protocols will include a HTTPS variable with a value of “1” “yes”, or “on” when a request is received via SSL. So, this function returns “https” if such a value is found, and “http” otherwise.

**wsgiref.util.request_uri(environ[, include_query=1])**
Return the full request URI, optionally including the query string, using the algorithm found in the “URL Reconstruction” section of PEP 333. If include_query is false, the query string is not included in the resulting URI.

**wsgiref.util.application_uri(environ)**
Similar to request_uri(), except that the PATH_INFO and QUERY_STRING variables are ignored. The result is the base URI of the application object addressed by the request.
wsgiref.util.shift_path_info(environ)

Shift a single name from PATH_INFO to SCRIPT_NAME and return the name. The environ dictionary is modified in-place; use a copy if you need to keep the original PATH_INFO or SCRIPT_NAME intact.

If there are no remaining path segments in PATH_INFO, None is returned.

Typically, this routine is used to process each portion of a request URI path, for example to treat the path as a series of dictionary keys. This routine modifies the passed-in environment to make it suitable for invoking another WSGI application that is located at the target URI. For example, if there is a WSGI application at /foo, and the request URI path is /foo/bar/baz, and the WSGI application at /foo calls shift_path_info(), it will receive the string “bar”, and the environment will be updated to be suitable for passing to a WSGI application at /foo/bar. That is, SCRIPT_NAME will change from /foo to /foo/bar, and PATH_INFO will change from /bar/baz to /baz.

When PATH_INFO is just a “/”, this routine returns an empty string and appends a trailing slash to SCRIPT_NAME, even though empty path segments are normally ignored, and SCRIPT_NAME doesn’t normally end in a slash. This is intentional behavior, to ensure that an application can tell the difference between URIs ending in /x from ones ending in /x/ when using this routine to do object traversal.

wsgiref.util.setup_testing_defaults(environ)

Update environ with trivial defaults for testing purposes.

This routine adds various parameters required for WSGI, including HTTP_HOST, SERVER_NAME, SERVER_PORT, REQUEST_METHOD,
SCRIPT_NAME, PATH_INFO, and all of the PEP 333-defined wsgi.* variables. It only supplies default values, and does not replace any existing settings for these variables.

This routine is intended to make it easier for unit tests of WSGI servers and applications to set up dummy environments. It should NOT be used by actual WSGI servers or applications, since the data is fake!

Example usage:

```python
from wsgiref.util import setup_testing_defaults
from wsgiref.simple_server import make_server

# A relatively simple WSGI application. It's going to print
# environment dictionary after being updated by setup_testing_defaults.
def simple_app(environ, start_response):
    setup_testing_defaults(environ)

    status = '200 OK'
    headers = [('Content-type', 'text/plain')]

    start_response(status, headers)

    ret = ['%s: %s
' % (key, value)
           for key, value in environ.iteritems()]
    return ret

httpd = make_server('', 8000, simple_app)
print "Serving on port 8000..."
httpd.serve_forever()
```

In addition to the environment functions above, the wsgiref.util module also provides these miscellaneous utilities:

wsgiref.util.is_hop_by_hop(header_name)

Return true if ‘header_name’ is an HTTP/1.1 “Hop-by-Hop” header, as defined by RFC 2616.
class wsgiref.util.FileWrapper(filelike[, blksize=8192])

A wrapper to convert a file-like object to an iterator. The resulting objects support both __getitem__() and __iter__() iteration styles, for compatibility with Python 2.1 and Jython. As the object is iterated over, the optional blksize parameter will be repeatedly passed to the filelike object's read() method to obtain strings to yield. When read() returns an empty string, iteration is ended and is not resumable.

If filelike has a close() method, the returned object will also have a close() method, and it will invoke the filelike object's close() method when called.

Example usage:

```python
from StringIO import StringIO
from wsgiref.util import FileWrapper

# We're using a StringIO-buffer for as the file-like object
filelike = StringIO("This is an example file-like object"*10)
wrapper = FileWrapper(filelike, blksize=5)

for chunk in wrapper:
    print chunk
```
20.4.2. wsgiref.headers – WSGI response header tools

This module provides a single class, `Headers`, for convenient manipulation of WSGI response headers using a mapping-like interface.

```python
class wsgiref.headers.Headers(headers)
```

Create a mapping-like object wrapping `headers`, which must be a list of header name/value tuples as described in PEP 333. Any changes made to the new `Headers` object will directly update the `headers` list it was created with.

`Headers` objects support typical mapping operations including `__getitem__()`, `get()`, `__setitem__()`, `setdefault()`, `__delitem__()`, `__contains__()`, and `has_key()`. For each of these methods, the key is the header name (treated case-insensitively), and the value is the first value associated with that header name. Setting a header deletes any existing values for that header, then adds a new value at the end of the wrapped header list. Headers’ existing order is generally maintained, with new headers added to the end of the wrapped list.

Unlike a dictionary, `Headers` objects do not raise an error when you try to get or delete a key that isn’t in the wrapped header list. Getting a nonexistent header just returns `None`, and deleting a nonexistent header does nothing.

`Headers` objects also support `keys()`, `values()`, and `items()` methods. The lists returned by `keys()` and `items()` can include the same key more than once if there is a multi-valued header. The `len()` of a `Headers` object is the same as the length of its
items(), which is the same as the length of the wrapped header list. In fact, the items() method just returns a copy of the wrapped header list.

Calling str() on a Headers object returns a formatted string suitable for transmission as HTTP response headers. Each header is placed on a line with its value, separated by a colon and a space. Each line is terminated by a carriage return and line feed, and the string is terminated with a blank line.

In addition to their mapping interface and formatting features, Headers objects also have the following methods for querying and adding multi-valued headers, and for adding headers with MIME parameters:

get_all(name)

Return a list of all the values for the named header.

The returned list will be sorted in the order they appeared in the original header list or were added to this instance, and may contain duplicates. Any fields deleted and re-inserted are always appended to the header list. If no fields exist with the given name, returns an empty list.

add_header(name, value, **_params)

Add a (possibly multi-valued) header, with optional MIME parameters specified via keyword arguments.

name is the header field to add. Keyword arguments can be used to set MIME parameters for the header field. Each parameter must be a string or None. Underscores in parameter names are converted to dashes, since dashes are illegal in Python identifiers, but many MIME parameter names include dashes. If the parameter value is a string, it is added to the header value parameters in the form name="value". If it
is **None**, only the parameter name is added. (This is used for MIME parameters without a value.) Example usage:

```python
h.add_header('content-disposition', 'attachment', filename=None)
```

The above will add a header that looks like this:

```
Content-Disposition: attachment; filename="bud.gif"
```
20.4.3. wsgiref.simple_server – a simple WSGI HTTP server

This module implements a simple HTTP server (based on BaseHTTPServer) that serves WSGI applications. Each server instance serves a single WSGI application on a given host and port. If you want to serve multiple applications on a single host and port, you should create a WSGI application that parses PATH_INFO to select which application to invoke for each request. (E.g., using the shift_path_info() function from wsgiref.util.)

wsgiref.simple_server.make_server(host, port, app[, server_class=WSGIServer[, handler_class=WSGIRequestHandler]])

Create a new WSGI server listening on host and port, accepting connections for app. The return value is an instance of the supplied server_class, and will process requests using the specified handler_class. app must be a WSGI application object, as defined by PEP 333.

Example usage:

```python
from wsgiref.simple_server import make_server, demo_app

httpd = make_server('', 8000, demo_app)
print "Serving HTTP on port 8000..."

# Respond to requests until process is killed
httpd.serve_forever()

# Alternative: serve one request, then exit
httpd.handle_request()

wsgiref.simple_server.demo_app(environ, start_response)
```
This function is a small but complete WSGI application that returns a text page containing the message “Hello world!” and a list of the key/value pairs provided in the `environ` parameter. It's useful for verifying that a WSGI server (such as `wsgiref.simple_server`) is able to run a simple WSGI application correctly.

```python
class wsgiref.simple_server.WSGIServer(server_address, RequestHandlerClass)
```

Create a `WSGIServer` instance. `server_address` should be a `(host, port)` tuple, and `RequestHandlerClass` should be the subclass of `BaseHTTPServer.BaseHTTPRequestHandler` that will be used to process requests.

You do not normally need to call this constructor, as the `make_server()` function can handle all the details for you.

`WSGIServer` is a subclass of `BaseHTTPServer.HTTPServer`, so all of its methods (such as `serve_forever()` and `handle_request()`) are available. `WSGIServer` also provides these WSGI-specific methods:

```python
set_app(application)
```

Sets the callable `application` as the WSGI application that will receive requests.

```python
get_app()
```

Returns the currently-set application callable.

Normally, however, you do not need to use these additional methods, as `set_app()` is normally called by `make_server()`, and the `get_app()` exists mainly for the benefit of request handler instances.
class wsgiref.simple_server.WSGIRequestHandler(request, client_address, server)

Create an HTTP handler for the given request (i.e. a socket), client_address (a (host, port) tuple), and server (WSGIServer instance).

You do not need to create instances of this class directly; they are automatically created as needed by WSGIServer objects. You can, however, subclass this class and supply it as a handler_class to the make_server() function. Some possibly relevant methods for overriding in subclasses:

get_environ()

Returns a dictionary containing the WSGI environment for a request. The default implementation copies the contents of the WSGIServer object’s base_environ dictionary attribute and then adds various headers derived from the HTTP request. Each call to this method should return a new dictionary containing all of the relevant CGI environment variables as specified in PEP 333.

get_stderr()

Return the object that should be used as the wsgi.errors stream. The default implementation just returns sys.stderr.

handle()

Process the HTTP request. The default implementation creates a handler instance using a wsgiref.handlers class to implement the actual WSGI application interface.
When creating new WSGI application objects, frameworks, servers, or middleware, it can be useful to validate the new code's conformance using `wsgiref.validate`. This module provides a function that creates WSGI application objects that validate communications between a WSGI server or gateway and a WSGI application object, to check both sides for protocol conformance.

Note that this utility does not guarantee complete PEP 333 compliance; an absence of errors from this module does not necessarily mean that errors do not exist. However, if this module does produce an error, then it is virtually certain that either the server or application is not 100% compliant.

This module is based on the `paste.lint` module from Ian Bicking's “Python Paste” library.

```
    wsgiref.validate.validator(application)
```

Wrap `application` and return a new WSGI application object. The returned application will forward all requests to the original `application`, and will check that both the `application` and the server invoking it are conforming to the WSGI specification and to RFC 2616.

Any detected nonconformance results in an `AssertionError` being raised; note, however, that how these errors are handled is server-dependent. For example, `wsgiref.simple_server` and other servers based on `wsgiref.handlers` (that don’t override the error handling methods to do something else) will simply output a message that an error has occurred, and dump the traceback to
sys.stderr or some other error stream.

This wrapper may also generate output using the warnings module to indicate behaviors that are questionable but which may not actually be prohibited by PEP 333. Unless they are suppressed using Python command-line options or the warnings API, any such warnings will be written to sys.stderr (not wsgi.errors, unless they happen to be the same object).

Example usage:

```python
from wsgiref.validate import validator
from wsgiref.simple_server import make_server

# Our callable object which is intentionally not compliant to the standard, so the validator is going to break
def simple_app(environ, start_response):
    status = '200 OK'  # HTTP Status
    headers = [('Content-type', 'text/plain')]  # HTTP Header
    start_response(status, headers)

    # This is going to break because we need to return a list, and the validator is going to inform us
    return ['Hello World']

# This is the application wrapped in a validator
validator_app = validator(simple_app)

httpd = make_server('', 8000, validator_app)

print "Listening on port 8000...."
httpd.serve_forever()
```
This module provides base handler classes for implementing WSGI servers and gateways. These base classes handle most of the work of communicating with a WSGI application, as long as they are given a CGI-like environment, along with input, output, and error streams.

```python
class wsgiref.handlers.CGIHandler

CGI-based invocation via `sys.stdin`, `sys.stdout`, `sys.stderr` and `os.environ`. This is useful when you have a WSGI application and want to run it as a CGI script. Simply invoke `CGIHandler().run(app)`, where `app` is the WSGI application object you wish to invoke.
```

This class is a subclass of `BaseCGIHandler` that sets `wsgi.run_once` to true, `wsgi.multithread` to false, and `wsgi.multiprocess` to true, and always uses `sys` and `os` to obtain the necessary CGI streams and environment.

```python
class wsgiref.handlers.BaseCGIHandler(stdin, stdout, stderr, environ[, multithread=True[, multiprocess=False]]])
```

Similar to `CGIHandler`, but instead of using the `sys` and `os` modules, the CGI environment and I/O streams are specified explicitly. The `multithread` and `multiprocess` values are used to set the `wsgi.multithread` and `wsgi.multiprocess` flags for any applications run by the handler instance.

This class is a subclass of `SimpleHandler` intended for use with software other than HTTP “origin servers”. If you are writing a gateway protocol implementation (such as CGI, FastCGI, SCGI, etc.) that uses a `status:` header to send an HTTP status, you
probably want to subclass this instead of SimpleHandler.

```python
class wsgiref.handlers.SimpleHandler(stdin, stdout, stderr, environ[, multithread=True[, multiprocessing=False]])
```

Similar to BaseCGIHandler, but designed for use with HTTP origin servers. If you are writing an HTTP server implementation, you will probably want to subclass this instead of BaseCGIHandler

This class is a subclass of BaseHandler. It overrides the __init__(), get_stdin(), get_stderr(), add_cgi_vars(), _write(), and _flush() methods to support explicitly setting the environment and streams via the constructor. The supplied environment and streams are stored in the stdin, stdout, stderr, and environ attributes.

```python
class wsgiref.handlers.BaseHandler
```

This is an abstract base class for running WSGI applications. Each instance will handle a single HTTP request, although in principle you could create a subclass that was reusable for multiple requests.

BaseHandler instances have only one method intended for external use:

```python
run(app)
```

Run the specified WSGI application, `app`.

All of the other BaseHandler methods are invoked by this method in the process of running the application, and thus exist primarily to allow customizing the process.

The following methods MUST be overridden in a subclass:

```python
_write(data)
```
Buffer the string \textit{data} for transmission to the client. It's okay if this method actually transmits the data; \texttt{BaseHandler} just separates write and flush operations for greater efficiency when the underlying system actually has such a distinction.

\texttt{\_flush()}

Force buffered data to be transmitted to the client. It's okay if this method is a no-op (i.e., if \texttt{\_write()} actually sends the data).

\texttt{get\_stdin()}

Return an input stream object suitable for use as the \texttt{wsgi\_input} of the request currently being processed.

\texttt{get\_stderr()}

Return an output stream object suitable for use as the \texttt{wsgi\_errors} of the request currently being processed.

\texttt{add\_cgi\_vars()}

Insert CGI variables for the current request into the \texttt{environ} attribute.

Here are some other methods and attributes you may wish to override. This list is only a summary, however, and does not include every method that can be overridden. You should consult the docstrings and source code for additional information before attempting to create a customized \texttt{BaseHandler} subclass.

Attributes and methods for customizing the WSGI environment:

\texttt{wsgi\_multithread}

The value to be used for the \texttt{wsgi\_multithread} environment variable. It defaults to true in \texttt{BaseHandler}, but may have a different default (or be set by the constructor) in the other subclasses.
wsgi_multiprocess
The value to be used for the `wsgi.multiprocess` environment variable. It defaults to true in `BaseHandler`, but may have a different default (or be set by the constructor) in the other subclasses.

wsgi_run_once
The value to be used for the `wsgi.run_once` environment variable. It defaults to false in `BaseHandler`, but `CGIHandler` sets it to true by default.

os_environ
The default environment variables to be included in every request’s WSGI environment. By default, this is a copy of `os.environ` at the time that `wsgiref.handlers` was imported, but subclasses can either create their own at the class or instance level. Note that the dictionary should be considered read-only, since the default value is shared between multiple classes and instances.

server_software
If the `origin_server` attribute is set, this attribute's value is used to set the default `SERVER_SOFTWARE` WSGI environment variable, and also to set a default `Server:` header in HTTP responses. It is ignored for handlers (such as `BaseCGIHandler` and `CGIHandler`) that are not HTTP origin servers.

get_scheme()
Return the URL scheme being used for the current request. The default implementation uses the `guess_scheme()` function from `wsgiref.util` to guess whether the scheme should be “http” or “https”, based on the current request’s `environ` variables.

setup_environ()
Set the `environ` attribute to a fully-populated WSGI environment. The default implementation uses all of the above methods and attributes, plus the `get_stdin()`, `get_stderr()`, and `add_cgi_vars()` methods and the `wsgi_file_wrapper` attribute. It also inserts a `SERVER_SOFTWARE` key if not present, as long as the `origin_server` attribute is a true value and the `server_software` attribute is set.

Methods and attributes for customizing exception handling:

`log_exception(exc_info)`
Log the `exc_info` tuple in the server log. `exc_info` is a `(type, value, traceback)` tuple. The default implementation simply writes the traceback to the request's `wsgi.errors` stream and flushes it. Subclasses can override this method to change the format or retarget the output, mail the traceback to an administrator, or whatever other action may be deemed suitable.

`traceback_limit`
The maximum number of frames to include in tracebacks output by the default `log_exception()` method. If `None`, all frames are included.

`error_output(environ, start_response)`
This method is a WSGI application to generate an error page for the user. It is only invoked if an error occurs before headers are sent to the client.

This method can access the current error information using `sys.exc_info()`, and should pass that information to `start_response` when calling it (as described in the “Error Handling” section of PEP 333).
The default implementation just uses the `error_status`, `error_headers`, and `error_body` attributes to generate an output page. Subclasses can override this to produce more dynamic error output.

Note, however, that it’s not recommended from a security perspective to spit out diagnostics to any old user; ideally, you should have to do something special to enable diagnostic output, which is why the default implementation doesn’t include any.

**error_status**
The HTTP status used for error responses. This should be a status string as defined in [PEP 333](https://www.python.org/dev/peps/pep-0333/); it defaults to a 500 code and message.

**error_headers**
The HTTP headers used for error responses. This should be a list of WSGI response headers `((name, value))` tuples), as described in [PEP 333](https://www.python.org/dev/peps/pep-0333/). The default list just sets the content type to `text/plain`.

**error_body**
The error response body. This should be an HTTP response body string. It defaults to the plain text, “A server error occurred. Please contact the administrator.”

Methods and attributes for [PEP 333](https://www.python.org/dev/peps/pep-0333/)’s “Optional Platform-Specific File Handling” feature:

**wsgi_file_wrapper**
A `wsgi.file_wrapper` factory, or `None`. The default value of this attribute is the `FileWrapper` class from `wsgiref.util`.

**sendfile()**
Override to implement platform-specific file transmission. This
method is called only if the application's return value is an instance of the class specified by the `wsgi_file_wrapper` attribute. It should return a true value if it was able to successfully transmit the file, so that the default transmission code will not be executed. The default implementation of this method just returns a false value.

Miscellaneous methods and attributes:

**origin_server**

This attribute should be set to a true value if the handler's `_write()` and `_flush()` are being used to communicate directly to the client, rather than via a CGI-like gateway protocol that wants the HTTP status in a special Status: header.

This attribute's default value is true in `BaseHandler`, but false in `BaseCGIHandler` and `CGIHandler`.

**http_version**

If `origin_server` is true, this string attribute is used to set the HTTP version of the response set to the client. It defaults to "1.0".
This is a working “Hello World” WSGI application:

```python
from wsgiref.simple_server import make_server

# Every WSGI application must have an application object - a callable object that accepts two arguments. For that purpose, we're going to use a function (note that you're not limited to a function, you can use a class for example). The first argument passed to the function is a dictionary containing CGI-style environment variables and the second variable is the callable object (see PEP 333).

def hello_world_app(environ, start_response):
    status = '200 OK'  # HTTP Status
    headers = [('Content-type', 'text/plain')]  # HTTP Headers
    start_response(status, headers)

    # The returned object is going to be printed
    return ['Hello World']

httpd = make_server('', 8000, hello_world_app)
print "Serving on port 8000..."

# Serve until process is killed
httpd.serve_forever()
```
20.5. urllib — Open arbitrary resources by URL

**Note:** The urllib module has been split into parts and renamed in Python 3.0 to `urllib.request`, `urllib.parse`, and `urllib.error`. The `2to3` tool will automatically adapt imports when converting your sources to 3.0. Also note that the `urllib.urlopen()` function has been removed in Python 3.0 in favor of `urllib2.urlopen()`.

This module provides a high-level interface for fetching data across the World Wide Web. In particular, the `urlopen()` function is similar to the built-in function `open()`, but accepts Universal Resource Locators (URLs) instead of filenames. Some restrictions apply — it can only open URLs for reading, and no seek operations are available.

**Warning:** When opening HTTPS URLs, it is not attempted to validate the server certificate. Use at your own risk!
20.5.1. High-level interface

```
urllib.urlopen(url[, data[, proxies]])
```

Open a network object denoted by a URL for reading. If the URL does not have a scheme identifier, or if it has `file:` as its scheme identifier, this opens a local file (without universal newlines); otherwise it opens a socket to a server somewhere on the network. If the connection cannot be made the `IOError` exception is raised. If all went well, a file-like object is returned. This supports the following methods: `read()`, `readline()`, `readlines()`, `fileno()`, `close()`, `info()`, `getcode()` and `geturl()`. It also has proper support for the `iterator` protocol. One caveat: the `read()` method, if the size argument is omitted or negative, may not read until the end of the data stream; there is no good way to determine that the entire stream from a socket has been read in the general case.

Except for the `info()`, `getcode()` and `geturl()` methods, these methods have the same interface as for file objects — see section `File Objects` in this manual. (It is not a built-in file object, however, so it can’t be used at those few places where a true built-in file object is required.)

The `info()` method returns an instance of the class `mimetools.Message` containing meta-information associated with the URL. When the method is HTTP, these headers are those returned by the server at the head of the retrieved HTML page (including Content-Length and Content-Type). When the method is FTP, a Content-Length header will be present if (as is now usual) the server passed back a file length in response to the FTP retrieval request. A Content-Type header will be present if the MIME type can be guessed. When the method is local-file,
returned headers will include a Date representing the file’s last-modified time, a Content-Length giving file size, and a Content-Type containing a guess at the file’s type. See also the description of the `mimetypes` module.

The `geturl()` method returns the real URL of the page. In some cases, the HTTP server redirects a client to another URL. The `urlopen()` function handles this transparently, but in some cases the caller needs to know which URL the client was redirected to. The `geturl()` method can be used to get at this redirected URL.

The `getcode()` method returns the HTTP status code that was sent with the response, or `None` if the URL is no HTTP URL.

If the `url` uses the `http:` scheme identifier, the optional `data` argument may be given to specify a `POST` request (normally the request type is `GET`). The `data` argument must be in standard `application/x-www-form-urlencoded` format; see the `urlencode()` function below.

The `urlopen()` function works transparently with proxies which do not require authentication. In a Unix or Windows environment, set the `http_proxy`, or `ftp_proxy` environment variables to a URL that identifies the proxy server before starting the Python interpreter. For example (the '%' is the command prompt):

```
% http_proxy="http://www.someproxy.com:3128"
% export http_proxy
% python
... 
```

The `no_proxy` environment variable can be used to specify hosts which shouldn't be reached via proxy; if set, it should be a comma-separated list of hostname suffixes, optionally with port appended, for example `cern.ch,ncsa.uiuc.edu,some.host:8080`. 
In a Windows environment, if no proxy environment variables are set, proxy settings are obtained from the registry’s Internet Settings section.

In a Mac OS X environment, `urlopen()` will retrieve proxy information from the OS X System Configuration Framework, which can be managed with Network System Preferences panel.

Alternatively, the optional `proxies` argument may be used to explicitly specify proxies. It must be a dictionary mapping scheme names to proxy URLs, where an empty dictionary causes no proxies to be used, and `None` (the default value) causes environmental proxy settings to be used as discussed above. For example:

```python
# Use http://www.someproxy.com:3128 for http proxying
proxies = {'http': 'http://www.someproxy.com:3128'}
filehandle = urllib.urlopen(some_url, proxies=proxies)

# Don't use any proxies
filehandle = urllib.urlopen(some_url, proxies={})

# Use proxies from environment - both versions are equivalent
filehandle = urllib.urlopen(some_url, proxies=None)
filehandle = urllib.urlopen(some_url)
```

Proxies which require authentication for use are not currently supported; this is considered an implementation limitation.

*Changed in version 2.3:* Added the `proxies` support.

*Changed in version 2.6:* Added `getcode()` to returned object and support for the `no_proxy` environment variable.

*Deprecated since version 2.6:* The `urlopen()` function has been removed in Python 3.0 in favor of `urllib2.urlopen()`.
Copy a network object denoted by a URL to a local file, if necessary. If the URL points to a local file, or a valid cached copy of the object exists, the object is not copied. Return a tuple (filename, headers) where filename is the local file name under which the object can be found, and headers is whatever the info() method of the object returned by urlopen() returned (for a remote object, possibly cached). Exceptions are the same as for urlopen().

The second argument, if present, specifies the file location to copy to (if absent, the location will be a tempfile with a generated name). The third argument, if present, is a hook function that will be called once on establishment of the network connection and once after each block read thereafter. The hook will be passed three arguments; a count of blocks transferred so far, a block size in bytes, and the total size of the file. The third argument may be -1 on older FTP servers which do not return a file size in response to a retrieval request.

If the url uses the http: scheme identifier, the optional data argument may be given to specify a POST request (normally the request type is GET). The data argument must in standard application/x-www-form-urlencoded format; see the urlencode() function below.

Changed in version 2.5: urlretrieve() will raise ContentTooShortError when it detects that the amount of data available was less than the expected amount (which is the size reported by a Content-Length header). This can occur, for example, when the download is interrupted.

The Content-Length is treated as a lower bound: if there's more data to read, urlretrieve() reads more data, but if less data is available, it raises the exception.
You can still retrieve the downloaded data in this case, it is stored in the `content` attribute of the exception instance.

If no `Content-Length` header was supplied, `urlretrieve()` can not check the size of the data it has downloaded, and just returns it. In this case you just have to assume that the download was successful.

**urllib._urlopener**

The public functions `urlopen()` and `urlretrieve()` create an instance of the `FancyURLopener` class and use it to perform their requested actions. To override this functionality, programmers can create a subclass of `URLopener` or `FancyURLopener`, then assign an instance of that class to the `urllib._urlopener` variable before calling the desired function. For example, applications may want to specify a different `User-Agent` header than `URLopener` defines. This can be accomplished with the following code:

```python
import urllib

class AppURLopener(urllib.FancyURLopener):
    version = "App/1.7"

urllib._urlopener = AppURLopener()

urllib.urlcleanup()

Clear the cache that may have been built up by previous calls to `urlretrieve()`.
20.5.2. Utility functions

urllib.quote(string[, safe])

Replace special characters in string using the %xx escape. Letters, digits, and the characters '_.-' are never quoted. By default, this function is intended for quoting the path section of the URL. The optional safe parameter specifies additional characters that should not be quoted — its default value is '/'.

Example: quote('/~connolly/') yields '/%7econnolly/'.

urllib.quote_plus(string[, safe])

Like quote(), but also replaces spaces by plus signs, as required for quoting HTML form values when building up a query string to go into a URL. Plus signs in the original string are escaped unless they are included in safe. It also does not have safe default to '/'.

urllib.unquote(string)

Replace %xx escapes by their single-character equivalent.

Example: unquote('/%7Econnolly/') yields '/~connolly/'.

urllib.unquote_plus(string)

Like unquote(), but also replaces plus signs by spaces, as required for unquoting HTML form values.

urllib.urlencode(query[, doseq])

Convert a mapping object or a sequence of two-element tuples to a “percent-encoded” string, suitable to pass to urlopen() above as the optional data argument. This is useful to pass a dictionary
of form fields to a `POST` request. The resulting string is a series of `key=value` pairs separated by `&` characters, where both `key` and `value` are quoted using `quote_plus()` above. When a sequence of two-element tuples is used as the `query` argument, the first element of each tuple is a key and the second is a value. The value element in itself can be a sequence and in that case, if the optional parameter `doseq` is evaluates to `True`, individual `key=value` pairs separated by `&` are generated for each element of the value sequence for the key. The order of parameters in the encoded string will match the order of parameter tuples in the sequence. The `urlparse` module provides the functions `parse_qs()` and `parse_qsl()` which are used to parse query strings into Python data structures.

`urllib.pathname2url(path)`

Convert the pathname `path` from the local syntax for a path to the form used in the path component of a URL. This does not produce a complete URL. The return value will already be quoted using the `quote()` function.

`urllib.url2pathname(path)`

Convert the path component `path` from an percent-encoded URL to the local syntax for a path. This does not accept a complete URL. This function uses `unquote()` to decode `path`.

`urllib.getproxies()`

This helper function returns a dictionary of scheme to proxy server URL mappings. It scans the environment for variables named `<scheme>_proxy` for all operating systems first, and when it cannot find it, looks for proxy information from Mac OSX System Configuration for Mac OS X and Windows Systems Registry for Windows.
20.5.3. URL Opener objects

class urllib.URLopener([proxies, **x509])

Base class for opening and reading URLs. Unless you need to support opening objects using schemes other than http:, ftp:, or file:, you probably want to use FancyURLopener.

By default, the URLopener class sends a User-Agent header of urllib/VVV, where VVV is the urllib version number. Applications can define their own User-Agent header by subclassing URLopener or FancyURLopener and setting the class attribute version to an appropriate string value in the subclass definition.

The optional proxies parameter should be a dictionary mapping scheme names to proxy URLs, where an empty dictionary turns proxies off completely. Its default value is None, in which case environmental proxy settings will be used if present, as discussed in the definition of urlopen(), above.

Additional keyword parameters, collected in x509, may be used for authentication of the client when using the https: scheme. The keywords key_file and cert_file are supported to provide an SSL key and certificate; both are needed to support client authentication.

URLopener objects will raise an IOError exception if the server returns an error code.

open(fullurl[, data])

Open fullurl using the appropriate protocol. This method sets up cache and proxy information, then calls the
appropriate open method with its input arguments. If the scheme is not recognized, `open_unknown()` is called. The `data` argument has the same meaning as the `data` argument of `urlopen()`.

```python
open_unknown(fullurl[, data])
```
Overridable interface to open unknown URL types.

```python
retrieve(url[, filename[, reporthook[, data]]])
```
Retrieves the contents of `url` and places it in `filename`. The return value is a tuple consisting of a local filename and either a `mimetypes.Message` object containing the response headers (for remote URLs) or `None` (for local URLs). The caller must then open and read the contents of `filename`. If `filename` is not given and the URL refers to a local file, the input filename is returned. If the URL is non-local and `filename` is not given, the filename is the output of `tempfile.mktemp()` with a suffix that matches the suffix of the last path component of the input URL. If `reporthook` is given, it must be a function accepting three numeric parameters. It will be called after each chunk of data is read from the network. `reporthook` is ignored for local URLs.

If the `url` uses the `http:` scheme identifier, the optional `data` argument may be given to specify a POST request (normally the request type is GET). The `data` argument must in standard `application/x-www-form-urlencoded` format; see the `urlencode()` function below.

```python
version
```
Variable that specifies the user agent of the opener object. To get `urllib` to tell servers that it is a particular user agent, set this in a subclass as a class variable or in
the constructor before calling the base constructor.

```python
class urllib.FancyURLopener(...)
```

FancyURLopener subclasses URLopener providing default handling for the following HTTP response codes: 301, 302, 303, 307 and 401. For the 30x response codes listed above, the Location header is used to fetch the actual URL. For 401 response codes (authentication required), basic HTTP authentication is performed. For the 30x response codes, recursion is bounded by the value of the maxtries attribute, which defaults to 10.

For all other response codes, the method `http_error_default()` is called which you can override in subclasses to handle the error appropriately.

**Note:** According to the letter of [RFC 2616](https://tools.ietf.org/html/rfc2616), 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and urllib reproduces this behaviour.

The parameters to the constructor are the same as those for URLopener.

**Note:**

When performing basic authentication, a FancyURLopener instance calls its `prompt_user_passwd()` method. The default implementation asks the users for the required information on the controlling terminal. A subclass may override this method to support more appropriate behavior if needed.

The FancyURLopener class offers one additional method that
should be overloaded to provide the appropriate behavior:

```python
prompt_user_passwd(host, realm)
```

Return information needed to authenticate the user at the given host in the specified security realm. The return value should be a tuple, `(user, password)`, which can be used for basic authentication.

The implementation prompts for this information on the terminal; an application should override this method to use an appropriate interaction model in the local environment.

```
exception urllib.ContentTooShortError(msg[, content])
```

This exception is raised when the `urlretrieve()` function detects that the amount of the downloaded data is less than the expected amount (given by the `Content-Length` header). The `content` attribute stores the downloaded (and supposedly truncated) data.

New in version 2.5.
20.5.4. urllib Restrictions

- Currently, only the following protocols are supported: HTTP, (versions 0.9 and 1.0), FTP, and local files.

- The caching feature of `urlretrieve()` has been disabled until I find the time to hack proper processing of Expiration time headers.

- There should be a function to query whether a particular URL is in the cache.

- For backward compatibility, if a URL appears to point to a local file but the file can’t be opened, the URL is re-interpreted using the FTP protocol. This can sometimes cause confusing error messages.

- The `urlopen()` and `urlretrieve()` functions can cause arbitrarily long delays while waiting for a network connection to be set up. This means that it is difficult to build an interactive Web client using these functions without using threads.

- The data returned by `urlopen()` or `urlretrieve()` is the raw data returned by the server. This may be binary data (such as an image), plain text or (for example) HTML. The HTTP protocol provides type information in the reply header, which can be inspected by looking at the `Content-Type` header. If the returned data is HTML, you can use the module `httplib` to parse it.

- The code handling the FTP protocol cannot differentiate between a file and a directory. This can lead to unexpected behavior when attempting to read a URL that points to a file that is not accessible. If the URL ends in a `/`, it is assumed to refer to a directory and will be handled accordingly. But if an attempt to
read a file leads to a 550 error (meaning the URL cannot be found or is not accessible, often for permission reasons), then the path is treated as a directory in order to handle the case when a directory is specified by a URL but the trailing / has been left off. This can cause misleading results when you try to fetch a file whose read permissions make it inaccessible; the FTP code will try to read it, fail with a 550 error, and then perform a directory listing for the unreadable file. If fine-grained control is needed, consider using the ftplib module, subclassing FancyURLopener, or changing _urlopener to meet your needs.

- This module does not support the use of proxies which require authentication. This may be implemented in the future.

- Although the urllib module contains (undocumented) routines to parse and unparse URL strings, the recommended interface for URL manipulation is in module urlparse.
20.5.5. Examples

Here is an example session that uses the GET method to retrieve a URL containing parameters:

```python
>>> import urllib
>>> params = urllib.urlencode({'spam': 1, 'eggs': 2, 'bacon': 0}
>>> f = urllib.urlopen("http://www.musical.com/cgi-bin/query?%s")
>>> print f.read()
```

The following example uses the POST method instead:

```python
>>> import urllib
>>> params = urllib.urlencode({'spam': 1, 'eggs': 2, 'bacon': 0}
>>> f = urllib.urlopen("http://www.musical.com/cgi-bin/query",
>>> print f.read()
```

The following example uses an explicitly specified HTTP proxy, overriding environment settings:

```python
>>> import urllib
>>> proxies = {'http': 'http://proxy.example.com:8080/'}
>>> opener = urllib.FancyURLopener(proxies)
>>> f = opener.open("http://www.python.org")
>>> f.read()
```

The following example uses no proxies at all, overriding environment settings:

```python
>>> import urllib
>>> opener = urllib.FancyURLopener({})
>>> f = opener.open("http://www.python.org")
>>> f.read()
```
20.6. urllib2 — extensible library for opening URLs

**Note:** The urllib2 module has been split across several modules in Python 3.0 named urllib.request and urllib.error. The 2to3 tool will automatically adapt imports when converting your sources to 3.0.

The urllib2 module defines functions and classes which help in opening URLs (mostly HTTP) in a complex world — basic and digest authentication, redirections, cookies and more.

The urllib2 module defines the following functions:

```python
urllib2.urlopen(url[, data][, timeout])
```

Open the URL `url`, which can be either a string or a `Request` object.

**Warning:** HTTPS requests do not do any verification of the server’s certificate.

`data` may be a string specifying additional data to send to the server, or `None` if no such data is needed. Currently HTTP requests are the only ones that use `data`; the HTTP request will be a POST instead of a GET when the `data` parameter is provided. `data` should be a buffer in the standard `application/x-www-form-urlencoded` format. The `urllib.urlencode()` function takes a mapping or sequence of 2-tuples and returns a string in this format. urllib2 module sends HTTP/1.1 requests with `Connection:close` header included.

The optional `timeout` parameter specifies a timeout in seconds for
blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). This actually only works for HTTP, HTTPS and FTP connections.

This function returns a file-like object with two additional methods:

- **geturl()** — return the URL of the resource retrieved, commonly used to determine if a redirect was followed
- **info()** — return the meta-information of the page, such as headers, in the form of an *mimetools.Message* instance (see Quick Reference to HTTP Headers)

Raises *URLError* on errors.

Note that *None* may be returned if no handler handles the request (though the default installed global *OpenerDirector* uses *UnknownHandler* to ensure this never happens).

In addition, default installed *ProxyHandler* makes sure the requests are handled through the proxy when they are set.

*Changed in version 2.6: timeout was added.*

**urllib2.install_opener**(opener)

Install an *OpenerDirector* instance as the default global opener. Installing an opener is only necessary if you want urlopen to use that opener; otherwise, simply call *OpenerDirector.open()* instead of *urlopen()* . The code does not check for a real *OpenerDirector*, and any class with the appropriate interface will work.

**urllib2.build_opener**([handler, ...])

Return an *OpenerDirector* instance, which chains the handlers in the order given. *handlers* can be either instances of *BaseHandler*,
or subclasses of `BaseHandler` (in which case it must be possible to call the constructor without any parameters). Instances of the following classes will be in front of the `handlers`, unless the `handlers` contain them, instances of them or subclasses of them: `ProxyHandler`, `UnknownHandler`, `HTTPHandler`, `HTTPDefaultErrorHandler`, `HTTPRedirectHandler`, `FTPHandler`, `FileHandler`, `HTTPErrorProcessor`.

If the Python installation has SSL support (i.e., if the `ssl` module can be imported), `HTTPSHandler` will also be added.

Beginning in Python 2.3, a `BaseHandler` subclass may also change its `handler_order` member variable to modify its position in the handlers list.

The following exceptions are raised as appropriate:

```python
exception urllib2.URLError
    The handlers raise this exception (or derived exceptions) when they run into a problem. It is a subclass of `IOError`.

    reason
        The reason for this error. It can be a message string or another exception instance (`socket.error` for remote URLs, `OSError` for local URLs).
```

```python
exception urllib2.HTTPError
    Though being an exception (a subclass of `URLError`), an `HTTPError` can also function as a non-exceptional file-like return value (the same thing that `urlopen()` returns). This is useful when handling exotic HTTP errors, such as requests for authentication.

    code
        An HTTP status code as defined in RFC 2616. This numeric
value corresponds to a value found in the dictionary of codes as found in
`BaseHTTPServer.BaseHTTPRequestHandler.responses`.

The following classes are provided:

class `urllib2.Request([url[, data][, headers][, origin_req_host][, unverifiable]])`

This class is an abstraction of a URL request.

* url should be a string containing a valid URL.

* data may be a string specifying additional data to send to the server, or `None` if no such data is needed. Currently HTTP requests are the only ones that use `data`; the HTTP request will be a POST instead of a GET when the `data` parameter is provided. `data` should be a buffer in the standard `application/x-www-form-urlencoded` format. The `urllib.urlencode()` function takes a mapping or sequence of 2-tuples and returns a string in this format.

* headers should be a dictionary, and will be treated as if `add_header()` was called with each key and value as arguments. This is often used to “spoof” the `User-Agent` header, which is used by a browser to identify itself – some HTTP servers only allow requests coming from common browsers as opposed to scripts. For example, Mozilla Firefox may identify itself as

```quote
"Mozilla/5.0 (X11; U; Linux i686) Gecko/20071127 Firefox/2.0.0.11"
```

while `urllib2`'s default user agent string is

```quote
"Python-urllib/2.6"
```

(On Python 2.6).

The final two arguments are only of interest for correct handling of third-party HTTP cookies:
`origin_req_host` should be the request-host of the origin transaction, as defined by RFC 2965. It defaults to `cookielib.request_host(self)`. This is the host name or IP address of the original request that was initiated by the user. For example, if the request is for an image in an HTML document, this should be the request-host of the request for the page containing the image.

`unverifiable` should indicate whether the request is unverifiable, as defined by RFC 2965. It defaults to False. An unverifiable request is one whose URL the user did not have the option to approve. For example, if the request is for an image in an HTML document, and the user had no option to approve the automatic fetching of the image, this should be true.

```python
class urllib2.OpenerDirector
    The OpenerDirector class opens URLs via BaseHandlers chained together. It manages the chaining of handlers, and recovery from errors.

class urllib2.BaseHandler
    This is the base class for all registered handlers — and handles only the simple mechanics of registration.

class urllib2.HTTPDefaultErrorHandler
    A class which defines a default handler for HTTP error responses; all responses are turned into HTTPError exceptions.

class urllib2.HTTPRedirectHandler
    A class to handle redirections.

class urllib2.HTTPCookieProcessor([cookiejar])
    A class to handle HTTP Cookies.

class urllib2.ProxyHandler([proxies])
```
Cause requests to go through a proxy. If `proxies` is given, it must be a dictionary mapping protocol names to URLs of proxies. The default is to read the list of proxies from the environment variables. If no proxy environment variables are set, in a Windows environment, proxy settings are obtained from the registry’s Internet Settings section and in a Mac OS X environment, proxy information is retrieved from the OS X System Configuration Framework.

To disable autodetected proxy pass an empty dictionary.

```python
class urllib2.HTTPPasswordMgr
    Keep a database of (realm, uri) -> (user, password) mappings.

class urllib2.HTTPPasswordMgrWithDefaultRealm
    Keep a database of (realm, uri) -> (user, password) mappings. A realm of `None` is considered a catch-all realm, which is searched if no other realm fits.

class urllib2.AbstractBasicAuthHandler([password_mgr])
    This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. `password_mgr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported.

class urllib2.HTTPBasicAuthHandler([password_mgr])
    Handle authentication with the remote host. `password_mgr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported.

class urllib2.ProxyBasicAuthHandler([password_mgr])
```
Handle authentication with the proxy. `password_mgr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported.

class `urllib2.AbstractDigestAuthHandler([password_mgr])`
This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. `password_mgr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported.

class `urllib2.HTTPDigestAuthHandler([password_mgr])`
Handle authentication with the remote host. `password_mgr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported.

class `urllib2.ProxyDigestAuthHandler([password_mgr])`
Handle authentication with the proxy. `password_mgr`, if given, should be something that is compatible with `HTTPPasswordMgr`; refer to section `HTTPPasswordMgr Objects` for information on the interface that must be supported.

class `urllib2.HTTPHandler`
A class to handle opening of HTTP URLs.

class `urllib2.HTTPSHandler`
A class to handle opening of HTTPS URLs.

class `urllib2.FileHandler`
Open local files.

class `urllib2.FTPHandler`
Open FTP URLs.

*class urllib2.CacheFTPHandler*

Open FTP URLs, keeping a cache of open FTP connections to minimize delays.

*class urllib2.UnknownHandler*

A catch-all class to handle unknown URLs.
20.6.1. Request Objects

The following methods describe all of Request's public interface, and so all must be overridden in subclasses.

Request. **add_data**(data)
Set the Request data to data. This is ignored by all handlers except HTTP handlers — and there it should be a byte string, and will change the request to be POST rather than GET.

Request. **get_method**()
Return a string indicating the HTTP request method. This is only meaningful for HTTP requests, and currently always returns 'GET' or 'POST'.

Request. **has_data**()
Return whether the instance has a non-None data.

Request. **get_data**()
Return the instance's data.

Request. **add_header**(key, val)
Add another header to the request. Headers are currently ignored by all handlers except HTTP handlers, where they are added to the list of headers sent to the server. Note that there cannot be more than one header with the same name, and later calls will overwrite previous calls in case the key collides. Currently, this is no loss of HTTP functionality, since all headers which have meaning when used more than once have a (header-specific) way of gaining the same functionality using only one header.

Request. **add_unredirected_header**(key, header)
Add a header that will not be added to a redirected request.
New in version 2.4.

Request. **has_header**(header)

Return whether the instance has the named header (checks both regular and unredirected).

New in version 2.4.

Request. **get_full_url**()

Return the URL given in the constructor.

Request. **get_type**()

Return the type of the URL — also known as the scheme.

Request. **get_host**()

Return the host to which a connection will be made.

Request. **get_selector**()

Return the selector — the part of the URL that is sent to the server.

Request. **set_proxy**(host, type)

Prepare the request by connecting to a proxy server. The host and type will replace those of the instance, and the instance’s selector will be the original URL given in the constructor.

Request. **get_origin_req_host**()

Return the request-host of the origin transaction, as defined by RFC 2965. See the documentation for the Request constructor.

Request. **is_unverifiable**()

Return whether the request is unverifiable, as defined by RFC 2965. See the documentation for the Request constructor.
20.6.2. OpenerDirector Objects

OpenerDirector instances have the following methods:

OpenerDirector. **add_handler**(handler)

*handler* should be an instance of BaseHandler. The following methods are searched, and added to the possible chains (note that HTTP errors are a special case).

- **protocol_open** — signal that the handler knows how to open protocol URLs.
- **http_error_type** — signal that the handler knows how to handle HTTP errors with HTTP error code *type*.
- **protocol_error** — signal that the handler knows how to handle errors from (non-http) protocol.
- **protocol_request** — signal that the handler knows how to pre-process protocol requests.
- **protocol_response** — signal that the handler knows how to post-process protocol responses.

OpenerDirector. **open**(url[, data][, timeout])

Open the given *url* (which can be a request object or a string), optionally passing the given *data*. Arguments, return values and exceptions raised are the same as those of *urlopen()* (which simply calls the open() method on the currently installed global OpenerDirector). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). The timeout feature actually works only for HTTP, HTTPS and FTP connections).

*Changed in version 2.6: timeout was added.*
**OpenerDirector.error**(proto[, arg[, ...]])

Handle an error of the given protocol. This will call the registered error handlers for the given protocol with the given arguments (which are protocol specific). The HTTP protocol is a special case which uses the HTTP response code to determine the specific error handler; refer to the `http_error_*()` methods of the handler classes.

Return values and exceptions raised are the same as those of `urlopen()`.

OpenerDirector objects open URLs in three stages:

The order in which these methods are called within each stage is determined by sorting the handler instances.

1. Every handler with a method named like `protocol_request` has that method called to pre-process the request.

2. Handlers with a method named like `protocol_open` are called to handle the request. This stage ends when a handler either returns a non-`None` value (ie. a response), or raises an exception (usually `URLError`). Exceptions are allowed to propagate.

In fact, the above algorithm is first tried for methods named `default_open()`. If all such methods return `None`, the algorithm is repeated for methods named like `protocol_open`. If all such methods return `None`, the algorithm is repeated for methods named `unknown_open()`.

Note that the implementation of these methods may involve calls of the parent `OpenerDirector` instance’s `open()` and `error()` methods.
3. Every handler with a method named like `protocol_response` has that method called to post-process the response.
20.6.3. BaseHandler Objects

**BaseHandler** objects provide a couple of methods that are directly useful, and others that are meant to be used by derived classes. These are intended for direct use:

**BaseHandler**. **add_parent**(director)

Add a director as parent.

**BaseHandler**. **close**()

Remove any parents.

The following members and methods should only be used by classes derived from **BaseHandler**.

**Note:** The convention has been adopted that subclasses defining `protocol_request()` or `protocol_response()` methods are named *Processor; all others are named *Handler.

**BaseHandler**. **parent**

A valid **OpenerDirector**, which can be used to open using a different protocol, or handle errors.

**BaseHandler**. **default_open**(req)

This method is *not* defined in **BaseHandler**, but subclasses should define it if they want to catch all URLs.

This method, if implemented, will be called by the parent **OpenerDirector**. It should return a file-like object as described in the return value of the `open()` of **OpenerDirector**, or **None**. It should raise **URLError**, unless a truly exceptional thing happens (for example, **MemoryError** should not be mapped to **URLError**).
This method will be called before any protocol-specific open method.

BaseHandler. protocol_open(req)
("protocol" is to be replaced by the protocol name.)

This method is not defined in BaseHandler, but subclasses should define it if they want to handle URLs with the given protocol.

This method, if defined, will be called by the parent OpenerDirector. Return values should be the same as for default_open().

BaseHandler. unknown_open(req)
This method is not defined in BaseHandler, but subclasses should define it if they want to catch all URLs with no specific registered handler to open it.

This method, if implemented, will be called by the parent OpenerDirector. Return values should be the same as for default_open().

BaseHandler. http_error_default(req, fp, code, msg, hdrs)
This method is not defined in BaseHandler, but subclasses should override it if they intend to provide a catch-all for otherwise unhandled HTTP errors. It will be called automatically by the OpenerDirector getting the error, and should not normally be called in other circumstances.

req will be a Request object, fp will be a file-like object with the HTTP error body, code will be the three-digit code of the error, msg will be the user-visible explanation of the code and hdrs will be a mapping object with the headers of the error.
Return values and exceptions raised should be the same as those of `urlopen()`.

`BaseHandler.http_error_nnn(req, fp, code, msg, hdrs)`

`nnn` should be a three-digit HTTP error code. This method is also not defined in `BaseHandler`, but will be called, if it exists, on an instance of a subclass, when an HTTP error with code `nnn` occurs.

Subclasses should override this method to handle specific HTTP errors.

Arguments, return values and exceptions raised should be the same as for `http_error_default()`.

`BaseHandler.protocol_request(req)`

(“protocol” is to be replaced by the protocol name.)

This method is not defined in `BaseHandler`, but subclasses should define it if they want to pre-process requests of the given protocol.

This method, if defined, will be called by the parent `OpenerDirector`. `req` will be a `Request` object. The return value should be a `Request` object.

`BaseHandler.protocol_response(req, response)`

(“protocol” is to be replaced by the protocol name.)

This method is not defined in `BaseHandler`, but subclasses should define it if they want to post-process responses of the given protocol.

This method, if defined, will be called by the parent `OpenerDirector`. `req` will be a `Request` object. `response` will be an
object implementing the same interface as the return value of `urlopen()`. The return value should implement the same interface as the return value of `urlopen()`.
20.6.4. HTTPRedirectHandler Objects

**Note:** Some HTTP redirections require action from this module’s client code. If this is the case, HTTPError is raised. See RFC 2616 for details of the precise meanings of the various redirection codes.

HTTPRedirectHandler. `redirect_request(req, fp, code, msg, hdrs, newurl)`

Return a `Request` or `None` in response to a redirect. This is called by the default implementations of the `http_error_30*()` methods when a redirection is received from the server. If a redirection should take place, return a new `Request` to allow `http_error_30*()` to perform the redirect to `newurl`. Otherwise, raise HTTPError if no other handler should try to handle this URL, or return `None` if you can’t but another handler might.

**Note:** The default implementation of this method does not strictly follow RFC 2616, which says that 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and the default implementation reproduces this behavior.

HTTPRedirectHandler. `http_error_301(req, fp, code, msg, hdrs)`

Redirect to the Location: or URI: URL. This method is called by the parent OpenerDirector when getting an HTTP ‘moved permanently’ response.

HTTPRedirectHandler. `http_error_302(req, fp, code, msg, hdrs)`

The same as `http_error_301()`, but called for the ‘found’
The same as `http_error_301()`, but called for the ‘see other’ response.

The same as `http_error_301()`, but called for the ‘temporary redirect’ response.
20.6.5. HTTPCookieProcessor Objects

New in version 2.4.

`HTTPCookieProcessor` instances have one attribute:

HTTPCookieProcessor. `cookiejar`

The `cookielib.CookieJar` in which cookies are stored.
20.6.6. ProxyHandler Objects

ProxyHandler. **protocol_open**(request)

("protocol" is to be replaced by the protocol name.)

The **ProxyHandler** will have a method **protocol_open** for every protocol which has a proxy in the proxies dictionary given in the constructor. The method will modify requests to go through the proxy, by calling **request.set_proxy()**, and call the next handler in the chain to actually execute the protocol.
These methods are available on `HTTPPasswordMgr` and `HTTPPasswordMgrWithDefaultRealm` objects.

`HTTPPasswordMgr.add_password(realm, uri, user, passwd)`

`uri` can be either a single URI, or a sequence of URIs. `realm`, `user` and `passwd` must be strings. This causes `(user, passwd)` to be used as authentication tokens when authentication for `realm` and a super-URI of any of the given URIs is given.

`HTTPPasswordMgr.find_user_password(realm, authuri)`

Get user/password for given realm and URI, if any. This method will return `(None, None)` if there is no matching user/password.

For `HTTPPasswordMgrWithDefaultRealm` objects, the realm `None` will be searched if the given `realm` has no matching user/password.
20.6.8. AbstractBasicAuthHandler Objects

AbstractBasicAuthHandler. **http_error_auth_reqed**(*authreq, host, req, headers*)

Handle an authentication request by getting a user/password pair, and re-trying the request. *authreq* should be the name of the header where the information about the realm is included in the request, *host* specifies the URL and path to authenticate for, *req* should be the (failed) Request object, and *headers* should be the error headers.

*host* is either an authority (e.g. "python.org") or a URL containing an authority component (e.g. "http://python.org/"). In either case, the authority must not contain a userinfo component (so, "python.org" and "python.org:80" are fine, "joe:password@python.org" is not).
20.6.9. HTTPBasicAuthHandler Objects

HTTPBasicAuthHandler.http_error_401(req, fp, code, msg, hdrs)
   Retry the request with authentication information, if available.
20.6.10. ProxyBasicAuthHandler Objects

ProxyBasicAuthHandler.\texttt{http\_error\_407}(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.
20.6.11. AbstractDigestAuthHandler

Objects

AbstractDigestAuthHandler.\texttt{http\_error\_auth\_reqed}(\texttt{authreq, host, req, headers})

\texttt{authreq} should be the name of the header where the information about the realm is included in the request, \texttt{host} should be the host to authenticate to, \texttt{req} should be the (failed) \texttt{Request} object, and \texttt{headers} should be the error headers.
20.6.12. HTTPDigestAuthHandler Objects

HTTPDigestAuthHandler.http_error_401(req, fp, code, msg, hdrs)

Retry the request with authentication information, if available.
20.6.13. ProxyDigestAuthHandler Objects

ProxyDigestAuthHandler. **http_error_407**(*req, fp, code, msg, hdrs*)

Retry the request with authentication information, if available.
20.6.14. HTTPHandler Objects

HTTPHandler. **http_open**(req)

Send an HTTP request, which can be either GET or POST, depending on **req.has_data()**.
20.6.15. HTTPSHandler Objects

HTTPSHandler. **https_open**(req)

Send an HTTPS request, which can be either GET or POST, depending on `req.has_data()`.
20.6.16. FileHandler Objects

FileHandler. **file_open**(req)

Open the file locally, if there is no host name, or the host name is 'localhost'. Change the protocol to ftp otherwise, and retry opening it using parent.
20.6.17. FTPHandler Objects

`FTPHandler.ftp_open(req)`

Open the FTP file indicated by `req`. The login is always done with empty username and password.
CacheFTPHandler objects are FTPHandler objects with the following additional methods:

CacheFTPHandler. `setTimeout(t)`
   Set timeout of connections to $t$ seconds.

CacheFTPHandler. `setMaxConns(m)`
   Set maximum number of cached connections to $m$. 
20.6.19. UnknownHandler Objects

UnknownHandler. unknown_open()
Raise a URLError exception.
20.6.20. HTTPErrorProcessor Objects

New in version 2.4.

HTTPErrorProcessor. unknown_open()

Process HTTP error responses.

For 200 error codes, the response object is returned immediately.

For non-200 error codes, this simply passes the job on to the protocol_error_code handler methods, via OpenerDirector.error(). Eventually, urllib2.HTTPDefaultErrorHandler will raise an HTTPError if no other handler handles the error.
20.6.21. Examples

This example gets the python.org main page and displays the first 100 bytes of it:

```python
>>> import urllib2
>>> f = urllib2.urlopen('http://www.python.org/')
>>> print f.read(100)
<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN">
<?xml-stylesheet href="./css/ht2html
```

Here we are sending a data-stream to the stdin of a CGI and reading the data it returns to us. Note that this example will only work when the Python installation supports SSL.

```python
>>> import urllib2
>>> req = urllib2.Request(url='https://localhost/cgi-bin/test.cgi'
... data='This data is passed to stdin of
>>> f = urllib2.urlopen(req)
>>> print f.read()
Got Data: "This data is passed to stdin of the CGI"
```

The code for the sample CGI used in the above example is:

```python
#!/usr/bin/env python
import sys
data = sys.stdin.read()
print 'Content-type: text-plain

Got Data: "%s"' % data
```

Use of Basic HTTP Authentication:

```python
import urllib2
# Create an OpenerDirector with support for Basic HTTP Authenti
auth_handler = urllib2.HTTPBasicAuthHandler()
auth_handler.add_password(realme='PDQ Application',
uri='https://mahler:8092/site-updates
user='klem',
passwd='kadidd!ehopper')
```
opener = urllib2.build_opener(auth_handler)
# ...and install it globally so it can be used with urlopen.
urllib2.install_opener(opener)
urllib2.urlopen('http://www.example.com/login.html')

build_opener() provides many handlers by default, including a ProxyHandler. By default, ProxyHandler uses the environment variables named `<scheme>_proxy`, where `<scheme>` is the URL scheme involved. For example, the `http_proxy` environment variable is read to obtain the HTTP proxy's URL.

This example replaces the default ProxyHandler with one that uses programatically-supplied proxy URLs, and adds proxy authorization support with ProxyBasicAuthHandler.

```python
proxy_handler = urllib2.ProxyHandler({'http': 'http://www.example.com:3128/'}
proxy_auth_handler = urllib2.ProxyBasicAuthHandler()
proxy_auth_handler.add_password('realm', 'host', 'username', 'password'

opener = urllib2.build_opener(proxy_handler, proxy_auth_handler)
# This time, rather than install the OpenerDirector, we use it opener.open('http://www.example.com/login.html')
```

Adding HTTP headers:

Use the `headers` argument to the Request constructor, or:

```python
import urllib2
req = urllib2.Request('http://www.example.com/)
req.add_header('Referer', 'http://www.python.org/'
r = urllib2.urlopen(req)
```

OpenerDirector automatically adds a User-Agent header to every Request. To change this:

```python
import urllib2
opener = urllib2.build_opener()```
opener.addheaders = [('User-agent', 'Mozilla/5.0')]

opener.open('http://www.example.com/')

Also, remember that a few standard headers (Content-Length, Content-Type and Host) are added when the Request is passed to urlopen() (or OpenerDirector.open()).
20.7. `httpclient` — HTTP protocol client

**Note:** The `httpclient` module has been renamed to `http.client` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

This module defines classes which implement the client side of the HTTP and HTTPS protocols. It is normally not used directly — the module `urllib` uses it to handle URLs that use HTTP and HTTPS.

**Note:** HTTPS support is only available if the `socket` module was compiled with SSL support.

**Note:** The public interface for this module changed substantially in Python 2.0. The `HTTP` class is retained only for backward compatibility with 1.5.2. It should not be used in new code. Refer to the online docstrings for usage.

The module provides the following classes:

```python
class httpclient.HTTPConnection(host[, port[, strict[, timeout[, source_address]]]]))
```

An `HTTPConnection` instance represents one transaction with an HTTP server. It should be instantiated passing it a host and optional port number. If no port number is passed, the port is extracted from the host string if it has the form `host:port`, else the default HTTP port (80) is used. When True, the optional parameter `strict` (which defaults to a false value) causes `BadStatusLine` to be raised if the status line can’t be parsed as a valid HTTP/1.0 or 1.1 status line. If the optional `timeout`
parameter is given, blocking operations (like connection attempts) will timeout after that many seconds (if it is not given, the global default timeout setting is used). The optional `source_address` parameter may be a tuple of a (host, port) to use as the source address the HTTP connection is made from.

For example, the following calls all create instances that connect to the server at the same host and port:

```python
>>> h1 = httplib.HTTPConnection('www.cwi.nl')
>>> h2 = httplib.HTTPConnection('www.cwi.nl:80')
>>> h3 = httplib.HTTPConnection('www.cwi.nl', 80)
>>> h3 = httplib.HTTPConnection('www.cwi.nl', 80, timeout=10)
```

*New in version 2.0.*

*Changed in version 2.6: timeout was added.*

*Changed in version 2.7: source_address was added.*

```python
class httplib.HTTPSConnection(host[, port[, key_file[, cert_file[, strict[, timeout[, source_address]]]]]])
```

A subclass of `HTTPConnection` that uses SSL for communication with secure servers. Default port is 443. `key_file` is the name of a PEM formatted file that contains your private key. `cert_file` is a PEM formatted certificate chain file.

**Warning:** This does not do any verification of the server’s certificate.

*New in version 2.0.*

*Changed in version 2.6: timeout was added.*

*Changed in version 2.7: source_address was added.*
class `httpLib.HTTPResponse`(`sock[, debuglevel=0][, strict=0]`)  
Class whose instances are returned upon successful connection. Not instantiated directly by user.

*New in version 2.0.*

class `httpLib.HTTPMessage`  
An `HTTPMessage` instance is used to hold the headers from an HTTP response. It is implemented using the `mimetypes.Message` class and provides utility functions to deal with HTTP Headers. It is not directly instantiated by the users.

The following exceptions are raised as appropriate:

*exception* `httpLib.HTTPException`  
The base class of the other exceptions in this module. It is a subclass of `Exception`.

*New in version 2.0.*

class `httpLib.NotConnected`  
A subclass of `HTTPException`.

*New in version 2.0.*

class `httpLib.InvalidURL`  
A subclass of `HTTPException`, raised if a port is given and is either non-numeric or empty.

*New in version 2.0.*

class `httpLib.UnknownProtocol`  
A subclass of `HTTPException`.

*New in version 2.0.*
exception `httplib.UnknownTransferEncoding`
   A subclass of `HTTPException`.
   
   New in version 2.0.

exception `httplib.UnimplementedFileMode`
   A subclass of `HTTPException`.
   
   New in version 2.0.

exception `httplib.IncompleteRead`
   A subclass of `HTTPException`.
   
   New in version 2.0.

exception `httplib.ImproperConnectionState`
   A subclass of `HTTPException`.
   
   New in version 2.0.

exception `httplib.CannotSendRequest`
   A subclass of `ImproperConnectionState`.
   
   New in version 2.0.

exception `httplib.CannotSendHeader`
   A subclass of `ImproperConnectionState`.
   
   New in version 2.0.

exception `httplib.ResponseNotReady`
   A subclass of `ImproperConnectionState`.
   
   New in version 2.0.

exception `httplib.BadStatusLine`
A subclass of `HTTPException`. Raised if a server responds with a HTTP status code that we don’t understand.

*New in version 2.0.*

The constants defined in this module are:

**`httplib.HTTP_PORT`**

The default port for the HTTP protocol (always 80).

**`httplib.HTTPS_PORT`**

The default port for the HTTPS protocol (always 443).

and also the following constants for integer status codes:

**httplib.responses**

This dictionary maps the HTTP 1.1 status codes to the W3C names.

Example: `httplib.responses[httplib.NOT_FOUND]` is 'Not Found'.

*New in version 2.5.*
20.7.1. HTTPConnection Objects

HTTPConnection instances have the following methods:

**HTTPConnection.** `request()` \( \text{\texttt{request}}( \text{\texttt{method}, \texttt{url}[\texttt{body}[\texttt{headers}]]}) \)

This will send a request to the server using the HTTP request method `method` and the selector `url`. If the `body` argument is present, it should be a string of data to send after the headers are finished. Alternatively, it may be an open file object, in which case the contents of the file is sent; this file object should support `fileno()` and `read()` methods. The header Content-Length is automatically set to the correct value. The `headers` argument should be a mapping of extra HTTP headers to send with the request.

*Changed in version 2.6:* `body` can be a file object.

**HTTPConnection.** `getresponse()`

Should be called after a request is sent to get the response from the server. Returns an `HTTPResponse` instance.

**Note:** Note that you must have read the whole response before you can send a new request to the server.

**HTTPConnection.** `set_debuglevel()` \( \text{\texttt{set\_debuglevel}(level)} \)

Set the debugging level (the amount of debugging output printed). The default debug level is 0, meaning no debugging output is printed.

**HTTPConnection.** `set_tunneled` \( \text{\texttt{set\_tunneled}(host, port=None, headers=None)} \)

Set the host and the port for HTTP Connect Tunnelling. Normally used when it is required to do HTTPS Connection through a proxy.
The headers argument should be a mapping of extra HTTP headers to be sent with the CONNECT request.

*New in version 2.7.*

HTTPConnection `.connect()`

Connect to the server specified when the object was created.

HTTPConnection `.close()`

Close the connection to the server.

As an alternative to using the `request()` method described above, you can also send your request step by step, by using the four functions below.

HTTPConnection `.putrequest(request, selector[, skip_host[, skip_accept_encoding]])`

This should be the first call after the connection to the server has been made. It sends a line to the server consisting of the `request` string, the `selector` string, and the HTTP version (HTTP/1.1). To disable automatic sending of `Host:` or `Accept-Encoding:` headers (for example to accept additional content encodings), specify `skip_host` or `skip_accept_encoding` with non-False values.

*Changed in version 2.4*: `skip_accept_encoding` argument added.

HTTPConnection `.putheader(header, argument[, ...])`

Send an RFC 822-style header to the server. It sends a line to the server consisting of the header, a colon and a space, and the first argument. If more arguments are given, continuation lines are sent, each consisting of a tab and an argument.
HTTPConnection. **endheaders()**

Send a blank line to the server, signalling the end of the headers.

HTTPConnection. **send(data)**

Send data to the server. This should be used directly only after the **endheaders()** method has been called and before **getresponse()** is called.
20.7.2. HTTPResponse Objects

HTTPResponse instances have the following methods and attributes:

HTTPResponse.read([amt])
Reads and returns the response body, or up to the next amt bytes.

HTTPResponse.getheader(name[, default])
Get the contents of the header name, or default if there is no matching header.

HTTPResponse.getheaders()
Return a list of (header, value) tuples.

    New in version 2.4.

HTTPResponse.fileno()
Returns the fileno of the underlying socket.

HTTPResponse.msg
A mimetools.Message instance containing the response headers.

HTTPResponse.version
HTTP protocol version used by server. 10 for HTTP/1.0, 11 for HTTP/1.1.

HTTPResponse.status
Status code returned by server.

HTTPResponse.reason
Reason phrase returned by server.
Here is an example session that uses the **GET** method:

```python
>>> import httplib
>>> conn = httplib.HTTPConnection("www.python.org")
>>> conn.request("GET", "/index.html")
>>> r1 = conn.getresponse()
>>> print r1.status, r1.reason
200 OK
>>> data1 = r1.read()
>>> conn.request("GET", "/parrot.spam")
>>> r2 = conn.getresponse()
>>> print r2.status, r2.reason
404 Not Found
>>> data2 = r2.read()
>>> conn.close()
```

Here is an example session that uses the **HEAD** method. Note that the **HEAD** method never returns any data.

```python
>>> import httplib
>>> conn = httplib.HTTPConnection("www.python.org")
>>> conn.request("HEAD", "/index.html")
>>> res = conn.getresponse()
>>> print res.status, res.reason
200 OK
>>> data = res.read()
>>> print len(data)
0
>>> data == ''
True
```

Here is an example session that shows how to **POST** requests:

```python
>>> import httplib, urllib
>>> params = urllib.urlencode({'spam': 1, 'eggs': 2, 'bacon': 0})
>>> headers = 
... "Content-type": "application/x-www-form-urlencoded"
... "Accept": "text/plain"
>>> conn = httplib.HTTPConnection("musical.mojam.com:80")
```
```python
>>> conn.request("POST", "/cgi-bin/query", params, headers)
>>> response = conn.getresponse()
>>> print response.status, response.reason
200 OK
>>> data = response.read()
>>> conn.close()
```
20.8. ftplib — FTP protocol client

This module defines the class `FTP` and a few related items. The `FTP` class implements the client side of the FTP protocol. You can use this to write Python programs that perform a variety of automated FTP jobs, such as mirroring other ftp servers. It is also used by the module `urllib` to handle URLs that use FTP. For more information on FTP (File Transfer Protocol), see Internet RFC 959.

Here's a sample session using the `ftplib` module:

```python
>>> from ftplib import FTP
>>> ftp = FTP('ftp.cwi.nl')  # connect to host, default port
>>> ftp.login()  # user anonymous, passwd anonymous
>>> ftp.retrlines('LIST')  # list directory contents
total 24418
drwxrwsr-x 5 ftp-usr pdmaint 1536 Mar 20 09:48 .
dr-xr-srwt 105 ftp-usr pdmaint 1536 Mar 21 14:32 ..
-rw-r--r-- 1 ftp-usr pdmaint 5305 Mar 20 09:48 INDEX
...
>>> ftp.retrbinary('RETR README', open('README', 'wb').write)
'226 Transfer complete.'
>>> ftp.quit()
```

The module defines the following items:

```python
class ftplib.FTP([host[, user[, passwd[, acct[, timeout]]]]])
```

Return a new instance of the `FTP` class. When `host` is given, the method call `connect(host)` is made. When `user` is given, additionally the method call `login(user, passwd, acct)` is made (where `passwd` and `acct` default to the empty string when not given). The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if is not specified, the global default timeout setting will be used).
Changed in version 2.6: timeout was added.

```python
class ftplib.FTP_TLS([host[, user[, passwd[, acct[, keyfile[, certfile[, timeout]]]]]])
```

A `FTP` subclass which adds TLS support to FTP as described in [RFC 4217](https://tools.ietf.org/html/rfc4217). Connect as usual to port 21 implicitly securing the FTP control connection before authenticating. Securing the data connection requires the user to explicitly ask for it by calling the `prot_p()` method. `keyfile` and `certfile` are optional – they can contain a PEM formatted private key and certificate chain file name for the SSL connection.

New in version 2.7.

Here’s a sample session using the `FTP_TLS` class:

```python
>>> from ftplib import FTP_TLS
>>> ftps = FTP_TLS('ftp.python.org')
>>> ftps.login()  # login anonymously before securing control channel
>>> ftps.prot_p()  # switch to secure data connection
>>> ftps.retrlines('LIST')  # list directory content securely
```

```
total 9
```

```
 drwxr-xr-x 8 root wheel 1024 Jan 3 1994 .

'226 Transfer complete.'
```

```python
>>> ftps.quit()
```

`exception` `ftplib.error_reply`

Exception raised when an unexpected reply is received from the server.
Exception raised when an error code signifying a temporary error (response codes in the range 400–499) is received.

Exception raised when an error code signifying a permanent error (response codes in the range 500–599) is received.

Exception raised when a reply is received from the server that does not fit the response specifications of the File Transfer Protocol, i.e. begin with a digit in the range 1–5.

The set of all exceptions (as a tuple) that methods of FTP instances may raise as a result of problems with the FTP connection (as opposed to programming errors made by the caller). This set includes the four exceptions listed above as well as socket.error and IOError.

See also:

Module netrc
Parser for the .netrc file format. The file .netrc is typically used by FTP clients to load user authentication information before prompting the user.

The file Tools/scripts/ftpmirror.py in the Python source distribution is a script that can mirror FTP sites, or portions thereof, using the ftplib module. It can be used as an extended example that applies this module.
20.8.1. FTP Objects

Several methods are available in two flavors: one for handling text files and another for binary files. These are named for the command which is used followed by `lines` for the text version or `binary` for the binary version.

**FTP** instances have the following methods:

**FTP.** `set_debuglevel(level)`

Set the instance’s debugging level. This controls the amount of debugging output printed. The default, `0`, produces no debugging output. A value of `1` produces a moderate amount of debugging output, generally a single line per request. A value of `2` or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

**FTP.** `connect(host[, port[, timeout]])`

Connect to the given host and port. The default port number is `21`, as specified by the FTP protocol specification. It is rarely needed to specify a different port number. This function should be called only once for each instance; it should not be called at all if a host was given when the instance was created. All other methods can only be used after a connection has been made.

The optional `timeout` parameter specifies a timeout in seconds for the connection attempt. If no `timeout` is passed, the global default timeout setting will be used.

*Changed in version 2.6: timeout was added.*

**FTP.** `getwelcome()`

Return the welcome message sent by the server in reply to the
initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

**FTP. login([user[, passwd[, acct]])**

Log in as the given `user`. The `passwd` and `acct` parameters are optional and default to the empty string. If no `user` is specified, it defaults to `'anonymous'`. If `user` is `'anonymous'`, the default `passwd` is `'anonymous@'`. This function should be called only once for each instance, after a connection has been established; it should not be called at all if a host and user were given when the instance was created. Most FTP commands are only allowed after the client has logged in. The `acct` parameter supplies “accounting information”; few systems implement this.

**FTP. abort()**

Abort a file transfer that is in progress. Using this does not always work, but it’s worth a try.

**FTP. sendcmd(command)**

Send a simple command string to the server and return the response string.

**FTP. voidcmd(command)**

Send a simple command string to the server and handle the response. Return nothing if a response code corresponding to success (codes in the range 200–299) is received. Raise `error_reply` otherwise.

**FTP. retrbinary(command, callback[, maxblocksize[, rest]])**

Retrieve a file in binary transfer mode. `command` should be an appropriate `RETR` command: `RETR filename`. The `callback` function is called for each block of data received, with a single string argument giving the data block. The optional `maxblocksize` argument specifies the maximum chunk size to read on the low-
level socket object created to do the actual transfer (which will also be the largest size of the data blocks passed to \texttt{callback}). A reasonable default is chosen. \texttt{rest} means the same thing as in the \texttt{transfercmd()} method.

\textbf{FTP.} \texttt{retrlines(command[, callback])}

Retrieve a file or directory listing in ASCII transfer mode. \texttt{command} should be an appropriate \texttt{RETR} command (see \texttt{retrbinary()}) or a command such as \texttt{LIST, NLST} or \texttt{MLSD} (usually just the string 'LIST'). \texttt{LIST} retrieves a list of files and information about those files. \texttt{NLST} retrieves a list of file names. On some servers, \texttt{MLSD} retrieves a machine readable list of files and information about those files. The \texttt{callback} function is called for each line with a string argument containing the line with the trailing CRLF stripped. The default \texttt{callback} prints the line to \texttt{sys.stdout}.

\textbf{FTP.} \texttt{set_pasv(boolean)}

Enable “passive” mode if \texttt{boolean} is true, other disable passive mode. (In Python 2.0 and before, passive mode was off by default; in Python 2.1 and later, it is on by default.)

\textbf{FTP.} \texttt{storbinary(command, file[, blocksize, callback, rest])}

Store a file in binary transfer mode. \texttt{command} should be an appropriate \texttt{STOR} command: "STOR filename". \texttt{file} is an open file object which is read until EOF using its \texttt{read()} method in blocks of size \texttt{blocksize} to provide the data to be stored. The \texttt{blocksize} argument defaults to 8192. \texttt{callback} is an optional single parameter callable that is called on each block of data after it is sent. \texttt{rest} means the same thing as in the \texttt{transfercmd()} method.

\textit{Changed in version 2.1:} default for \texttt{blocksize} added.
*Changed in version 2.6:* callback parameter added.

*Changed in version 2.7:* rest parameter added.

FTPy. **`storlines(command, file[, callback])`**

Store a file in ASCII transfer mode. `command` should be an appropriate `STOR` command (see `storbinary()`). Lines are read until EOF from the open file object `file` using its `readline()` method to provide the data to be stored. `callback` is an optional single parameter callable that is called on each line after it is sent.

*Changed in version 2.6:* callback parameter added.

FTPy. **`transfercmd(cmd[, rest])`**

Initiate a transfer over the data connection. If the transfer is active, send a `EPRT` or `PORT` command and the transfer command specified by `cmd`, and accept the connection. If the server is passive, send a `EPSV` or `PASV` command, connect to it, and start the transfer command. Either way, return the socket for the connection.

If optional `rest` is given, a `REST` command is sent to the server, passing `rest` as an argument. `rest` is usually a byte offset into the requested file, telling the server to restart sending the file’s bytes at the requested offset, skipping over the initial bytes. Note however that RFC 959 requires only that `rest` be a string containing characters in the printable range from ASCII code 33 to ASCII code 126. The `transfercmd()` method, therefore, converts `rest` to a string, but no check is performed on the string’s contents. If the server does not recognize the `REST` command, an `error_reply` exception will be raised. If this happens, simply call `transfercmd()` without a `rest` argument.
FTP\. ntransfercmd\(\text{cmd}, \text{rest}\)\\
Like \text{transfercmd()}, but returns a tuple of the data connection and the expected size of the data. If the expected size could not be computed, \text{None} will be returned as the expected size. \text{cmd} and \text{rest} means the same thing as in \text{transfercmd()}.

FTP\. nlst\(\text{argument}[, ...]\)\\
Return a list of file names as returned by the \text{NLST} command. The optional \text{argument} is a directory to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the \text{NLST} command.

FTP\. dir\(\text{argument}[, ...]\)\\
Produce a directory listing as returned by the \text{LIST} command, printing it to standard output. The optional \text{argument} is a directory to list (default is the current server directory). Multiple arguments can be used to pass non-standard options to the \text{LIST} command. If the last argument is a function, it is used as a \text{callback} function as for \text{retrlines()}; the default prints to \text{sys.stdout}. This method returns \text{None}.

FTP\. rename\(\text{fromname}, \text{toname}\)\\
Rename file \text{fromname} on the server to \text{toname}.

FTP\. delete\(\text{filename}\)\\
Remove the file named \text{filename} from the server. If successful, returns the text of the response, otherwise raises \text{error_perm} on permission errors or \text{error_reply} on other errors.

FTP\. cwd\(\text{pathname}\)\\
Set the current directory on the server.

FTP\. mkd\(\text{pathname}\)
Create a new directory on the server.

FTP. **pwd()**
Return the pathname of the current directory on the server.

FTP. **rmd**(dirname)
Remove the directory named *dirname* on the server.

FTP. **size**(filename)
Request the size of the file named *filename* on the server. On success, the size of the file is returned as an integer, otherwise *None* is returned. Note that the **SIZE** command is not standardized, but is supported by many common server implementations.

FTP. **quit()**
Send a **QUIT** command to the server and close the connection. This is the “polite” way to close a connection, but it may raise an exception if the server responds with an error to the **QUIT** command. This implies a call to the **close()** method which renders the FTP instance useless for subsequent calls (see below).

FTP. **close()**
Close the connection unilaterally. This should not be applied to an already closed connection such as after a successful call to **quit()**. After this call the FTP instance should not be used any more (after a call to **close()** or **quit()** you cannot reopen the connection by issuing another **login()** method).
20.8.2. FTP_TLS Objects

**FTP_TLS** class inherits from **FTP**, defining these additional objects:

**FTP_TLS.** *ssl_version*

The SSL version to use (defaults to *TLSv1*).

**FTP_TLS.** *auth()*

Set up secure control connection by using TLS or SSL, depending on what specified in *ssl_version()* attribute.

**FTP_TLS.** *prot_p()*

Set up secure data connection.

**FTP_TLS.** *prot_c()*

Set up clear text data connection.
This module defines a class, `POP3`, which encapsulates a connection to a POP3 server and implements the protocol as defined in RFC 1725. The `POP3` class supports both the minimal and optional command sets. Additionally, this module provides a class `POP3_SSL`, which provides support for connecting to POP3 servers that use SSL as an underlying protocol layer.

Note that POP3, though widely supported, is obsolescent. The implementation quality of POP3 servers varies widely, and too many are quite poor. If your mailserver supports IMAP, you would be better off using the `imaplib.IMAP4` class, as IMAP servers tend to be better implemented.

A single class is provided by the `poplib` module:

```python
class poplib.POP3(host[, port[, timeout]])
```

This class implements the actual POP3 protocol. The connection is created when the instance is initialized. If `port` is omitted, the standard POP3 port (110) is used. The optional `timeout` parameter specifies a timeout in seconds for the connection attempt (if not specified, the global default timeout setting will be used).

*Changed in version 2.6: timeout was added.*

```python
class poplib.POP3_SSL(host[, port[, keyfile[, certfile]]])
```

This is a subclass of `POP3` that connects to the server over an SSL encrypted socket. If `port` is not specified, 995, the standard POP3-over-SSL port is used. `keyfile` and `certfile` are also optional - they can contain a PEM formatted private key and certificate chain file for the SSL connection.
New in version 2.4.

One exception is defined as an attribute of the `poplib` module:

```python
exception poplib.error_proto

Exception raised on any errors from this module (errors from `socket` module are not caught). The reason for the exception is passed to the constructor as a string.
```

- **Module imaplib**
  The standard Python IMAP module.

- **Frequently Asked Questions About Fetchmail**
  The FAQ for the `fetchmail` POP/IMAP client collects information on POP3 server variations and RFC noncompliance that may be useful if you need to write an application based on the POP protocol.
20.9.1. POP3 Objects

All POP3 commands are represented by methods of the same name, in lower-case; most return the response text sent by the server.

An **POP3** instance has the following methods:

**POP3. `set_debuglevel(level)`**
Set the instance’s debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

**POP3. `getwelcome()`**
Returns the greeting string sent by the POP3 server.

**POP3. `user(username)`**
Send user command, response should indicate that a password is required.

**POP3. `pass_(password)`**
Send password, response includes message count and mailbox size. Note: the mailbox on the server is locked until `quit()` is called.

**POP3. `apop(user, secret)`**
Use the more secure APOP authentication to log into the POP3 server.

**POP3. `rpop(user)`**
Use RPOP authentication (similar to UNIX r-commands) to log into POP3 server.

**POP3. `stat()`**
Get mailbox status. The result is a tuple of 2 integers: `(message count, mailbox size)`.

**POP3. `list([which])`**
Request message list, result is in the form `(response, ['mesg_num octets', ...], octets)`. If `which` is set, it is the message to list.

**POP3. `retr(which)`**
Retrieve whole message number `which`, and set its seen flag. Result is in form `(response, ['line', ...], octets)`.

**POP3. `dele(which)`**
Flag message number `which` for deletion. On most servers deletions are not actually performed until QUIT (the major exception is Eudora QPOP, which deliberately violates the RFCs by doing pending deletes on any disconnect).

**POP3. `rset()`**
Remove any deletion marks for the mailbox.

**POP3. `noop()`**
Do nothing. Might be used as a keep-alive.

**POP3. `quit()`**
Signoff: commit changes, unlock mailbox, drop connection.

**POP3. `top(which, howmuch)`**
Retrieves the message header plus `howmuch` lines of the message after the header of message number `which`. Result is in form `(response, ['line', ...], octets)`. 
The POP3 TOP command this method uses, unlike the RETR command, doesn't set the message's seen flag; unfortunately, TOP is poorly specified in the RFCs and is frequently broken in off-brand servers. Test this method by hand against the POP3 servers you will use before trusting it.

POP3.uidl([which])

Return message digest (unique id) list. If which is specified, result contains the unique id for that message in the form 'response mesgnum uid', otherwise result is list (response, ['mesgnum uid', ...], octets).

Instances of POP3_SSL have no additional methods. The interface of this subclass is identical to its parent.
Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```python
import getpass, poplib
M = poplib.POP3('localhost')
M.user(getpass.getuser())
M.pass_(getpass.getpass())
numMessages = len(M.list()[1])
for i in range(numMessages):
    for j in M.retr(i+1)[1]:
        print j
```

At the end of the module, there is a test section that contains a more extensive example of usage.
This module defines three classes, `IMAP4`, `IMAP4_SSL` and `IMAP4_stream`, which encapsulate a connection to an IMAP4 server and implement a large subset of the IMAP4rev1 client protocol as defined in RFC 2060. It is backward compatible with IMAP4 (RFC 1730) servers, but note that the `STATUS` command is not supported in IMAP4.

Three classes are provided by the `imaplib` module, `IMAP4` is the base class:

```python
class imaplib.IMAP4([host[, port]])
```

This class implements the actual IMAP4 protocol. The connection is created and protocol version (IMAP4 or IMAP4rev1) is determined when the instance is initialized. If `host` is not specified, `'.'` (the local host) is used. If `port` is omitted, the standard IMAP4 port (143) is used.

Three exceptions are defined as attributes of the `IMAP4` class:

```python
exception IMAP4.error
```

Exception raised on any errors. The reason for the exception is passed to the constructor as a string.

```python
exception IMAP4.abort
```

IMAP4 server errors cause this exception to be raised. This is a sub-class of `IMAP4.error`. Note that closing the instance and instantiating a new one will usually allow recovery from this exception.

```python
exception IMAP4.readonly
```
This exception is raised when a writable mailbox has its status changed by the server. This is a sub-class of \texttt{IMAP4.error}. Some other client now has write permission, and the mailbox will need to be re-opened to re-obtain write permission.

There’s also a subclass for secure connections:

\begin{verbatim}
class imaplib.IMAP4_SSL([host[, port[, keyfile[, certfile]]]])

This is a subclass derived from \texttt{IMAP4} that connects over an SSL encrypted socket (to use this class you need a socket module that was compiled with SSL support). If \texttt{host} is not specified, "" (the local host) is used. If \texttt{port} is omitted, the standard IMAP4-over-SSL port (993) is used. \texttt{keyfile} and \texttt{certfile} are also optional - they can contain a PEM formatted private key and certificate chain file for the SSL connection.

The second subclass allows for connections created by a child process:

\begin{verbatim}
class imaplib.IMAP4_stream(command)

This is a subclass derived from \texttt{IMAP4} that connects to the stdin/stdout file descriptors created by passing \texttt{command} to \texttt{os.popen2()}.

\textit{New in version 2.3.}
\end{verbatim}

The following utility functions are defined:

\begin{verbatim}
imaplib.Internaldate2tuple(datestr)

Parse an IMAP4 \texttt{INTERNALDATE} string and return corresponding local time. The return value is a \texttt{time.struct_time} instance or None if the string has wrong format.

imaplib.Int2AP(num)
\end{verbatim}
Converts an integer into a string representation using characters from the set [A .. P].

imaplib.\texttt{ParseFlags(flagstr)}

Converts an IMAP4 \texttt{FLAGS} response to a tuple of individual flags.

imaplib.\texttt{Time2Internaldate(date\_time)}

Convert \texttt{date\_time} to an IMAP4 \texttt{INTERNALDATE} representation. The return value is a string in the form: "DD-Mmm-YYYY HH:MM:SS +HHMM" (including double-quotes). The \texttt{date\_time} argument can be a number (int or float) representing seconds since epoch (as returned by \texttt{time.time()}), a 9-tuple representing local time (as returned by \texttt{time.localtime()}), or a double-quoted string. In the last case, it is assumed to already be in the correct format.

Note that IMAP4 message numbers change as the mailbox changes; in particular, after an \texttt{EXPUNGE} command performs deletions the remaining messages are renumbered. So it is highly advisable to use UIDs instead, with the UID command.

At the end of the module, there is a test section that contains a more extensive example of usage.

\textbf{See also:} Documents describing the protocol, and sources and binaries for servers implementing it, can all be found at the University of Washington’s \textit{IMAP Information Center} (http://www.washington.edu/imap/).
20.10.1. IMAP4 Objects

All IMAP4rev1 commands are represented by methods of the same name, either upper-case or lower-case.

All arguments to commands are converted to strings, except for AUTHENTICATE, and the last argument to APPEND which is passed as an IMAP4 literal. If necessary (the string contains IMAP4 protocol-sensitive characters and isn't enclosed with either parentheses or double quotes) each string is quoted. However, the password argument to the LOGIN command is always quoted. If you want to avoid having an argument string quoted (eg: the flags argument to STORE) then enclose the string in parentheses (eg: r'("\Deleted")').

Each command returns a tuple: (type, [data, ...]) where type is usually 'OK' or 'NO', and data is either the text from the command response, or mandated results from the command. Each data is either a string, or a tuple. If a tuple, then the first part is the header of the response, and the second part contains the data (ie: ‘literal’ value).

The message_set options to commands below is a string specifying one or more messages to be acted upon. It may be a simple message number ('1'), a range of message numbers ('2:4'), or a group of non-contiguous ranges separated by commas ('1:3,6:9'). A range can contain an asterisk to indicate an infinite upper bound ('3:*').

An IMAP4 instance has the following methods:

IMAP4. append(mailbox, flags, date_time, message)
    Append message to named mailbox.
**IMAP4. authenticate**(mechanism, authobject)

Authenticate command — requires response processing.

*mechanism* specifies which authentication mechanism is to be used - it should appear in the instance variable `capabilities` in the form `AUTH=mechanism`.

*authobject* must be a callable object:

```python
data = authobject(response)
```

It will be called to process server continuation responses. It should return `data` that will be encoded and sent to server. It should return `None` if the client abort response `*` should be sent instead.

**IMAP4. check()**

Checkpoint mailbox on server.

**IMAP4. close()**

Close currently selected mailbox. Deleted messages are removed from writable mailbox. This is the recommended command before `LOGOUT`.

**IMAP4. copy(message_set, new_mailbox)**

Copy `message_set` messages onto end of `new_mailbox`.

**IMAP4. create(mailbox)**

Create new mailbox named `mailbox`.

**IMAP4. delete(mailbox)**

Delete old mailbox named `mailbox`.

**IMAP4. deleteacl(mailbox, who)**

Delete the ACLs (remove any rights) set for who on mailbox.
New in version 2.4.

**IMAP4. expunge()**
Permanently remove deleted items from selected mailbox. Generates an `expunge` response for each deleted message. Returned data contains a list of `expunge` message numbers in order received.

**IMAP4. fetch(message_set, message_parts)**
Fetch (parts of) messages. `message_parts` should be a string of message part names enclosed within parentheses, eg: "(uid body[text])". Returned data are tuples of message part envelope and data.

**IMAP4. getacl(mailbox)**
Get the ACLS for `mailbox`. The method is non-standard, but is supported by the Cyrus server.

**IMAP4. getannotation(mailbox, entry, attribute)**
Retrieve the specified annotations for `mailbox`. The method is non-standard, but is supported by the Cyrus server.

New in version 2.5.

**IMAP4. getquota(root)**
Get the quota root's resource usage and limits. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

New in version 2.3.

**IMAP4. getquotaroot(mailbox)**
Get the list of quota roots for the named `mailbox`. This method is part of the IMAP4 QUOTA extension defined in rfc2087.
New in version 2.3.

**IMAP4**. `list([directory[, pattern]])`

List mailbox names in `directory` matching `pattern`. `directory` defaults to the top-level mail folder, and `pattern` defaults to match anything. Returned data contains a list of `LIST` responses.

**IMAP4**. `login(user, password)`

Identify the client using a plaintext password. The `password` will be quoted.

**IMAP4**. `login_cram_md5(user, password)`

Force use of CRAM-MD5 authentication when identifying the client to protect the password. Will only work if the server `CAPABILITY` response includes the phrase `AUTH=CRAM-MD5`.

New in version 2.3.

**IMAP4**. `logout()`

Shutdown connection to server. Returns server `BYE` response.

**IMAP4**. `lsub([directory[, pattern]])`

List subscribed mailbox names in directory matching `pattern`. `directory` defaults to the top level directory and `pattern` defaults to match any mailbox. Returned data are tuples of message part envelope and data.

**IMAP4**. `myrights(mailbox)`

Show my ACLs for a mailbox (i.e. the rights that I have on mailbox).

New in version 2.4.

**IMAP4**. `namespace()`
Returns IMAP namespaces as defined in RFC2342.

New in version 2.3.

**IMAP4. `noop()`**

Send `NOOP` to server.

**IMAP4. `open(host, port)`**

Opens socket to `port` at `host`. This method is implicitly called by the `IMAP4` constructor. The connection objects established by this method will be used in the `read`, `readline`, `send`, and `shutdown` methods. You may override this method.

**IMAP4. `partial(message_num, message_part, start, length)`**

Fetch truncated part of a message. Returned data is a tuple of message part envelope and data.

**IMAP4. `proxyauth(user)`**

Assume authentication as `user`. Allows an authorised administrator to proxy into any user’s mailbox.

New in version 2.3.

**IMAP4. `read(size)`**

Reads `size` bytes from the remote server. You may override this method.

**IMAP4. `readline()`**

Reads one line from the remote server. You may override this method.

**IMAP4. `recent()`**

Prompt server for an update. Returned data is `None` if no new messages, else value of `RECENT` response.
**IMAP4. rename(oldmailbox, newmailbox)**

Rename mailbox named `oldmailbox` to `newmailbox`.

**IMAP4. response(code)**

Return data for response `code` if received, or `None`. Returns the given code, instead of the usual type.

**IMAP4. search(charset, criterion[,...])**

Search mailbox for matching messages. `charset` may be `None`, in which case no CHARSET will be specified in the request to the server. The IMAP protocol requires that at least one criterion be specified; an exception will be raised when the server returns an error.

Example:

```
# M is a connected IMAP4 instance...
typ, msgnums = M.search(None, 'FROM', "LDJ")
```

```
# or:
typ, msgnums = M.search(None, '(FROM "LDJ")')
```

**IMAP4. select([mailbox[, readonly]])**

Select a mailbox. Returned data is the count of messages in `mailbox` (EXISTS response). The default `mailbox` is "INBOX". If the `readonly` flag is set, modifications to the mailbox are not allowed.

**IMAP4. send(data)**

Sends `data` to the remote server. You may override this method.

**IMAP4. setacl(mailbox, who, what)**

Set an ACL for `mailbox`. The method is non-standard, but is supported by the cyrus server.
**IMAP4. `setannotation(mailbox, entry, attribute[, ...])`**

Set annotations for `mailbox`. The method is non-standard, but is supported by the `cyrus` server.

*New in version 2.5.*

**IMAP4. `setquota(root, limits)`**

Set the quota `root`'s resource limits. This method is part of the IMAP4 QUOTA extension defined in rfc2087.

*New in version 2.3.*

**IMAP4. `shutdown()`**

Close connection established in `open`. This method is implicitly called by `IMAP4.logout()`. You may override this method.

**IMAP4. `socket()`**

Returns socket instance used to connect to server.

**IMAP4. `sort(sort_criteria, charset, search_criterion[, ...])`**

The `sort` command is a variant of `search` with sorting semantics for the results. Returned data contains a space separated list of matching message numbers.

Sort has two arguments before the `search_criterion` argument(s); a parenthesized list of `sort_criteria`, and the searching `charset`. Note that unlike `search`, the searching `charset` argument is mandatory. There is also a `uid` `sort` command which corresponds to `sort` the way that `uid_search` corresponds to `search`. The `sort` command first searches the mailbox for messages that match the given searching criteria using the `charset` argument for the interpretation of strings in the searching criteria. It then returns the numbers of matching messages.
This is an IMAP4rev1 extension command.

**IMAP4. status**(*mailbox*, *names*)

Request named status conditions for *mailbox*.

**IMAP4. store**(*message_set*, *command*, *flag_list*)

Alters flag dispositions for messages in *mailbox*. *command* is specified by section 6.4.6 of RFC 2060 as being one of “FLAGS”, “+FLAGS”, or “-FLAGS”, optionally with a suffix of “.SILENT”.

For example, to set the delete flag on all messages:

```python
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    M.store(num, '+FLAGS', '\Deleted')
M.expunge()
```

**IMAP4. subscribe**(*mailbox*)

Subscribe to new mailbox.

**IMAP4. thread**(*threading_algorithm*, *charset*, *search_criterion*, ...)

The *thread* command is a variant of *search* with threading semantics for the results. Returned data contains a space separated list of thread members.

Thread members consist of zero or more messages numbers, delimited by spaces, indicating successive parent and child.

Thread has two arguments before the *search_criterion* argument(s); a *threading_algorithm*, and the searching *charset*. Note that unlike *search*, the searching *charset* argument is mandatory. There is also a uid *thread* command which corresponds to *thread* the way that uid *search* corresponds to *search*. The *thread* command first searches the mailbox for messages that match the given searching criteria using the
charset argument for the interpretation of strings in the searching criteria. It then returns the matching messages threaded according to the specified threading algorithm.

This is an IMAP4rev1 extension command.

New in version 2.4.

**IMAP4. uid**(command, arg[, ...])

Execute command args with messages identified by UID, rather than message number. Returns response appropriate to command. At least one argument must be supplied; if none are provided, the server will return an error and an exception will be raised.

**IMAP4. unsubscribe**(mailbox)

Unsubscribe from old mailbox.

**IMAP4. xatom**(name[, arg[, ...]])

Allow simple extension commands notified by server in CAPABILITY response.

Instances of IMAP4_SSL have just one additional method:

**IMAP4_SSL. ssl**(())

Returns SSLObject instance used for the secure connection with the server.

The following attributes are defined on instances of IMAP4:

**IMAP4. PROTOCOL_VERSION**

The most recent supported protocol in the CAPABILITY response from the server.

**IMAP4. debug**
Integer value to control debugging output. The initialize value is taken from the module variable `debug`. Values greater than three trace each command.
20.10.2. IMAP4 Example

Here is a minimal example (without error checking) that opens a mailbox and retrieves and prints all messages:

```python
import getpass, imaplib
M = imaplib.IMAP4()
M.login(getpass.getuser(), getpass.getpass())
M.select()
typ, data = M.search(None, 'ALL')
for num in data[0].split():
    typ, data = M.fetch(num, '(RFC822)'
    print 'Message %s
%s
' % (num, data[0][1])
M.close()
M.logout()
```
This module defines the class `NNTP` which implements the client side of the NNTP protocol. It can be used to implement a news reader or poster, or automated news processors. For more information on NNTP (Network News Transfer Protocol), see Internet RFC 977.

Here are two small examples of how it can be used. To list some statistics about a newsgroup and print the subjects of the last 10 articles:

```python
>>> s = NNTP('news.gmane.org')
>>> resp, count, first, last, name = s.group('gmane.comp.python.committers')
>>> print 'Group', name, 'has', count, 'articles, range', first, 'to', last
Group gmane.comp.python.committers has 1071 articles, range 1 to 1071
>>> resp, subs = s.xhdr('subject', first + '-' + last)
>>> for id, sub in subs[-10:]:
...    print id, sub
... 1062 Re: Mercurial Status?
1063 Re: [python-committers] (Windows) buildbots on 3.x
1064 Re: Mercurial Status?
1065 Re: Mercurial Status?
1066 Python 2.6.6 status
1067 Commit Privileges for Ask Solem
1068 Re: Commit Privileges for Ask Solem
1069 Re: Commit Privileges for Ask Solem
1070 Re: Commit Privileges for Ask Solem
1071 2.6.6 rc 2
```

To post an article from a file (this assumes that the article has valid headers, and that you have right to post on the particular newsgroup):

```python
>>> s = NNTP('news.gmane.org')
>>> f = open('/tmp/article')
```
class nntplib.NNTP(host[, port[, user[, password[, readermode]][, usenetrc]]]])

Return a new instance of the NNTP class, representing a connection to the NNTP server running on host host, listening at port port. The default port is 119. If the optional user and password are provided, or if suitable credentials are present in ~/.netrc and the optional flag usenetrc is true (the default), the AUTHINFO USER and AUTHINFO PASS commands are used to identify and authenticate the user to the server. If the optional flag readermode is true, then a mode reader command is sent before authentication is performed. Reader mode is sometimes necessary if you are connecting to an NNTP server on the local machine and intend to call reader-specific commands, such as group. If you get unexpected NNTPPermanentErrors, you might need to set readermode. readermode defaults to None. usenetrc defaults to True.

Changed in version 2.4: usenetrc argument added.

exception nntplib.NNTPError

Derived from the standard exception Exception, this is the base class for all exceptions raised by the nntplib module.

exception nntplib.NNTPReplyError

Exception raised when an unexpected reply is received from the server. For backwards compatibility, the exception error_reply is equivalent to this class.
`exception nntplib.NNTPTemporaryError`  
Exception raised when an error code in the range 400–499 is received. For backwards compatibility, the exception `error_temp` is equivalent to this class.

`exception nntplib.NNTPPermanentError`  
Exception raised when an error code in the range 500–599 is received. For backwards compatibility, the exception `error_perm` is equivalent to this class.

`exception nntplib.NNTPProtocolError`  
Exception raised when a reply is received from the server that does not begin with a digit in the range 1–5. For backwards compatibility, the exception `error_proto` is equivalent to this class.

`exception nntplib.NNTpDataError`  
Exception raised when there is some error in the response data. For backwards compatibility, the exception `error_data` is equivalent to this class.
NNTP instances have the following methods. The response that is returned as the first item in the return tuple of almost all methods is the server’s response: a string beginning with a three-digit code. If the server’s response indicates an error, the method raises one of the above exceptions.

**NNTP.getwelcome()**

Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

**NNTP.set_debuglevel(level)**

Set the instance’s debugging level. This controls the amount of debugging output printed. The default, 0, produces no debugging output. A value of 1 produces a moderate amount of debugging output, generally a single line per request or response. A value of 2 or higher produces the maximum amount of debugging output, logging each line sent and received on the connection (including message text).

**NNTP.newgroups(date, time[, file])**

Send a **NEWGROUPS** command. The date argument should be a string of the form 'yymmdd' indicating the date, and time should be a string of the form 'hhmms' indicating the time. Return a pair (response, groups) where groups is a list of group names that are new since the given date and time. If the file parameter is supplied, then the output of the **NEWGROUPS** command is stored in a file. If file is a string, then the method will open a file object with that name, write to it then close it. If file is a file object, then it will start calling write() on it to store the lines of the command
output. If file is supplied, then the returned list is an empty list.

NNTP. `newnews(group, date, time[, file])`
Send a `NEWNEWS` command. Here, group is a group name or '*', and date and time have the same meaning as for `newgroups()`. Return a pair (response, articles) where articles is a list of message ids. If the file parameter is supplied, then the output of the `NEWNEWS` command is stored in a file. If file is a string, then the method will open a file object with that name, write to it then close it. If file is a file object, then it will start calling `write()` on it to store the lines of the command output. If file is supplied, then the returned list is an empty list.

NNTP. `list([file])`
Send a `LIST` command. Return a pair (response, list) where list is a list of tuples. Each tuple has the form (group, last, first, flag), where group is a group name, last and first are the last and first article numbers (as strings), and flag is 'y' if posting is allowed, 'n' if not, and 'm' if the newsgroup is moderated. (Note the ordering: last, first.) If the file parameter is supplied, then the output of the `LIST` command is stored in a file. If file is a string, then the method will open a file object with that name, write to it then close it. If file is a file object, then it will start calling `write()` on it to store the lines of the command output. If file is supplied, then the returned list is an empty list.

NNTP. `descriptions(grouppattern)`
Send a `LIST NEWSGROUPS` command, where grouppattern is a wildmat string as specified in RFC2980 (it's essentially the same as DOS or UNIX shell wildcard strings). Return a pair (response, list), where list is a list of tuples containing (name, title).
New in version 2.4.

**NNTP. `description(group)`**

Get a description for a single group `group`. If more than one group matches (if `group` is a real wildmat string), return the first match. If no group matches, return an empty string.

This elides the response code from the server. If the response code is needed, use `descriptions()`.

New in version 2.4.

**NNTP. `group(name)`**

Send a `GROUP` command, where `name` is the group name. Return a tuple `(response, count, first, last, name)` where `count` is the (estimated) number of articles in the group, `first` is the first article number in the group, `last` is the last article number in the group, and `name` is the group name. The numbers are returned as strings.

**NNTP. `help([file])`**

Send a `HELP` command. Return a pair `(response, list)` where `list` is a list of help strings. If the `file` parameter is supplied, then the output of the `HELP` command is stored in a file. If `file` is a string, then the method will open a file object with that name, write to it then close it. If `file` is a file object, then it will start calling `write()` on it to store the lines of the command output. If `file` is supplied, then the returned `list` is an empty list.

**NNTP. `stat(id)`**

Send a `STAT` command, where `id` is the message id (enclosed in `<` and `>`) or an article number (as a string). Return a triple `(response, number, id)` where `number` is the article number (as a string) and `id` is the message id (enclosed in `<` and `>`).
NNTP. **next()**

Send a **NEXT** command. Return as for **stat()**.

NNTP. **last()**

Send a **LAST** command. Return as for **stat()**.

NNTP. **head(id)**

Send a **HEAD** command, where *id* has the same meaning as for **stat()**. Return a tuple `(response, number, id, list)` where the first three are the same as for **stat()**, and *list* is a list of the article's headers (an uninterpreted list of lines, without trailing newlines).

NNTP. **body(id[, file])**

Send a **BODY** command, where *id* has the same meaning as for **stat()**. If the *file* parameter is supplied, then the body is stored in a file. If *file* is a string, then the method will open a file object with that name, write to it then close it. If *file* is a file object, then it will start calling **write()** on it to store the lines of the body. Return as for **head()**. If *file* is supplied, then the returned *list* is an empty list.

NNTP. **article(id)**

Send an **ARTICLE** command, where *id* has the same meaning as for **stat()**. Return as for **head()**.

NNTP. **slave()**

Send a **SLAVE** command. Return the server's **response**.

NNTP. **xhdr(header, string[, file])**

Send an **XHDR** command. This command is not defined in the RFC but is a common extension. The *header* argument is a header keyword, e.g. '*subject*'. The *string* argument should
have the form 'first-last' where first and last are the first and last article numbers to search. Return a pair (response, list), where list is a list of pairs (id, text), where id is an article number (as a string) and text is the text of the requested header for that article. If the file parameter is supplied, then the output of the XHDR command is stored in a file. If file is a string, then the method will open a file object with that name, write to it then close it. If file is a file object, then it will start calling write() on it to store the lines of the command output. If file is supplied, then the returned list is an empty list.

NNTP.post(file)
Post an article using the POST command. The file argument is an open file object which is read until EOF using its readline() method. It should be a well-formed news article, including the required headers. The post() method automatically escapes lines beginning with ..

NNTP.ihave(id, file)
Send an IHAVE command. id is a message id (enclosed in '<' and '>'). If the response is not an error, treat file exactly as for the post() method.

NNTP.date()
Return a triple (response, date, time), containing the current date and time in a form suitable for the newnews() and newgroups() methods. This is an optional NNTP extension, and may not be supported by all servers.

NNTP.xgtitle(name[, file])
Process an XGTITLE command, returning a pair (response, list), where list is a list of tuples containing (name, title). If the
file parameter is supplied, then the output of the XGTITLE command is stored in a file. If file is a string, then the method will open a file object with that name, write to it then close it. If file is a file object, then it will start calling write() on it to store the lines of the command output. If file is supplied, then the returned list is an empty list. This is an optional NNTP extension, and may not be supported by all servers.

RFC2980 says “It is suggested that this extension be deprecated”. Use descriptions() or description() instead.

NNTP. xover(start, end[, file])
Return a pair (resp, list). list is a list of tuples, one for each article in the range delimited by the start and end article numbers. Each tuple is of the form (article number, subject, poster, date, id, references, size, lines). If the file parameter is supplied, then the output of the XOVER command is stored in a file. If file is a string, then the method will open a file object with that name, write to it then close it. If file is a file object, then it will start calling write() on it to store the lines of the command output. If file is supplied, then the returned list is an empty list. This is an optional NNTP extension, and may not be supported by all servers.

NNTP. xpath(id)
Return a pair (resp, path), where path is the directory path to the article with message ID id. This is an optional NNTP extension, and may not be supported by all servers.

NNTP. quit()
Send a quit command and close the connection. Once this method has been called, no other methods of the NNTP object should be called.
20.12. smtplib — SMTP protocol client

The smtplib module defines an SMTP client session object that can be used to send mail to any Internet machine with an SMTP or ESMTP listener daemon. For details of SMTP and ESMTP operation, consult RFC 821 (Simple Mail Transfer Protocol) and RFC 1869 (SMTP Service Extensions).

```python
class smtplib.SMTP([host[, port[, local_hostname[, timeout]]]])
```

A `SMTP` instance encapsulates an SMTP connection. It has methods that support a full repertoire of SMTP and ESMTP operations. If the optional host and port parameters are given, the `SMTP connect()` method is called with those parameters during initialization. An `SMTPConnectError` is raised if the specified host doesn’t respond correctly. The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

For normal use, you should only require the initialization/connect, `sendmail()`, and `quit()` methods. An example is included below.

*Changed in version 2.6: timeout was added.*

```python
class smtplib.SMTP_SSL([host[, port[, local_hostname[, keyfile[, certfile[, timeout]]]]]])
```

A `SMTP_SSL` instance behaves exactly the same as instances of `SMTP`. `SMTP_SSL` should be used for situations where SSL is required from the beginning of the connection and using `starttls()` is not appropriate. If `host` is not specified, the local
host is used. If port is omitted, the standard SMTP-over-SSL port (465) is used. keyfile and certfile are also optional, and can contain a PEM formatted private key and certificate chain file for the SSL connection. The optional timeout parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

New in version 2.6.

class smtplib.LMTP([host[, port[, local_hostname]])

The LMTP protocol, which is very similar to ESMTP, is heavily based on the standard SMTP client. It’s common to use Unix sockets for LMTP, so our connect() method must support that as well as a regular host:port server. To specify a Unix socket, you must use an absolute path for host, starting with a ‘/’.

Authentication is supported, using the regular SMTP mechanism. When using a Unix socket, LMTP generally don’t support or require any authentication, but your mileage might vary.

New in version 2.6.

A nice selection of exceptions is defined as well:

exception smtplib.SMTPException
Base exception class for all exceptions raised by this module.

exception smtplib.SMTPServerDisconnected
This exception is raised when the server unexpectedly disconnects, or when an attempt is made to use the SMTP instance before connecting it to a server.

exception smtplib.SMTPResponseException
Base class for all exceptions that include an SMTP error code.
These exceptions are generated in some instances when the SMTP server returns an error code. The error code is stored in the `smtp_code` attribute of the error, and the `smtp_error` attribute is set to the error message.

**exception** `smtplib.SMTPSenderRefused`

Sender address refused. In addition to the attributes set by on all `SMTPResponseException` exceptions, this sets ‘sender’ to the string that the SMTP server refused.

**exception** `smtplib.SMTPRecipientsRefused`

All recipient addresses refused. The errors for each recipient are accessible through the attribute `recipients`, which is a dictionary of exactly the same sort as `SMTP.sendmail()` returns.

**exception** `smtplib.SMTPDataError`

The SMTP server refused to accept the message data.

**exception** `smtplib.SMTPConnectError`

Error occurred during establishment of a connection with the server.

**exception** `smtplib.SMTPHeloError`

The server refused our `HELO` message.

**exception** `smtplib.SMTPAuthenticationError`

SMTP authentication went wrong. Most probably the server didn’t accept the username/password combination provided.

**See also:**

**RFC 821** - Simple Mail Transfer Protocol

Protocol definition for SMTP. This document covers the model, operating procedure, and protocol details for SMTP.

**RFC 1869** - SMTP Service Extensions
Definition of the ESMTP extensions for SMTP. This describes a framework for extending SMTP with new commands, supporting dynamic discovery of the commands provided by the server, and defines a few additional commands.
20.12.1. SMTP Objects

An **SMTP** instance has the following methods:

**SMTP. set_debuglevel(level)**
Set the debug output level. A true value for *level* results in debug messages for connection and for all messages sent to and received from the server.

**SMTP. connect([host[, port]])**
Connect to a host on a given port. The defaults are to connect to the local host at the standard SMTP port (25). If the hostname ends with a colon (':') followed by a number, that suffix will be stripped off and the number interpreted as the port number to use. This method is automatically invoked by the constructor if a host is specified during instantiation.

**SMTP. docmd(cmd[, argstring])**
Send a command *cmd* to the server. The optional argument *argstring* is simply concatenated to the command, separated by a space.

This returns a 2-tuple composed of a numeric response code and the actual response line (multiline responses are joined into one long line.)

In normal operation it should not be necessary to call this method explicitly. It is used to implement other methods and may be useful for testing private extensions.

If the connection to the server is lost while waiting for the reply, **SMTPServerDisconnected** will be raised.
SMTP. **helo([hostname])**

Identify yourself to the SMTP server using HELO. The hostname argument defaults to the fully qualified domain name of the local host. The message returned by the server is stored as the **helo_resp** attribute of the object.

In normal operation it should not be necessary to call this method explicitly. It will be implicitly called by the `sendmail()` when necessary.

SMTP. **ehlo([hostname])**

Identify yourself to an ESMTP server using EHLO. The hostname argument defaults to the fully qualified domain name of the local host. Examine the response for ESMTP option and store them for use by has_extn(). Also sets several informational attributes: the message returned by the server is stored as the **ehlo_resp** attribute, **does_esmtp** is set to true or false depending on whether the server supports ESMTP, and **esmtp_features** will be a dictionary containing the names of the SMTP service extensions this server supports, and their parameters (if any).

Unless you wish to use `has_extn()` before sending mail, it should not be necessary to call this method explicitly. It will be implicitly called by `sendmail()` when necessary.

SMTP. **ehlo_or_helo_if_needed()**

This method call **ehlo()** and or **helo()** if there has been no previous ESMTP EHLO or HELO command this session. It tries ESMTP EHLO first.

SMTPHeloError

The server didn’t reply properly to the HELO greeting.
New in version 2.6.

**SMTP. has_extn(name)**
Return **True** if *name* is in the set of SMTP service extensions returned by the server, **False** otherwise. Case is ignored.

**SMTP. verify(address)**
Check the validity of an address on this server using SMTP VRFY. Returns a tuple consisting of code 250 and a full RFC 822 address (including human name) if the user address is valid. Otherwise returns an SMTP error code of 400 or greater and an error string.

**Note:** Many sites disable SMTP VRFY in order to foil spammers.

**SMTP. login(user, password)**
Log in on an SMTP server that requires authentication. The arguments are the username and the password to authenticate with. If there has been no previous EHLO or HELO command this session, this method tries ESMTP EHLO first. This method will return normally if the authentication was successful, or may raise the following exceptions:

**SMTPHeloError**
The server didn’t reply properly to the HELO greeting.

**SMTPAuthenticationError**
The server didn’t accept the username/password combination.

**SMTPException**
No suitable authentication method was found.
Put the SMTP connection in TLS (Transport Layer Security) mode. All SMTP commands that follow will be encrypted. You should then call `ehlo()` again.

If `keyfile` and `certfile` are provided, these are passed to the `socket` module’s `ssl()` function.

If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first.

*Changed in version 2.6.*

**SMTPHeloError**

The server didn’t reply properly to the `HELO` greeting.

**SMTPException**

The server does not support the STARTTLS extension.

*Changed in version 2.6.*

**RuntimeError**

SSL/TLS support is not available to your Python interpreter.

Send mail. The required arguments are an RFC 822 from-address string, a list of RFC 822 to-address strings (a bare string will be treated as a list with 1 address), and a message string. The caller may pass a list of ESMTP options (such as `8bitmime`) to be used in `MAIL FROM` commands as `mail_options`. ESMTP options (such as `DSN` commands) that should be used with all `RCPT` commands can be passed as `rcpt_options`. (If you need to use different ESMTP options to different recipients you have to
use the low-level methods such as `mail()`, `rcpt()` and `data()` to send the message."

**Note:** The `from_addr` and `to_addrs` parameters are used to construct the message envelope used by the transport agents. The SMTP does not modify the message headers in any way.

If there has been no previous `EHLO` or `HELO` command this session, this method tries ESMTP `EHLO` first. If the server does ESMTP, message size and each of the specified options will be passed to it (if the option is in the feature set the server advertises). If `EHLO` fails, `HELO` will be tried and ESMTP options suppressed.

This method will return normally if the mail is accepted for at least one recipient. Otherwise it will raise an exception. That is, if this method does not raise an exception, then someone should get your mail. If this method does not raise an exception, it returns a dictionary, with one entry for each recipient that was refused. Each entry contains a tuple of the SMTP error code and the accompanying error message sent by the server.

This method may raise the following exceptions:

**SMTPRecipientsRefused**

All recipients were refused. Nobody got the mail. The `recipients` attribute of the exception object is a dictionary with information about the refused recipients (like the one returned when at least one recipient was accepted).

**SMTPHe10Erro**

The server didn’t reply properly to the `HELO` greeting.

**SMTPSenderRefused**

The server didn’t accept the `from_addr`. 
SMTPDataError

The server replied with an unexpected error code (other than a refusal of a recipient).

Unless otherwise noted, the connection will be open even after an exception is raised.

SMTP.quit()

Terminate the SMTP session and close the connection. Return the result of the SMTP quit command.

Changed in version 2.6: Return a value.

Low-level methods corresponding to the standard SMTP/ESMTP commands HELP, RSET, NOOP, MAIL, RCPT, and DATA are also supported. Normally these do not need to be called directly, so they are not documented here. For details, consult the module code.
20.12.2. SMTP Example

This example prompts the user for addresses needed in the message envelope ('To' and 'From' addresses), and the message to be delivered. Note that the headers to be included with the message must be included in the message as entered; this example doesn't do any processing of the RFC 822 headers. In particular, the 'To' and 'From' addresses must be included in the message headers explicitly.

```python
import smtplib

def prompt(prompt):
    return raw_input(prompt).strip()

fromaddr = prompt("From: ")
toaddrs = prompt("To: ").split()
print "Enter message, end with ^D (Unix) or ^Z (Windows):
#
# Add the From: and To: headers at the start!
msg = ("From: %s\r\nTo: %s\r\n\n" % (fromaddr, ", ".join(toaddrs)))
while 1:
    try:
        line = raw_input()
    except EOFError:
        break
    if not line:
        break
    msg = msg + line

print "Message length is " + repr(len(msg))

server = smtplib.SMTP('localhost')
server.set_debuglevel(1)
server.sendmail(fromaddr, toaddrs, msg)
server.quit()
```

Note: In general, you will want to use the email package's features to construct an email message, which you can then
convert to a string and send via `sendmail()`; see `email: Examples`. 
This module offers several classes to implement SMTP servers. One is a generic do-nothing implementation, which can be overridden, while the other two offer specific mail-sending strategies.
20.13.1. SMTPServer Objects

```
class smtpd.SMTPServer(localaddr, remoteaddr)

Create a new SMTPServer object, which binds to local address
localaddr. It will treat remoteaddr as an upstream SMTP relayer.
It inherits from asyncore.dispatcher, and so will insert itself into
asyncore's event loop on instantiation.

process_message(peer, mailfrom, rcpttos, data)

Raise NotImplemented exception. Override this in
subclasses to do something useful with this message.
Whatever was passed in the constructor as remoteaddr will
be available as the _remoteaddr attribute. peer is the remote
host's address, mailfrom is the envelope originator, rcpttos are
the envelope recipients and data is a string containing the
contents of the e-mail (which should be in RFC 2822 format).
```
20.13.2. DebuggingServer Objects

```python
class smtpd.DebuggingServer(localaddr, remoteaddr)
    Create a new debugging server. Arguments are as per
    SMTPServer. Messages will be discarded, and printed on stdout.
```
20.13.3. PureProxy Objects

class smtplib.PureProxy(localaddr, remoteaddr)

Create a new pure proxy server. Arguments are as per SMTPServer. Everything will be relayed to remoteaddr. Note that running this has a good chance to make you into an open relay, so please be careful.
20.13.4. MailmanProxy Objects

```python
class smtpd.MailmanProxy(localaddr, remoteaddr)
    Create a new pure proxy server. Arguments are as per
    SMTPServer. Everything will be relayed to remoteaddr, unless
    local mailman configurations knows about an address, in which
    case it will be handled via mailman. Note that running this has a
    good chance to make you into an open relay, so please be
careful.
```

*Python v2.7.2 documentation* » The Python Standard Library » 20. Internet Protocols and Support » previous | next | modules | index
20. Internet Protocols and Support
The `telnetlib` module provides a `Telnet` class that implements the Telnet protocol. See RFC 854 for details about the protocol. In addition, it provides symbolic constants for the protocol characters (see below), and for the telnet options. The symbolic names of the telnet options follow the definitions in `arpa/telnet.h`, with the leading `TELOPT_` removed. For symbolic names of options which are traditionally not included in `arpa/telnet.h`, see the module source itself.

The symbolic constants for the telnet commands are: IAC, DONT, DO, WONT, WILL, SE (Subnegotiation End), NOP (No Operation), DM (Data Mark), BRK (Break), IP (Interrupt process), AO (Abort output), AYT (Are You There), EC (Erase Character), EL (Erase Line), GA (Go Ahead), SB (Subnegotiation Begin).

```python
class telnetlib.Telnet([host[, port[, timeout]]])
```

`Telnet` represents a connection to a Telnet server. The instance is initially not connected by default; the `open()` method must be used to establish a connection. Alternatively, the host name and optional port number can be passed to the constructor, to, in which case the connection to the server will be established before the constructor returns. The optional `timeout` parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

Do not reopen an already connected instance.

This class has many `read_*()` methods. Note that some of them raise `EOFError` when the end of the connection is read, because they can return an empty string for other reasons. See the
individual descriptions below.

*Changed in version 2.6: timeout was added.*

**See also:**

**RFC 854 - Telnet Protocol Specification**
- Definition of the Telnet protocol.
20.14.1. Telnet Objects

Telnet instances have the following methods:

Telnet.`read_until(expected[, timeout])`
Read until a given string, `expected`, is encountered or until `timeout` seconds have passed.

When no match is found, return whatever is available instead, possibly the empty string. Raise `EOFError` if the connection is closed and no cooked data is available.

Telnet.`read_all()`
Read all data until EOF; block until connection closed.

Telnet.`read_some()`
Read at least one byte of cooked data unless EOF is hit. Return `'in` if EOF is hit. Block if no data is immediately available.

Telnet.`read_very_eager()`
Read everything that can be without blocking in I/O (eager).

Raise `EOFError` if connection closed and no cooked data available. Return `'in` if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

Telnet.`read_eager()`
Read readily available data.

Raise `EOFError` if connection closed and no cooked data available. Return `'in` if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.
Telnet.read_lazy()

Process and return data already in the queues (lazy).

Raise EOFError if connection closed and no data available. Return '' if no cooked data available otherwise. Do not block unless in the midst of an IAC sequence.

Telnet.read_very_lazу()

Return any data available in the cooked queue (very lazy).

Raise EOFError if connection closed and no data available. Return '' if no cooked data available otherwise. This method never blocks.

Telnet.read_sb_data()

Return the data collected between a SB/SE pair (suboption begin/end). The callback should access these data when it was invoked with a SE command. This method never blocks.

_new in version 2.3._

Telnet.open(host[, port[, timeout]])

Connect to a host. The optional second argument is the port number, which defaults to the standard Telnet port (23). The optional timeout parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used).

Do not try to reopen an already connected instance.

_Changed in version 2.6: timeout was added._

Telnet.msg(msg[, *args])

Print a debug message when the debug level is > 0. If extra
arguments are present, they are substituted in the message using the standard string formatting operator.

Telnet. **set_debuglevel(debuglevel)**
Set the debug level. The higher the value of `debuglevel`, the more debug output you get (on `sys.stdout`).

Telnet. **close()**
Close the connection.

Telnet. **get_socket()**
Return the socket object used internally.

Telnet. **fileno()**
Return the file descriptor of the socket object used internally.

Telnet. **write(buffer)**
Write a string to the socket, doubling any IAC characters. This can block if the connection is blocked. May raise `socket.error` if the connection is closed.

Telnet. **interact()**
Interaction function, emulates a very dumb Telnet client.

Telnet. **mt_interact()**
Multithreaded version of `interact()`.

Telnet. **expect(list[, timeout])**
Read until one from a list of a regular expressions matches.

The first argument is a list of regular expressions, either compiled (`re.RegexObject` instances) or uncompiled (strings). The optional second argument is a timeout, in seconds; the default is to block indefinitely.
Return a tuple of three items: the index in the list of the first regular expression that matches; the match object returned; and the text read up till and including the match.

If end of file is found and no text was read, raise `EOFError`. Otherwise, when nothing matches, return `(-1, None, text)` where `text` is the text received so far (may be the empty string if a timeout happened).

If a regular expression ends with a greedy match (such as `.*)` or if more than one expression can match the same input, the results are non-deterministic, and may depend on the I/O timing.

`Telnet.set_option_negotiation_callback(callback)`
Each time a telnet option is read on the input flow, this `callback` (if set) is called with the following parameters: `callback(telnet socket, command (DO/DONT/WILL/WONT), option)`. No other action is done afterwards by telnetlib.
A simple example illustrating typical use:

```python
import getpass
import sys
import telnetlib

HOST = "localhost"
user = raw_input("Enter your remote account: ")
password = getpass.getpass()

tn = telnetlib.Telnet(HOST)

tn.read_until("login: ")
tn.write(user + "\n")
if password:
    tn.read_until("Password: ")
    tn.write(password + "\n")

tn.write("ls\n")
tn.write("exit\n")

print tn.read_all()
```
20.15. `uuid` — UUID objects according to RFC 4122

*New in version 2.5.*

This module provides immutable `uuid` objects (the `UUID` class) and the functions `uuid1()`, `uuid3()`, `uuid4()`, `uuid5()` for generating version 1, 3, 4, and 5 UUIDs as specified in [RFC 4122](https://tools.ietf.org/html/rfc4122).

If all you want is a unique ID, you should probably call `uuid1()` or `uuid4()`. Note that `uuid1()` may compromise privacy since it creates a UUID containing the computer's network address. `uuid4()` creates a random UUID.

```python
class uuid.UUID([hex[, bytes[, bytes_le[, fields[, int[, version]]]]]])
```

Create a UUID from either a string of 32 hexadecimal digits, a string of 16 bytes as the `bytes` argument, a string of 16 bytes in little-endian order as the `bytes_le` argument, a tuple of six integers (32-bit `time_low`, 16-bit `time_mid`, 16-bit `time_hi_version`, 8-bit `clock_seq_hi_variant`, 8-bit `clock_seq_low`, 48-bit `node`) as the `fields` argument, or a single 128-bit integer as the `int` argument. When a string of hex digits is given, curly braces, hyphens, and a URN prefix are all optional. For example, these expressions all yield the same UUID:

```python
UUID('12345678-1234-5678-1234-567812345678')
UUID('12345678123456781234567812345678')
UUID('urn:uuid:12345678-1234-5678-1234-567812345678')
UUID(bytes='\x12\x34\x56\x78'*4)
UUID(bytes_le='\x78\x56\x34\x12\x34\x12\x78\x56' +
       '\x12\x34\x56\x78\x12\x34\x56\x78')
UUID(fields=(0x12345678, 0x1234, 0x5678, 0x12, 0x34, 0x567812345678))
UUID(int=0x1234567812345678123456781234567812345678)
```
Exactly one of `hex`, `bytes`, `bytes_le`, `fields`, or `int` must be given. The `version` argument is optional; if given, the resulting UUID will have its variant and version number set according to RFC 4122, overriding bits in the given `hex`, `bytes`, `bytes_le`, `fields`, or `int`.

**UUID** instances have these read-only attributes:

**UUID.bytes**
- The UUID as a 16-byte string (containing the six integer fields in big-endian byte order).

**UUID.bytes_le**
- The UUID as a 16-byte string (with `time_low`, `time_mid`, and `time_hi_version` in little-endian byte order).

**UUID.fields**
- A tuple of the six integer fields of the UUID, which are also available as six individual attributes and two derived attributes:

<table>
<thead>
<tr>
<th>Field</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>time_low</code></td>
<td>the first 32 bits of the UUID</td>
</tr>
<tr>
<td><code>time_mid</code></td>
<td>the next 16 bits of the UUID</td>
</tr>
<tr>
<td><code>time_hi_version</code></td>
<td>the next 16 bits of the UUID</td>
</tr>
<tr>
<td><code>clock_seq_hi_variant</code></td>
<td>the next 8 bits of the UUID</td>
</tr>
<tr>
<td><code>clock_seq_low</code></td>
<td>the next 8 bits of the UUID</td>
</tr>
<tr>
<td><code>node</code></td>
<td>the last 48 bits of the UUID</td>
</tr>
<tr>
<td><code>time</code></td>
<td>the 60-bit timestamp</td>
</tr>
<tr>
<td><code>clock_seq</code></td>
<td>the 14-bit sequence number</td>
</tr>
</tbody>
</table>

**UUID.hex**
- The UUID as a 32-character hexadecimal string.

**UUID.int**
- The UUID as a 128-bit integer.
**UUID.urn**

The UUID as a URN as specified in RFC 4122.

**UUID.variant**

The UUID variant, which determines the internal layout of the UUID. This will be one of the integer constants `RESERVED_NCS`, `RFC_4122`, `RESERVED_MICROSOFT`, or `RESERVED_FUTURE`.

**UUID.version**

The UUID version number (1 through 5, meaningful only when the variant is `RFC_4122`).

The `uuid` module defines the following functions:

`uuid.getnode()`

Get the hardware address as a 48-bit positive integer. The first time this runs, it may launch a separate program, which could be quite slow. If all attempts to obtain the hardware address fail, we choose a random 48-bit number with its eighth bit set to 1 as recommended in RFC 4122. “Hardware address” means the MAC address of a network interface, and on a machine with multiple network interfaces the MAC address of any one of them may be returned.

`uuid.uuid1([node[, clock_seq]])`

Generate a UUID from a host ID, sequence number, and the current time. If `node` is not given, `getnode()` is used to obtain the hardware address. If `clock_seq` is given, it is used as the sequence number; otherwise a random 14-bit sequence number is chosen.

`uuid.uuid3(namespace, name)`

Generate a UUID based on the MD5 hash of a namespace identifier (which is a UUID) and a name (which is a string).
uuid.**uuid4()**
Generate a random UUID.

uuid.**uuid5(namespace, name)**
Generate a UUID based on the SHA-1 hash of a namespace identifier (which is a UUID) and a name (which is a string).

The **uuid** module defines the following namespace identifiers for use with **uuid3()** or **uuid5()**.

uuid.**NAMESPACE_DNS**
When this namespace is specified, the *name* string is a fully-qualified domain name.

uuid.**NAMESPACE_URL**
When this namespace is specified, the *name* string is a URL.

uuid.**NAMESPACE_OID**
When this namespace is specified, the *name* string is an ISO OID.

uuid.**NAMESPACE_X500**
When this namespace is specified, the *name* string is an X.500 DN in DER or a text output format.

The **uuid** module defines the following constants for the possible values of the **variant** attribute:

uuid.**RESERVED_NCS**
Reserved for NCS compatibility.

uuid.**RFC_4122**
Specifies the UUID layout given in **RFC 4122**.

uuid.**RESERVED_MICROSOFT**
Reserved for Microsoft compatibility.
uuid. RESERVED_FUTURE
   Reserved for future definition.

RFC 4122 - A Universally Unique IDentifier (UUID) URN Namespace
   This specification defines a Uniform Resource Name namespace for UUIDs, the internal format of UUIDs, and methods of generating UUIDs.
20.15.1. Example

Here are some examples of typical usage of the uuid module:

```python
>>> import uuid

# make a UUID based on the host ID and current time
>>> uuid.uuid1()
UUID('a8098c1a-f86e-11da-bd1a-00112444be1e')

# make a UUID using an MD5 hash of a namespace UUID and a name
>>> uuid.uuid3(uuid.NAMESPACE_DNS, 'python.org')
UUID('6fa459ea-ee8a-3ca4-894e-db77e160355e')

# make a random UUID
>>> uuid.uuid4()
UUID('16fd2706-8baf-433b-82eb-8c7fada847da')

# make a UUID using a SHA-1 hash of a namespace UUID and a name
>>> uuid.uuid5(uuid.NAMESPACE_DNS, 'python.org')
UUID('886313e1-3b8a-5372-9b90-0c9aee199e5d')

# make a UUID from a string of hex digits (braces and hyphens ignored)
>>> x = uuid.UUID('{00010203-0405-0607-0809-0a0b0c0d0e0f}')

# convert a UUID to a string of hex digits in standard form
>>> str(x)
'00010203-0405-0607-0809-0a0b0c0d0e0f'

# get the raw 16 bytes of the UUID
>>> x.bytes
'\x00\x01\x02\x03\x04\x05\x06\x07\x08\x09\x0a\x0b\x0c\x0d\x0e\x0f'

# make a UUID from a 16-byte string
>>> uuid.UUID(bytes=x.bytes)
UUID('00010203-0405-0607-0809-0a0b0c0d0e0f')
```
20.16. urlparse — Parse URLs into components

Note: The `urlparse` module is renamed to `urllib.parse` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

This module defines a standard interface to break Uniform Resource Locator (URL) strings up in components (addressing scheme, network location, path etc.), to combine the components back into a URL string, and to convert a “relative URL” to an absolute URL given a “base URL.”

The module has been designed to match the Internet RFC on Relative Uniform Resource Locators (and discovered a bug in an earlier draft!). It supports the following URL schemes: file, ftp, gopher, hdl, http, https, imap, mailto, mms, news, nntp, prospero, rsync, rtsp, rtspu, sftp, shttp, sip, sips, snews, svn, svn+ssh, telnet, wais.

New in version 2.5: Support for the sftp and sips schemes.

See also: Latest version of the `urlparse` module Python source code

The `urlparse` module defines the following functions:

```python
urlparse(urlstring[, scheme[, allow_fragments]])
```

Parse a URL into six components, returning a 6-tuple. This corresponds to the general structure of a URL: `scheme://netloc/path;parameters?query#fragment`. Each tuple item is a string, possibly empty. The components are not broken
up in smaller parts (for example, the network location is a single string), and % escapes are not expanded. The delimiters as shown above are not part of the result, except for a leading slash in the path component, which is retained if present. For example:

```python
>>> from urlparse import urlparse
>>> o = urlparse('http://www.cwi.nl:80/%7Eguido/Python.html')
>>> o  # doctest: +NORMALIZE_WHITESPACE
ParseResult(scheme='http', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html',
            params='', query='', fragment='')
>>> o.scheme
'http'
>>> o.port
80
>>> o.geturl()
'http://www.cwi.nl:80/%7Eguido/Python.html'
```

Following the syntax specifications in RFC 1808, urlparse recognizes a netloc only if it is properly introduced by ‘//’. Otherwise the input is presumed to be a relative URL and thus to start with a path component.

```python
>>> from urlparse import urlparse
>>> urlparse('//www.cwi.nl:80/%7Eguido/Python.html')
ParseResult(scheme='', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html',
            params='', query='', fragment='')
>>> urlparse('www.cwi.nl:80/%7Eguido/Python.html')
ParseResult(scheme='', netloc='', path='www.cwi.nl:80/%7Eguido/Python.html',
            params='', query='', fragment='')
>>> urlparse('help/Python.html')
ParseResult(scheme='', netloc='', path='help/Python.html',
            params='', query='', fragment='')
```

If the scheme argument is specified, it gives the default addressing scheme, to be used only if the URL does not specify one. The default value for this argument is the empty string.

If the allow_fragments argument is false, fragment identifiers are not allowed, even if the URL's addressing scheme normally does
support them. The default value for this argument is `True`.

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheme</td>
<td>0</td>
<td>URL scheme specifier</td>
<td>empty string</td>
</tr>
<tr>
<td>netloc</td>
<td>1</td>
<td>Network location part</td>
<td>empty string</td>
</tr>
<tr>
<td>path</td>
<td>2</td>
<td>Hierarchical path</td>
<td>empty string</td>
</tr>
<tr>
<td>params</td>
<td>3</td>
<td>Parameters for last path element</td>
<td>empty string</td>
</tr>
<tr>
<td>query</td>
<td>4</td>
<td>Query component</td>
<td>empty string</td>
</tr>
<tr>
<td>fragment</td>
<td>5</td>
<td>Fragment identifier</td>
<td>empty string</td>
</tr>
<tr>

<td></td>
<td>User name</td>
<td><code>None</code></td>
</tr>
<tr>
<td>password</td>
<td></td>
<td>Password</td>
<td><code>None</code></td>
</tr>
<tr>
<td>hostname</td>
<td></td>
<td>Host name (lower case)</td>
<td><code>None</code></td>
</tr>
<tr>
<td>port</td>
<td></td>
<td>Port number as integer, if present</td>
<td><code>None</code></td>
</tr>
</tbody>
</table>

See section *Results of `urlparse()` and `urlsplit()`* for more information on the result object.

*Changed in version 2.5:* Added attributes to return value.

*Changed in version 2.7:* Added IPv6 URL parsing capabilities.

```python
tuple.parse_qs(qs[, keep_blank_values[, strict_parsing]])
```

Parse a query string given as a string argument (data of type `application/x-www-form-urlencoded`). Data are returned as a dictionary. The dictionary keys are the unique query variable names and the values are lists of values for each name.
The optional argument `keep_blank_values` is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument `strict_parsing` is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a `ValueError` exception.

Use the `urllib.urlencode()` function to convert such dictionaries into query strings.

*New in version 2.6:* Copied from the `cgi` module.

```python
urlparse.parse_qs(qs[, keep_blank_values[, strict_parsing]])
```

Parse a query string given as a string argument (data of type `application/x-www-form-urlencoded`). Data are returned as a list of name, value pairs.

The optional argument `keep_blank_values` is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument `strict_parsing` is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a `ValueError` exception.

Use the `urllib.urlencode()` function to convert such lists of pairs into query strings.
New in version 2.6: Copied from the `cgi` module.

`urlparse.urlunparse(parts)`
Construct a URL from a tuple as returned by `urlparse()`. The `parts` argument can be any six-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a ? with an empty query; the RFC states that these are equivalent).

`urlparse.urlsplit(urlstring[, scheme[, allow_fragments]])` This is similar to `urlparse()`, but does not split the params from the URL. This should generally be used instead of `urlparse()` if the more recent URL syntax allowing parameters to be applied to each segment of the `path` portion of the URL (see RFC 2396) is wanted. A separate function is needed to separate the path segments and parameters. This function returns a 5-tuple: (addressing scheme, network location, path, query, fragment identifier).

The return value is actually an instance of a subclass of `tuple`. This class has the following additional read-only convenience attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Index</th>
<th>Value</th>
<th>Value if not present</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheme</td>
<td>0</td>
<td>URL scheme specifier</td>
<td>empty string</td>
</tr>
<tr>
<td>netloc</td>
<td>1</td>
<td>Network location part</td>
<td>empty string</td>
</tr>
<tr>
<td>path</td>
<td>2</td>
<td>Hierarchical path</td>
<td>empty string</td>
</tr>
<tr>
<td>query</td>
<td>3</td>
<td>Query component</td>
<td>empty string</td>
</tr>
<tr>
<td>fragment</td>
<td>4</td>
<td>Fragment identifier</td>
<td>empty string</td>
</tr>
<tr>
<td>username</td>
<td></td>
<td>User name</td>
<td><code>None</code></td>
</tr>
<tr>
<td>password</td>
<td></td>
<td>Password</td>
<td><code>None</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Host name (lower</td>
<td></td>
</tr>
</tbody>
</table>
See section *Results of urlparse() and urlsplit()* for more information on the result object.

*New in version 2.2.*

*Changed in version 2.5:* Added attributes to return value.

**urlparse. urlunsplit(parts)**

Combine the elements of a tuple as returned by `urlsplit()` into a complete URL as a string. The `parts` argument can be any five-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a ? with an empty query; the RFC states that these are equivalent).

*New in version 2.2.*

**urlparse. urljoin(base, url[, allow_fragments])**

Construct a full (“absolute”) URL by combining a “base URL” (`base`) with another URL (`url`). Informally, this uses components of the base URL, in particular the addressing scheme, the network location and (part of) the path, to provide missing components in the relative URL. For example:

```python
>>> from urllib.parse import urljoin
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html', 'FAQ.html')
'http://www.cwi.nl/%7Eguido/FAQ.html'
```

The `allow_fragments` argument has the same meaning and default as for `urlparse()`.
Note: If url is an absolute URL (that is, starting with // or scheme://), the url's host name and/or scheme will be present in the result. For example:

```python
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html', ...
    '//www.python.org/%7Eguido')
'http://www.python.org/%7Eguido'
```

If you do not want that behavior, preprocess the url with `urlsplit()` and `urlunsplit()`, removing possible scheme and netloc parts.

`urlparse.urldefrag(url)`

If url contains a fragment identifier, returns a modified version of url with no fragment identifier, and the fragment identifier as a separate string. If there is no fragment identifier in url, returns url unmodified and an empty string.

**RFC 3986 - Uniform Resource Identifiers**

This is the current standard (STD66). Any changes to urlparse module should conform to this. Certain deviations could be observed, which are mostly due backward compatibility purposes and for certain de-facto parsing requirements as commonly observed in major browsers.

**RFC 2732 - Format for Literal IPv6 Addresses in URL's.**

This specifies the parsing requirements of IPv6 URLs.

**RFC 2396 - Uniform Resource Identifiers (URI): Generic Syntax**

Document describing the generic syntactic requirements for both Uniform Resource Names (URNs) and Uniform Resource Locators (URLs).

**RFC 2368 - The mailto URL scheme.**

Parsing requirements for mailto url schemes.
**RFC 1808 - Relative Uniform Resource Locators**

This Request For Comments includes the rules for joining an absolute and a relative URL, including a fair number of “Abnormal Examples” which govern the treatment of border cases.

**RFC 1738 - Uniform Resource Locators (URL)**

This specifies the formal syntax and semantics of absolute URLs.
20.16.1. Results of `urlparse()` and `urlsplit()`

The result objects from the `urlparse()` and `urlsplit()` functions are subclasses of the `tuple` type. These subclasses add the attributes described in those functions, as well as provide an additional method:

```
parse_result.geturl()
```

Return the re-combined version of the original URL as a string. This may differ from the original URL in that the scheme will always be normalized to lower case and empty components may be dropped. Specifically, empty parameters, queries, and fragment identifiers will be removed.

The result of this method is a fixpoint if passed back through the original parsing function:

```
>>> import urlparse
>>> url = 'HTTP://www.Python.org/doc/#'

>>> r1 = urlparse.urlsplit(url)
>>> r1.geturl()
'http://www.Python.org/doc/'

>>> r2 = urlparse.urlsplit(r1.geturl())
>>> r2.geturl()
'http://www.Python.org/doc/'
```

New in version 2.5.

The following classes provide the implementations of the parse results:

```
class urlparse.BaseResult
```

Base class for the concrete result classes. This provides most of
the attribute definitions. It does not provide a `geturl()` method. It is derived from `tuple`, but does not override the `_init__()` or `_new__()` methods.

```python
class urlparse.ParseResult(scheme, netloc, path, params, query, fragment)
```
Concrete class for `urlparse()` results. The `_new__()` method is overridden to support checking that the right number of arguments are passed.

```python
class urlparse.SplitResult(scheme, netloc, path, query, fragment)
```
Concrete class for `urlsplit()` results. The `_new__()` method is overridden to support checking that the right number of arguments are passed.
The **SocketServer** module has been renamed to **socketserver** in Python 3.0. The **2to3** tool will automatically adapt imports when converting your sources to 3.0.

The **SocketServer** module simplifies the task of writing network servers.

There are four basic server classes: **TCPServer** uses the Internet TCP protocol, which provides for continuous streams of data between the client and server. **UDPServer** uses datagrams, which are discrete packets of information that may arrive out of order or be lost while in transit. The more infrequently used **UnixStreamServer** and **UnixDatagramServer** classes are similar, but use Unix domain sockets; they're not available on non-Unix platforms. For more details on network programming, consult a book such as W. Richard Steven's UNIX Network Programming or Ralph Davis's Win32 Network Programming.

These four classes process requests *synchronously*; each request must be completed before the next request can be started. This isn't suitable if each request takes a long time to complete, because it requires a lot of computation, or because it returns a lot of data which the client is slow to process. The solution is to create a separate process or thread to handle each request; the **ForkingMixIn** and **ThreadingMixIn** mix-in classes can be used to support asynchronous behaviour.

Creating a server requires several steps. First, you must create a request handler class by subclassing the **BaseRequestHandler** class...
and overriding its `handle()` method; this method will process incoming requests. Second, you must instantiate one of the server classes, passing it the server’s address and the request handler class. Finally, call the `handle_request()` or `serve_forever()` method of the server object to process one or many requests.

When inheriting from `ThreadingMixIn` for threaded connection behavior, you should explicitly declare how you want your threads to behave on an abrupt shutdown. The `ThreadingMixIn` class defines an attribute `daemon_threads`, which indicates whether or not the server should wait for thread termination. You should set the flag explicitly if you would like threads to behave autonomously; the default is `False`, meaning that Python will not exit until all threads created by `ThreadingMixIn` have exited.

Server classes have the same external methods and attributes, no matter what network protocol they use.
There are five classes in an inheritance diagram, four of which represent synchronous servers of four types:

```
+------------+
| BaseServer |
+------------+
     v
+-----------+ +------------------+
| TCPServer |------->| UnixStreamServer |
+-----------+ +------------------+
     v
+-----------+ +--------------------+
| UDPServer |------->| UnixDatagramServer |
+-----------+ +--------------------+
```

Note that `UnixDatagramServer` derives from `UDPServer`, not from `UnixStreamServer` — the only difference between an IP and a Unix stream server is the address family, which is simply repeated in both Unix server classes.

Forking and threading versions of each type of server can be created using the `ForkingMixIn` and `ThreadingMixIn` mix-in classes. For instance, a threading UDP server class is created as follows:

```python
class ThreadingUDPServer(ThreadingMixIn, UDPServer): pass
```

The mix-in class must come first, since it overrides a method defined in `UDPServer`. Setting the various member variables also changes the behavior of the underlying server mechanism.

To implement a service, you must derive a class from `BaseRequestHandler` and redefine its `handle()` method. You can then
run various versions of the service by combining one of the server classes with your request handler class. The request handler class must be different for datagram or stream services. This can be hidden by using the handler subclasses StreamRequestHandler or DatagramRequestHandler.

Of course, you still have to use your head! For instance, it makes no sense to use a forking server if the service contains state in memory that can be modified by different requests, since the modifications in the child process would never reach the initial state kept in the parent process and passed to each child. In this case, you can use a threading server, but you will probably have to use locks to protect the integrity of the shared data.

On the other hand, if you are building an HTTP server where all data is stored externally (for instance, in the file system), a synchronous class will essentially render the service “deaf” while one request is being handled – which may be for a very long time if a client is slow to receive all the data it has requested. Here a threading or forking server is appropriate.

In some cases, it may be appropriate to process part of a request synchronously, but to finish processing in a forked child depending on the request data. This can be implemented by using a synchronous server and doing an explicit fork in the request handler class handle() method.

Another approach to handling multiple simultaneous requests in an environment that supports neither threads nor fork() (or where these are too expensive or inappropriate for the service) is to maintain an explicit table of partially finished requests and to use select() to decide which request to work on next (or whether to handle a new incoming request). This is particularly important for stream services where each client can potentially be connected for a
long time (if threads or subprocesses cannot be used). See asyncore for another way to manage this.
20.17.2. Server Objects

```
class SocketServer.BaseServer
    This is the superclass of all Server objects in the module. It defines the interface, given below, but does not implement most of the methods, which is done in subclasses.

BaseServer.fileno()
    Return an integer file descriptor for the socket on which the server is listening. This function is most commonly passed to select.select(), to allow monitoring multiple servers in the same process.

BaseServer.handle_request()
    Process a single request. This function calls the following methods in order: get_request(), verify_request(), and process_request(). If the user-provided handle() method of the handler class raises an exception, the server’s handle_error() method will be called. If no request is received within self.timeout seconds, handle_timeout() will be called and handle_request() will return.

BaseServer.serve_forever(poll_interval=0.5)
    Handle requests until an explicit shutdown() request. Polls for shutdown every poll_interval seconds.

BaseServer.shutdown()
    Tells the serve_forever() loop to stop and waits until it does.

New in version 2.6.

BaseServer.address_family
    The family of protocols to which the server’s socket belongs.
```
Common examples are `socket.AF_INET` and `socket.AF_UNIX`.

**BaseServer.**`RequestHandlerClass`  
The user-provided request handler class; an instance of this class is created for each request.

**BaseServer.**`server_address`  
The address on which the server is listening. The format of addresses varies depending on the protocol family; see the documentation for the socket module for details. For Internet protocols, this is a tuple containing a string giving the address, and an integer port number: (`'127.0.0.1', 80`), for example.

**BaseServer.**`socket`  
The socket object on which the server will listen for incoming requests.

The server classes support the following class variables:

**BaseServer.**`allow_reuse_address`  
Whether the server will allow the reuse of an address. This defaults to `False`, and can be set in subclasses to change the policy.

**BaseServer.**`request_queue_size`  
The size of the request queue. If it takes a long time to process a single request, any requests that arrive while the server is busy are placed into a queue, up to `request_queue_size` requests. Once the queue is full, further requests from clients will get a "Connection denied" error. The default value is usually 5, but this can be overridden by subclasses.

**BaseServer.**`socket_type`  
The type of socket used by the server; `socket.SOCK_STREAM` and `socket.SOCK_DGRAM` are two common values.
**BaseServer.**timeout

Timeout duration, measured in seconds, or None if no timeout is desired. If handle_request() receives no incoming requests within the timeout period, the handle_timeout() method is called.

There are various server methods that can be overridden by subclasses of base server classes like TCPServer; these methods aren't useful to external users of the server object.

**BaseServer.**finish_request()

Actually processes the request by instantiating RequestHandlerClass and calling its handle() method.

**BaseServer.**get_request()

Must accept a request from the socket, and return a 2-tuple containing the new socket object to be used to communicate with the client, and the client's address.

**BaseServer.**handle_error(request, client_address)

This function is called if the RequestHandlerClass's handle() method raises an exception. The default action is to print the traceback to standard output and continue handling further requests.

**BaseServer.**handle_timeout()

This function is called when the timeout attribute has been set to a value other than None and the timeout period has passed with no requests being received. The default action for forking servers is to collect the status of any child processes that have exited, while in threading servers this method does nothing.

**BaseServer.**process_request(request, client_address)

Calls finish_request() to create an instance of the RequestHandlerClass. If desired, this function can create a new
process or thread to handle the request; the `ForkingMixIn` and `ThreadingMixIn` classes do this.

**BaseServer**. `server_activate()`  
Called by the server’s constructor to activate the server. The default behavior just `listen()`s to the server’s socket. May be overridden.

**BaseServer**. `server_bind()`  
Called by the server’s constructor to bind the socket to the desired address. May be overridden.

**BaseServer**. `verify_request(request, client_address)`  
Must return a Boolean value; if the value is `True`, the request will be processed, and if it’s `False`, the request will be denied. This function can be overridden to implement access controls for a server. The default implementation always returns `True`. 
20.17.3. RequestHandler Objects

The request handler class must define a new `handle()` method, and can override any of the following methods. A new instance is created for each request.

RequestHandler. `finish()`

Called after the `handle()` method to perform any clean-up actions required. The default implementation does nothing. If `setup()` or `handle()` raise an exception, this function will not be called.

RequestHandler. `handle()`

This function must do all the work required to service a request. The default implementation does nothing. Several instance attributes are available to it; the request is available as `self.request`; the client address as `self.client_address`; and the server instance as `self.server`, in case it needs access to per-server information.

The type of `self.request` is different for datagram or stream services. For stream services, `self.request` is a socket object; for datagram services, `self.request` is a pair of string and socket. However, this can be hidden by using the request handler subclasses `StreamRequestHandler` or `DatagramRequestHandler`, which override the `setup()` and `finish()` methods, and provide `self.rfile` and `self.wfile` attributes. `self.rfile` and `self.wfile` can be read or written, respectively, to get the request data or return data to the client.

RequestHandler. `setup()`

Called before the `handle()` method to perform any initialization actions required. The default implementation does nothing.
20.17.4. Examples

20.17.4.1. **SocketServer.TCPServer** Example

This is the server side:

```python
import SocketServer

class MyTCPHandler(SocketServer.BaseRequestHandler):
    """
    The RequestHandler class for our server.

    It is instantiated once per connection to the server, and m
    override the handle() method to implement communication to
    client.
    """

    def handle(self):
        # self.request is the TCP socket connected to the client
        self.data = self.request.recv(1024).strip()
        print '"%s wrote:" % self.client_address[0]
        print self.data
        # just send back the same data, but upper-cased
        self.request.send(self.data.upper())

if __name__ == '__main__':
    HOST, PORT = "localhost", 9999

    # Create the server, binding to localhost on port 9999
    server = SocketServer.TCPServer((HOST, PORT), MyTCPHandler)

    # Activate the server; this will keep running until you
    # interrupt the program with Ctrl-C
    server.serve_forever()
```

An alternative request handler class that makes use of streams (file-like objects that simplify communication by providing the standard file interface):

```python
class MyTCPHandler(SocketServer.StreamRequestHandler):
```
def handle(self):
    # self.rfile is a file-like object created by the handler;
    # we can now use e.g. readline() instead of raw recv()
    self.data = self.rfile.readline().strip()
    print "%s wrote:" % self.client_address[0]
    print self.data
    # Likewise, self.wfile is a file-like object used to write
    # to the client
    self.wfile.write(self.data.upper())

The difference is that the readline() call in the second handler will call recv() multiple times until it encounters a newline character, while the single recv() call in the first handler will just return what has been sent from the client in one send() call.

This is the client side:

```python
import socket
import sys

HOST, PORT = "localhost", 9999
data = ".".join(sys.argv[1:])

# Create a socket (SOCK_STREAM means a TCP socket)
sock = socket.socket(socket.AF_INET, socket.SOCK_STREAM)

# Connect to server and send data
sock.connect((HOST, PORT))
sock.send(data + "\n")

# Receive data from the server and shut down
received = sock.recv(1024)
sock.close()

print "Sent: %s" % data
print "Received: %s" % received
```

The output of the example should look something like this:

Server:
$ python TCPServer.py
127.0.0.1 wrote:
hello world with TCP
127.0.0.1 wrote:
python is nice

Client:

$ python TCPClient.py hello world with TCP
Sent: hello world with TCP
Received: HELLO WORLD WITH TCP
$ python TCPClient.py python is nice
Sent: python is nice
Received: PYTHON IS NICE

20.17.4.2. **SocketServer.UDPServer** Example

This is the server side:

```python
import SocketServer

class MyUDPHandler(SocketServer.BaseRequestHandler):
    """
    This class works similar to the TCP handler class, except that
    self.request consists of a pair of data and client socket, and
    since there is no connection the client address must be given explicitly
    when sending data back via sendto().
    """

    def handle(self):
        data = self.request[0].strip()
        socket = self.request[1]
        print "%s wrote:" % self.client_address[0]
        print data
        socket.sendto(data.upper(), self.client_address)

if __name__ == "__main__":
    HOST, PORT = "localhost", 9999
    server = SocketServer.UDPServer((HOST, PORT), MyUDPHandler)
    server.serve_forever()
```

This is the client side:
import socket
import sys

HOST, PORT = "localhost", 9999
data = " ".join(sys.argv[1:]):

# SOCK_DGRAM is the socket type to use for UDP sockets
sock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)

# As you can see, there is no connect() call; UDP has no connections.
# Instead, data is directly sent to the recipient via sendto().
sock.sendto(data + "\n", (HOST, PORT))
received = sock.recv(1024)

print "Sent: %s" % data
print "Received: %s" % received

The output of the example should look exactly like for the TCP server example.

20.17.4.3. Asynchronous Mixins

To build asynchronous handlers, use the ThreadingMixIn and ForkingMixIn classes.

An example for the ThreadingMixIn class:

import socket
import threading
import SocketServer

class ThreadedTCPRequestHandler(SocketServer.BaseRequestHandler):
    def handle(self):
        data = self.request.recv(1024)
        cur_thread = threading.currentThread()
        response = "%s: %s" % (cur_thread.getName(), data)
        self.request.send(response)

class ThreadedTCPServer(SocketServer.ThreadingMixIn, SocketServer.TCPServer):
    pass
```python
def client(ip, port, message):
    sock = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
    sock.connect((ip, port))
    sock.send(message)
    response = sock.recv(1024)
    print "Received: %s" % response
    sock.close()

if __name__ == '__main__':
    # Port 0 means to select an arbitrary unused port
    HOST, PORT = "localhost", 0

    server = ThreadedTCPServer((HOST, PORT), ThreadedTCPRequestHandler)
    ip, port = server.server_address

    # Start a thread with the server -- that thread will then start
    # more thread for each request
    server_thread = threading.Thread(target=server.serve_forever)
    # Exit the server thread when the main thread terminates
    server_thread.setDaemon(True)
    server_thread.start()
    print "Server loop running in thread:", server_thread.getName()

    client(ip, port, "Hello World 1")
    client(ip, port, "Hello World 2")
    client(ip, port, "Hello World 3")

    server.shutdown()
```

The output of the example should look something like this:

```
$ python ThreadedTCPServer.py
Server loop running in thread: Thread-1
Received: Thread-2: Hello World 1
Received: Thread-3: Hello World 2
Received: Thread-4: Hello World 3
```

The `ForkingMixIn` class is used in the same way, except that the server will spawn a new process for each request.
20.18. BaseHTTPServer — Basic HTTP server

**Note:** The `BaseHTTPServer` module has been merged into `http.server` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

This module defines two classes for implementing HTTP servers (Web servers). Usually, this module isn’t used directly, but is used as a basis for building functioning Web servers. See the `SimpleHTTPServer` and `CGIHTTPServer` modules.

The first class, `HTTPServer`, is a `SocketServer.TCPServer` subclass, and therefore implements the `SocketServer.BaseServer` interface. It creates and listens at the HTTP socket, dispatching the requests to a handler. Code to create and run the server looks like this:

```python
def run(server_class=BaseHTTPServer.HTTPServer, handler_class=BaseHTTPServer.BaseHTTPRequestHandler):
    server_address = ('', 8000)
    httpd = server_class(server_address, handler_class)
    httpd.serve_forever()
```

```python
class BaseHTTPServer.HTTPServer(server_address, RequestHandlerClass)
```

This class builds on the `TCPServer` class by storing the server address as instance variables named `server_name` and `server_port`. The server is accessible by the handler, typically through the handler’s `server` instance variable.

```python
class BaseHTTPServer.BaseHTTPRequestHandler(request, client_address, server)
```

This class is used to handle the HTTP requests that arrive at the
server. By itself, it cannot respond to any actual HTTP requests; it must be subclassed to handle each request method (e.g. GET or POST). **BaseHTTPRequestHandler** provides a number of class and instance variables, and methods for use by subclasses.

The handler will parse the request and the headers, then call a method specific to the request type. The method name is constructed from the request. For example, for the request method **SPAM**, the **do_SPAM()** method will be called with no arguments. All of the relevant information is stored in instance variables of the handler. Subclasses should not need to override or extend the **__init__()** method.

**BaseHTTPRequestHandler** has the following instance variables:

**client_address**
Contains a tuple of the form (host, port) referring to the client’s address.

**server**
Contains the server instance.

**command**
Contains the command (request type). For example, 'GET'.

**path**
Contains the request path.

**request_version**
Contains the version string from the request. For example, 'HTTP/1.0'.

**headers**
Holds an instance of the class specified by the **MessageClass** class variable. This instance parses and manages the headers in the HTTP request.
rfile
Contains an input stream, positioned at the start of the optional input data.

wfile
Contains the output stream for writing a response back to the client. Proper adherence to the HTTP protocol must be used when writing to this stream.

BaseHTTPRequestHandler has the following class variables:

server_version
Specifies the server software version. You may want to override this. The format is multiple whitespace-separated strings, where each string is of the form name[/version]. For example, 'BaseHTTP/0.2'.

sys_version
Contains the Python system version, in a form usable by the version_string method and the server_version class variable. For example, 'Python/1.4'.

error_message_format
Specifies a format string for building an error response to the client. It uses parenthesized, keyed format specifiers, so the format operand must be a dictionary. The code key should be an integer, specifying the numeric HTTP error code value. message should be a string containing a (detailed) error message of what occurred, and explain should be an explanation of the error code number. Default message and explain values can found in the responses class variable.

error_content_type
Specifies the Content-Type HTTP header of error responses sent to the client. The default value is 'text/html'.

New in version 2.6: Previously, the content type was always
protocol_version

This specifies the HTTP protocol version used in responses. If set to 'HTTP/1.1', the server will permit HTTP persistent connections; however, your server must then include an accurate Content-Length header (using send_header()) in all of its responses to clients. For backwards compatibility, the setting defaults to 'HTTP/1.0'.

MessageClass

Specifies a rfc822.Message-like class to parse HTTP headers. Typically, this is not overridden, and it defaults to mimetools.Message.

responses

This variable contains a mapping of error code integers to two-element tuples containing a short and long message. For example, {code: (shortmessage, longmessage)}. The shortmessage is usually used as the message key in an error response, and longmessage as the explain key (see the error_message_format class variable).

A BaseHTTPRequestHandler instance has the following methods:

handle()

Calls handle_one_request() once (or, if persistent connections are enabled, multiple times) to handle incoming HTTP requests. You should never need to override it; instead, implement appropriate do_*() methods.

handle_one_request()

This method will parse and dispatch the request to the appropriate do_*() method. You should never need to override it.
**send_error**(*code*, *message*)
Sends and logs a complete error reply to the client. The numeric *code* specifies the HTTP error code, with *message* as optional, more specific text. A complete set of headers is sent, followed by text composed using the `error_message_format` class variable.

**send_response**(*code*, *message*)
Sends a response header and logs the accepted request. The HTTP response line is sent, followed by *Server* and *Date* headers. The values for these two headers are picked up from the `version_string()` and `date_time_string()` methods, respectively.

**send_header**(*keyword*, *value*)
Writes a specific HTTP header to the output stream. *keyword* should specify the header keyword, with *value* specifying its value.

**end_headers**()
Sends a blank line, indicating the end of the HTTP headers in the response.

**log_request**(*code*, *size*)
Logs an accepted (successful) request. *code* should specify the numeric HTTP code associated with the response. If a size of the response is available, then it should be passed as the *size* parameter.

**log_error**(...)
Logs an error when a request cannot be fulfilled. By default, it passes the message to `log_message()`, so it takes the same arguments (*format* and additional values).

**log_message**(*format*, ...)
Logs an arbitrary message to `sys.stderr`. This is typically overridden to create custom error logging mechanisms. The `format` argument is a standard printf-style format string, where the additional arguments to `log_message()` are applied as inputs to the formatting. The client address and current date and time are prefixed to every message logged.

---

**version_string()**

Returns the server software's version string. This is a combination of the `server_version` and `sys_version` class variables.

**date_time_string([timestamp])**

Returns the date and time given by `timestamp` (which must be in the format returned by `time.time()`), formatted for a message header. If `timestamp` is omitted, it uses the current date and time.

The result looks like 'Sun, 06 Nov 1994 08:49:37 GMT'.

*New in version 2.5:* The `timestamp` parameter.

**log_date_time_string()**

Returns the current date and time, formatted for logging.

**address_string()**

Returns the client address, formatted for logging. A name lookup is performed on the client's IP address.
20.18.1. More examples

To create a server that doesn't run forever, but until some condition is fulfilled:

```python
def run_while_true(server_class=BaseHTTPServer.HTTPServer,
                   handler_class=BaseHTTPServer.BaseHTTPRequestHandler):
    """
    This assumes that keep_running() is a function of no arguments
    is tested initially and after each request. If its return
    is true, the server continues.
    """
    server_address = ('', 8000)
    httpd = server_class(server_address, handler_class)
    while keep_running():
        httpd.handle_request()
```

**Module CGIHTTPServer**
Extended request handler that supports CGI scripts.

**Module SimpleHTTPServer**
Basic request handler that limits response to files actually under the document root.
20.19. SimpleHTTPServer — Simple HTTP request handler

Note: The SimpleHTTPServer module has been merged into http.server in Python 3.0. The 2to3 tool will automatically adapt imports when converting your sources to 3.0.

The SimpleHTTPServer module defines a single class, SimpleHTTPRequestHandler, which is interface-compatible with BaseHTTPServer.BaseHTTPRequestHandler.

The SimpleHTTPServer module defines the following class:

```python
class SimpleHTTPServer.SimpleHTTPRequestHandler(request, client_address, server)
```

This class serves files from the current directory and below, directly mapping the directory structure to HTTP requests.

A lot of the work, such as parsing the request, is done by the base class BaseHTTPServer.BaseHTTPRequestHandler. This class implements the do_GET() and do_HEAD() functions.

The following are defined as class-level attributes of SimpleHTTPRequestHandler:

- **server_version**
  
  This will be "SimpleHTTP/" + __version__, where __version__ is defined at the module level.

- **extensions_map**
  
  A dictionary mapping suffixes into MIME types. The default is signified by an empty string, and is considered to be
application/octet-stream. The mapping is used case-insensitively, and so should contain only lower-cased keys.

The SimpleHTTPRequestHandler class defines the following methods:

**do_HEAD()**
This method serves the 'HEAD' request type: it sends the headers it would send for the equivalent GET request. See the do_GET() method for a more complete explanation of the possible headers.

**do_GET()**
The request is mapped to a local file by interpreting the request as a path relative to the current working directory.

If the request was mapped to a directory, the directory is checked for a file named `index.html` or `index.htm` (in that order). If found, the file's contents are returned; otherwise a directory listing is generated by calling the list_directory() method. This method uses os.listdir() to scan the directory, and returns a 404 error response if the listdir() fails.

If the request was mapped to a file, it is opened and the contents are returned. Any IOError exception in opening the requested file is mapped to a 404, 'File not found' error. Otherwise, the content type is guessed by calling the guess_type() method, which in turn uses the extensions_map variable.

A 'Content-type:' header with the guessed content type is output, followed by a 'Content-Length:' header with the file's size and a 'Last-Modified:' header with the file's modification time.
Then follows a blank line signifying the end of the headers, and then the contents of the file are output. If the file’s MIME type starts with text/ the file is opened in text mode; otherwise binary mode is used.

The test() function in the SimpleHTTPServer module is an example which creates a server using the SimpleHTTPRequestHandler as the Handler.

*New in version 2.5:* The 'Last-Modified' header.

The SimpleHTTPServer module can be used in the following manner in order to set up a very basic web server serving files relative to the current directory.

```python
import SimpleHTTPServer
import SocketServer

PORT = 8000

Handler = SimpleHTTPServer.SimpleHTTPRequestHandler

httpd = SocketServer.TCPServer(('', PORT), Handler)

print "serving at port", PORT
httpd.serve_forever()
```

The SimpleHTTPServer module can also be invoked directly using the -m switch of the interpreter with a port number argument. Similar to the previous example, this serves the files relative to the current directory.

```bash
python -m SimpleHTTPServer 8000
```

Module BaseHTTPServer
Base class implementation for Web server and request handler.
20.20. **CGIHTTPServer — CGI-capable HTTP request handler**

**Note:** The **CGIHTTPServer** module has been merged into **http.server** in Python 3.0. The **2to3** tool will automatically adapt imports when converting your sources to 3.0.

The **CGIHTTPServer** module defines a request-handler class, interface compatible with **BaseHTTPServer.BaseHTTPRequestHandler** and inherits behavior from **SimpleHTTPServer.SimpleHTTPRequestHandler** but can also run CGI scripts.

**Note:** This module can run CGI scripts on Unix and Windows systems.

**Note:** CGI scripts run by the **CGIHTTPRequestHandler** class cannot execute redirects (HTTP code 302), because code 200 (script output follows) is sent prior to execution of the CGI script. This pre-empts the status code.

The **CGIHTTPServer** module defines the following class:

```
class CGIHTTPServer.CGIHTTPRequestHandler(request, client_address, server)
```

This class is used to serve either files or output of CGI scripts from the current directory and below. Note that mapping HTTP hierarchic structure to local directory structure is exactly as in **SimpleHTTPServer.SimpleHTTPRequestHandler**.

The class will however, run the CGI script, instead of serving it as a file, if it guesses it to be a CGI script. Only directory-based CGI are used — the other common server configuration is to treat
special extensions as denoting CGI scripts.

The `do_GET()` and `do_HEAD()` functions are modified to run CGI scripts and serve the output, instead of serving files, if the request leads to somewhere below the `cgi_directories` path.

The `CGIHTTPRequestHandler` defines the following data member:

- **cgi_directories**
  
  This defaults to `['/cgi-bin', '/htbin']` and describes directories to treat as containing CGI scripts.

The `CGIHTTPRequestHandler` defines the following methods:

- **do_POST()**
  
  This method serves the `POST` request type, only allowed for CGI scripts. Error 501, “Can only POST to CGI scripts”, is output when trying to POST to a non-CGI url.

Note that CGI scripts will be run with UID of user nobody, for security reasons. Problems with the CGI script will be translated to error 403.

For example usage, see the implementation of the `test()` function.

---

### See also:

- **Module BaseHTTPServer**
  
  Base class implementation for Web server and request handler.
20.21. `cookielib` — Cookie handling for HTTP clients

**Note:** The `cookielib` module has been renamed to `http.cookiejar` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

*N ew in version 2.4.*

The `cookielib` module defines classes for automatic handling of HTTP cookies. It is useful for accessing web sites that require small pieces of data – *cookies* – to be set on the client machine by an HTTP response from a web server, and then returned to the server in later HTTP requests.

Both the regular Netscape cookie protocol and the protocol defined by [RFC 2965](https://tools.ietf.org/html/rfc2965) are handled. RFC 2965 handling is switched off by default. [RFC 2109](https://tools.ietf.org/html/rfc2109) cookies are parsed as Netscape cookies and subsequently treated either as Netscape or RFC 2965 cookies according to the ‘policy’ in effect. Note that the great majority of cookies on the Internet are Netscape cookies. `cookielib` attempts to follow the de-facto Netscape cookie protocol (which differs substantially from that set out in the original Netscape specification), including taking note of the *max-age* and *port* cookie-attributes introduced with RFC 2965.

**Note:** The various named parameters found in `Set-Cookie` and `Set-Cookie2` headers (eg. *domain* and *expires*) are conventionally referred to as *attributes*. To distinguish them from Python attributes, the documentation for this module uses the term *cookie-attribute* instead.
The module defines the following exception:

```python
exception cookielib.LoadError
    Instances of FileCookieJar raise this exception on failure to load cookies from a file.
```

Note: For backwards-compatibility with Python 2.4 (which raised an IOError), LoadError is a subclass of IOError.

The following classes are provided:

```python
class cookielib.CookieJar(policy=None)
    policy is an object implementing the CookiePolicy interface.

    The CookieJar class stores HTTP cookies. It extracts cookies from HTTP requests, and returns them in HTTP responses. CookieJar instances automatically expire contained cookies when necessary. Subclasses are also responsible for storing and retrieving cookies from a file or database.
```

```python
class cookielib.FileCookieJar(filename, delayload=None, policy=None)
    policy is an object implementing the CookiePolicy interface. For the other arguments, see the documentation for the corresponding attributes.

    A CookieJar which can load cookies from, and perhaps save cookies to, a file on disk. Cookies are NOT loaded from the named file until either the load() or revert() method is called. Subclasses of this class are documented in section FileCookieJar subclasses and co-operation with web browsers.
```

```python
class cookielib.CookiePolicy
    This class is responsible for deciding whether each cookie should
be accepted from / returned to the server.

```python
class cookielib.DefaultCookiePolicy(blocked_domains=None, allowed_domains=None, netscape=True, rfc2965=False, rfc2109_as_netscape=None, hide_cookie2=False, strict_domain=False, strict_rfc2965_unverifiable=True, strict_ns_unverifiable=False, strict_ns_domain=DefaultCookiePolicy.DomainLiberal, strict_ns_set_initial_dollar=False, strict_ns_set_path=False)
```

Constructor arguments should be passed as keyword arguments only. `blocked_domains` is a sequence of domain names that we never accept cookies from, nor return cookies to. `allowed_domains` if not `None`, this is a sequence of the only domains for which we accept and return cookies. For all other arguments, see the documentation for `CookiePolicy` and `DefaultCookiePolicy` objects.

`DefaultCookiePolicy` implements the standard accept / reject rules for Netscape and RFC 2965 cookies. By default, RFC 2109 cookies (ie. cookies received in a `Set-Cookie` header with a version cookie-attribute of 1) are treated according to the RFC 2965 rules. However, if RFC 2965 handling is turned off or `rfc2109_as_netscape` is True, RFC 2109 cookies are 'downgraded' by the `CookieJar` instance to Netscape cookies, by setting the `version` attribute of the `Cookie` instance to 0. `DefaultCookiePolicy` also provides some parameters to allow some fine-tuning of policy.

```python
class cookielib.Cookie
```

This class represents Netscape, RFC 2109 and RFC 2965 cookies. It is not expected that users of `cookielib` construct their own `Cookie` instances. Instead, if necessary, call `make_cookies()` on a `CookieJar` instance.
See also:

Module urllib2
URL opening with automatic cookie handling.

Module Cookie
HTTP cookie classes, principally useful for server-side code. The cookielib and Cookie modules do not depend on each other.

http://wp.netscape.com/newsref/std/cookie_spec.html
The specification of the original Netscape cookie protocol. Though this is still the dominant protocol, the ‘Netscape cookie protocol’ implemented by all the major browsers (and cookielib) only bears a passing resemblance to the one sketched out in cookie_spec.html.

RFC 2109 - HTTP State Management Mechanism
Obsoleted by RFC 2965. Uses Set-Cookie with version=1.

RFC 2965 - HTTP State Management Mechanism
The Netscape protocol with the bugs fixed. Uses Set-Cookie2 in place of Set-Cookie. Not widely used.

http://kristol.org/cookie/errata.html
Unfinished errata to RFC 2965.

RFC 2964 - Use of HTTP State Management

CookieJar objects support the iterator protocol for iterating over contained Cookie objects.

CookieJar has the following methods:

CookieJar.add_cookie_header(request)
Add correct Cookie header to request.

If policy allows (ie. the rfc2965 and hide_cookie2 attributes of the CookieJar's CookiePolicy instance are true and false respectively), the Cookie2 header is also added when appropriate.

The request object (usually a urllib2.Request instance) must support the methods get_full_url(), get_host(), get_type(), unverifiable(), get_origin_req_host(), has_header(), get_header(), header_items(), and add_unredirected_header(), as documented by urllib2.

CookieJar.extract_cookies(response, request)
Extract cookies from HTTP response and store them in the CookieJar, where allowed by policy.

The CookieJar will look for allowable Set-Cookie and Set-Cookie2 headers in the response argument, and store cookies as appropriate (subject to the CookiePolicy.set_ok() method's approval).

The response object (usually the result of a call to
`urllib2.urlopen()`, or similar) should support an `info()` method, which returns an object with a `getallmatchingheaders()` method (usually a `mimetypes.Message` instance).

The `request` object (usually a `urllib2.Request` instance) must support the methods `get_full_url()`, `get_host()`, `unverifiable()`, and `get_origin_req_host()`, as documented by `urllib2`. The request is used to set default values for cookie-attributes as well as for checking that the cookie is allowed to be set.

CookieJar. **set_policy**(policy)
Set the `CookiePolicy` instance to be used.

CookieJar. **make_cookies**(response, request)
Return sequence of `Cookie` objects extracted from `response` object.

See the documentation for `extract_cookies()` for the interfaces required of the `response` and `request` arguments.

CookieJar. **set_cookie_if_ok**(cookie, request)
Set a `Cookie` if policy says it's OK to do so.

CookieJar. **set_cookie**(cookie)
Set a `Cookie`, without checking with policy to see whether or not it should be set.

CookieJar. **clear**(domain[, path[, name]])
Clear some cookies.

If invoked without arguments, clear all cookies. If given a single argument, only cookies belonging to that `domain` will be removed. If given two arguments, cookies belonging to the specified
domain and URL path are removed. If given three arguments, then the cookie with the specified domain, path and name is removed.

Raises KeyError if no matching cookie exists.

CookieJar.clear_session_cookies()
Discard all session cookies.

Discards all contained cookies that have a true discard attribute (usually because they had either no max-age or expires cookie-attribute, or an explicit discard cookie-attribute). For interactive browsers, the end of a session usually corresponds to closing the browser window.

Note that the save() method won’t save session cookies anyway, unless you ask otherwise by passing a true ignore_discard argument.

FileCookieJar implements the following additional methods:

FileCookieJar.save(filename=None, ignore_discard=False, ignore.expires=False)
Save cookies to a file.

This base class raises NotImplementedError. Subclasses may leave this method unimplemented.

filename is the name of file in which to save cookies. If filename is not specified, self.filename is used (whose default is the value passed to the constructor, if any); if self.filename is None, ValueError is raised.

ignore_discard: save even cookies set to be discarded. ignore.expires: save even cookies that have expired
The file is overwritten if it already exists, thus wiping all the cookies it contains. Saved cookies can be restored later using the load() or revert() methods.

FileCookieJar.load(filename=None, ignore_discard=False, ignore_expires=False)

Load cookies from a file.

Old cookies are kept unless overwritten by newly loaded ones.

Arguments are as for save().

The named file must be in the format understood by the class, or LoadError will be raised. Also, IOError may be raised, for example if the file does not exist.

**Note:** For backwards-compatibility with Python 2.4 (which raised an IOError), LoadError is a subclass of IOError.

FileCookieJar.revert(filename=None, ignore_discard=False, ignore_expires=False)

Clear all cookies and reload cookies from a saved file.

revert() can raise the same exceptions as load(). If there is a failure, the object’s state will not be altered.

FileCookieJar instances have the following public attributes:

FileCookieJar.filename

Filename of default file in which to keep cookies. This attribute may be assigned to.

FileCookieJar.delayload

If true, load cookies lazily from disk. This attribute should not be assigned to. This is only a hint, since this only affects
performance, not behaviour (unless the cookies on disk are changing). A CookieJar object may ignore it. None of the FileCookieJar classes included in the standard library lazily loads cookies.
20.21.2. FileCookieJar subclasses and cooperation with web browsers

The following CookieJar subclasses are provided for reading and writing.

```python
class cookielib.MozillaCookieJar(filename, delayload=None, policy=None)
```

A FileCookieJar that can load from and save cookies to disk in the Mozilla cookies.txt file format (which is also used by the Lynx and Netscape browsers).

**Note:** Version 3 of the Firefox web browser no longer writes cookies in the cookies.txt file format.

**Note:** This loses information about RFC 2965 cookies, and also about newer or non-standard cookie-attributes such as `port`.

**Warning:** Back up your cookies before saving if you have cookies whose loss / corruption would be inconvenient (there are some subtleties which may lead to slight changes in the file over a load / save round-trip).

Also note that cookies saved while Mozilla is running will get clobbered by Mozilla.

```python
class cookielib.LWPCookieJar(filename, delayload=None, policy=None)
```

A FileCookieJar that can load from and save cookies to disk in format compatible with the libwww-perl library’s `Set-Cookie3` file format. This is convenient if you want to store cookies in a
human-readable file.
20.21.3. CookiePolicy Objects

Objects implementing the `CookiePolicy` interface have the following methods:

CookiePolicy. **set_ok**(cookie, request)

Return boolean value indicating whether cookie should be accepted from server.

*cookie* is a `cookielib.Cookie` instance. *request* is an object implementing the interface defined by the documentation for `CookieJar.extract_cookies()`.

CookiePolicy. **return_ok**(cookie, request)

Return boolean value indicating whether cookie should be returned to server.

*cookie* is a `cookielib.Cookie` instance. *request* is an object implementing the interface defined by the documentation for `CookieJar.add_cookie_header()`.

CookiePolicy. **domain_return_ok**(domain, request)

Return false if cookies should not be returned, given cookie domain.

This method is an optimization. It removes the need for checking every cookie with a particular domain (which might involve reading many files). Returning true from `domain_return_ok()` and `path_return_ok()` leaves all the work to `return_ok()`.

If `domain_return_ok()` returns true for the cookie domain, `path_return_ok()` is called for the cookie path. Otherwise, `path_return_ok()` and `return_ok()` are never called for that
cookie domain. If `path_return_ok()` returns true, `return_ok()` is called with the `Cookie` object itself for a full check. Otherwise, `return_ok()` is never called for that cookie path.

Note that `domain_return_ok()` is called for every `cookie` domain, not just for the `request` domain. For example, the function might be called with both `.example.com` and `www.example.com` if the request domain is `www.example.com`. The same goes for `path_return_ok()`.

The `request` argument is as documented for `return_ok()`.

CookiePolicy. `path_return_ok(path, request)`
Return false if cookies should not be returned, given cookie path.

See the documentation for `domain_return_ok()`.

In addition to implementing the methods above, implementations of the `CookiePolicy` interface must also supply the following attributes, indicating which protocols should be used, and how. All of these attributes may be assigned to.

CookiePolicy. `netscape`
Implement Netscape protocol.

CookiePolicy. `rfc2965`
Implement RFC 2965 protocol.

CookiePolicy. `hide_cookie2`
Don’t add Cookie2 header to requests (the presence of this header indicates to the server that we understand RFC 2965 cookies).

The most useful way to define a `CookiePolicy` class is by subclassing from `DefaultCookiePolicy` and overriding some or all of
the methods above. CookiePolicy itself may be used as a 'null policy' to allow setting and receiving any and all cookies (this is unlikely to be useful).
20.21.4. DefaultCookiePolicy Objects

Implements the standard rules for accepting and returning cookies.

Both RFC 2965 and Netscape cookies are covered. RFC 2965 handling is switched off by default.

The easiest way to provide your own policy is to override this class and call its methods in your overridden implementations before adding your own additional checks:

```python
import cookielib
class MyCookiePolicy(cookielib.DefaultCookiePolicy):
    def set_ok(self, cookie, request):
        if not cookielib.DefaultCookiePolicy.set_ok(self, cookie):
            return False
        if i_dont_want_to_store_this_cookie(cookie):
            return False
        return True
```

In addition to the features required to implement the `CookiePolicy` interface, this class allows you to block and allow domains from setting and receiving cookies. There are also some strictness switches that allow you to tighten up the rather loose Netscape protocol rules a little bit (at the cost of blocking some benign cookies).

A domain blacklist and whitelist is provided (both off by default). Only domains not in the blacklist and present in the whitelist (if the whitelist is active) participate in cookie setting and returning. Use the `blocked_domains` constructor argument, and `blocked_domains()` and `set_blocked_domains()` methods (and the corresponding argument and methods for `allowed_domains`). If you set a whitelist, you can turn it off again by setting it to `None`. 
Domains in block or allow lists that do not start with a dot must equal the cookie domain to be matched. For example, "example.com" matches a blacklist entry of "example.com", but "www.example.com" does not. Domains that do start with a dot are matched by more specific domains too. For example, both "www.example.com" and "www.coyote.example.com" match ".example.com" (but "example.com" itself does not). IP addresses are an exception, and must match exactly. For example, if blocked_domains contains "192.168.1.2" and ".168.1.2", 192.168.1.2 is blocked, but 193.168.1.2 is not.

**DefaultCookiePolicy** implements the following additional methods:

**DefaultCookiePolicy**. `blocked_domains()`  
Return the sequence of blocked domains (as a tuple).

**DefaultCookiePolicy**. `set_blocked_domains(blocked_domains)`  
Set the sequence of blocked domains.

**DefaultCookiePolicy**. `is_blocked(domain)`  
Return whether `domain` is on the blacklist for setting or receiving cookies.

**DefaultCookiePolicy**. `allowed_domains()`  
Return `None`, or the sequence of allowed domains (as a tuple).

**DefaultCookiePolicy**. `set_allowed_domains(allowed_domains)`  
Set the sequence of allowed domains, or `None`.

**DefaultCookiePolicy**. `is_not_allowed(domain)`  
Return whether `domain` is not on the whitelist for setting or receiving cookies.

**DefaultCookiePolicy** instances have the following attributes, which are all initialised from the constructor arguments of the same name,
and which may all be assigned to.

DefaultCookiePolicy. **rfc2109_as_netscape**

If true, request that the CookieJar instance downgrade RFC 2109 cookies (ie. cookies received in a Set-Cookie header with a version cookie-attribute of 1) to Netscape cookies by setting the version attribute of the Cookie instance to 0. The default value is **None**, in which case RFC 2109 cookies are downgraded if and only if RFC 2965 handling is turned off. Therefore, RFC 2109 cookies are downgraded by default.

*New in version 2.5.*

General strictness switches:

DefaultCookiePolicy. **strict_domain**

Don't allow sites to set two-component domains with country-code top-level domains like .co.uk, .gov.uk, .co.nz etc. This is far from perfect and isn't guaranteed to work!

RFC 2965 protocol strictness switches:

DefaultCookiePolicy. **strict_rfc2965_unverifiable**

Follow RFC 2965 rules on unverifiable transactions (usually, an unverifiable transaction is one resulting from a redirect or a request for an image hosted on another site). If this is false, cookies are *never* blocked on the basis of verifiability.

Netscape protocol strictness switches:

DefaultCookiePolicy. **strict_ns_unverifiable**

apply RFC 2965 rules on unverifiable transactions even to Netscape cookies

DefaultCookiePolicy. **strict_ns_domain**

Flags indicating how strict to be with domain-matching rules for
Netscape cookies. See below for acceptable values.

DefaultCookiePolicy. **strict_ns_set_initial_dollar**

Ignore cookies in Set-Cookie: headers that have names starting with '$_'.

DefaultCookiePolicy. **strict_ns_set_path**

Don’t allow setting cookies whose path doesn’t path-match request URI.

**strict_ns_domain** is a collection of flags. Its value is constructed by or-ing together (for example, `DomainStrictNoDots|DomainStrictNonDomain` means both flags are set).

DefaultCookiePolicy. **DomainStrictNoDots**

When setting cookies, the ‘host prefix’ must not contain a dot (eg. `www.foo.bar.com` can’t set a cookie for `.bar.com`, because `www.foo` contains a dot).

DefaultCookiePolicy. **DomainStrictNonDomain**

Cookies that did not explicitly specify a domain cookie-attribute can only be returned to a domain equal to the domain that set the cookie (eg. `spam.example.com` won’t be returned cookies from `example.com` that had no domain cookie-attribute).

DefaultCookiePolicy. **DomainRFC2965Match**

When setting cookies, require a full RFC 2965 domain-match.

The following attributes are provided for convenience, and are the most useful combinations of the above flags:

DefaultCookiePolicy. **DomainLiberal**

Equivalent to 0 (ie. all of the above Netscape domain strictness flags switched off).
DefaultCookiePolicy. **DomainStrict**

Equivalent to DomainStrictNoDots|DomainStrictNonDomain.
20.21.5. Cookie Objects

Cookie instances have Python attributes roughly corresponding to the standard cookie-attributes specified in the various cookie standards. The correspondence is not one-to-one, because there are complicated rules for assigning default values, because the max-age and expires cookie-attributes contain equivalent information, and because RFC 2109 cookies may be ‘downgraded’ by cookielib from version 1 to version 0 (Netscape) cookies.

Assignment to these attributes should not be necessary other than in rare circumstances in a CookiePolicy method. The class does not enforce internal consistency, so you should know what you’re doing if you do that.

Cookie. version
   Integer or None. Netscape cookies have version 0. RFC 2965 and RFC 2109 cookies have a version cookie-attribute of 1. However, note that cookielib may ‘downgrade’ RFC 2109 cookies to Netscape cookies, in which case version is 0.

Cookie. name
   Cookie name (a string).

Cookie. value
   Cookie value (a string), or None.

Cookie. port
   String representing a port or a set of ports (eg. ‘80’, or ‘80,8080’), or None.

Cookie. path
   Cookie path (a string, eg. '/acme/rocket_launchers').
Cookie. **secure**
   True if cookie should only be returned over a secure connection.

Cookie. **expires**
   Integer expiry date in seconds since epoch, or *None*. See also the
   *is_expired()* method.

Cookie. **discard**
   True if this is a session cookie.

Cookie. **comment**
   String comment from the server explaining the function of this
   cookie, or *None*.

Cookie. **comment_url**
   URL linking to a comment from the server explaining the function
   of this cookie, or *None*.

Cookie. **rfc2109**
   True if this cookie was received as an RFC 2109 cookie (ie. the
   cookie arrived in a *Set-Cookie* header, and the value of the
   Version cookie-attribute in that header was 1). This attribute is
   provided because *cookielib* may ‘downgrade’ RFC 2109 cookies
to Netscape cookies, in which case *version* is 0.

   *New in version 2.5.*

Cookie. **port_specified**
   True if a port or set of ports was explicitly specified by the server
   (in the *Set-Cookie / Set-Cookie2* header).

Cookie. **domain_specified**
   True if a domain was explicitly specified by the server.

Cookie. **domain_initial_dot**
   True if the domain explicitly specified by the server began with a
Cookies may have additional non-standard cookie-attributes. These may be accessed using the following methods:

```python
Cookie.has_nonstandard_attr(name)
```
Return true if cookie has the named cookie-attribute.

```python
Cookie.get_nonstandard_attr(name, default=None)
```
If cookie has the named cookie-attribute, return its value. Otherwise, return `default`.

```python
Cookie.set_nonstandard_attr(name, value)
```
Set the value of the named cookie-attribute.

The `Cookie` class also defines the following method:

```python
Cookie.is_expired([now=None])
```
True if cookie has passed the time at which the server requested it should expire. If `now` is given (in seconds since the epoch), return whether the cookie has expired at the specified time.
20.21.6. Examples

The first example shows the most common usage of `cookielib`:

```python
import cookielib, urllib2
cj = cookielib.CookieJar()
opener = urllib2.build_opener(urllib2.HTTPCookieProcessor(cj))
r = opener.open("http://example.com/")
```

This example illustrates how to open a URL using your Netscape, Mozilla, or Lynx cookies (assumes Unix/Netscape convention for location of the cookies file):

```python
import os, cookielib, urllib2
cj = cookielib.MozillaCookieJar()
cj.load(os.path.join(os.path.expanduser('~'), ".netscape", "cookie")
opener = urllib2.build_opener(urllib2.HTTPCookieProcessor(cj))
r = opener.open("http://example.com/")
```

The next example illustrates the use of `DefaultCookiePolicy`. Turn on RFC 2965 cookies, be more strict about domains when setting and returning Netscape cookies, and block some domains from setting cookies or having them returned:

```python
import urllib2
from cookielib import CookieJar, DefaultCookiePolicy
policy = DefaultCookiePolicy(
    rfc2965=True, strict_ns_domain=DefaultCookiePolicy.DomainStrict
    blocked_domains=["ads.net", ".ads.net"])
cj = CookieJar(policy)
opener = urllib2.build_opener(urllib2.HTTPCookieProcessor(cj))
r = opener.open("http://example.com/")
```

20.22. **Cookie — HTTP state management**

**Note:** The `Cookie` module has been renamed to `http.cookies` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

The `Cookie` module defines classes for abstracting the concept of cookies, an HTTP state management mechanism. It supports both simple string-only cookies, and provides an abstraction for having any serializable data-type as cookie value.

The module formerly strictly applied the parsing rules described in the [RFC 2109](https://tools.ietf.org/html/rfc2109) and [RFC 2068](https://tools.ietf.org/html/rfc2068) specifications. It has since been discovered that MSIE 3.0x doesn’t follow the character rules outlined in those specs. As a result, the parsing rules used are a bit less strict.

**Note:** On encountering an invalid cookie, `CookieError` is raised, so if your cookie data comes from a browser you should always prepare for invalid data and catch `CookieError` on parsing.

```python
exception Cookie.CookieError
    Exception failing because of RFC 2109 invalidity: incorrect attributes, incorrect Set-Cookie header, etc.
```

```python
class Cookie.BaseCookie([input])
    This class is a dictionary-like object whose keys are strings and whose values are `Morsel` instances. Note that upon setting a key to a value, the value is first converted to a `Morsel` containing the key and the value.
```
If *input* is given, it is passed to the `load()` method.

```python
class Cookie.SimpleCookie([input])
```
This class derives from `BaseCookie` and overrides `value_decode()` and `value_encode()` to be the identity and `str()` respectively.

```python
class Cookie.SerialCookie([input])
```
This class derives from `BaseCookie` and overrides `value_decode()` and `value_encode()` to be the `pickle.loads()` and `pickle.dumps()`.

**Deprecated since version 2.3:** Reading pickled values from untrusted cookie data is a huge security hole, as pickle strings can be crafted to cause arbitrary code to execute on your server. It is supported for backwards compatibility only, and may eventually go away.

```python
class Cookie.SmartCookie([input])
```
This class derives from `BaseCookie`. It overrides `value_decode()` to be `pickle.loads()` if it is a valid pickle, and otherwise the value itself. It overrides `value_encode()` to be `pickle.dumps()` unless it is a string, in which case it returns the value itself.

**Deprecated since version 2.3:** The same security warning from `SerialCookie` applies here.

A further security note is warranted. For backwards compatibility, the `cookie` module exports a class named `Cookie` which is just an alias for `SmartCookie`. This is probably a mistake and will likely be removed in a future version. You should not use the `Cookie` class in your applications, for the same reason why you should not use the `SerialCookie` class.

**Module** `cookielib`  
HTTP cookie handling for web clients. The `cookielib` and `Cookie` modules do not depend on each other.

**RFC 2109 - HTTP State Management Mechanism**  
This is the state management specification implemented by this module.
20.22.1. Cookie Objects

BaseCookie. **value_decode(val)**
Return a decoded value from a string representation. Return value can be any type. This method does nothing in BaseCookie — it exists so it can be overridden.

BaseCookie. **value_encode(val)**
Return an encoded value. val can be any type, but return value must be a string. This method does nothing in BaseCookie — it exists so it can be overridden.

In general, it should be the case that value_encode() and value_decode() are inverses on the range of value_decode.

BaseCookie. **output([attrs[, header[, sep]]])**
Return a string representation suitable to be sent as HTTP headers. attrs and header are sent to each Morsel's output() method. sep is used to join the headers together, and is by default the combination '\r\n' (CRLF).

*Changed in version 2.5:* The default separator has been changed from '\n' to match the cookie specification.

BaseCookie. **js_output([attrs])**
Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP headers was sent.

The meaning for attrs is the same as in output().

BaseCookie. **load(rawdata)**
If `rawdata` is a string, parse it as an `HTTP_COOKIE` and add the values found there as `Morsel`s. If it is a dictionary, it is equivalent to:

```python
for k, v in rawdata.items():
    cookie[k] = v
```
class Cookie. Morsel

Abstract a key/value pair, which has some RFC 2109 attributes.

Morsels are dictionary-like objects, whose set of keys is constant — the valid RFC 2109 attributes, which are

- expires
- path
- comment
- domain
- max-age
- secure
- version
- httponly

The attribute `httponly` specifies that the cookie is only transferred in HTTP requests, and is not accessible through JavaScript. This is intended to mitigate some forms of cross-site scripting.

The keys are case-insensitive.

*New in version 2.6*: The `httponly` attribute was added.

Morsel. **value**

The value of the cookie.

Morsel. **coded_value**

The encoded value of the cookie — this is what should be sent.

Morsel. **key**

The name of the cookie.
Morsel. `set(key, value, coded_value)`

Set the `key`, `value` and `coded_value` members.

Morsel. `isReservedKey(K)`

Whether `K` is a member of the set of keys of a `Morsel`.

Morsel. `output([attrs[, header]])`  
Return a string representation of the Morsel, suitable to be sent as an HTTP header. By default, all the attributes are included, unless `attrs` is given, in which case it should be a list of attributes to use. `header` is by default "Set-Cookie:"

Morsel. `js_output([attrs])`

Return an embeddable JavaScript snippet, which, if run on a browser which supports JavaScript, will act the same as if the HTTP header was sent.

The meaning for `attrs` is the same as in `output()`.

Morsel. `OutputString([attrs])`

Return a string representing the Morsel, without any surrounding HTTP or JavaScript.

The meaning for `attrs` is the same as in `output()`.
The following example demonstrates how to use the `Cookie` module.

```python
>>> import Cookie
>>> C = Cookie.SimpleCookie()
>>> C["fig"] = "newton"
>>> C["sugar"] = "wafer"
>>> print C  # generate HTTP headers
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> print C.output()  # same thing
Set-Cookie: fig=newton
Set-Cookie: sugar=wafer
>>> C = Cookie.SimpleCookie()
>>> C["rocky"] = "road"
>>> C["rocky"]["path"] = "/cookie"
>>> print C.output(header="Cookie:"
Cookie: rocky=road; Path=/cookie
>>> print C.output(attrs=[], header="Cookie:"
Cookie: rocky=road
>>> C = Cookie.SimpleCookie()
>>> C.load("chips=ahoy; vienna=finger")  # load from a string (HTTP header)
>>> print C
Set-Cookie: chips=ahoy
Set-Cookie: vienna=finger
>>> C = Cookie.SimpleCookie()
>>> C.load('keebler="E=everybody; L="Loves"; fudge=\012;"
>>> print C
Set-Cookie: keebler="E=everybody; L="Loves"; fudge=\012;"
>>> C = Cookie.SimpleCookie()
>>> C["oreo"] = "doublestuff"
>>> C["oreo"]["path"] = "/"
>>> print C
Set-Cookie: oreo=doublestuff; Path=/
>>> C["twix"] = "none for you"
>>> C["twix"].value
'none for you'
>>> C = Cookie.SimpleCookie()
>>> C["number"] = 7  # equivalent to C["number"] = str(7)
>>> C["string"] = "seven"
>>> C["number"].value
'7'
```
>>> C["string"]).value
'seven'
>>> print C
Set-Cookie: number=7
Set-Cookie: string=seven
>>> # SerialCookie and SmartCookie are deprecated
>>> # using it can cause security loopholes in your code.
>>> C = Cookie.SerialCookie()
>>> C["number"] = 7
>>> C["string"] = "seven"
>>> C["number").value
7
>>> C["string").value
'seven'
>>> print C
Set-Cookie: number=I7\012.
Set-Cookie: string=S'seven'\012p1\012.
>>> C = Cookie.SmartCookie()
>>> C["number"] = 7
>>> C["string"] = "seven"
>>> C["number").value
7
>>> C["string").value
'seven'
>>> print C
Set-Cookie: number=I7\012.
Set-Cookie: string=seven
20.23. xmlrpclib — XML-RPC client access

**Note:** The xmlrpclib module has been renamed to xmlrpc.client in Python 3.0. The 2to3 tool will automatically adapt imports when converting your sources to 3.0.

*New in version 2.2.*

XML-RPC is a Remote Procedure Call method that uses XML passed via HTTP as a transport. With it, a client can call methods with parameters on a remote server (the server is named by a URI) and get back structured data. This module supports writing XML-RPC client code; it handles all the details of translating between conformable Python objects and XML on the wire.

```python
class xmlrpclib.ServerProxy(uri[, transport[, encoding[, verbose[, allow_none[, use_datetime]]]]])
```

A `ServerProxy` instance is an object that manages communication with a remote XML-RPC server. The required first argument is a URI (Uniform Resource Indicator), and will normally be the URL of the server. The optional second argument is a transport factory instance; by default it is an internal `SafeTransport` instance for https: URLs and an internal HTTP `Transport` instance otherwise. The optional third argument is an encoding, by default UTF-8. The optional fourth argument is a debugging flag. If `allow_none` is true, the Python constant `None` will be translated into XML; the default behaviour is for `None` to raise a `TypeError`. This is a commonly-used extension to the XML-RPC specification, but isn’t supported by all clients and servers; see [http://ontosys.com/xml-rpc/extensions.php](http://ontosys.com/xml-rpc/extensions.php) for a description. The `use_datetime` flag can be used to cause date/time values to be presented as
**datetime.datetime** objects; this is false by default. **datetime.datetime** objects may be passed to calls.

Both the HTTP and HTTPS transports support the URL syntax extension for HTTP Basic Authentication: http://user:pass@host:port/path. The **user:pass** portion will be base64-encoded as an HTTP ‘Authorization’ header, and sent to the remote server as part of the connection process when invoking an XML-RPC method. You only need to use this if the remote server requires a Basic Authentication user and password.

The returned instance is a proxy object with methods that can be used to invoke corresponding RPC calls on the remote server. If the remote server supports the introspection API, the proxy can also be used to query the remote server for the methods it supports (service discovery) and fetch other server-associated metadata.

**ServerProxy** instance methods take Python basic types and objects as arguments and return Python basic types and classes. Types that are conformable (e.g. that can be marshalled through XML), include the following (and except where noted, they are unmarshalled as the same Python type):

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boolean</strong></td>
<td>The <strong>True</strong> and <strong>False</strong> constants</td>
</tr>
<tr>
<td><strong>integers</strong></td>
<td>Pass in directly</td>
</tr>
<tr>
<td><strong>floating-point numbers</strong></td>
<td>Pass in directly</td>
</tr>
<tr>
<td><strong>strings</strong></td>
<td>Pass in directly</td>
</tr>
<tr>
<td><strong>arrays</strong></td>
<td>Any Python sequence type containing conformable elements. Arrays are returned as lists</td>
</tr>
<tr>
<td><strong>A Python dictionary. Keys must be</strong></td>
<td></td>
</tr>
<tr>
<td>structures</td>
<td>strings, values may be any conformable type. Objects of user-defined classes can be passed in; only their <code>__dict__</code> attribute is transmitted.</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>dates</td>
<td>in seconds since the epoch (pass in an instance of the <code>DateTime</code> class) or a <code>datetime.datetime</code> instance.</td>
</tr>
<tr>
<td>binary data</td>
<td>pass in an instance of the <code>Binary</code> wrapper class</td>
</tr>
</tbody>
</table>

This is the full set of data types supported by XML-RPC. Method calls may also raise a special `Fault` instance, used to signal XML-RPC server errors, or `ProtocolError` used to signal an error in the HTTP/HTTPS transport layer. Both `Fault` and `ProtocolError` derive from a base class called `Error`. Note that even though starting with Python 2.2 you can subclass built-in types, the `xmlrpclib` module currently does not marshal instances of such subclasses.

When passing strings, characters special to XML such as `<`, `>`, and `&` will be automatically escaped. However, it's the caller's responsibility to ensure that the string is free of characters that aren't allowed in XML, such as the control characters with ASCII values between 0 and 31 (except, of course, tab, newline and carriage return); failing to do this will result in an XML-RPC request that isn't well-formed XML. If you have to pass arbitrary strings via XML-RPC, use the `Binary` wrapper class described below.

`Server` is retained as an alias for `ServerProxy` for backwards compatibility. New code should use `ServerProxy`.

*Changed in version 2.5:* The `use_datetime` flag was added.
Changed in version 2.6: Instances of new-style classes can be passed in if they have an __dict__ attribute and don’t have a base class that is marshalled in a special way.

The official specification.

**Unofficial XML-RPC Errata**
Fredrik Lundh’s “unofficial errata, intended to clarify certain details in the XML-RPC specification, as well as hint at ‘best practices’ to use when designing your own XML-RPC implementations.”
20.23.1. ServerProxy Objects

A `ServerProxy` instance has a method corresponding to each remote procedure call accepted by the XML-RPC server. Calling the method performs an RPC, dispatched by both name and argument signature (e.g. the same method name can be overloaded with multiple argument signatures). The RPC finishes by returning a value, which may be either returned data in a conformant type or a `Fault` or `ProtocolError` object indicating an error.

Servers that support the XML introspection API support some common methods grouped under the reserved `system` member:

```python
ServerProxy.system.listMethods()
```

This method returns a list of strings, one for each (non-system) method supported by the XML-RPC server.

```python
ServerProxy.system.methodSignature(name)
```

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns an array of possible signatures for this method. A signature is an array of types. The first of these types is the return type of the method, the rest are parameters.

Because multiple signatures (ie. overloading) is permitted, this method returns a list of signatures rather than a singleton.

Signatures themselves are restricted to the top level parameters expected by a method. For instance if a method expects one array of structs as a parameter, and it returns a string, its signature is simply “string, array”. If it expects three integers and returns a string, its signature is “string, int, int, int”.
If no signature is defined for the method, a non-array value is returned. In Python this means that the type of the returned value will be something other than list.

ServerProxy.system.methodHelp(name)

This method takes one parameter, the name of a method implemented by the XML-RPC server. It returns a documentation string describing the use of that method. If no such string is available, an empty string is returned. The documentation string may contain HTML markup.
20.23.2. Boolean Objects

This class may be initialized from any Python value; the instance returned depends only on its truth value. It supports various Python operators through \_\_cmp\_\(), \_\_repr\_\(), \_\_int\_\(), and \_\_nonzero\_\() methods, all implemented in the obvious ways.

It also has the following method, supported mainly for internal use by the unmarshalling code:

Boolean.\texttt{encode(out)}

Write the XML-RPC encoding of this Boolean item to the output stream object.

A working example follows. The server code:

```python
import xmlrpclib
from SimpleXMLRPCServer import SimpleXMLRPCServer

def is_even(n):
    return n\%2 == 0

server = SimpleXMLRPCServer(\"localhost\", 8000)
print \"Listening on port 8000...\"
server.register_function(is_even, \"is_even\")
server.serve_forever()
```

The client code for the preceding server:

```python
import xmlrpclib

print \"3 \ is \ even: %s\" % str(proxy.is_even(3))
print \"100 \ is \ even: %s\" % str(proxy.is_even(100))
```
20.23.3. DateTime Objects

This class may be initialized with seconds since the epoch, a time tuple, an ISO 8601 time/date string, or a `datetime.datetime` instance. It has the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

DateTime. `decode(string)`
Accept a string as the instance's new time value.

DateTime. `encode(out)`
Write the XML-RPC encoding of this DateTime item to the `out` stream object.

It also supports certain of Python's built-in operators through `__cmp__()` and `__repr__()` methods.

A working example follows. The server code:

```python
import datetime
from SimpleXMLRPCServer import SimpleXMLRPCServer
import xmlrpclib

def today():
    today = datetime.datetime.today()
    return xmlrpclib.DateTime(today)

server = SimpleXMLRPCServer(('localhost', 8000))
print "Listening on port 8000..."
server.register_function(today, "today")
server.serve_forever()
```

The client code for the preceding server:

```python
import xmlrpclib
import datetime
```
proxy = xmlrpclib.ServerProxy("http://localhost:8000/")

today = proxy.today()
# convert the ISO8601 string to a datetime object
converted = datetime.datetime.strptime(today.value, "%Y%m%dT%H:%M:%S")

print "Today: %s" % converted.strftime("%d.%m.%Y, %H:%M")
20.23.4. Binary Objects

This class may be initialized from string data (which may include NULs). The primary access to the content of a Binary object is provided by an attribute:

**Binary.data**

The binary data encapsulated by the Binary instance. The data is provided as an 8-bit string.

Binary objects have the following methods, supported mainly for internal use by the marshalling/unmarshalling code:

**Binary.decode(string)**

Accept a base64 string and decode it as the instance’s new data.

**Binary.encode(out)**

Write the XML-RPC base 64 encoding of this binary item to the out stream object.

The encoded data will have newlines every 76 characters as per RFC 2045 section 6.8, which was the de facto standard base64 specification when the XML-RPC spec was written.

It also supports certain of Python’s built-in operators through a \_\_cmp\_\_( ) method.

Example usage of the binary objects. We’re going to transfer an image over XMLRPC:

```python
from SimpleXMLRPCServer import SimpleXMLRPCServer
import xmlrpclib

def python_logo():
    with open("python_logo.jpg", "rb") as handle:
```
```
return xmlrpclib.Binary(handle.read())

server = SimpleXMLRPCServer(('localhost', 8000))
print "Listening on port 8000..."
server.register_function(python_logo, 'python_logo')
server.serve_forever()
```

The client gets the image and saves it to a file:

```
import xmlrpclib

proxy = xmlrpclib.ServerProxy("http://localhost:8000/")
with open("fetched_python_logo.jpg", "wb") as handle:
    handle.write(proxy.python_logo().data)
```
20.23.5. Fault Objects

A **Fault** object encapsulates the content of an XML-RPC fault tag. Fault objects have the following members:

**Fault. faultCode**
- A string indicating the fault type.

**Fault. faultString**
- A string containing a diagnostic message associated with the fault.

In the following example we're going to intentionally cause a **Fault** by returning a complex type object. The server code:

```python
from SimpleXMLRPCServer import SimpleXMLRPCServer

# A marshalling error is going to occur because we're returning
# complex number

def add(x,y):
    return x+y+0j

server = SimpleXMLRPCServer(("localhost", 8000))
print "Listening on port 8000..."
server.register_function(add, 'add')

server.serve_forever()
```

The client code for the preceding server:

```python
import xmlrpclib

proxy = xmlrpclib.ServerProxy("http://localhost:8000/")

try:
    proxy.add(2, 5)
except xmlrpclib.Fault, err:
    print "A fault occurred"
    print "Fault code: %d" % err.faultCode
```
print "Fault string: %s" % err.faultString
20.23.6. ProtocolError Objects

A ProtocolError object describes a protocol error in the underlying transport layer (such as a 404 'not found' error if the server named by the URI does not exist). It has the following members:

ProtocolError. url
The URI or URL that triggered the error.

ProtocolError. errcode
The error code.

ProtocolError. errmsg
The error message or diagnostic string.

ProtocolError. headers
A string containing the headers of the HTTP/HTTPS request that triggered the error.

In the following example we're going to intentionally cause a ProtocolError by providing an URI that doesn't point to an XMLRPC server:

```python
import xmlrpclib

# create a ServerProxy with an URI that doesn't respond to XMLR
proxy = xmlrpclib.ServerProxy("http://www.google.com/")

try:
    proxy.some_method()
except xmlrpclib.ProtocolError, err:
    print "A protocol error occurred"
    print "URL: %s" % err.url
    print "HTTP/HTTPS headers: %s" % err.headers
    print "Error code: %d" % err.errcode
    print "Error message: %s" % err.errmsg
```
20.23.7. MultiCall Objects

New in version 2.4.

In http://www.xmlrpc.com/discuss/msgReader%241208, an approach is presented to encapsulate multiple calls to a remote server into a single request.

```python
class xmlrpclib.MultiCall(server)

Create an object used to boxcar method calls. server is the eventual target of the call. Calls can be made to the result object, but they will immediately return None, and only store the call name and parameters in the MultiCall object. Calling the object itself causes all stored calls to be transmitted as a single system.multicall request. The result of this call is a generator; iterating over this generator yields the individual results.
```

A usage example of this class follows. The server code

```python
from SimpleXMLRPCServer import SimpleXMLRPCServer
def add(x, y):
    return x+y
def subtract(x, y):
    return x-y
def multiply(x, y):
    return x*y
def divide(x, y):
    return x/y

# A simple server with simple arithmetic functions
server = SimpleXMLRPCServer(('localhost', 8000))
print "Listening on port 8000..."
server.register_multicall_functions()
server.register_function(add, 'add')
```
```
server.register_function(subtract, 'subtract')
server.register_function(multiply, 'multiply')
server.register_function(divide, 'divide')
server.serve_forever()
```

The client code for the preceding server:

```
import xmlrpclib

proxy = xmlrpclib.ServerProxy("http://localhost:8000/")
multicall = xmlrpclib.MultiCall(proxy)
multicall.add(7,3)
multicall.subtract(7,3)
multicall.multiply(7,3)
multicall.divide(7,3)
result = multicall()

print "7+3=%d, 7-3=%d, 7*3=%d, 7/3=%d" % tuple(result)
```
20.23.8. Convenience Functions

xmlrpclib.boolean(value)

Convert any Python value to one of the XML-RPC Boolean constants, True or False.

xmlrpclib.dumps(params[, methodname[, methodresponse[, encoding[, allow_none]]]])

Convert params into an XML-RPC request. or into a response if methodresponse is true. params can be either a tuple of arguments or an instance of the Fault exception class. If methodresponse is true, only a single value can be returned, meaning that params must be of length 1. encoding, if supplied, is the encoding to use in the generated XML; the default is UTF-8. Python’s None value cannot be used in standard XML-RPC; to allow using it via an extension, provide a true value for allow_none.

xmlrpclib.loads(data[, use_datetime])

Convert an XML-RPC request or response into Python objects, a (params, methodname). params is a tuple of argument; methodname is a string, or None if no method name is present in the packet. If the XML-RPC packet represents a fault condition, this function will raise a Fault exception. The use_datetime flag can be used to cause date/time values to be presented as datetime.datetime objects; this is false by default.

Changed in version 2.5: The use_datetime flag was added.
To access an XML-RPC server through a proxy, you need to define a custom transport. The following example shows how:

```python
import xmlrpclib, httplib

class ProxiedTransport(xmlrpclib.Transport):
    def set_proxy(self, proxy):
        self.proxy = proxy
    def make_connection(self, host):
        self.realhost = host
        h = httplib.HTTP(self.proxy)
        return h
    def send_request(self, connection, handler, request_body):
        connection.putrequest("POST", 'http://%s%s' % (self.realhost, request_body))
    def send_host(self, connection, host):
        connection.putheader('Host', self.realhost)

p = ProxiedTransport()
p.set_proxy('proxy-server:8080')
print server.currentTime.getCurrentTime()
```
20.23.10. Example of Client and Server Usage

See SimpleXMLRPCServer Example.
20.24. SimpleXMLRPCServer — Basic XML-RPC server

Note: The SimpleXMLRPCServer module has been merged into xmlrpc.server in Python 3.0. The 2to3 tool will automatically adapt imports when converting your sources to 3.0.

New in version 2.2.

The SimpleXMLRPCServer module provides a basic server framework for XML-RPC servers written in Python. Servers can either be free standing, using SimpleXMLRPCServer, or embedded in a CGI environment, using CGIXMLRPCRequestHandler.

SimpleXMLRPCServer(addr[, requestHandler[, logRequests[, allow_none[, encoding[, bind_and_activate]]]]]])

Create a new server instance. This class provides methods for registration of functions that can be called by the XML-RPC protocol. The requestHandler parameter should be a factory for request handler instances; it defaults to SimpleXMLRPCRequestHandler. The addr and requestHandler parameters are passed to the SocketServer.TCPServer constructor. If logRequests is true (the default), requests will be logged; setting this parameter to false will turn off logging. The allow_none and encoding parameters are passed on to xmlrpclib and control the XML-RPC responses that will be returned from the server. The bind_and_activate parameter controls whether server_bind() and server_activate() are called immediately by the constructor; it defaults to true. Setting it to false allows code to manipulate the allow_reuse_address class variable before the address is bound.
Changed in version 2.5: The `allow_none` and `encoding` parameters were added.

Changed in version 2.6: The `bind_and_activate` parameter was added.

class SimpleXMLRPCServer.CGIXMLRPCRequestHandler([`allow_none`],
`encoding`])

Create a new instance to handle XML-RPC requests in a CGI environment. The `allow_none` and `encoding` parameters are passed on to `xmlrpclib` and control the XML-RPC responses that will be returned from the server.

New in version 2.3.

Changed in version 2.5: The `allow_none` and `encoding` parameters were added.

class SimpleXMLRPCServer.SimpleXMLRPCRequestHandler

Create a new request handler instance. This request handler supports `POST` requests and modifies logging so that the `logRequests` parameter to the `SimpleXMLRPCServer` constructor parameter is honored.
20.24.1. SimpleXMLRPCServer Objects

The SimpleXMLRPCServer class is based on SocketServer.TCPServer and provides a means of creating simple, stand alone XML-RPC servers.

SimpleXMLRPCServer.register_function(function[, name])

Register a function that can respond to XML-RPC requests. If name is given, it will be the method name associated with function, otherwise function.__name__ will be used. name can be either a normal or Unicode string, and may contain characters not legal in Python identifiers, including the period character.

SimpleXMLRPCServer.register_instance(instance[, allow_dotted_names])

Register an object which is used to expose method names which have not been registered using register_function(). If instance contains a _dispatch() method, it is called with the requested method name and the parameters from the request. Its API is def _dispatch(self, method, params) (note that params does not represent a variable argument list). If it calls an underlying function to perform its task, that function is called as func(*params), expanding the parameter list. The return value from _dispatch() is returned to the client as the result. If instance does not have a _dispatch() method, it is searched for an attribute matching the name of the requested method.

If the optional allow_dotted_names argument is true and the instance does not have a _dispatch() method, then if the requested method name contains periods, each component of the method name is searched for individually, with the effect that
a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

**Warning:** Enabling the `allow_dotted_names` option allows intruders to access your module's global variables and may allow intruders to execute arbitrary code on your machine. Only use this option on a secure, closed network.

*Changed in version 2.3.5,: 2.4.1 allow_dotted_names was added to plug a security hole; prior versions are insecure.*

**SimpleXMLRPCServer.** `register_introspection_functions()`

Registers the XML-RPC introspection functions `system.listMethods`, `system.methodHelp` and `system.methodSignature`.

*New in version 2.3.*

**SimpleXMLRPCServer.** `register_multicall_functions()`

Registers the XML-RPC multicall function `system.multicall`.

**SimpleXMLRPCRequestHandler.** `rpc_paths`

An attribute value that must be a tuple listing valid path portions of the URL for receiving XML-RPC requests. Requests posted to other paths will result in a 404 “no such page” HTTP error. If this tuple is empty, all paths will be considered valid. The default value is `('/', '/RPC2')`.

*New in version 2.5.*

**SimpleXMLRPCRequestHandler.** `encode_threshold`

If this attribute is not `None`, responses larger than this value will be encoded using the `gzip` transfer encoding, if permitted by the client. The default is `1400` which corresponds roughly to a single
TCP packet.

*New in version 2.7.*

### 20.24.1.1. SimpleXMLRPCServer Example

Server code:

```python
from SimpleXMLRPCServer import SimpleXMLRPCServer
from SimpleXMLRPCServer import SimpleXMLRPCRequestHandler

# Restrict to a particular path.
class RequestHandler(SimpleXMLRPCRequestHandler):
    rpc_paths = ('/RPC2',)

# Create server
server = SimpleXMLRPCServer(('localhost', 8000),
                              requestHandler=RequestHandler)
server.register_introspection_functions()

# Register pow() function; this will use the value of
# pow.__name__ as the name, which is just 'pow'.
server.register_function(pow)

# Register a function under a different name
def adder_function(x, y):
    return x + y
server.register_function(adder_function, 'add')

# Register an instance; all the methods of the instance are
# published as XML-RPC methods (in this case, just 'div').
class MyFuncs:
    def div(self, x, y):
        return x // y
server.register_instance(MyFuncs())

# Run the server's main loop
server.serve_forever()
```

The following client code will call the methods made available by the preceding server:
import xmlrpclib

s = xmlrpclib.ServerProxy('http://localhost:8000')
print s.pow(2, 3)  # Returns 2**3 = 8
print s.add(2, 3)  # Returns 5
print s.div(5, 2)  # Returns 5//2 = 2

# Print list of available methods
print s.system.listMethods()
The `CGIXMLRPCRequestHandler` class can be used to handle XML-RPC requests sent to Python CGI scripts.

**CGIXMLRPCRequestHandler.register_function(function[, name])**

Register a function that can respond to XML-RPC requests. If `name` is given, it will be the method name associated with function, otherwise `function.__name__` will be used. `name` can be either a normal or Unicode string, and may contain characters not legal in Python identifiers, including the period character.

**CGIXMLRPCRequestHandler.register_instance(instance)**

Register an object which is used to expose method names which have not been registered using `register_function()`. If instance contains a `_dispatch()` method, it is called with the requested method name and the parameters from the request; the return value is returned to the client as the result. If instance does not have a `_dispatch()` method, it is searched for an attribute matching the name of the requested method; if the requested method name contains periods, each component of the method name is searched for individually, with the effect that a simple hierarchical search is performed. The value found from this search is then called with the parameters from the request, and the return value is passed back to the client.

**CGIXMLRPCRequestHandler.register_introspection_functions()**

Register the XML-RPC introspection functions `system.listMethods`, `system.methodHelp` and `system.methodSignature`.

**CGIXMLRPCRequestHandler.register_multicall_functions()**
Register the XML-RPC multicall function `system.multicall`.

```python
CGIXMLRPCRequestHandler().handle_request([request_text = None])
```

Handle a XML-RPC request. If `request_text` is given, it should be the POST data provided by the HTTP server, otherwise the contents of stdin will be used.

Example:

```python
class MyFuncs:
    def div(self, x, y) : return x // y

handler = CGIXMLRPCRequestHandler()
handler.register_function(pow)
handler.register_function(lambda x,y: x+y, 'add')
handler.register_introspection_functions()
handler.register_instance(MyFuncs())
handler.handle_request()
```
20.25. DocXMLRPCServer — Self-documenting XML-RPC server

**Note:** The DocXMLRPCServer module has been merged into xmlrpc.server in Python 3.0. The 2to3 tool will automatically adapt imports when converting your sources to 3.0.

*New in version 2.3.*

The DocXMLRPCServer module extends the classes found in SimpleXMLRPCServer to serve HTML documentation in response to HTTP GET requests. Servers can either be free standing, using DocXMLRPCServer, or embedded in a CGI environment, using DocCGIXMLRPCRequestHandler.

```python
class DocXMLRPCServer. DocXMLRPCServer(addr[, requestHandler[, logRequests[, allow_none[, encoding[, bind_and_activate]]]]])

Create a new server instance. All parameters have the same meaning as for SimpleXMLRPCServer.SimpleXMLRPCServer; requestHandler defaults to DocXMLRPCRequestHandler.
```

```python
class DocXMLRPCServer. DocCGIXMLRPCRequestHandler

Create a new instance to handle XML-RPC requests in a CGI environment.
```

```python
class DocXMLRPCServer. DocXMLRPCRequestHandler

Create a new request handler instance. This request handler supports XML-RPC POST requests, documentation GET requests, and modifies logging so that the logRequests parameter to the DocXMLRPCServer constructor parameter is honored.
```
20.25.1. DocXMLRPCServer Objects

The DocXMLRPCServer class is derived from SimpleXMLRPCServer.SimpleXMLRPCServer and provides a means of creating self-documenting, stand alone XML-RPC servers. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

DocXMLRPCServer.set_server_title(server_title)

Set the title used in the generated HTML documentation. This title will be used inside the HTML “title” element.

DocXMLRPCServer.set_server_name(server_name)

Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a “h1” element.

DocXMLRPCServer.set_server_documentation(server_documentation)

Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.
20.25.2. DocCGIXMLRPCRequestHandler

The `DocCGIXMLRPCRequestHandler` class is derived from `SimpleXMLRPCServer.CGIXMLRPCRequestHandler` and provides a means of creating self-documenting, XML-RPC CGI scripts. HTTP POST requests are handled as XML-RPC method calls. HTTP GET requests are handled by generating pydoc-style HTML documentation. This allows a server to provide its own web-based documentation.

`DocCGIXMLRPCRequestHandler.set_server_title(server_title)`

Set the title used in the generated HTML documentation. This title will be used inside the HTML “title” element.

`DocCGIXMLRPCRequestHandler.set_server_name(server_name)`

Set the name used in the generated HTML documentation. This name will appear at the top of the generated documentation inside a “h1” element.

`DocCGIXMLRPCRequestHandler.set_server_documentation(server_doc)`

Set the description used in the generated HTML documentation. This description will appear as a paragraph, below the server name, in the documentation.
21. Multimedia Services

The modules described in this chapter implement various algorithms or interfaces that are mainly useful for multimedia applications. They are available at the discretion of the installation. Here’s an overview:

- **21.1. audioop** — Manipulate raw audio data
- **21.2. imageop** — Manipulate raw image data
- **21.3. aifc** — Read and write AIFF and AIFC files
- **21.4. sunau** — Read and write Sun AU files
  - 21.4.1. AU_read Objects
  - 21.4.2. AU_write Objects
- **21.5. wave** — Read and write WAV files
  - 21.5.1. Wave_read Objects
  - 21.5.2. Wave_write Objects
- **21.6. chunk** — Read IFF chunked data
- **21.7. colorsys** — Conversions between color systems
- **21.8. imghdr** — Determine the type of an image
- **21.9. sndhdr** — Determine type of sound file
- **21.10. ossaudiodev** — Access to OSS-compatible audio devices
  - 21.10.1. Audio Device Objects
  - 21.10.2. Mixer Device Objects
21.1. audioop — Manipulate raw audio data

The audioop module contains some useful operations on sound fragments. It operates on sound fragments consisting of signed integer samples 8, 16 or 32 bits wide, stored in Python strings. This is the same format as used by the al and sunaudiodev modules. All scalar items are integers, unless specified otherwise.

This module provides support for a-LAW, u-LAW and Intel/DVI ADPCM encodings.

A few of the more complicated operations only take 16-bit samples, otherwise the sample size (in bytes) is always a parameter of the operation.

The module defines the following variables and functions:

*exception* audioop.error

This exception is raised on all errors, such as unknown number of bytes per sample, etc.

audioop.add(fragment1, fragment2, width)

Return a fragment which is the addition of the two samples passed as parameters. *width* is the sample width in bytes, either 1, 2 or 4. Both fragments should have the same length.

audioop.adpcm2lin(adpcmfragment, width, state)

Decode an Intel/DVI ADPCM coded fragment to a linear fragment. See the description of *lin2adpcm()* for details on ADPCM coding. Return a tuple (sample, newstate) where the sample has the width specified in *width*. 
audioop. **alaw2lin**(fragment, width)

Convert sound fragments in a-LAW encoding to linearly encoded sound fragments. a-LAW encoding always uses 8 bits samples, so *width* refers only to the sample width of the output fragment here.

*New in version 2.5.*

audioop. **avg**(fragment, width)

Return the average over all samples in the fragment.

audioop. **avgpp**(fragment, width)

Return the average peak-peak value over all samples in the fragment. No filtering is done, so the usefulness of this routine is questionable.

audioop. **bias**(fragment, width, bias)

Return a fragment that is the original fragment with a bias added to each sample.

audioop. **cross**(fragment, width)

Return the number of zero crossings in the fragment passed as an argument.

audioop. **findfactor**(fragment, reference)

Return a factor $F$ such that $\text{rms}(\text{add}(\text{fragment}, \text{mul}(\text{reference, } - F)))$ is minimal, i.e., return the factor with which you should multiply *reference* to make it match as well as possible to *fragment*. The fragments should both contain 2-byte samples.

The time taken by this routine is proportional to $\text{len}(\text{fragment})$.

audioop. **findfit**(fragment, reference)

Try to match *reference* as well as possible to a portion of *fragment* (which should be the longer fragment). This is
(conceptually) done by taking slices out of \textit{fragment}, using \texttt{findfactor()} to compute the best match, and minimizing the result. The fragments should both contain 2-byte samples. Return a tuple \((\text{offset}, \text{factor})\) where \text{offset} is the (integer) offset into \textit{fragment} where the optimal match started and \text{factor} is the (floating-point) factor as per \texttt{findfactor()}.

\texttt{audioop.findmax(fragment, length)}

Search \textit{fragment} for a slice of length \textit{length} samples (not bytes!) with maximum energy, i.e., return \(i\) for which \(\text{rms}(\text{fragment}[i*2: (i+\text{length})*2])\) is maximal. The fragments should both contain 2-byte samples.

The routine takes time proportional to \text{len(fragment)}.

\texttt{audioop.getsample(fragment, width, index)}

Return the value of sample \textit{index} from the fragment.

\texttt{audioop.lin2adpcm(fragment, width, state)}

Convert samples to 4 bit Intel/DVI ADPCM encoding. ADPCM coding is an adaptive coding scheme, whereby each 4 bit number is the difference between one sample and the next, divided by a (varying) step. The Intel/DVI ADPCM algorithm has been selected for use by the IMA, so it may well become a standard.

\textit{state} is a tuple containing the state of the coder. The coder returns a tuple \((\text{adpcmfrag}, \text{newstate})\), and the \text{newstate} should be passed to the next call of \texttt{lin2adpcm()}. In the initial call, \texttt{None} can be passed as the state. \texttt{adpcmfrag} is the ADPCM coded fragment packed 2 4-bit values per byte.

\texttt{audioop.lin2alaw(fragment, width)}

Convert samples in the audio fragment to a-LAW encoding and return this as a Python string. a-LAW is an audio encoding format
whereby you get a dynamic range of about 13 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

*New in version 2.5.*

**audioop.** `lin2lin(fragment, width, newwidth)`

Convert samples between 1-, 2- and 4-byte formats.

**Note:** In some audio formats, such as .WAV files, 16 and 32 bit samples are signed, but 8 bit samples are unsigned. So when converting to 8 bit wide samples for these formats, you need to also add 128 to the result:

```python
new_frames = audioop.lin2lin(frames, old_width, 1)
new_frames = audioop.bias(new_frames, 1, 128)
```

The same, in reverse, has to be applied when converting from 8 to 16 or 32 bit width samples.

**audioop.** `lin2ulaw(fragment, width)`

Convert samples in the audio fragment to u-LAW encoding and return this as a Python string. u-LAW is an audio encoding format whereby you get a dynamic range of about 14 bits using only 8 bit samples. It is used by the Sun audio hardware, among others.

**audioop.** `minmax(fragment, width)`

Return a tuple consisting of the minimum and maximum values of all samples in the sound fragment.

**audioop.** `max(fragment, width)`

Return the maximum of the absolute value of all samples in a fragment.

**audioop.** `maxpp(fragment, width)`

Return the maximum peak-peak value in the sound fragment.
audioop.mul(fragment, width, factor)

Return a fragment that has all samples in the original fragment multiplied by the floating-point value factor. Overflow is silently ignored.

audioop.ratecv(fragment, width, nchannels, inrate, outrate, state[, weightA[, weightB]])

Convert the frame rate of the input fragment.

state is a tuple containing the state of the converter. The converter returns a tuple (newfragment, newstate), and newstate should be passed to the next call of ratecv(). The initial call should pass None as the state.

The weightA and weightB arguments are parameters for a simple digital filter and default to 1 and 0 respectively.

audioop.reverse(fragment, width)

Reverse the samples in a fragment and returns the modified fragment.

audioop.rms(fragment, width)

Return the root-mean-square of the fragment, i.e. \( \sqrt{\text{sum}(S_i^2)/n} \).

This is a measure of the power in an audio signal.

audioop.tomono(fragment, width, lfactor, rfactor)

Convert a stereo fragment to a mono fragment. The left channel is multiplied by lfactor and the right channel by rfactor before adding the two channels to give a mono signal.

audioop.tostereo(fragment, width, lfactor, rfactor)

Generate a stereo fragment from a mono fragment. Each pair of
samples in the stereo fragment are computed from the mono sample, whereby left channel samples are multiplied by \( lfactor \) and right channel samples by \( rfactor \).

\[
\text{audioop.\texttt{ulaw2lin}(\text{fragment}, \text{width})}
\]

Convert sound fragments in u-LAW encoding to linearly encoded sound fragments. u-LAW encoding always uses 8 bits samples, so \( \text{width} \) refers only to the sample width of the output fragment here.

Note that operations such as \texttt{mul()} or \texttt{max()} make no distinction between mono and stereo fragments, i.e. all samples are treated equal. If this is a problem the stereo fragment should be split into two mono fragments first and recombinined later. Here is an example of how to do that:

```python
def mul_stereo(sample, width, lfactor, rfactor):
    lsample = audioop.tomono(sample, width, 1, 0)
    rsample = audioop.tomono(sample, width, 0, 1)
    lsample = audioop.mul(lsample, width, lfactor)
    rsample = audioop.mul(rsample, width, rfactor)
    lsample = audioop.tostereo(lsample, width, 1, 0)
    rsample = audioop.tostereo(rsample, width, 0, 1)
    return audioop.add(lsample, rsample, width)
```

If you use the ADPCM coder to build network packets and you want your protocol to be stateless (i.e. to be able to tolerate packet loss) you should not only transmit the data but also the state. Note that you should send the \textit{initial} state (the one you passed to \texttt{lin2adpcm()}) along to the decoder, not the final state (as returned by the coder). If you want to use \texttt{struct.struct()} to store the state in binary you can code the first element (the predicted value) in 16 bits and the second (the delta index) in 8.

The ADPCM coders have never been tried against other ADPCM coders, only against themselves. It could well be that I misinterpreted
the standards in which case they will not be interoperable with the respective standards.

The `find*()` routines might look a bit funny at first sight. They are primarily meant to do echo cancellation. A reasonably fast way to do this is to pick the most energetic piece of the output sample, locate that in the input sample and subtract the whole output sample from the input sample:

```python
def echocancel(outputdata, inputdata):
    pos = audioop.findmax(outputdata, 800)  # one tenth second
    out_test = outputdata[pos*2:]
    in_test = inputdata[pos*2:]
    ipos, factor = audioop.findfit(in_test, out_test)
    # Optional (for better cancellation):
    # factor = audioop.findfactor(in_test[ipos*2:ipos*2+len(out_test)],
    #    out_test)
    prefill = '\0'*(pos+ipos)*2
    postfill = '\0'*(len(inputdata)-len(prefill)-len(outputdata)
    outputdata = prefill + audioop.mul(outputdata, 2, -factor) +
    return audioop.add(inputdata, outputdata, 2)
```

Python v2.7.2 documentation » The Python Standard Library » 21. Multimedia Services »
21.2. imageop — Manipulate raw image data

*Deprecated since version 2.6:* The `imageop` module has been removed in Python 3.0.

The `imageop` module contains some useful operations on images. It operates on images consisting of 8 or 32 bit pixels stored in Python strings. This is the same format as used by `gl.lrectwrite()` and the `imgfile` module.

The module defines the following variables and functions:

- `exception imageop.error`  
  This exception is raised on all errors, such as unknown number of bits per pixel, etc.

- `imageop.crop(image, psize, width, height, x0, y0, x1, y1)`  
  Return the selected part of `image`, which should be `width` by `height` in size and consist of pixels of `psize` bytes. `x0`, `y0`, `x1` and `y1` are like the `gl.lrectread()` parameters, i.e. the boundary is included in the new image. The new boundaries need not be inside the picture. Pixels that fall outside the old image will have their value set to zero. If `x0` is bigger than `x1` the new image is mirrored. The same holds for the `y` coordinates.

- `imageop.scale(image, psize, width, height, newwidth, newheight)`  
  Return `image` scaled to size `newwidth` by `newheight`. No interpolation is done, scaling is done by simple-minded pixel duplication or removal. Therefore, computer-generated images or dithered images will not look nice after scaling.
imageop. `tovideo(image, psize, width, height)`
Run a vertical low-pass filter over an image. It does so by computing each destination pixel as the average of two vertically-aligned source pixels. The main use of this routine is to forestall excessive flicker if the image is displayed on a video device that uses interlacing, hence the name.

imageop. `grey2mono(image, width, height, threshold)`
Convert a 8-bit deep greyscale image to a 1-bit deep image by thresholding all the pixels. The resulting image is tightly packed and is probably only useful as an argument to `mono2grey()`.

imageop. `dither2mono(image, width, height)`
Convert an 8-bit greyscale image to a 1-bit monochrome image using a (simple-minded) dithering algorithm.

imageop. `mono2grey(image, width, height, p0, p1)`
Convert a 1-bit monochrome image to an 8 bit greyscale or color image. All pixels that are zero-valued on input get value \( p0 \) on output and all one-value input pixels get value \( p1 \) on output. To convert a monochrome black-and-white image to greyscale pass the values 0 and 255 respectively.

imageop. `grey2grey4(image, width, height)`
Convert an 8-bit greyscale image to a 4-bit greyscale image without dithering.

imageop. `grey2grey2(image, width, height)`
Convert an 8-bit greyscale image to a 2-bit greyscale image without dithering.

imageop. `dither2grey2(image, width, height)`
Convert an 8-bit greyscale image to a 2-bit greyscale image with dithering. As for `dither2mono()`, the dithering algorithm is
Currently very simple.

```
imageop. grey42grey(image, width, height)
```
Convert a 4-bit greyscale image to an 8-bit greyscale image.

```
imageop. grey22grey(image, width, height)
```
Convert a 2-bit greyscale image to an 8-bit greyscale image.

```
imageop. backward_compatible
```
If set to 0, the functions in this module use a non-backward compatible way of representing multi-byte pixels on little-endian systems. The SGI for which this module was originally written is a big-endian system, so setting this variable will have no effect. However, the code wasn't originally intended to run on anything else, so it made assumptions about byte order which are not universal. Setting this variable to 0 will cause the byte order to be reversed on little-endian systems, so that it then is the same as on big-endian systems.
21.3. `aifc` — Read and write AIFF and AIFC files

This module provides support for reading and writing AIFF and AIFC files. AIFF is Audio Interchange File Format, a format for storing digital audio samples in a file. AIFF-C is a newer version of the format that includes the ability to compress the audio data.

**Note:** Some operations may only work under IRIX; these will raise `ImportError` when attempting to import the `cl` module, which is only available on IRIX.

Audio files have a number of parameters that describe the audio data. The sampling rate or frame rate is the number of times per second the sound is sampled. The number of channels indicate if the audio is mono, stereo, or quadro. Each frame consists of one sample per channel. The sample size is the size in bytes of each sample. Thus a frame consists of `nchannels*samplesize` bytes, and a second’s worth of audio consists of `nchannels*samplesize*framerate` bytes.

For example, CD quality audio has a sample size of two bytes (16 bits), uses two channels (stereo) and has a frame rate of 44,100 frames/second. This gives a frame size of 4 bytes (2*2), and a second’s worth occupies 2*2*44100 bytes (176,400 bytes).

Module `aifc` defines the following function:

```
aifc.open(file[, mode])
```

Open an AIFF or AIFF-C file and return an object instance with methods that are described below. The argument `file` is either a string naming a file or a file object. `mode` must be `'r'` or `'rb'`. 
when the file must be opened for reading, or 'w' or 'wb' when the file must be opened for writing. If omitted, file.mode is used if it exists, otherwise 'rb' is used. When used for writing, the file object should be seekable, unless you know ahead of time how many samples you are going to write in total and use writeframesraw() and setnframes().

Objects returned by open() when a file is opened for reading have the following methods:

aifc.getnchannels()
Return the number of audio channels (1 for mono, 2 for stereo).

aifc.getsampwidth()
Return the size in bytes of individual samples.

aifc.getframerate()
Return the sampling rate (number of audio frames per second).

aifc.getnframes()
Return the number of audio frames in the file.

aifc.getcomptype()
Return a four-character string describing the type of compression used in the audio file. For AIFF files, the returned value is 'NONE'.

aifc.getcompname()
Return a human-readable description of the type of compression used in the audio file. For AIFF files, the returned value is 'not compressed'.

aifc.getparams()
Return a tuple consisting of all of the above values in the above order.
aifc.getmarkers()

Return a list of markers in the audio file. A marker consists of a tuple of three elements. The first is the mark ID (an integer), the second is the mark position in frames from the beginning of the data (an integer), the third is the name of the mark (a string).

aifc.getmark(id)

Return the tuple as described in getmarkers() for the mark with the given id.

aifc.readframes(nframes)

Read and return the next nframes frames from the audio file. The returned data is a string containing for each frame the uncompressed samples of all channels.

aifc.rewind()

Rewind the read pointer. The next readframes() will start from the beginning.

aifc.setpos(pos)

Seek to the specified frame number.

aifc.tell()

Return the current frame number.

aifc.close()

Close the AIFF file. After calling this method, the object can no longer be used.

Objects returned by open() when a file is opened for writing have all the above methods, except for readframes() and setpos(). In addition the following methods exist. The get*() methods can only be called after the corresponding set*() methods have been called. Before the first writeframes() or writeframesraw(), all parameters
except for the number of frames must be filled in.

aifc.\texttt{aiff()}
Create an AIFF file. The default is that an AIFF-C file is created, unless the name of the file ends in \texttt{.aiff} in which case the default is an AIFF file.

aifc.\texttt{aifc()}
Create an AIFF-C file. The default is that an AIFF-C file is created, unless the name of the file ends in \texttt{.aiff} in which case the default is an AIFF file.

\texttt{aifc.setnchannels(nchannels)}
Specify the number of channels in the audio file.

\texttt{aifc.setsampwidth(width)}
Specify the size in bytes of audio samples.

\texttt{aifc.setframerate(rate)}
Specify the sampling frequency in frames per second.

\texttt{aifc.setnframes(nframes)}
Specify the number of frames that are to be written to the audio file. If this parameter is not set, or not set correctly, the file needs to support seeking.

\texttt{aifc.setcomptype(type, name)}
Specify the compression type. If not specified, the audio data will not be compressed. In AIFF files, compression is not possible. The name parameter should be a human-readable description of the compression type, the type parameter should be a four-character string. Currently the following compression types are supported: \texttt{NONE}, ULAW, ALAW, G722.

\texttt{aifc.setparams(nchannels, sampwidth, framerate, comtype,}
Set all the above parameters at once. The argument is a tuple consisting of the various parameters. This means that it is possible to use the result of a `getparams()` call as argument to `setparams()`.

```python
compname
```

aifc.setmark(id, pos, name)

Add a mark with the given id (larger than 0), and the given name at the given position. This method can be called at any time before `close()`.

```python
aifc.tell()
```

Return the current write position in the output file. Useful in combination with `setmark()`.

```python
aifc.writeframes(data)
```

Write data to the output file. This method can only be called after the audio file parameters have been set.

```python
aifc.writeframesraw(data)
```

Like `writeframes()`, except that the header of the audio file is not updated.

```python
aifc.close()
```

Close the AIFF file. The header of the file is updated to reflect the actual size of the audio data. After calling this method, the object can no longer be used.
21.4. sunau — Read and write Sun AU files

The sunau module provides a convenient interface to the Sun AU sound format. Note that this module is interface-compatible with the modules aifc and wave.

An audio file consists of a header followed by the data. The fields of the header are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>magic word</td>
<td>The four bytes .snd.</td>
</tr>
<tr>
<td>header size</td>
<td>Size of the header, including info, in bytes.</td>
</tr>
<tr>
<td>data size</td>
<td>Physical size of the data, in bytes.</td>
</tr>
<tr>
<td>encoding</td>
<td>Indicates how the audio samples are encoded.</td>
</tr>
<tr>
<td>sample rate</td>
<td>The sampling rate.</td>
</tr>
<tr>
<td># of channels</td>
<td>The number of channels in the samples.</td>
</tr>
<tr>
<td>info</td>
<td>ASCII string giving a description of the audio file (padded with null bytes).</td>
</tr>
</tbody>
</table>

Apart from the info field, all header fields are 4 bytes in size. They are all 32-bit unsigned integers encoded in big-endian byte order.

The sunau module defines the following functions:

sunau. open(file, mode)

If file is a string, open the file by that name, otherwise treat it as a seekable file-like object. mode can be any of

'r'

Read only mode.

'w'

Write mode.
Write only mode.

Note that it does not allow read/write files.

A \textit{mode} of \texttt{r'} returns a \texttt{AU\_read} object, while a \textit{mode} of \texttt{w'} or \texttt{wb'} returns a \texttt{AU\_write} object.

\texttt{sunau.\texttt{openfp}(file, mode)}

A synonym for \texttt{open()}, maintained for backwards compatibility.

The \texttt{sunau} module defines the following exception:

\texttt{exception sunau.\texttt{Error}}

An error raised when something is impossible because of Sun AU specs or implementation deficiency.

The \texttt{sunau} module defines the following data items:

\texttt{sunau.\texttt{AUDIO\_FILE\_MAGIC}}

An integer every valid Sun AU file begins with, stored in big-endian form. This is the string \texttt{.snd} interpreted as an integer.

\texttt{sunau.\texttt{AUDIO\_FILE\_ENCODING\_MULAW\_8}}
\texttt{sunau.\texttt{AUDIO\_FILE\_ENCODING\_LINEAR\_8}}
\texttt{sunau.\texttt{AUDIO\_FILE\_ENCODING\_LINEAR\_16}}
\texttt{sunau.\texttt{AUDIO\_FILE\_ENCODING\_LINEAR\_24}}
\texttt{sunau.\texttt{AUDIO\_FILE\_ENCODING\_LINEAR\_32}}
\texttt{sunau.\texttt{AUDIO\_FILE\_ENCODING\_ALAW\_8}}

Values of the encoding field from the AU header which are supported by this module.

\texttt{sunau.\texttt{AUDIO\_FILE\_ENCODING\_FLOAT}}
\texttt{sunau.\texttt{AUDIO\_FILE\_ENCODING\_DOUBLE}}
\texttt{sunau.\texttt{AUDIO\_FILE\_ENCODING\_ADPCM\_G721}}
\texttt{sunau.\texttt{AUDIO\_FILE\_ENCODING\_ADPCM\_G722}}
\texttt{sunau.\texttt{AUDIO\_FILE\_ENCODING\_ADPCM\_G723\_3}}
\texttt{sunau.\texttt{AUDIO\_FILE\_ENCODING\_ADPCM\_G723\_5}}

Additional known values of the encoding field from the AU
header, but which are not supported by this module.
21.4.1. AU_read Objects

AU_read objects, as returned by `open()` above, have the following methods:

**AU_read.close()**
Close the stream, and make the instance unusable. (This is called automatically on deletion.)

**AU_read.getnchannels()**
Returns number of audio channels (1 for mono, 2 for stereo).

**AU_read.getsampwidth()**
Returns sample width in bytes.

**AU_read.getframerate()**
Returns sampling frequency.

**AU_read.getnframes()**
Returns number of audio frames.

**AU_read.getcomptype()**
Returns compression type. Supported compression types are 'ULAW', 'ALAW' and 'NONE'.

**AU_read.getcompname()**
Human-readable version of `getcomptype()`. The supported types have the respective names 'CCITT G.711 u-law', 'CCITT G.711 A-law' and 'not compressed'.

**AU_read.getparams()**
Returns a tuple `(nchannels, sampwidth, framerate, nframes, comptype, compname)`, equivalent to output of the `get*()` methods.
**AU_read.readframes(n)**
Reads and returns at most $n$ frames of audio, as a string of bytes. The data will be returned in linear format. If the original data is in u-LAW format, it will be converted.

**AU_read.rewind()**
Rewind the file pointer to the beginning of the audio stream.

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

**AU_read.setpos(pos)**
Set the file pointer to the specified position. Only values returned from `tell()` should be used for `pos`.

**AU_read.tell()**
Return current file pointer position. Note that the returned value has nothing to do with the actual position in the file.

The following two functions are defined for compatibility with the `aifc`, and don’t do anything interesting.

**AU_read.getmarkers()**
Returns None.

**AU_read.getmark(id)**
Raise an error.
21.4.2. AU_write Objects

AU_write objects, as returned by open() above, have the following methods:

- `AU_write.setnchannels(n)`
  Set the number of channels.

- `AU_write.setsampwidth(n)`
  Set the sample width (in bytes.)

- `AU_write.setframerate(n)`
  Set the frame rate.

- `AU_write.setnframes(n)`
  Set the number of frames. This can be later changed, when and if more frames are written.

- `AU_write.setcomptype(type, name)`
  Set the compression type and description. Only 'NONE' and 'ULAW' are supported on output.

- `AU_write.setparams(tuple)`
  The tuple should be (nchannels, sampwidth, framerate, nframes, comptype, compname), with values valid for the set*() methods. Set all parameters.

- `AU_write.tell()`
  Return current position in the file, with the same disclaimer for the AU_read.tell() and AU_read.setpos() methods.

- `AU_write.writeframesraw(data)`
  Write audio frames, without correcting nframes.
\texttt{AU\_write.writeframes(data)}

Write audio frames and make sure \textit{nframes} is correct.

\texttt{AU\_write.close()}

Make sure \textit{nframes} is correct, and close the file.

This method is called upon deletion.

Note that it is invalid to set any parameters after calling \texttt{writeframes()} or \texttt{writeframesraw()}. 
21.5. `wave` — Read and write WAV files

The `wave` module provides a convenient interface to the WAV sound format. It does not support compression/decompression, but it does support mono/stereo.

The `wave` module defines the following function and exception:

```python
wave.open(file[, mode])
```

If `file` is a string, open the file by that name, otherwise treat it as a seekable file-like object. `mode` can be any of

- `'r'`, `'rb'`
  Read only mode.
- `'w'`, `'wb'`
  Write only mode.

Note that it does not allow read/write WAV files.

A `mode` of `'r'` or `'rb'` returns a `Wave_read` object, while a `mode` of `'w'` or `'wb'` returns a `Wave_write` object. If `mode` is omitted and a file-like object is passed as `file`, `file.mode` is used as the default value for `mode` (the `'b'` flag is still added if necessary).

If you pass in a file-like object, the wave object will not close it when its `close()` method is called; it is the caller's responsibility to close the file object.

```python
wave.openfp(file, mode)
```

A synonym for `open()`, maintained for backwards compatibility.
### Error
An error raised when something is impossible because it violates the WAV specification or hits an implementation deficiency.
21.5.1. Wave_read Objects

Wave_read objects, as returned by `open()`, have the following methods:

Wave_read.close()
Close the stream if it was opened by `wave`, and make the instance unusable. This is called automatically on object collection.

Wave_read.getnchannels()
Returns number of audio channels (1 for mono, 2 for stereo).

Wave_read.getsampwidth()
Returns sample width in bytes.

Wave_read.getframerate()
Returns sampling frequency.

Wave_read.getnframes()
Returns number of audio frames.

Wave_read.getcomptype()
Returns compression type (`NONE` is the only supported type).

Wave_read.getcompname()
Human-readable version of `getcomptype()`. Usually 'not compressed' parallels 'NONE'.

Wave_read.getparams()
Returns a tuple `(nchannels, sampwidth, framerate, nframes, comptype, compname)`, equivalent to output of the `get*()` methods.
Wave_read. `readframes(n)`

Reads and returns at most $n$ frames of audio, as a string of bytes.

Wave_read. `rewind()`

Rewind the file pointer to the beginning of the audio stream.

The following two methods are defined for compatibility with the `aifc` module, and don’t do anything interesting.

Wave_read. `getmarkers()`

Returns None.

Wave_read. `getmark(id)`

Raise an error.

The following two methods define a term “position” which is compatible between them, and is otherwise implementation dependent.

Wave_read. `setpos(pos)`

Set the file pointer to the specified position.

Wave_read. `tell()`

Return current file pointer position.
21.5.2. Wave_write Objects

Wave_write objects, as returned by `open()`, have the following methods:

Wave_write.close()
Make sure `nframes` is correct, and close the file if it was opened by `wave`. This method is called upon object collection.

Wave_write.setnchannels(n)
Set the number of channels.

Wave_write.setsampwidth(n)
Set the sample width to `n` bytes.

Wave_write.setframerate(n)
Set the frame rate to `n`.

Wave_write.setnframes(n)
Set the number of frames to `n`. This will be changed later if more frames are written.

Wave_write.setcomptype(type, name)
Set the compression type and description. At the moment, only compression type `NONE` is supported, meaning no compression.

Wave_write.setparams(tuple)
The tuple should be `(nchannels, sampwidth, framerate, nframes, comptype, compname)`, with values valid for the set*() methods. Sets all parameters.

Wave_write.tell()
Return current position in the file, with the same disclaimer for the
Wave_read.tell() and Wave_read.setpos() methods.

Wave_write.writeframesraw(data)
Write audio frames, without correcting nframes.

Wave_write.writeframes(data)
Write audio frames and make sure nframes is correct.

Note that it is invalid to set any parameters after calling writeframes() or writeframesraw(), and any attempt to do so will raise wave.Error.
21.6. chunk — Read IFF chunked data

This module provides an interface for reading files that use EA IFF 85 chunks. [1] This format is used in at least the Audio Interchange File Format (AIFF/AIFF-C) and the Real Media File Format (RMFF). The WAVE audio file format is closely related and can also be read using this module.

A chunk has the following structure:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Length</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>Chunk ID</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Size of chunk in big-endian byte order, not including the header</td>
</tr>
<tr>
<td>8</td>
<td>$n$</td>
<td>Data bytes, where $n$ is the size given in the preceding field</td>
</tr>
<tr>
<td>$8 + n$</td>
<td>0 or 1</td>
<td>Pad byte needed if $n$ is odd and chunk alignment is used</td>
</tr>
</tbody>
</table>

The ID is a 4-byte string which identifies the type of chunk.

The size field (a 32-bit value, encoded using big-endian byte order) gives the size of the chunk data, not including the 8-byte header.

Usually an IFF-type file consists of one or more chunks. The proposed usage of the `Chunk` class defined here is to instantiate an instance at the start of each chunk and read from the instance until it reaches the end, after which a new instance can be instantiated. At the end of the file, creating a new instance will fail with a `EOFError` exception.

```python
class chunk: Chunk(file[, align, bigendian, inclheader])
```
Class which represents a chunk. The *file* argument is expected to be a file-like object. An instance of this class is specifically allowed. The only method that is needed is `read()`. If the methods `seek()` and `tell()` are present and don’t raise an exception, they are also used. If these methods are present and raise an exception, they are expected to not have altered the object. If the optional argument `align` is true, chunks are assumed to be aligned on 2-byte boundaries. If `align` is false, no alignment is assumed. The default value is true. If the optional argument `bigendian` is false, the chunk size is assumed to be in little-endian order. This is needed for WAVE audio files. The default value is true. If the optional argument `inclheader` is true, the size given in the chunk header includes the size of the header. The default value is false.

A Chunk object supports the following methods:

`getname()`

Returns the name (ID) of the chunk. This is the first 4 bytes of the chunk.

`getsize()`

Returns the size of the chunk.

`close()`

Close and skip to the end of the chunk. This does not close the underlying file.

The remaining methods will raise IOError if called after the `close()` method has been called.

`isatty()`

Returns `False`.

`seek(pos[, whence])`
Set the chunk’s current position. The *whence* argument is optional and defaults to \(0\) (absolute file positioning); other values are \(1\) (seek relative to the current position) and \(2\) (seek relative to the file’s end). There is no return value. If the underlying file does not allow seek, only forward seeks are allowed.

**tell()**

Return the current position into the chunk.

**read([size])**

Read at most `size` bytes from the chunk (less if the read hits the end of the chunk before obtaining `size` bytes). If the `size` argument is negative or omitted, read all data until the end of the chunk. The bytes are returned as a string object. An empty string is returned when the end of the chunk is encountered immediately.

**skip()**

Skip to the end of the chunk. All further calls to `read()` for the chunk will return `''. If you are not interested in the contents of the chunk, this method should be called so that the file points to the start of the next chunk.

**Footnotes**

The \texttt{colorsys} module defines bidirectional conversions of color values between colors expressed in the RGB (Red Green Blue) color space used in computer monitors and three other coordinate systems: YIQ, HLS (Hue Lightness Saturation) and HSV (Hue Saturation Value). Coordinates in all of these color spaces are floating point values. In the YIQ space, the Y coordinate is between 0 and 1, but the I and Q coordinates can be positive or negative. In all other spaces, the coordinates are all between 0 and 1.

\begin{quote}
\textbf{See also:} More information about color spaces can be found at \url{http://www.poynton.com/ColorFAQ.html} and \url{http://www.cambridgeincolour.com/tutorials/color-spaces.htm}.
\end{quote}

The \texttt{colorsys} module defines the following functions:

\begin{quote}
\texttt{colorsys.\texttt{rgb\_to\_yiq}(r, g, b)}
\hspace{1cm} Convert the color from RGB coordinates to YIQ coordinates.
\end{quote}

\begin{quote}
\texttt{colorsys.\texttt{yiq\_to\_rgb}(y, i, q)}
\hspace{1cm} Convert the color from YIQ coordinates to RGB coordinates.
\end{quote}

\begin{quote}
\texttt{colorsys.\texttt{rgb\_to\_hls}(r, g, b)}
\hspace{1cm} Convert the color from RGB coordinates to HLS coordinates.
\end{quote}

\begin{quote}
\texttt{colorsys.\texttt{hls\_to\_rgb}(h, l, s)}
\hspace{1cm} Convert the color from HLS coordinates to RGB coordinates.
\end{quote}

\begin{quote}
\texttt{colorsys.\texttt{rgb\_to\_hsv}(r, g, b)}
\hspace{1cm} Convert the color from RGB coordinates to HSV coordinates.
\end{quote}
colors\texttt{sys.} \texttt{hsv\_to\_rgb}(h, s, v)

Convert the color from HSV coordinates to RGB coordinates.

Example:

```python
>>> import colors\texttt{sys}
>>> colors\texttt{sys.rgb\_to\_hsv}(.3, .4, .2)
(0.25, 0.5, 0.4)
>>> colors\texttt{sys.hsv\_to\_rgb}(0.25, 0.5, 0.4)
(0.3, 0.4, 0.2)
```
21.8. `imghdr` — Determine the type of an image

The `imghdr` module determines the type of image contained in a file or byte stream.

The `imghdr` module defines the following function:

```python
imghdr.what(filename[, h])
```

Tests the image data contained in the file named by `filename`, and returns a string describing the image type. If optional `h` is provided, the `filename` is ignored and `h` is assumed to contain the byte stream to test.

The following image types are recognized, as listed below with the return value from `what()`:

<table>
<thead>
<tr>
<th>Value</th>
<th>Image format</th>
</tr>
</thead>
<tbody>
<tr>
<td>'rgb'</td>
<td>SGI ImgLib Files</td>
</tr>
<tr>
<td>'gif'</td>
<td>GIF 87a and 89a Files</td>
</tr>
<tr>
<td>'pbm'</td>
<td>Portable Bitmap Files</td>
</tr>
<tr>
<td>'pgm'</td>
<td>Portable Graymap Files</td>
</tr>
<tr>
<td>'ppm'</td>
<td>Portable Pixmap Files</td>
</tr>
<tr>
<td>'tiff'</td>
<td>TIFF Files</td>
</tr>
<tr>
<td>'rast'</td>
<td>Sun Raster Files</td>
</tr>
<tr>
<td>'xbm'</td>
<td>X Bitmap Files</td>
</tr>
<tr>
<td>'jpeg'</td>
<td>JPEG data in JFIF or Exif formats</td>
</tr>
<tr>
<td>'bmp'</td>
<td>BMP files</td>
</tr>
<tr>
<td>'png'</td>
<td>Portable Network Graphics</td>
</tr>
</tbody>
</table>

*New in version 2.5:* Exif detection.
You can extend the list of file types `imghdr` can recognize by appending to this variable:

```
import imghdr
imghdr.tests
```

A list of functions performing the individual tests. Each function takes two arguments: the byte-stream and an open file-like object. When `what()` is called with a byte-stream, the file-like object will be `None`.

The test function should return a string describing the image type if the test succeeded, or `None` if it failed.

Example:

```
>>> import imghdr
>>> imghdr.what('/tmp/bass.gif')
'gif'
```
The **sndhdr** provides utility functions which attempt to determine the type of sound data which is in a file. When these functions are able to determine what type of sound data is stored in a file, they return a tuple \((\text{type}, \text{sampling\_rate}, \text{channels}, \text{frames}, \text{bits\_per\_sample})\). The value for \text{type} indicates the data type and will be one of the strings \{'aifc', 'aiff', 'au', 'hcom', 'sndr', 'sndt', 'voc', 'wav', '8svx', 'sb', 'ub', 'ul'\}. The \text{sampling\_rate} will be either the actual value or 0 if unknown or difficult to decode. Similarly, \text{channels} will be either the number of channels or 0 if it cannot be determined or if the value is difficult to decode. The value for \text{frames} will be either the number of frames or -1. The last item in the tuple, \text{bits\_per\_sample}, will either be the sample size in bits or \'A\' for A-LAW or \'U\' for u-LAW.

**sndhdr**.\textbf{what}(\textit{filename})

Determines the type of sound data stored in the file \textit{filename} using \textbf{whathdr()}. If it succeeds, returns a tuple as described above, otherwise \textbf{None} is returned.

**sndhdr**.\textbf{whathdr}(\textit{filename})

Determines the type of sound data stored in a file based on the file header. The name of the file is given by \textit{filename}. This function returns a tuple as described above on success, or \textbf{None}. 
21.10. **ossaudiodev — Access to OSS-compatible audio devices**

*Platforms:* Linux, FreeBSD

*New in version 2.3.*

This module allows you to access the OSS (Open Sound System) audio interface. OSS is available for a wide range of open-source and commercial Unices, and is the standard audio interface for Linux and recent versions of FreeBSD.

**See also:**

*Open Sound System Programmer’s Guide*
   
   the official documentation for the OSS C API

The module defines a large number of constants supplied by the OSS device driver; see `<sys/soundcard.h>` on either Linux or FreeBSD for a listing.

`ossaudiodev` defines the following variables and functions:

```exception` ossaudiodev.OSSAudioError`

This exception is raised on certain errors. The argument is a string describing what went wrong.

(If `ossaudiodev` receives an error from a system call such as `open()`, `write()`, or `ioctl()`, it raises `IOError`. Errors detected directly by `ossaudiodev` result in `OSSAudioError`.)

(For backwards compatibility, the exception class is also available as `ossaudiodev.error`.)*
ossaudiodev.\texttt{open([device], mode)}

Open an audio device and return an OSS audio device object. This object supports many file-like methods, such as \texttt{read()}, \texttt{write()}, and \texttt{fileno()} (although there are subtle differences between conventional Unix read/write semantics and those of OSS audio devices). It also supports a number of audio-specific methods; see below for the complete list of methods.

\textit{device} is the audio device filename to use. If it is not specified, this module first looks in the environment variable \texttt{AUDIODEV} for a device to use. If not found, it falls back to /dev/dsp.

\textit{mode} is one of 'r' for read-only (record) access, 'w' for write-only (playback) access and 'rw' for both. Since many sound cards only allow one process to have the recorder or player open at a time, it is a good idea to open the device only for the activity needed. Further, some sound cards are half-duplex: they can be opened for reading or writing, but not both at once.

Note the unusual calling syntax: the \textit{first} argument is optional, and the second is required. This is a historical artifact for compatibility with the older \texttt{linuxaudiodev} module which \texttt{ossaudiodev} supersedes.

ossaudiodev.\texttt{openmixer([device])}

Open a mixer device and return an OSS mixer device object. \textit{device} is the mixer device filename to use. If it is not specified, this module first looks in the environment variable \texttt{MIXERDEV} for a device to use. If not found, it falls back to /dev/mixer.
21.10.1. Audio Device Objects

Before you can write to or read from an audio device, you must call three methods in the correct order:

1. `setfmt()` to set the output format
2. `channels()` to set the number of channels
3. `speed()` to set the sample rate

Alternately, you can use the `setparameters()` method to set all three audio parameters at once. This is more convenient, but may not be as flexible in all cases.

The audio device objects returned by `open()` define the following methods and (read-only) attributes:

- `oss_audio_device.close()`
  
  Explicitly close the audio device. When you are done writing to or reading from an audio device, you should explicitly close it. A closed device cannot be used again.

- `oss_audio_device.fileno()`
  
  Return the file descriptor associated with the device.

- `oss_audio_device.read(size)`
  
  Read `size` bytes from the audio input and return them as a Python string. Unlike most Unix device drivers, OSS audio devices in blocking mode (the default) will block `read()` until the entire requested amount of data is available.

- `oss_audio_device.write(data)`
  
  Write the Python string `data` to the audio device and return the number of bytes written. If the audio device is in blocking mode
(the default), the entire string is always written (again, this is different from usual Unix device semantics). If the device is in non-blocking mode, some data may not be written — see `writeall()`.

`oss_audio_device.writeall(data)`

Write the entire Python string `data` to the audio device: waits until the audio device is able to accept data, writes as much data as it will accept, and repeats until `data` has been completely written. If the device is in blocking mode (the default), this has the same effect as `write`; `writeall()` is only useful in non-blocking mode. Has no return value, since the amount of data written is always equal to the amount of data supplied.

The following methods each map to exactly one `ioctl()` system call. The correspondence is obvious: for example, `setfmt()` corresponds to the `SNDCTL_DSP_SETFMT` ioctl, and `sync()` to `SNDCTL_DSP_SYNC` (this can be useful when consulting the OSS documentation). If the underlying `ioctl()` fails, they all raise `IOError`.

`oss_audio_device.nonblock()`

Put the device into non-blocking mode. Once in non-blocking mode, there is no way to return it to blocking mode.

`oss_audio_device.getfmts()`

Return a bitmask of the audio output formats supported by the soundcard. Some of the formats supported by OSS are:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFMT_MU_LAW</td>
<td>a logarithmic encoding (used by Sun .au files and /dev/audio)</td>
</tr>
<tr>
<td>AFMT_A_LAW</td>
<td>a logarithmic encoding</td>
</tr>
<tr>
<td>AFMTIMA_ADPCM</td>
<td>a 4:1 compressed format defined by the Interactive Multimedia Association</td>
</tr>
<tr>
<td>AFMT_U8</td>
<td>Unsigned, 8-bit audio</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td>AFMT_S16_LE</td>
<td>Signed, 16-bit audio, little-endian byte order (as used by Intel processors)</td>
</tr>
<tr>
<td>AFMT_S16_BE</td>
<td>Signed, 16-bit audio, big-endian byte order (as used by 68k, PowerPC, Sparc)</td>
</tr>
<tr>
<td>AFMT_S8</td>
<td>Signed, 8-bit audio</td>
</tr>
<tr>
<td>AFMT_U16_LE</td>
<td>Unsigned, 16-bit little-endian audio</td>
</tr>
<tr>
<td>AFMT_U16_BE</td>
<td>Unsigned, 16-bit big-endian audio</td>
</tr>
</tbody>
</table>

Consult the OSS documentation for a full list of audio formats, and note that most devices support only a subset of these formats. Some older devices only support **AFMT_U8**; the most common format used today is **AFMT_S16_LE**.

**oss_audio_device.setfmt(format)**

Try to set the current audio format to `format`—see `getfmts()` for a list. Returns the audio format that the device was set to, which may not be the requested format. May also be used to return the current audio format—do this by passing an “audio format” of **AFMT_QUERY**.

**oss_audio_device.channels(nchannels)**

Set the number of output channels to `nchannels`. A value of 1 indicates monophonic sound, 2 stereophonic. Some devices may have more than 2 channels, and some high-end devices may not support mono. Returns the number of channels the device was set to.

**oss_audio_device.speed(samplerate)**

Try to set the audio sampling rate to `samplerate` samples per second. Returns the rate actually set. Most sound devices don't support arbitrary sampling rates. Common rates are:

<table>
<thead>
<tr>
<th>Rate</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8000</td>
<td>default rate for <code>/dev/audio</code></td>
</tr>
</tbody>
</table>
11025 speech recording
22050
44100 CD quality audio (at 16 bits/sample and 2 channels)
96000 DVD quality audio (at 24 bits/sample)

oss_audio_device. **sync()**
Wait until the sound device has played every byte in its buffer. (This happens implicitly when the device is closed.) The OSS documentation recommends closing and re-opening the device rather than using **sync()**.

oss_audio_device. **reset()**
Immediately stop playing or recording and return the device to a state where it can accept commands. The OSS documentation recommends closing and re-opening the device after calling **reset()**.

oss_audio_device. **post()**
Tell the driver that there is likely to be a pause in the output, making it possible for the device to handle the pause more intelligently. You might use this after playing a spot sound effect, before waiting for user input, or before doing disk I/O.

The following convenience methods combine several ioctlks, or one ioctl and some simple calculations.

oss_audio_device. **setparameters**(*format, nchannels, samplerate*, \[, strict=False\])
Set the key audio sampling parameters—sample format, number of channels, and sampling rate—in one method call. *format, nchannels, and samplerate* should be as specified in the *setfmt(), channels(), and speed()* methods. If **strict** is true,
setparameters() checks to see if each parameter was actually set to the requested value, and raises OSSAudioError if not. Returns a tuple (format, nchannels, samplerate) indicating the parameter values that were actually set by the device driver (i.e., the same as the return values of setfmt(), channels(), and speed()).

For example,

```python
(fmt, channels, rate) = dsp.setparameters(fmt, channels, rate)
```

is equivalent to

```python
fmt = dsp.setfmt(fmt)
channels = dsp.channels(channels)
rate = dsp.rate(channels)
```

oss_audio_device.bufsize()

Returns the size of the hardware buffer, in samples.

oss_audio_device.obufcount()

Returns the number of samples that are in the hardware buffer yet to be played.

oss_audio_device.obuffree()

Returns the number of samples that could be queued into the hardware buffer to be played without blocking.

Audio device objects also support several read-only attributes:

oss_audio_device.closed

Boolean indicating whether the device has been closed.

oss_audio_device.name

String containing the name of the device file.
oss_audio_device.mode

The I/O mode for the file, either "r", "rw", or "w".
21.10.2. Mixer Device Objects

The mixer object provides two file-like methods:

oss_mixer_device.close()

This method closes the open mixer device file. Any further attempts to use the mixer after this file is closed will raise an IOError.

oss_mixer_device.fileno()

Returns the file handle number of the open mixer device file.

The remaining methods are specific to audio mixing:

oss_mixer_device.controls()

This method returns a bitmask specifying the available mixer controls ("Control" being a specific mixable "channel", such as SOUND_MIXER_PCM or SOUND_MIXER_SYNTH). This bitmask indicates a subset of all available mixer controls—the SOUND_MIXER_ constants defined at module level. To determine if, for example, the current mixer object supports a PCM mixer, use the following Python code:

```python
mixer=ossaudiodev.openmixer()
if mixer.controls() & (1 << ossaudiodev.SOUND_MIXER_PCM):
    # PCM is supported
    ... code ...
```

For most purposes, the SOUND_MIXER_VOLUME (master volume) and SOUND_MIXER_PCM controls should suffice—but code that uses the mixer should be flexible when it comes to choosing mixer controls. On the Gravis Ultrasound, for example, SOUND_MIXER_VOLUME does not exist.
oss_mixer_device. **stereocontrols()**

Returns a bitmask indicating stereo mixer controls. If a bit is set, the corresponding control is stereo; if it is unset, the control is either monophonic or not supported by the mixer (use in combination with controls() to determine which).

See the code example for the controls() function for an example of getting data from a bitmask.

oss_mixer_device. **reccontrols()**

Returns a bitmask specifying the mixer controls that may be used to record. See the code example for controls() for an example of reading from a bitmask.

oss_mixer_device. **get(control)**

Returns the volume of a given mixer control. The returned volume is a 2-tuple (left_volume, right_volume). Volumes are specified as numbers from 0 (silent) to 100 (full volume). If the control is monophonic, a 2-tuple is still returned, but both volumes are the same.

Raises **OSSAudioError** if an invalid control was specified, or **IOError** if an unsupported control is specified.

oss_mixer_device. **set(control, (left, right))**

Sets the volume for a given mixer control to (left, right). left and right must be ints and between 0 (silent) and 100 (full volume). On success, the new volume is returned as a 2-tuple. Note that this may not be exactly the same as the volume specified, because of the limited resolution of some soundcard's mixers.

Raises **OSSAudioError** if an invalid mixer control was specified, or if the specified volumes were out-of-range.
oss_mixer_device.get_recsrc()

This method returns a bitmask indicating which control(s) are currently being used as a recording source.

oss_mixer_device.set_recsrc(bitmask)

Call this function to specify a recording source. Returns a bitmask indicating the new recording source (or sources) if successful; raises IOError if an invalid source was specified. To set the current recording source to the microphone input:

```
mixer.setrecsrc (1 << ossaudiodev.SOUND_MIXER_MIC)
```
22. Internationalization

The modules described in this chapter help you write software that is independent of language and locale by providing mechanisms for selecting a language to be used in program messages or by tailoring output to match local conventions.

The list of modules described in this chapter is:

- **22.1. gettext — Multilingual internationalization services**
  - 22.1.1. GNU gettext API
  - 22.1.2. Class-based API
    - 22.1.2.1. The NullTranslations class
    - 22.1.2.2. The GNUTranslations class
    - 22.1.2.3. Solaris message catalog support
    - 22.1.2.4. The Catalog constructor
  - 22.1.3. Internationalizing your programs and modules
    - 22.1.3.1. Localizing your module
    - 22.1.3.2. Localizing your application
    - 22.1.3.3. Changing languages on the fly
    - 22.1.3.4. Deferred translations
    - 22.1.3.5. gettext() vs. lgettext()
  - 22.1.4. Acknowledgements
- **22.2. locale — Internationalization services**
  - 22.2.1. Background, details, hints, tips and caveats
  - 22.2.2. For extension writers and programs that embed Python
  - 22.2.3. Access to message catalogs
The Python Software Foundation is a non-profit corporation.

Please donate.

Last updated on Jun 12, 2011.

Found a bug?

Created using Sphinx 0.6.7.
The gettext module provides internationalization (I18N) and localization (L10N) services for your Python modules and applications. It supports both the GNU gettext message catalog API and a higher level, class-based API that may be more appropriate for Python files. The interface described below allows you to write your module and application messages in one natural language, and provide a catalog of translated messages for running under different natural languages.

Some hints on localizing your Python modules and applications are also given.
22.1.1. GNU gettext API

The gettext module defines the following API, which is very similar to the GNU gettext API. If you use this API you will affect the translation of your entire application globally. Often this is what you want if your application is monolingual, with the choice of language dependent on the locale of your user. If you are localizing a Python module, or if your application needs to switch languages on the fly, you probably want to use the class-based API instead.

`gettext.bindtextdomain(domain[, localedir])`

Bind the `domain` to the locale directory `localedir`. More concretely, `gettext` will look for binary `.mo` files for the given domain using the path (on Unix): `localedir/language/LC_MESSAGES/domain.mo`, where `languages` is searched for in the environment variables `LANGUAGE`, `LC_ALL`, `LC_MESSAGES`, and `LANG` respectively.

If `localedir` is omitted or `None`, then the current binding for `domain` is returned. [1]

`gettext.bind_textdomain_codeset(domain[, codeset])`

Bind the `domain` to `codeset`, changing the encoding of strings returned by the `gettext()` family of functions. If `codeset` is omitted, then the current binding is returned.

*New in version 2.4.*

`gettext.textdomain([domain])`

Change or query the current global domain. If `domain` is `None`, then the current global domain is returned, otherwise the global domain is set to `domain`, which is returned.
**gettext.gettext**(message)
Return the localized translation of message, based on the current global domain, language, and locale directory. This function is usually aliased as _() in the local namespace (see examples below).

**gettext.1gettext**(message)
Equivalent to gettext(), but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with bind_textdomain_codeset().

*New in version 2.4.*

**gettext.dgettext**(domain, message)
Like gettext(), but look the message up in the specified domain.

**gettext.idgettext**(domain, message)
Equivalent to dgettext(), but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with bind_textdomain_codeset().

*New in version 2.4.*

**gettext.ngettext**(singular, plural, n)
Like gettext(), but consider plural forms. If a translation is found, apply the plural formula to n, and return the resulting message (some languages have more than two plural forms). If no translation is found, return singular if n is 1; return plural otherwise.

The Plural formula is taken from the catalog header. It is a C or Python expression that has a free variable n; the expression evaluates to the index of the plural in the catalog. See the GNU gettext documentation for the precise syntax to be used in .po
files and the formulas for a variety of languages.

New in version 2.3.

gettext. **lngettext**(singular, plural, n)
Equivalent to **ngettext()**, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with **bind_textdomain_codeset()**.

New in version 2.4.

gettext. **dngettext**(domain, singular, plural, n)
Like **ngettext()**, but look the message up in the specified domain.

New in version 2.3.

gettext. **ldngettext**(domain, singular, plural, n)
Equivalent to **dngettext()**, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with **bind_textdomain_codeset()**.

New in version 2.4.

Note that GNU **gettext** also defines a **dcgettext()** method, but this was deemed not useful and so it is currently unimplemented.

Here's an example of typical usage for this API:

```python
import gettext
gettext.bindtextdomain('myapplication', '/path/to/my/language/directory')
gettext.textdomain('myapplication')
_
print _('This is a translatable string.')
```
22.1.2. Class-based API

The class-based API of the gettext module gives you more flexibility and greater convenience than the GNU gettext API. It is the recommended way of localizing your Python applications and modules. gettext defines a “translations” class which implements the parsing of GNU .mo format files, and has methods for returning either standard 8-bit strings or Unicode strings. Instances of this “translations” class can also install themselves in the built-in namespace as the function _().

```python
gettext.find(domain[, localedir[, languages[, all]]])
```

This function implements the standard .mo file search algorithm. It takes a domain, identical to what textdomain() takes. Optional localedir is as in bindtextdomain() Optional languages is a list of strings, where each string is a language code.

If localedir is not given, then the default system locale directory is used. [2] If languages is not given, then the following environment variables are searched: LANGUAGE, LC_ALL, LC_MESSAGES, and LANG. The first one returning a non-empty value is used for the languages variable. The environment variables should contain a colon separated list of languages, which will be split on the colon to produce the expected list of language code strings.

find() then expands and normalizes the languages, and then iterates through them, searching for an existing file built of these components:

```
localedir/language/LC_MESSAGES/domain.mo
```

The first such file name that exists is returned by find(). If no
such file is found, then None is returned. If all is given, it returns a list of all file names, in the order in which they appear in the languages list or the environment variables.

gettext.translation(domain[, localedir[, languages[, class_[, fallback[, codeset]]]]])

Return a Translations instance based on the domain, localedir, and languages, which are first passed to find() to get a list of the associated .mo file paths. Instances with identical .mo file names are cached. The actual class instantiated is either class_ if provided, otherwise GNUTranslations. The class's constructor must take a single file object argument. If provided, codeset will change the charset used to encode translated strings.

If multiple files are found, later files are used as fallbacks for earlier ones. To allow setting the fallback, copy.copy() is used to clone each translation object from the cache; the actual instance data is still shared with the cache.

If no .mo file is found, this function raises IOError if fallback is false (which is the default), and returns a NullTranslations instance if fallback is true.

Changed in version 2.4: Added the codeset parameter.

gettext.install(domain[, localedir[, unicode[, codeset[, names]]]])

This installs the function _() in Python's builtins namespace, based on domain, localedir, and codeset which are passed to the function translation(). The unicode flag is passed to the resulting translation object's install() method.

For the names parameter, please see the description of the
As seen below, you usually mark the strings in your application that are candidates for translation, by wrapping them in a call to the `()` function, like this:

```python
print _('This string will be translated.')
```

For convenience, you want the `()` function to be installed in Python's builtins namespace, so it is easily accessible in all modules of your application.

*Changed in version 2.4:* Added the `codeset` parameter.

*Changed in version 2.5:* Added the `names` parameter.

### 22.1.2.1. The NullTranslations class

Translation classes are what actually implement the translation of original source file message strings to translated message strings. The base class used by all translation classes is `NullTranslations`; this provides the basic interface you can use to write your own specialized translation classes. Here are the methods of `NullTranslations`:

```python
class gettext.NullTranslations([fp])
```

Takes an optional file object `fp`, which is ignored by the base class. Initializes “protected” instance variables `_info` and `_charset` which are set by derived classes, as well as `_fallback`, which is set through `add_fallback()`. It then calls `self._parse(fp)` if `fp` is not `None`.

```python
_parse(fp)
```

No-op’d in the base class, this method takes file object `fp`, and
reads the data from the file, initializing its message catalog. If you have an unsupported message catalog file format, you should override this method to parse your format.

**add_fallback(fallback)**
Add `fallback` as the fallback object for the current translation object. A translation object should consult the fallback if it cannot provide a translation for a given message.

**gettext**(message)
If a fallback has been set, forward `gettext()` to the fallback. Otherwise, return the translated message. Overridden in derived classes.

**lgettext**(message)
If a fallback has been set, forward `lgettext()` to the fallback. Otherwise, return the translated message. Overridden in derived classes.

*New in version 2.4.*

**ugettext**(message)
If a fallback has been set, forward `ugettext()` to the fallback. Otherwise, return the translated message as a Unicode string. Overridden in derived classes.

**ngettext**(singular, plural, n)
If a fallback has been set, forward `ngettext()` to the fallback. Otherwise, return the translated message. Overridden in derived classes.

*New in version 2.3.*

**lngettext**(singular, plural, n)
If a fallback has been set, forward `ngettext()` to the fallback.
Otherwise, return the translated message. Overridden in derived classes.

*New in version 2.4.*

`ungettext(singular, plural, n)`

If a fallback has been set, forward `ungettext()` to the fallback. Otherwise, return the translated message as a Unicode string. Overridden in derived classes.

*New in version 2.3.*

`info()`

Return the “protected” `_info` variable.

`charset()`

Return the “protected” `_charset` variable.

`output_charset()`

Return the “protected” `_output_charset` variable, which defines the encoding used to return translated messages.

*New in version 2.4.*

`set_output_charset(charset)`

Change the “protected” `_output_charset` variable, which defines the encoding used to return translated messages.

*New in version 2.4.*

`install([unicode[, names]])`

If the `unicode` flag is false, this method installs `self.gettext()` into the built-in namespace, binding it to `_`. If `unicode` is true, it binds `self.ugettext()` instead. By default, `unicode` is false.
If the *names* parameter is given, it must be a sequence containing the names of functions you want to install in the builtins namespace in addition to `_()`. Supported names are 'gettext' (bound to `self.gettext()` or `self.ugettext()` according to the *unicode* flag), 'ngettext' (bound to `self.ngettext()` or `self.ungettext()` according to the *unicode* flag), 'lgettext' and 'lngettext'.

Note that this is only one way, albeit the most convenient way, to make the `_()` function available to your application. Because it affects the entire application globally, and specifically the built-in namespace, localized modules should never install `_()`. Instead, they should use this code to make `_()` available to their module:

```python
import gettext
t = gettext.translation('mymodule', ...)
_ = t.gettext
```

This puts `_()` only in the module’s global namespace and so only affects calls within this module.

*Changed in version 2.5:* Added the *names* parameter.

### 22.1.2.2. The GNUTranslations class

The *gettext* module provides one additional class derived from *NullTranslations*: **GNUTranslations**. This class overrides `_parse()` to enable reading GNU *gettext* format .mo files in both big-endian and little-endian format. It also coerces both message ids and message strings to Unicode.

**GNUTranslations** parses optional meta-data out of the translation catalog. It is convention with GNU *gettext* to include meta-data as
the translation for the empty string. This meta-data is in RFC 822-style key: value pairs, and should contain the Project-Id-Version key. If the key Content-Type is found, then the charset property is used to initialize the “protected” _charset instance variable, defaulting to None if not found. If the charset encoding is specified, then all message ids and message strings read from the catalog are converted to Unicode using this encoding. The ugettext() method always returns a Unicode, while the gettext() returns an encoded 8-bit string. For the message id arguments of both methods, either Unicode strings or 8-bit strings containing only US-ASCII characters are acceptable. Note that the Unicode version of the methods (i.e. ugettext() and ungettext()) are the recommended interface to use for internationalized Python programs.

The entire set of key/value pairs are placed into a dictionary and set as the “protected” _info instance variable.

If the .mo file’s magic number is invalid, or if other problems occur while reading the file, instantiating a GNUTranslations class can raise IOError.

The following methods are overridden from the base class implementation:

GNUTranslations.gettext(message)

Look up the message id in the catalog and return the corresponding message string, as an 8-bit string encoded with the catalog’s charset encoding, if known. If there is no entry in the catalog for the message id, and a fallback has been set, the look up is forwarded to the fallback’s gettext() method. Otherwise, the message id is returned.

GNUTranslations.lgettext(message)
Equivalent to `gettext()`, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `set_output_charset()`.

*New in version 2.4.*

**GNUTranslations. `uggettext(message)`**

Look up the `message` id in the catalog and return the corresponding message string, as a Unicode string. If there is no entry in the catalog for the `message` id, and a fallback has been set, the look up is forwarded to the fallback’s `uggettext()` method. Otherwise, the `message` id is returned.

**GNUTranslations. `ngettext(singular, plural, n)`**

Do a plural-forms lookup of a message id. `singular` is used as the message id for purposes of lookup in the catalog, while `n` is used to determine which plural form to use. The returned message string is an 8-bit string encoded with the catalog’s charset encoding, if known.

If the message id is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback’s `ngettext()` method. Otherwise, when `n` is 1 `singular` is returned, and `plural` is returned in all other cases.

*New in version 2.3.*

**GNUTranslations. `lngettext(singular, plural, n)`**

Equivalent to `gettext()`, but the translation is returned in the preferred system encoding, if no other encoding was explicitly set with `set_output_charset()`.

*New in version 2.4.*

**GNUTranslations. `ungettext(singular, plural, n)`**
Do a plural-forms lookup of a message id. *singular* is used as the message id for purposes of lookup in the catalog, while *n* is used to determine which plural form to use. The returned message string is a Unicode string.

If the message id is not found in the catalog, and a fallback is specified, the request is forwarded to the fallback’s `ungettext()` method. Otherwise, when *n* is 1 *singular* is returned, and *plural* is returned in all other cases.

Here is an example:

```python
n = len(os.listdir('.'))
cat = GNUTranslations(somefile)
message = cat.ungettext(
    'There is %(num)d file in this directory',
    'There are %(num)d files in this directory',
    n) % {'num': n}
```

*New in version 2.3.*

### 22.1.2.3. Solaris message catalog support

The Solaris operating system defines its own binary `.mo` file format, but since no documentation can be found on this format, it is not supported at this time.

### 22.1.2.4. The Catalog constructor

GNOME uses a version of the `gettext` module by James Henstridge, but this version has a slightly different API. Its documented usage was:

```python
import gettext
cat = gettext.Catalog(domain, localedir)
_ = cat.gettext
print _('hello world')
```
For compatibility with this older module, the function `catalog()` is an alias for the `translation()` function described above.

One difference between this module and Henstridge’s: his catalog objects supported access through a mapping API, but this appears to be unused and so is not currently supported.
22.1.3. Internationalizing your programs and modules

Internationalization (I18N) refers to the operation by which a program is made aware of multiple languages. Localization (L10N) refers to the adaptation of your program, once internationalized, to the local language and cultural habits. In order to provide multilingual messages for your Python programs, you need to take the following steps:

1. prepare your program or module by specially marking translatable strings
2. run a suite of tools over your marked files to generate raw messages catalogs
3. create language specific translations of the message catalogs
4. use the gettext module so that message strings are properly translated

In order to prepare your code for I18N, you need to look at all the strings in your files. Any string that needs to be translated should be marked by wrapping it in `_(...'')` — that is, a call to the function `_()`.

For example:

```python
filename = 'mylog.txt'
message = _('writing a log message')
fp = open(filename, 'w')
fp.write(message)
fp.close()
```

In this example, the string 'writing a log message' is marked as a candidate for translation, while the strings 'mylog.txt' and 'w' are not.

The Python distribution comes with two tools which help you
generate the message catalogs once you’ve prepared your source code. These may or may not be available from a binary distribution, but they can be found in a source distribution, in the Tools/i18n directory.

The pygettext [3] program scans all your Python source code looking for the strings you previously marked as translatable. It is similar to the GNU gettext program except that it understands all the intricacies of Python source code, but knows nothing about C or C++ source code. You don’t need GNU gettext unless you’re also going to be translating C code (such as C extension modules).

pygettext generates textual Uniforum-style human readable message catalog .pot files, essentially structured human readable files which contain every marked string in the source code, along with a placeholder for the translation strings. pygettext is a command line script that supports a similar command line interface as xgettext; for details on its use, run:

```
pygettext.py --help
```

Copies of these .pot files are then handed over to the individual human translators who write language-specific versions for every supported natural language. They send you back the filled in language-specific versions as a .po file. Using the msgfmt.py [4] program (in the Tools/i18n directory), you take the .po files from your translators and generate the machine-readable .mo binary catalog files. The .mo files are what the gettext module uses for the actual translation processing during run-time.

How you use the gettext module in your code depends on whether you are internationalizing a single module or your entire application. The next two sections will discuss each case.
22.1.3.1. Localizing your module

If you are localizing your module, you must take care not to make global changes, e.g. to the built-in namespace. You should not use the GNU gettext API but instead the class-based API.

Let’s say your module is called “spam” and the module’s various natural language translation .mo files reside in /usr/share/locale in GNU gettext format. Here’s what you would put at the top of your module:

```python
import gettext
t = gettext.translation('spam', '/usr/share/locale')
_ = t.lgettext
```

If your translators were providing you with Unicode strings in their .po files, you’d instead do:

```python
import gettext
t = gettext.translation('spam', '/usr/share/locale')
_ = t.ugettext
```

22.1.3.2. Localizing your application

If you are localizing your application, you can install the _() function globally into the built-in namespace, usually in the main driver file of your application. This will let all your application-specific files just use _('...') without having to explicitly install it in each file.

In the simple case then, you need only add the following bit of code to the main driver file of your application:

```python
import gettext
ggettext.install('myapplication')
```

If you need to set the locale directory or the unicode flag, you can
pass these into the `install()` function:

```python
import gettext
gettext.install('myapplication', '/usr/share/locale', unicode=1)
```

### 22.1.3.3. Changing languages on the fly

If your program needs to support many languages at the same time, you may want to create multiple translation instances and then switch between them explicitly, like so:

```python
import gettext

lang1 = gettext.translation('myapplication', languages=['en'])
lang2 = gettext.translation('myapplication', languages=['fr'])
lang3 = gettext.translation('myapplication', languages=['de'])

# start by using language1
lang1.install()

# ... time goes by, user selects language 2
lang2.install()

# ... more time goes by, user selects language 3
lang3.install()
```

### 22.1.3.4. Deferred translations

In most coding situations, strings are translated where they are coded. Occasionally however, you need to mark strings for translation, but defer actual translation until later. A classic example is:

```python
animals = ['mollusk',
          'albatross',
          'rat',
          'penguin',
          'python', ]

# ...
```
Here, you want to mark the strings in the `animals` list as being translatable, but you don’t actually want to translate them until they are printed.

Here is one way you can handle this situation:

```python
def _(message): return message

animals = [_(mollusk),
          _(albatross),
          _(rat),
          _(penguin),
          _(python),
]

del _

# ...
for a in animals:
    print _(a)
```

This works because the dummy definition of `_()` simply returns the string unchanged. And this dummy definition will temporarily override any definition of `_()` in the built-in namespace (until the `del` command). Take care, though if you have a previous definition of `_()` in the local namespace.

Note that the second use of `_()` will not identify “a” as being translatable to the `pygettext` program, since it is not a string.

Another way to handle this is with the following example:

```python
def N_(message): return message

animals = [N_(mollusk),
           N_(albatross),
           N_(rat),
           N_(penguin),
```
In this case, you are marking translatable strings with the function \texttt{\_\_()}, \cite{5} which won't conflict with any definition of \_(). However, you will need to teach your message extraction program to look for translatable strings marked with \texttt{\_\_()}. \texttt{pygettext} and \texttt{xpot} both support this through the use of command line switches.

### 22.1.3.5. 	exttt{gettext()} vs. \texttt{lgettext()}

In Python 2.4 the \texttt{l gettext()} family of functions were introduced. The intention of these functions is to provide an alternative which is more compliant with the current implementation of GNU gettext. Unlike \texttt{gettext()}, which returns strings encoded with the same codeset used in the translation file, \texttt{l gettext()} will return strings encoded with the preferred system encoding, as returned by \texttt{locale.getpreferredencoding()}. Also notice that Python 2.4 introduces new functions to explicitly choose the codeset used in translated strings. If a codeset is explicitly set, even \texttt{l gettext()} will return translated strings in the requested codeset, as would be expected in the GNU gettext implementation.
The following people contributed code, feedback, design suggestions, previous implementations, and valuable experience to the creation of this module:

- Peter Funk
- James Henstridge
- Juan David Ibáñez Palomar
- Marc-André Lemburg
- Martin von Löwis
- François Pinard
- Barry Warsaw
- Gustavo Niemeyer

Footnotes

[1] The default locale directory is system dependent; for example, on RedHat Linux it is /usr/share/locale, but on Solaris it is /usr/lib/locale. The gettext module does not try to support these system dependent defaults; instead its default is sys.prefix/share/locale. For this reason, it is always best to call bindtextdomain() with an explicit absolute path at the start of your application.

[2] See the footnote for bindtextdomain() above.

[3] François Pinard has written a program called xpot which does a similar job. It is available as part of his po-utils package at http://po-utils.progiciels-bpi.ca/.

[4] msgfmt.py is binary compatible with GNU msgfmt except that it provides a simpler, all-Python implementation. With this and pygettext.py, you generally won’t need to install the GNU gettext package to internationalize your Python applications.

[5] The choice of N_() here is totally arbitrary; it could have just as easily been MarkThisStringForTranslation().
22.2. locale — Internationalization services

The `locale` module opens access to the POSIX locale database and functionality. The POSIX locale mechanism allows programmers to deal with certain cultural issues in an application, without requiring the programmer to know all the specifics of each country where the software is executed.

The `locale` module is implemented on top of the `_locale` module, which in turn uses an ANSI C locale implementation if available.

The `locale` module defines the following exception and functions:

`exception locale.Error`

Exception raised when `setlocale()` fails.

`locale.setlocale(category[, locale])`

If `locale` is specified, it may be a string, a tuple of the form `(language code, encoding)`, or `None`. If it is a tuple, it is converted to a string using the locale aliasing engine. If `locale` is given and not `None`, `setlocale()` modifies the locale setting for the `category`. The available categories are listed in the data description below. The value is the name of a locale. An empty string specifies the user’s default settings. If the modification of the locale fails, the exception `Error` is raised. If successful, the new locale setting is returned.

If `locale` is omitted or `None`, the current setting for `category` is returned.

`setlocale()` is not thread-safe on most systems. Applications
typically start with a call of

```python
import locale
locale.setlocale(locale.LC_ALL, '')
```

This sets the locale for all categories to the user’s default setting (typically specified in the LANG environment variable). If the locale is not changed thereafter, using multithreading should not cause problems.

*Changed in version 2.0:* Added support for tuple values of the `locale` parameter.

`locale.localeconv()`

Returns the database of the local conventions as a dictionary. This dictionary has the following strings as keys:

<table>
<thead>
<tr>
<th>Category</th>
<th>Key</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>LC_NUMERIC</td>
<td>'decimal_point'</td>
<td>Decimal point character.</td>
</tr>
<tr>
<td></td>
<td>'grouping'</td>
<td>Sequence of numbers specifying which relative positions the 'thousands_sep' is expected. If the sequence is terminated with CHAR_MAX, no further grouping is performed. If the sequence terminates with a 0, the last group size is repeatedly</td>
</tr>
<tr>
<td>Key</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>'thousands_sep'</td>
<td>Character used between groups.</td>
<td></td>
</tr>
<tr>
<td><strong>LC_MONETARY</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>'int_curr_symbol'</td>
<td>International currency symbol.</td>
<td></td>
</tr>
<tr>
<td>'currency_symbol'</td>
<td>Local currency symbol.</td>
<td></td>
</tr>
<tr>
<td>'p_cs_precedes/n_cs_precedes'</td>
<td>Whether the currency symbol precedes the value (for positive resp. negative values).</td>
<td></td>
</tr>
<tr>
<td>'p_sep_by_space/n_sep_by_space'</td>
<td>Whether the currency symbol is separated from the value by a space (for positive resp. negative values).</td>
<td></td>
</tr>
<tr>
<td>'mon_decimal_point'</td>
<td>Decimal point used for monetary values.</td>
<td></td>
</tr>
<tr>
<td>'frac_digits'</td>
<td>Number of fractional digits used in local formatting of monetary values.</td>
<td></td>
</tr>
<tr>
<td>Key</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>'int_frac_digits'</td>
<td>International formatting of monetary values.</td>
<td></td>
</tr>
<tr>
<td>'mon_thousands_sep'</td>
<td>Group separator used for monetary values.</td>
<td></td>
</tr>
<tr>
<td>'mon_grouping'</td>
<td>Equivalent to 'grouping', used for monetary values.</td>
<td></td>
</tr>
<tr>
<td>'positive_sign'</td>
<td>Symbol used to annotate a positive monetary value.</td>
<td></td>
</tr>
<tr>
<td>'negative_sign'</td>
<td>Symbol used to annotate a negative monetary value.</td>
<td></td>
</tr>
<tr>
<td>'p_sign_posn/n_sign_posn'</td>
<td>The position of the sign (for positive resp. negative values), see below.</td>
<td></td>
</tr>
</tbody>
</table>

All numeric values can be set to `CHAR_MAX` to indicate that there is no value specified in this locale.

The possible values for 'p_sign_posn' and 'n_sign_posn' are given below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Currency and value are surrounded by parentheses.</td>
</tr>
<tr>
<td></td>
<td>Description</td>
</tr>
<tr>
<td>---</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>1</td>
<td>The sign should precede the value and currency symbol.</td>
</tr>
<tr>
<td>2</td>
<td>The sign should follow the value and currency symbol.</td>
</tr>
<tr>
<td>3</td>
<td>The sign should immediately precede the value.</td>
</tr>
<tr>
<td>4</td>
<td>The sign should immediately follow the value.</td>
</tr>
<tr>
<td>CHAR_MAX</td>
<td>Nothing is specified in this locale.</td>
</tr>
</tbody>
</table>

Locale. **nl_langinfo**(option)

Return some locale-specific information as a string. This function is not available on all systems, and the set of possible options might also vary across platforms. The possible argument values are numbers, for which symbolic constants are available in the locale module.

The **nl_langinfo()** function accepts one of the following keys. Most descriptions are taken from the corresponding description in the GNU C library.

Locale. **CODESET**

Get a string with the name of the character encoding used in the selected locale.

Locale. **D_T_FMT**

Get a string that can be used as a format string for **strftime()** to represent date and time in a locale-specific way.

Locale. **D_FMT**

Get a string that can be used as a format string for **strftime()** to represent a date in a locale-specific way.

Locale. **T_FMT**

Get a string that can be used as a format string for **strftime()** to represent a time in a locale-specific way.
locale. **T_FMT_AMPM**

Get a format string for `strftime()` to represent time in the am/pm format.

**DAY_1** . . . **DAY_7**

Get the name of the n-th day of the week.

**Note:** This follows the US convention of **DAY_1** being Sunday, not the international convention (ISO 8601) that Monday is the first day of the week.

**ABDAY_1** . . . **ABDAY_7**

Get the abbreviated name of the n-th day of the week.

**MON_1** . . . **MON_12**

Get the name of the n-th month.

**ABMON_1** . . . **ABMON_12**

Get the abbreviated name of the n-th month.

locale. **RADIXCHAR**

Get the radix character (decimal dot, decimal comma, etc.)

locale. **THOUSEP**

Get the separator character for thousands (groups of three digits).

locale. **YESEXPR**

Get a regular expression that can be used with the `regex()` function to recognize a positive response to a yes/no question.

**Note:** The expression is in the syntax suitable for the `regex()` function from the C library, which might differ from the syntax used in `re`. 
locale. **NOEXPR**

Get a regular expression that can be used with the `regex(3)` function to recognize a negative response to a yes/no question.

locale. **CRNCYSTR**

Get the currency symbol, preceded by “-” if the symbol should appear before the value, “+” if the symbol should appear after the value, or “.” if the symbol should replace the radix character.

locale. **ERA**

Get a string that represents the era used in the current locale.

Most locales do not define this value. An example of a locale which does define this value is the Japanese one. In Japan, the traditional representation of dates includes the name of the era corresponding to the then-emperor’s reign.

Normally it should not be necessary to use this value directly. Specifying the `ε` modifier in their format strings causes the `strftime()` function to use this information. The format of the returned string is not specified, and therefore you should not assume knowledge of it on different systems.

locale. **ERA_D_T_FMT**

Get a format string for `strftime()` to represent date and time in a locale-specific era-based way.

locale. **ERA_D_FMT**

Get a format string for `strftime()` to represent a date in a locale-specific era-based way.

locale. **ERA_T_FMT**

Get a format string for `strftime()` to represent a time in a
locale-specific era-based way.

locale. **ALT_DIGITS**

Get a representation of up to 100 values used to represent the values 0 to 99.

locale. **getdefaultlocale([envvars])**

Tries to determine the default locale settings and returns them as a tuple of the form *(language code, encoding).*

According to POSIX, a program which has not called `setlocale(LC_ALL, '')` runs using the portable 'c' locale. Calling `setlocale(LC_ALL, '')` lets it use the default locale as defined by the **LANG** variable. Since we do not want to interfere with the current locale setting we thus emulate the behavior in the way described above.

To maintain compatibility with other platforms, not only the **LANG** variable is tested, but a list of variables given as envvars parameter. The first found to be defined will be used. **envvars** defaults to the search path used in GNU gettext; it must always contain the variable name **LANG**. The GNU gettext search path contains 'LANGUAGE', 'LC_ALL', 'LC_CTYPE', and **LANG**, in that order.

Except for the code 'c', the language code corresponds to RFC 1766. **language code** and **encoding** may be **None** if their values cannot be determined.

**New in version 2.0.**

locale. **getlocale([category])**

Returns the current setting for the given locale category as sequence containing **language code**, **encoding**. **category** may be
one of the \texttt{LC\_} values except \texttt{LC\_ALL}. It defaults to \texttt{LC\_CTYPE}.

Except for the code 'c', the language code corresponds to RFC \texttt{1766}. \textit{language code} and \textit{encoding} may be \texttt{None} if their values cannot be determined.

\textit{New in version 2.0.}

\texttt{locale.getpreferredencoding([do\_setlocale])}

Return the encoding used for text data, according to user preferences. User preferences are expressed differently on different systems, and might not be available programmatically on some systems, so this function only returns a guess.

On some systems, it is necessary to invoke \texttt{setlocale()} to obtain the user preferences, so this function is not thread-safe. If invoking \texttt{setlocale} is not necessary or desired, \texttt{do\_setlocale} should be set to \texttt{False}.

\textit{New in version 2.3.}

\texttt{locale.normalize(localetname)}

Returns a normalized locale code for the given locale name. The returned locale code is formatted for use with \texttt{setlocale()}. If normalization fails, the original name is returned unchanged.

If the given encoding is not known, the function defaults to the default encoding for the locale code just like \texttt{setlocale()}.

\textit{New in version 2.0.}

\texttt{locale.resetlocale([category])}

Sets the locale for \texttt{category} to the default setting.

The default setting is determined by calling \texttt{getdefaultlocale()}. 

category defaults to **LC_ALL**.

*New in version 2.0.*

locale. **strcoll**(string1, string2)

Compares two strings according to the current **LC_COLLATE** setting. As any other compare function, returns a negative, or a positive value, or 0, depending on whether string1 collates before or after string2 or is equal to it.

locale. **strxfrm**(string)

Transforms a string to one that can be used for the built-in function **cmp()**, and still returns locale-aware results. This function can be used when the same string is compared repeatedly, e.g. when collating a sequence of strings.

locale. **format**(format, val[, grouping[, monetary]])

Formats a number val according to the current **LC_NUMERIC** setting. The format follows the conventions of the % operator. For floating point values, the decimal point is modified if appropriate. If grouping is true, also takes the grouping into account.

If monetary is true, the conversion uses monetary thousands separator and grouping strings.

Please note that this function will only work for exactly one %char specifier. For whole format strings, use **format_string()**.

*Changed in version 2.5: Added the monetary parameter.*

locale. **format_string**(format, val[, grouping])

Processes formatting specifiers as in format % val, but takes the current locale settings into account.
**New in version 2.5.**

locale.\texttt{currency}(\texttt{val[, symbol[, grouping[, international]]]})

Formats a number \texttt{val} according to the current \texttt{LC_MONETARY} settings.

The returned string includes the currency symbol if \texttt{symbol} is true, which is the default. If \texttt{grouping} is true (which is not the default), grouping is done with the value. If \texttt{international} is true (which is not the default), the international currency symbol is used.

Note that this function will not work with the ‘C’ locale, so you have to set a locale via \texttt{setlocale()} first.

**New in version 2.5.**

locale.\texttt{str}(\texttt{float})

Formats a floating point number using the same format as the built-in function \texttt{str(float)}, but takes the decimal point into account.

locale.\texttt{atof}(\texttt{string})

Converts a string to a floating point number, following the \texttt{LC_NUMERIC} settings.

locale.\texttt{atoi}(\texttt{string})

Converts a string to an integer, following the \texttt{LC_NUMERIC} conventions.

locale.\texttt{LC_CTYPE}

Locale category for the character type functions. Depending on the settings of this category, the functions of module \texttt{string} dealing with case change their behaviour.
locale. **LC_COLLATE**
Locale category for sorting strings. The functions `strcoll()` and `strxfrm()` of the `locale` module are affected.

locale. **LC_TIME**
Locale category for the formatting of time. The function `time.strftime()` follows these conventions.

locale. **LC_MONETARY**
Locale category for formatting of monetary values. The available options are available from the `localeconv()` function.

locale. **LC_MESSAGES**
Locale category for message display. Python currently does not support application specific locale-aware messages. Messages displayed by the operating system, like those returned by `os.strerror()` might be affected by this category.

locale. **LC_NUMERIC**
Locale category for formatting numbers. The functions `format()`, `atoi()`, `atof()` and `str()` of the `locale` module are affected by that category. All other numeric formatting operations are not affected.

locale. **LC_ALL**
Combination of all locale settings. If this flag is used when the locale is changed, setting the locale for all categories is attempted. If that fails for any category, no category is changed at all. When the locale is retrieved using this flag, a string indicating the setting for all categories is returned. This string can be later used to restore the settings.

locale. **CHAR_MAX**
This is a symbolic constant used for different values returned by `localeconv()`.
Example:

```python
>>> import locale
>>> loc = locale.getlocale()  # get current locale
# use German locale; name might vary with platform
>>> locale.setlocale(locale.LC_ALL, 'de_DE')
>>> locale.strcoll('f\xe4n', 'foo')  # compare a string containing an umlaut
>>> locale.setlocale(locale.LC_ALL, '')  # use user's preferred locale
>>> locale.setlocale(locale.LC_ALL, 'C')  # use default (C) locale
>>> locale.setlocale(locale.LC_ALL, loc)  # restore saved locale
```
22.2.1. Background, details, hints, tips and caveats

The C standard defines the locale as a program-wide property that may be relatively expensive to change. On top of that, some implementation are broken in such a way that frequent locale changes may cause core dumps. This makes the locale somewhat painful to use correctly.

Initially, when a program is started, the locale is the C locale, no matter what the user’s preferred locale is. The program must explicitly say that it wants the user’s preferred locale settings by calling `setlocale(LC_ALL, '')`.

It is generally a bad idea to call `setlocale()` in some library routine, since as a side effect it affects the entire program. Saving and restoring it is almost as bad: it is expensive and affects other threads that happen to run before the settings have been restored.

If, when coding a module for general use, you need a locale independent version of an operation that is affected by the locale (such as `string.lower()`, or certain formats used with `time.strftime()`), you will have to find a way to do it without using the standard library routine. Even better is convincing yourself that using locale settings is okay. Only as a last resort should you document that your module is not compatible with non-C locale settings.

The case conversion functions in the `string` module are affected by the locale settings. When a call to the `setlocale()` function changes the `LC_CTYPE` settings, the variables `string.lowercase`, `string.uppercase` and `string.letters` are recalculated. Note that
code that uses these variable through `from ... import ...`, e.g. `from string import letters`, is not affected by subsequent `setlocale()` calls.

The only way to perform numeric operations according to the locale is to use the special functions defined by this module: `atof()`, `atoi()`, `format()`, `str()`. 
22.2.2. For extension writers and programs that embed Python

Extension modules should never call `setlocale()`, except to find out what the current locale is. But since the return value can only be used portably to restore it, that is not very useful (except perhaps to find out whether or not the locale is C).

When Python code uses the `locale` module to change the locale, this also affects the embedding application. If the embedding application doesn't want this to happen, it should remove the `_locale` extension module (which does all the work) from the table of built-in modules in the `config.c` file, and make sure that the `_locale` module is not accessible as a shared library.
22.2.3. Access to message catalogs

The locale module exposes the C library's gettext interface on systems that provide this interface. It consists of the functions gettext(), dgettext(), dcgettext(), textdomain(), bindtextdomain(), and bind_textdomain_codeset(). These are similar to the same functions in the gettext module, but use the C library's binary format for message catalogs, and the C library's search algorithms for locating message catalogs.

Python applications should normally find no need to invoke these functions, and should use gettext instead. A known exception to this rule are applications that link with additional C libraries which internally invoke gettext() or dcgettext(). For these applications, it may be necessary to bind the text domain, so that the libraries can properly locate their message catalogs.
23. Program Frameworks

The modules described in this chapter are frameworks that will largely dictate the structure of your program. Currently the modules described here are all oriented toward writing command-line interfaces.

The full list of modules described in this chapter is:

- **23.1. cmd** — Support for line-oriented command interpreters
  - 23.1.1. Cmd Objects
- **23.2. shlex** — Simple lexical analysis
  - 23.2.1. shlex Objects
  - 23.2.2. Parsing Rules
23.1. cmd — Support for line-oriented command interpreters

The `cmd` class provides a simple framework for writing line-oriented command interpreters. These are often useful for test harnesses, administrative tools, and prototypes that will later be wrapped in a more sophisticated interface.

**See also:** Latest version of the `cmd` module Python source code

```
class cmd.Cmd([completekey[, stdin[, stdout]]])
```

A `Cmd` instance or subclass instance is a line-oriented interpreter framework. There is no good reason to instantiate `cmd` itself; rather, it's useful as a superclass of an interpreter class you define yourself in order to inherit `cmd`'s methods and encapsulate action methods.

The optional argument `completekey` is the `readline` name of a completion key; it defaults to `Tab`. If `completekey` is not `None` and `readline` is available, command completion is done automatically.

The optional arguments `stdin` and `stdout` specify the input and output file objects that the `Cmd` instance or subclass instance will use for input and output. If not specified, they will default to `sys.stdin` and `sys.stdout`.

If you want a given `stdin` to be used, make sure to set the instance's `use_rawinput` attribute to `False`, otherwise `stdin` will be ignored.

*Changed in version 2.3:* The `stdin` and `stdout` parameters were
added.
23.1.1. Cmd Objects

A `Cmd` instance has the following methods:

```
Cmd.cmdloop([intro])
```

Repeatedly issue a prompt, accept input, parse an initial prefix off the received input, and dispatch to action methods, passing them the remainder of the line as argument.

The optional argument is a banner or intro string to be issued before the first prompt (this overrides the `intro` class member).

If the `readline` module is loaded, input will automatically inherit `bash`-like history-list editing (e.g. `Control-P` scrolls back to the last command, `Control-N` forward to the next one, `Control-F` moves the cursor to the right non-destructively, `Control-B` moves the cursor to the left non-destructively, etc.).

An end-of-file on input is passed back as the string `'EOF'`.

An interpreter instance will recognize a command name `foo` if and only if it has a method `do_foo()`. As a special case, a line beginning with the character `'?'` is dispatched to the method `do_help()`. As another special case, a line beginning with the character `'!'` is dispatched to the method `do_shell()` (if such a method is defined).

This method will return when the `postcmd()` method returns a true value. The `stop` argument to `postcmd()` is the return value from the command’s corresponding `do_*()` method.

If completion is enabled, completing commands will be done
automatically, and completing of commands args is done by calling `complete_foo()` with arguments `text`, `line`, `begidx`, and `endidx`. `text` is the string prefix we are attempting to match: all returned matches must begin with it. `line` is the current input line with leading whitespace removed, `begidx` and `endidx` are the beginning and ending indexes of the prefix text, which could be used to provide different completion depending upon which position the argument is in.

All subclasses of `Cmd` inherit a predefined `do_help()`. This method, called with an argument `'bar'`, invokes the corresponding method `help_bar()`, and if that is not present, prints the docstring of `do_bar()`, if available. With no argument, `do_help()` lists all available help topics (that is, all commands with corresponding `help_*()` methods or commands that have docstrings), and also lists any undocumented commands.

** Cmd. `onecmd(str)`
Interpret the argument as though it had been typed in response to the prompt. This may be overridden, but should not normally need to be; see the `precmd()` and `postcmd()` methods for useful execution hooks. The return value is a flag indicating whether interpretation of commands by the interpreter should stop. If there is a `do_*()` method for the command `str`, the return value of that method is returned, otherwise the return value from the `default()` method is returned.

** Cmd. `emptyline()`
Method called when an empty line is entered in response to the prompt. If this method is not overridden, it repeats the last nonempty command entered.

** Cmd. `default(line)`
Method called on an input line when the command prefix is not recognized. If this method is not overridden, it prints an error message and returns.

Cmd. **completedefault**(text, line, begidx, endidx)
Method called to complete an input line when no command-specific complete_*() method is available. By default, it returns an empty list.

Cmd. **precmd**(line)
Hook method executed just before the command line line is interpreted, but after the input prompt is generated and issued. This method is a stub in Cmd; it exists to be overridden by subclasses. The return value is used as the command which will be executed by the onecmd() method; the precmd() implementation may re-write the command or simply return line unchanged.

Cmd. **postcmd**(stop, line)
Hook method executed just after a command dispatch is finished. This method is a stub in Cmd; it exists to be overridden by subclasses. line is the command line which was executed, and stop is a flag which indicates whether execution will be terminated after the call to postcmd(); this will be the return value of the onecmd() method. The return value of this method will be used as the new value for the internal flag which corresponds to stop; returning false will cause interpretation to continue.

Cmd. **preloop()
Hook method executed once when cmdloop() is called. This method is a stub in Cmd; it exists to be overridden by subclasses.

Cmd. **postloop()
Hook method executed once when `cmdloop()` is about to return. This method is a stub in `cmd`; it exists to be overridden by subclasses.

Instances of `cmd` subclasses have some public instance variables:

**`Cmd.prompt`**

The prompt issued to solicit input.

**`Cmd.identchars`**

The string of characters accepted for the command prefix.

**`Cmd.lastcmd`**

The last nonempty command prefix seen.

**`Cmd.intro`**

A string to issue as an intro or banner. May be overridden by giving the `cmdloop()` method an argument.

**`Cmd.doc_header`**

The header to issue if the help output has a section for documented commands.

**`Cmd.misc_header`**

The header to issue if the help output has a section for miscellaneous help topics (that is, there are `help_*()` methods without corresponding `do_*()` methods).

**`Cmd.undoc_header`**

The header to issue if the help output has a section for undocumented commands (that is, there are `do_*()` methods without corresponding `help_*()` methods).

**`Cmd.ruler`**

The character used to draw separator lines under the help-message headers. If empty, no ruler line is drawn. It defaults to
Cmd. **use_rawinput**

A flag, defaulting to true. If true, `cmdloop()` uses `raw_input()` to display a prompt and read the next command; if false, `sys.stdout.write()` and `sys.stdin.readline()` are used. (This means that by importing `readline`, on systems that support it, the interpreter will automatically support **Emacs**-like line editing and command-history keystrokes.)
23.2. shlex — Simple lexical analysis

New in version 1.5.2.

The shlex class makes it easy to write lexical analyzers for simple syntaxes resembling that of the Unix shell. This will often be useful for writing minilanguages, (for example, in run control files for Python applications) or for parsing quoted strings.

Note: The shlex module currently does not support Unicode input.

The shlex module defines the following functions:

shlex.split(s[, comments[, posix]])

Split the string s using shell-like syntax. If comments is False (the default), the parsing of comments in the given string will be disabled (setting the commenters member of the shlex instance to the empty string). This function operates in POSIX mode by default, but uses non-POSIX mode if the posix argument is false.

New in version 2.3.

Changed in version 2.6: Added the posix parameter.

Note: Since the split() function instantiates a shlex instance, passing None for s will read the string to split from standard input.

The shlex module defines the following class:
class shlex.shlex([instream[, infile[, posix]]])

A `shlex` instance or subclass instance is a lexical analyzer object. The initialization argument, if present, specifies where to read characters from. It must be a file-/stream-like object with `read()` and `readline()` methods, or a string (strings are accepted since Python 2.3). If no argument is given, input will be taken from `sys.stdin`. The second optional argument is a filename string, which sets the initial value of the `infile` member. If the `instream` argument is omitted or equal to `sys.stdin`, this second argument defaults to “stdin”. The `posix` argument was introduced in Python 2.3, and defines the operational mode. When `posix` is not true (default), the `shlex` instance will operate in compatibility mode. When operating in POSIX mode, `shlex` will try to be as close as possible to the POSIX shell parsing rules.

See also:

Module ConfigParser
Parser for configuration files similar to the Windows `.ini` files.
23.2.1. shlex Objects

A *shlex* instance has the following methods:

shlex.*get_token()*

Return a token. If tokens have been stacked using *push_token()*, pop a token off the stack. Otherwise, read one from the input stream. If reading encounters an immediate end-of-file, *self.eof* is returned (the empty string (""") in non-POSIX mode, and *None* in POSIX mode).

shlex.*push_token(str)*

Push the argument onto the token stack.

shlex.*read_token()*

Read a raw token. Ignore the pushback stack, and do not interpret source requests. (This is not ordinarily a useful entry point, and is documented here only for the sake of completeness.)

shlex.*sourcehook(filename)*

When *shlex* detects a source request (see *source* below) this method is given the following token as argument, and expected to return a tuple consisting of a filename and an open file-like object.

Normally, this method first strips any quotes off the argument. If the result is an absolute pathname, or there was no previous source request in effect, or the previous source was a stream (such as *sys.stdin*), the result is left alone. Otherwise, if the result is a relative pathname, the directory part of the name of the file immediately before it on the source inclusion stack is prepended (this behavior is like the way the C preprocessor
handles `#include "file.h"`).

The result of the manipulations is treated as a filename, and returned as the first component of the tuple, with `open()` called on it to yield the second component. (Note: this is the reverse of the order of arguments in instance initialization!)

This hook is exposed so that you can use it to implement directory search paths, addition of file extensions, and other namespace hacks. There is no corresponding ‘close’ hook, but a shlex instance will call the `close()` method of the sourced input stream when it returns EOF.

For more explicit control of source stacking, use the `push_source()` and `pop_source()` methods.

**shlex.** `push_source(stream[, filename])`

Push an input source stream onto the input stack. If the filename argument is specified it will later be available for use in error messages. This is the same method used internally by the `sourcehook()` method.

*New in version 2.1.*

**shlex.** `pop_source()`

Pop the last-pushed input source from the input stack. This is the same method used internally when the lexer reaches EOF on a stacked input stream.

*New in version 2.1.*

**shlex.** `error_leader([file[, line]])`

This method generates an error message leader in the format of a Unix C compiler error label; the format is `"%s", line %d: `,
where the $%s$ is replaced with the name of the current source file and the $%d$ with the current input line number (the optional arguments can be used to override these).

This convenience is provided to encourage `shlex` users to generate error messages in the standard, parseable format understood by Emacs and other Unix tools.

Instances of `shlex` subclasses have some public instance variables which either control lexical analysis or can be used for debugging:

**shlex.commenters**
The string of characters that are recognized as comment beginners. All characters from the comment beginner to end of line are ignored. Includes just '#' by default.

**shlex.wordchars**
The string of characters that will accumulate into multi-character tokens. By default, includes all ASCII alphanumerics and underscore.

**shlex.whitespace**
Characters that will be considered whitespace and skipped. Whitespace bounds tokens. By default, includes space, tab, linefeed and carriage-return.

**shlex.escape**
Characters that will be considered as escape. This will be only used in POSIX mode, and includes just '\' by default.

*New in version 2.3.*

**shlex.quotes**
Characters that will be considered string quotes. The token accumulates until the same quote is encountered again (thus, different quote types protect each other as in the shell.) By
default, includes ASCII single and double quotes.

**shlex.escapedquotes**

Characters in quotes that will interpret escape characters defined in escape. This is only used in POSIX mode, and includes just `'` by default.

*New in version 2.3.*

**shlex.whitespace_split**

If True, tokens will only be split in whitespaces. This is useful, for example, for parsing command lines with shlex, getting tokens in a similar way to shell arguments.

*New in version 2.3.*

**shlex.infile**

The name of the current input file, as initially set at class instantiation time or stacked by later source requests. It may be useful to examine this when constructing error messages.

**shlex.instream**

The input stream from which this shlex instance is reading characters.

**shlex.source**

This member is **None** by default. If you assign a string to it, that string will be recognized as a lexical-level inclusion request similar to the source keyword in various shells. That is, the immediately following token will opened as a filename and input taken from that stream until EOF, at which point the close() method of that stream will be called and the input source will again become the original input stream. Source requests may be stacked any number of levels deep.

**shlex.debug**
If this member is numeric and 1 or more, a `shlex` instance will print verbose progress output on its behavior. If you need to use this, you can read the module source code to learn the details.

`shlex.lineno`
Source line number (count of newlines seen so far plus one).

`shlex.token`
The token buffer. It may be useful to examine this when catching exceptions.

`shlex.eof`
Token used to determine end of file. This will be set to the empty string (`''`), in non-POSIX mode, and to `None` in POSIX mode.

*New in version 2.3.*
23.2.2. Parsing Rules

When operating in non-POSIX mode, `shlex` will try to obey to the following rules.

- Quote characters are not recognized within words (Do"Not"Separate is parsed as the single word Do"Not"Separate);
- Escape characters are not recognized;
- Enclosing characters in quotes preserve the literal value of all characters within the quotes;
- Closing quotes separate words ("Do"Separate is parsed as Do and Separate);
- If `whitespace_split` is `False`, any character not declared to be a word character, whitespace, or a quote will be returned as a single-character token. If it is `True`, `shlex` will only split words in whitespaces;
- EOF is signaled with an empty string ('');
- It's not possible to parse empty strings, even if quoted.

When operating in POSIX mode, `shlex` will try to obey to the following parsing rules.

- Quotes are stripped out, and do not separate words ("Do"Not"Separate" is parsed as the single word DoNotSeparate);
- Non-quoted escape characters (e.g. '\') preserve the literal value of the next character that follows;
- Enclosing characters in quotes which are not part of escapedquotes (e.g. "'") preserve the literal value of all characters within the quotes;
- Enclosing characters in quotes which are part of escapedquotes (e.g. "'') preserves the literal value of all characters within the quotes, with the exception of the characters mentioned in
escape. The escape characters retain its special meaning only when followed by the quote in use, or the escape character itself. Otherwise the escape character will be considered a normal character.

- EOF is signaled with a None value;
- Quoted empty strings ('' ) are allowed;
24. Graphical User Interfaces with Tk

Tk/Tcl has long been an integral part of Python. It provides a robust and platform independent windowing toolkit, that is available to Python programmers using the Tkinter module, and its extensions, the Tix and the ttk modules.

The Tkinter module is a thin object-oriented layer on top of Tcl/Tk. To use Tkinter, you don’t need to write Tcl code, but you will need to consult the Tk documentation, and occasionally the Tcl documentation. Tkinter is a set of wrappers that implement the Tk widgets as Python classes. In addition, the internal module _tkinter provides a threadsafe mechanism which allows Python and Tcl to interact.

Tkinter’s chief virtues are that it is fast, and that it usually comes bundled with Python. Although its standard documentation is weak, good material is available, which includes: references, tutorials, a book and others. Tkinter is also famous for having an outdated look and feel, which has been vastly improved in Tk 8.5. Nevertheless, there are many other GUI libraries that you could be interested in. For more information about alternatives, see the Other Graphical User Interface Packages section.

24. Graphical User Interfaces with Tk
24.1. Tkinter — Python interface to Tcl/Tk

The Tkinter module ("Tk interface") is the standard Python interface to the Tk GUI toolkit. Both Tk and Tkinter are available on most Unix platforms, as well as on Windows systems. (Tk itself is not part of Python; it is maintained at ActiveState.)

**Note:** Tkinter has been renamed to tkinter in Python 3.0. The 2to3 tool will automatically adapt imports when converting your sources to 3.0.

**See also:**

**Python Tkinter Resources**
- The Python Tkinter Topic Guide provides a great deal of information on using Tk from Python and links to other sources of information on Tk.

**An Introduction to Tkinter**
- Fredrik Lundh's on-line reference material.

**Tkinter reference: a GUI for Python**
- On-line reference material.

**Python and Tkinter Programming**
**24.1.1. Tkinter Modules**

Most of the time, the `Tkinter` module is all you really need, but a number of additional modules are available as well. The Tk interface is located in a binary module named `_tkinter`. This module contains the low-level interface to Tk, and should never be used directly by application programmers. It is usually a shared library (or DLL), but might in some cases be statically linked with the Python interpreter.

In addition to the Tk interface module, `Tkinter` includes a number of Python modules. The two most important modules are the `Tkinter` module itself, and a module called `Tkconstants`. The former automatically imports the latter, so to use Tkinter, all you need to do is to import one module:

```
import Tkinter
```

Or, more often:

```
from Tkinter import *
```

```
class Tkinter.Tk(screenName=None, baseName=None,
className='Tk', useTk=1)
```

The `Tk` class is instantiated without arguments. This creates a toplevel widget of Tk which usually is the main window of an application. Each instance has its own associated Tcl interpreter.

*Changed in version 2.4*: The `useTk` parameter was added.

```
Tkinter.Tcl(screenName=None, baseName=None,
className='Tk', useTk=0)
```

The `Tcl()` function is a factory function which creates an object much like that created by the `Tk` class, except that it does not
initialize the Tk subsystem. This is most often useful when driving the Tcl interpreter in an environment where one doesn’t want to create extraneous toplevel windows, or where one cannot (such as Unix/Linux systems without an X server). An object created by the `Tcl()` object can have a Toplevel window created (and the Tk subsystem initialized) by calling its `loadtk()` method.

New in version 2.4.

Other modules that provide Tk support include:

**ScrolledText**
Text widget with a vertical scroll bar built in.

**tkColorChooser**
Dialog to let the user choose a color.

**tkCommonDialog**
Base class for the dialogs defined in the other modules listed here.

**tkFileDialog**
Common dialogs to allow the user to specify a file to open or save.

**tkFont**
Utilities to help work with fonts.

**tkMessageBox**
Access to standard Tk dialog boxes.

**tkSimpleDialog**
Basic dialogs and convenience functions.

**TkDnd**
Drag-and-drop support for Tkinter. This is experimental and should become deprecated when it is replaced with the Tk DND.

**turtle**
Turtle graphics in a Tk window.
These have been renamed as well in Python 3.0; they were all made submodules of the new `tkinter` package.
24.1.2. Tkinter Life Preserver

This section is not designed to be an exhaustive tutorial on either Tk or Tkinter. Rather, it is intended as a stop gap, providing some introductory orientation on the system.

Credits:

- Tkinter was written by Steen Lumholt and Guido van Rossum.
- Tk was written by John Ousterhout while at Berkeley.
- This Life Preserver was written by Matt Conway at the University of Virginia.
- The html rendering, and some liberal editing, was produced from a FrameMaker version by Ken Manheimer.
- Fredrik Lundh elaborated and revised the class interface descriptions, to get them current with Tk 4.2.
- Mike Clarkson converted the documentation to LaTeX, and compiled the User Interface chapter of the reference manual.

24.1.2.1. How To Use This Section

This section is designed in two parts: the first half (roughly) covers background material, while the second half can be taken to the keyboard as a handy reference.

When trying to answer questions of the form “how do I do blah”, it is often best to find out how to do “blah” in straight Tk, and then convert this back into the corresponding Tkinter call. Python programmers can often guess at the correct Python command by looking at the Tk documentation. This means that in order to use Tkinter, you will have to know a little bit about Tk. This document can’t fulfill that role, so the best we can do is point you to the best documentation that exists. Here are some hints:
• The authors strongly suggest getting a copy of the Tk man pages. Specifically, the man pages in the man directory are most useful. The man3 man pages describe the C interface to the Tk library and thus are not especially helpful for script writers.
• Addison-Wesley publishes a book called Tcl and the Tk Toolkit by John Ousterhout (ISBN 0-201-63337-X) which is a good introduction to Tcl and Tk for the novice. The book is not exhaustive, and for many details it defers to the man pages.
• Tkinter.py is a last resort for most, but can be a good place to go when nothing else makes sense.

### 24.1.2.2. A Simple Hello World Program

```python
from Tkinter import *

class Application(Frame):
    def say_hi(self):
        print "hi there, everyone!"

    def createWidgets(self):
        self.QUIT = Button(self)
        self.QUIT["text"] = "QUIT"
        self.QUIT["fg"] = "red"
        self.QUIT["command"] = self.quit

        self.QUIT.pack({"side": "left"})
```
self.hi_there = Button(self)
self.hi_there["text"] = "Hello",
self.hi_there["command"] = self.say_hi

self.hi_there.pack({"side": "left"})

def __init__(self, master=None):
    Frame.__init__(self, master)
    self.pack()
    self.createWidgets()

root = Tk()
app = Application(master=root)
app.mainloop()
root.destroy()
24.1.3. A (Very) Quick Look at Tcl/Tk

The class hierarchy looks complicated, but in actual practice, application programmers almost always refer to the classes at the very bottom of the hierarchy.

Notes:

- These classes are provided for the purposes of organizing certain functions under one namespace. They aren't meant to be instantiated independently.
- The Tk class is meant to be instantiated only once in an application. Application programmers need not instantiate one explicitly, the system creates one whenever any of the other classes are instantiated.
- The Widget class is not meant to be instantiated, it is meant only for subclassing to make “real” widgets (in C++, this is called an ‘abstract class’).

To make use of this reference material, there will be times when you will need to know how to read short passages of Tk and how to identify the various parts of a Tk command. (See section Mapping Basic Tk into Tkinter for the Tkinter equivalents of what’s below.)

Tk scripts are Tcl programs. Like all Tcl programs, Tk scripts are just lists of tokens separated by spaces. A Tk widget is just its class, the options that help configure it, and the actions that make it do useful things.

To make a widget in Tk, the command is always of the form:

```
classCommand newPathname options
```

`classCommand`
denotes which kind of widget to make (a button, a label, a menu...)

newPathname

is the new name for this widget. All names in Tk must be unique. To help enforce this, widgets in Tk are named with pathnames, just like files in a file system. The top level widget, the root, is called . (period) and children are delimited by more periods. For example, .myApp.controlPanel.okButton might be the name of a widget.

options

configure the widget’s appearance and in some cases, its behavior. The options come in the form of a list of flags and values. Flags are preceded by a ‘-‘, like Unix shell command flags, and values are put in quotes if they are more than one word.

For example:

```
button .fred -fg red -text "hi there"
  \_____________________/
 |                          |
 class new options
 command widget (-opt val -opt val ...)
```

Once created, the pathname to the widget becomes a new command. This new widget command is the programmer’s handle for getting the new widget to perform some action. In C, you’d express this as someAction(fred, someOptions), in C++, you would express this as fred.someAction(someOptions), and in Tk, you say:

```
.fred someAction someOptions
```

Note that the object name, .fred, starts with a dot.

As you’d expect, the legal values for someAction will depend on the
widget’s class: .fred disable works if fred is a button (fred gets greyed out), but does not work if fred is a label (disabling of labels is not supported in Tk).

The legal values of someOptions is action dependent. Some actions, like disable, require no arguments, others, like a text-entry box’s delete command, would need arguments to specify what range of text to delete.
24.1.4. Mapping Basic Tk into Tkinter

Class commands in Tk correspond to class constructors in Tkinter.

```python
button .fred       ===>  fred = Button()
```

The master of an object is implicit in the new name given to it at creation time. In Tkinter, masters are specified explicitly.

```python
button .panel.fred ===>  fred = Button(panel)
```

The configuration options in Tk are given in lists of hyphenated tags followed by values. In Tkinter, options are specified as keyword-arguments in the instance constructor, and keyword-args for configure calls or as instance indices, in dictionary style, for established instances. See section Setting Options on setting options.

```python
button .fred -fg red ===>  fred = Button(panel, fg = "red")
.fred configure -fg red ===>  fred["fg"] = red
OR ==>  fred.config(fg = "red")
```

In Tk, to perform an action on a widget, use the widget name as a command, and follow it with an action name, possibly with arguments (options). In Tkinter, you call methods on the class instance to invoke actions on the widget. The actions (methods) that a given widget can perform are listed in the Tkinter.py module.

```python
.fred invoke       ===>  fred.invoke()
```

To give a widget to the packer (geometry manager), you call pack with optional arguments. In Tkinter, the Pack class holds all this functionality, and the various forms of the pack command are implemented as methods. All widgets in Tkinter are subclassed
from the Packer, and so inherit all the packing methods. See the `Tix` module documentation for additional information on the Form geometry manager.

```
pack .fred -side left       ===>  fred.pack(side = "left")
```
24.1.5. How Tk and Tkinter are Related

From the top down:

Your App Here (Python)

A Python application makes a Tkinter call.

Tkinter (Python Module)

This call (say, for example, creating a button widget), is implemented in the Tkinter module, which is written in Python. This Python function will parse the commands and the arguments and convert them into a form that makes them look as if they had come from a Tk script instead of a Python script.

tkinter (C)

These commands and their arguments will be passed to a C function in the tkinter - note the lowercase - extension module.

Tk Widgets (C and Tcl)

This C function is able to make calls into other C modules, including the C functions that make up the Tk library. Tk is implemented in C and some Tcl. The Tcl part of the Tk widgets is used to bind certain default behaviors to widgets, and is executed once at the point where the Python Tkinter module is imported. (The user never sees this stage).

Tk (C)

The Tk part of the Tk Widgets implement the final mapping to ...

Xlib (C)

the Xlib library to draw graphics on the screen.
24.1.6. Handy Reference

24.1.6.1. Setting Options

Options control things like the color and border width of a widget. Options can be set in three ways:

At object creation time, using keyword arguments

```python
fred = Button(self, fg = "red", bg = "blue")
```

After object creation, treating the option name like a dictionary index

```python
fred["fg"] = "red"
fred["bg"] = "blue"
```

Use the config() method to update multiple attrs subsequent to object creation

```python
fred.config(fg = "red", bg = "blue")
```

For a complete explanation of a given option and its behavior, see the Tk man pages for the widget in question.

Note that the man pages list “STANDARD OPTIONS” and “WIDGET SPECIFIC OPTIONS” for each widget. The former is a list of options that are common to many widgets, the latter are the options that are idiosyncratic to that particular widget. The Standard Options are documented on the `options(3)` man page.

No distinction between standard and widget-specific options is made in this document. Some options don’t apply to some kinds of widgets. Whether a given widget responds to a particular option depends on the class of the widget; buttons have a `command` option, labels do not.
The options supported by a given widget are listed in that widget’s man page, or can be queried at runtime by calling the `config()` method without arguments, or by calling the `keys()` method on that widget. The return value of these calls is a dictionary whose key is the name of the option as a string (for example, `'relief'`) and whose values are 5-tuples.

Some options, like `bg` are synonyms for common options with long names (`bg` is shorthand for “background”). Passing the `config()` method the name of a shorthand option will return a 2-tuple, not 5-tuple. The 2-tuple passed back will contain the name of the synonym and the “real” option (such as `('bg', 'background')`).

<table>
<thead>
<tr>
<th>Index</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>option name</td>
<td>'relief'</td>
</tr>
<tr>
<td>1</td>
<td>option name for database lookup</td>
<td>'relief'</td>
</tr>
<tr>
<td>2</td>
<td>option class for database lookup</td>
<td>'Relief'</td>
</tr>
<tr>
<td>3</td>
<td>default value</td>
<td>'raised'</td>
</tr>
<tr>
<td>4</td>
<td>current value</td>
<td>'groove'</td>
</tr>
</tbody>
</table>

Example:

```python
>>> print fred.config()
{'relief': ('relief', 'relief', 'Relief', 'raised', 'groove')}
```

Of course, the dictionary printed will include all the options available and their values. This is meant only as an example.

24.1.6.2. The Packer

The packer is one of Tk's geometry-management mechanisms. Geometry managers are used to specify the relative positioning of the positioning of widgets within their container - their mutual master.
In contrast to the more cumbersome placer (which is used less commonly, and we do not cover here), the packer takes qualitative relationship specification - above, to the left of, filling, etc - and works everything out to determine the exact placement coordinates for you.

The size of any master widget is determined by the size of the “slave widgets” inside. The packer is used to control where slave widgets appear inside the master into which they are packed. You can pack widgets into frames, and frames into other frames, in order to achieve the kind of layout you desire. Additionally, the arrangement is dynamically adjusted to accommodate incremental changes to the configuration, once it is packed.

Note that widgets do not appear until they have had their geometry specified with a geometry manager. It’s a common early mistake to leave out the geometry specification, and then be surprised when the widget is created but nothing appears. A widget will appear only after it has had, for example, the packer’s pack() method applied to it.

The pack() method can be called with keyword-option/value pairs that control where the widget is to appear within its container, and how it is to behave when the main application window is resized. Here are some examples:

```python
defred.pack()  # defaults to side = "top"
defred.pack(side = "left")
defred.pack(expand = 1)
```

24.1.6.3. Packer Options

For more extensive information on the packer and the options that it can take, see the man pages and page 183 of John Ousterhout's book.

anchor
Anchor type. Denotes where the packer is to place each slave in its parcel.

expand

   Boolean, 0 or 1.

fill

   Legal values: 'x', 'y', 'both', 'none'.

ipadx and ipady

   A distance - designating internal padding on each side of the slave widget.

padx and pady

   A distance - designating external padding on each side of the slave widget.

side

   Legal values are: 'left', 'right', 'top', 'bottom'.

24.1.6.4. Coupling Widget Variables

The current-value setting of some widgets (like text entry widgets) can be connected directly to application variables by using special options. These options are variable, textvariable, onvalue, offvalue, and value. This connection works both ways: if the variable changes for any reason, the widget it's connected to will be updated to reflect the new value.

Unfortunately, in the current implementation of Tkinter it is not possible to hand over an arbitrary Python variable to a widget through a variable or textvariable option. The only kinds of variables for which this works are variables that are subclassed from a class called Variable, defined in the Tkinter module.

There are many useful subclasses of Variable already defined: StringVar, IntVar, DoubleVar, and BooleanVar. To read the current
value of such a variable, call the `get()` method on it, and to change its value you call the `set()` method. If you follow this protocol, the widget will always track the value of the variable, with no further intervention on your part.

For example:

```python
class App(Frame):
    def __init__(self, master=None):
        Frame.__init__(self, master)
        self.pack()

        self.entrythingy = Entry()
        self.entrythingy.pack()

        # here is the application variable
        self.contents = StringVar()
        # set it to some value
        self.contents.set("this is a variable")
        # tell the entry widget to watch this variable
        self.entrythingy["textvariable"] = self.contents

        # and here we get a callback when the user hits return.
        # we will have the program print out the value of the
        # application variable when the user hits return
        self.entrythingy.bind('<Key-Return>',
                              self.print_contents)

    def print_contents(self, event):
        print "hi. contents of entry is now ----->", \
        self.contents.get()
```

### 24.1.6.5. The Window Manager

In Tk, there is a utility command, `wm`, for interacting with the window manager. Options to the `wm` command allow you to control things like titles, placement, icon bitmaps, and the like. In Tkinter, these commands have been implemented as methods on the `wm` class. Toplevel widgets are subclassed from the `wm` class, and so can call
the `wm` methods directly.

To get at the toplevel window that contains a given widget, you can often just refer to the widget’s master. Of course if the widget has been packed inside of a frame, the master won’t represent a toplevel window. To get at the toplevel window that contains an arbitrary widget, you can call the `_root()` method. This method begins with an underscore to denote the fact that this function is part of the implementation, and not an interface to Tk functionality.

Here are some examples of typical usage:

```python
from Tkinter import *
class App(Frame):
    def __init__(self, master=None):
        Frame.__init__(self, master)
        self.pack()

# create the application
myapp = App()

# here are method calls to the window manager class
myapp.master.title("My Do-Nothing Application")
myapp.master.maxsize(1000, 400)

# start the program
myapp.mainloop()
```

### 24.1.6.6. Tk Option Data Types

**anchor**

Legal values are points of the compass: "n", "ne", "e", "se", "s", "sw", "w", "nw", and also "center".

**bitmap**

There are eight built-in, named bitmaps: 'error', 'gray25',
To specify an X bitmap filename, give the full path to the file, preceded with an @, as in 
"@/usr/contrib(bitmap/gumby.bit)"

boolean
You can pass integers 0 or 1 or the strings "yes" or "no".

callback
This is any Python function that takes no arguments. For example:

```python
def print_it():
    print "hi there"
fred["command"] = print_it
```

color
Colors can be given as the names of X colors in the rgb.txt file, or as strings representing RGB values in 4 bit: 
"#RGB", 8 bit: 
"#RRGGBB", 12 bit 
"#RRGGBBB", or 16 bit 

cursor
The standard X cursor names from cursorfont.h can be used, without the xc prefix. For example to get a hand cursor (xc_hand2), use the string "hand2". You can also specify a bitmap and mask file of your own. See page 179 of Ousterhout's book.

distance
Screen distances can be specified in either pixels or absolute distances. Pixels are given as numbers and absolute distances as strings, with the trailing character denoting units: c for centimetres, i for inches, m for millimetres, p for printer's points. For example, 3.5 inches is expressed as 
"3.5i".

font
Tk uses a list font name format, such as \{courier 10 bold\}. Font sizes with positive numbers are measured in points; sizes with negative numbers are measured in pixels.

### geometry
This is a string of the form `widthxheight`, where width and height are measured in pixels for most widgets (in characters for widgets displaying text). For example: `fred["geometry"] = "200x100"`.

### justify
Legal values are the strings: "left", "center", "right", and "fill".

### region
This is a string with four space-delimited elements, each of which is a legal distance (see above). For example: "2 3 4 5" and "3i 2i 4.5i 2i" and "3c 2c 4c 10.43c" are all legal regions.

### relief
Determines what the border style of a widget will be. Legal values are: "raised", "sunken", "flat", "groove", and "ridge".

### scrollcommand
This is almost always the `set()` method of some scrollbar widget, but can be any widget method that takes a single argument. Refer to the file `Demo/tkinter/matt/canvas-with-scrollbars.py` in the Python source distribution for an example.

### wrap:
Must be one of: "none", "char", or "word".

## 24.1.6.7. Bindings and Events

The bind method from the widget command allows you to watch for certain events and to have a callback function trigger when that
event type occurs. The form of the bind method is:

```python
def bind(self, sequence, func, add=''):```

where:

**sequence**

is a string that denotes the target kind of event. (See the bind man page and page 201 of John Ousterhout’s book for details).

**func**

is a Python function, taking one argument, to be invoked when the event occurs. An Event instance will be passed as the argument. (Functions deployed this way are commonly known as *callbacks*.)

**add**

is optional, either '' or '+'. Passing an empty string denotes that this binding is to replace any other bindings that this event is associated with. Passing a '+' means that this function is to be added to the list of functions bound to this event type.

For example:

```python
def turnRed(self, event):
    event.widget["activeforeground"] = "red"

self.button.bind("<Enter>", self.turnRed)
```

Notice how the widget field of the event is being accessed in the `turnRed()` callback. This field contains the widget that caught the X event. The following table lists the other event fields you can access, and how they are denoted in Tk, which can be useful when referring to the Tk man pages.

<table>
<thead>
<tr>
<th>Tk</th>
<th>Tkinter Event Field</th>
<th>Tk</th>
<th>Tkinter Event Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>%f</td>
<td>focus</td>
<td>%A</td>
<td>char</td>
</tr>
</tbody>
</table>
24.1.6.8. The index Parameter

A number of widgets require "index" parameters to be passed. These are used to point at a specific place in a Text widget, or to particular characters in an Entry widget, or to particular menu items in a Menu widget.

Entry widget indexes (index, view index, etc.)

Entry widgets have options that refer to character positions in the text being displayed. You can use these `Tkinter` functions to access these special points in text widgets:

- `AtEnd()`
  - refers to the last position in the text
- `AtInsert()`
  - refers to the point where the text cursor is
- `AtSelFirst()`
  - indicates the beginning point of the selected text
- `AtSelLast()`
  - denotes the last point of the selected text and finally
- `At(x[, y])`
  - refers to the character at pixel location x, y (with y not used in the case of a text entry widget, which contains a single line of text).

Text widget indexes
The index notation for Text widgets is very rich and is best described in the Tk man pages.

Menu indexes (menu.invoke(), menu.entryconfig(), etc.)
Some options and methods for menus manipulate specific menu entries. Anytime a menu index is needed for an option or a parameter, you may pass in:

- an integer which refers to the numeric position of the entry in the widget, counted from the top, starting with 0;
- the string 'active', which refers to the menu position that is currently under the cursor;
- the string "last" which refers to the last menu item;
- An integer preceded by @, as in @6, where the integer is interpreted as a y pixel coordinate in the menu's coordinate system;
- the string "none", which indicates no menu entry at all, most often used with menu.activate() to deactivate all entries, and finally,
- a text string that is pattern matched against the label of the menu entry, as scanned from the top of the menu to the bottom. Note that this index type is considered after all the others, which means that matches for menu items labelled last, active, or none may be interpreted as the above literals, instead.

24.1.6.9. Images

Bitmap/Pixelmap images can be created through the subclasses of Tkinter.Image:

- **BitmapImage** can be used for X11 bitmap data.
- **PhotoImage** can be used for GIF and PPM/PGM color bitmaps.
Either type of image is created through either the `file` or the `data` option (other options are available as well).

The image object can then be used wherever an `image` option is supported by some widget (e.g. labels, buttons, menus). In these cases, Tk will not keep a reference to the image. When the last Python reference to the image object is deleted, the image data is deleted as well, and Tk will display an empty box wherever the image was used.
24. Graphical User Interfaces with Tk
24.2. ttk — Tk themed widgets

The ttk module provides access to the Tk themed widget set, which has been introduced in Tk 8.5. If Python is not compiled against Tk 8.5 code may still use this module as long as Tile is installed. However, some features provided by the new Tk, like anti-aliased font rendering under X11, window transparency (on X11 you will need a composition window manager) will be missing.

The basic idea of ttk is to separate, to the extent possible, the code implementing a widget's behavior from the code implementing its appearance.

See also:

Tk Widget Styling Support
The document which brought up theming support for Tk
24.2.1. Using Ttk

To start using Ttk, import its module:

```python
import ttk
```

But code like this:

```python
from Tkinter import *
```

may optionally want to use this:

```python
from Tkinter import *
from ttk import *
```

And then several ttk widgets (Button, Checkbutton, Entry, Frame, Label, LabelFrame, Menubutton, PanedWindow, Radiobutton, Scale and Scrollbar) will automatically substitute for the Tk widgets.

This has the direct benefit of using the new widgets, giving better look & feel across platforms, but be aware that they are not totally compatible. The main difference is that widget options such as “fg”, “bg” and others related to widget styling are no longer present in Ttk widgets. Use ttk.Style to achieve the same (or better) styling.

See also:

Converting existing applications to use the Tile widgets

A text which talks in Tcl terms about differences typically found when converting applications to use the new widgets.
24.2.2. Ttk Widgets

Ttk comes with 17 widgets, 11 of which already exist in Tkinter: Button, Checkbutton, Entry, Frame, Label, LabelFrame, Menubutton, PanedWindow, Radiobutton, Scale and Scrollbar. The 6 new widget classes are: Combobox, Notebook, Progressbar, Separator, Sizegrip and Treeview. All of these classes are subclasses of Widget.

As said previously, you will notice changes in look-and-feel as well in the styling code. To demonstrate the latter, a very simple example is shown below.

Tk code:

```python
l1 = Tkinter.Label(text="Test", fg="black", bg="white")
l2 = Tkinter.Label(text="Test", fg="black", bg="white")
```

Corresponding Ttk code:

```python
style = ttk.Style()
style.configure("BW.TLabel", foreground="black", background="white")

l1 = ttk.Label(text="Test", style="BW.TLabel")
l2 = ttk.Label(text="Test", style="BW.TLabel")
```

For more information about TtkStyling read the style class documentation.
24.2.3. Widget

`ttk.Widget` defines standard options and methods supported by Tk themed widgets and is not supposed to be directly instantiated.

24.2.3.1. Standard Options

All the `ttk` widgets accept the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>class</td>
<td>Specifies the window class. The class is used when querying the option database for the window's other options, to determine the default bindtags for the window, and to select the widget's default layout and style. This is a read-only option which may only be specified when the window is created.</td>
</tr>
<tr>
<td>cursor</td>
<td>Specifies the mouse cursor to be used for the widget. If set to the empty string (the default), the cursor is inherited from the parent widget.</td>
</tr>
<tr>
<td>takefocus</td>
<td>Determines whether the window accepts the focus during keyboard traversal. 0, 1 or an empty string is returned. If 0, the window should be skipped entirely during keyboard traversal. If 1, the window should receive the input focus as long as it is viewable. An empty string means that the traversal scripts make the decision about whether or not to focus on the window.</td>
</tr>
<tr>
<td>style</td>
<td>May be used to specify a custom widget style.</td>
</tr>
</tbody>
</table>

24.2.3.2. Scrollable Widget Options

The following options are supported by widgets that are controlled by a scrollbar.
### 24.2.3.3. Label Options

The following options are supported by labels, buttons and other button-like widgets.

<table>
<thead>
<tr>
<th>option</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>Specifies a text string to be displayed inside the widget.</td>
</tr>
<tr>
<td>textvariable</td>
<td>Specifies a name whose value will be used in place of the text option resource.</td>
</tr>
<tr>
<td>underline</td>
<td>If set, specifies the index (0-based) of a character to underline in the text string. The underline character is used for mnemonic activation.</td>
</tr>
<tr>
<td>image</td>
<td>Specifies an image to display. This is a list of 1 or more elements. The first element is the default image name. The rest of the list is a sequence of statespec/value pairs as defined by <code>Style.map()</code>, specifying different images to use when the widget is in a particular state or a combination of states. All images in the list should have the same</td>
</tr>
</tbody>
</table>
24.2.3.4. Compatibility Options

<table>
<thead>
<tr>
<th>option</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>state</td>
<td>May be set to “normal” or “disabled” to control the “disabled” state bit. This is a write-only option: setting it changes the widget state, but the <code>Widget.state()</code> method does not affect this option.</td>
</tr>
</tbody>
</table>

24.2.3.5. Widget States

The widget state is a bitmap of independent state flags.

<table>
<thead>
<tr>
<th>flag</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>The mouse cursor is over the widget and pressing a mouse button will cause some action to occur.</td>
</tr>
<tr>
<td>disabled</td>
<td>Widget is disabled under program control.</td>
</tr>
<tr>
<td>focus</td>
<td>Widget has keyboard focus.</td>
</tr>
<tr>
<td>pressed</td>
<td>Widget is being pressed.</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>selected</td>
<td>“On”, “true”, or “current” for things like Checkbuttons and radiobuttons.</td>
</tr>
<tr>
<td>background</td>
<td>Windows and Mac have a notion of an “active” or foreground window. The background state is set for widgets in a background window, and cleared for those in the foreground window.</td>
</tr>
<tr>
<td>readonly</td>
<td>Widget should not allow user modification.</td>
</tr>
<tr>
<td>alternate</td>
<td>A widget-specific alternate user display format.</td>
</tr>
<tr>
<td>invalid</td>
<td>The widget’s value is invalid.</td>
</tr>
</tbody>
</table>

A state specification is a sequence of state names, optionally prefixed with an exclamation point indicating that the bit is off.

### 24.2.3.6. ttk.Widget

Besides the methods described below, the `ttk.Widget` class supports the `Tkinter.Widget.cget()` and `Tkinter.Widget.configure()` methods.

```python
class ttk.Widget
    identify(x, y)
        Returns the name of the element at position x y, or the empty string if the point does not lie within any element.

        x and y are pixel coordinates relative to the widget.

    instate(statespec[, callback=None[, *args[, **kw]]])
        Test the widget’s state. If a callback is not specified, returns True if the widget state matches statespec and False otherwise. If callback is specified then it is called with args if widget state matches statespec.

    state([statespec=None])
```

Modify or read widget state. If statespec is specified, sets the widget state accordingly and returns a new statespec indicating which flags were changed. If statespec is not specified, returns the currently-enabled state flags.

statespec will usually be a list or a tuple.
24.2.4. Combobox

The `ttk.Combobox` widget combines a text field with a pop-down list of values. This widget is a subclass of `Entry`.

Besides the methods inherited from `Widget` (`Widget.cget()`, `Widget.configure()`, `Widget.identify()`, `Widget.instate()`, and `Widget.state()`) and those inherited from `Entry` (`Entry.bbox()`, `Entry.delete()`, `Entry.icursor()`, `Entry.index()`, `Entry.inset()`, `Entry.selection()`, `Entry.xview()`), this class has some other methods, described at `ttk.Combobox`.

24.2.4.1. Options

This widget accepts the following options:

<table>
<thead>
<tr>
<th>option</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exportselection</td>
<td>Boolean value. If set, the widget selection is linked to the Window Manager selection (which can be returned by invoking <code>Misc.selection_get()</code>, for example).</td>
</tr>
<tr>
<td>justify</td>
<td>Specifies how the text is aligned within the widget. One of “left”, “center”, or “right”.</td>
</tr>
<tr>
<td>height</td>
<td>Specifies the height of the pop-down listbox, in rows.</td>
</tr>
<tr>
<td>postcommand</td>
<td>A script (possibly registered with <code>Misc.register()</code>)) that is called immediately before displaying the values. It may specify which values to display.</td>
</tr>
<tr>
<td>state</td>
<td>One of “normal”, “readonly”, or “disabled”. In the “readonly” state, the value may not be edited directly, and the user can only select one of the values from the dropdown list.</td>
</tr>
<tr>
<td>textvariable</td>
<td>Specifies a name whose value is linked to the widget value. Whenever the value associated with that name changes, the widget value is updated, and vice versa. See Tkinter.StringVar.</td>
</tr>
<tr>
<td>--------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>values</td>
<td>Specifies the list of values to display in the drop-down listbox.</td>
</tr>
<tr>
<td>width</td>
<td>Specifies an integer value indicating the desired width of the entry window, in average-size characters of the widget’s font.</td>
</tr>
</tbody>
</table>

### 24.2.4.2. Virtual events

The combobox widget generates a `<<ComboboxSelected>>` virtual event when the user selects an element from the list of values.

### 24.2.4.3. ttk.Combobox

```python
class ttk.Combobox
    current([newindex=None])
        If `newindex` is specified, sets the combobox value to the element position `newindex`. Otherwise, returns the index of the current value or -1 if the current value is not in the values list.

    get()
        Returns the current value of the combobox.

    set(value)
        Sets the value of the combobox to `value`.```
24.2.5. Notebook

The Ttk Notebook widget manages a collection of windows and displays a single one at a time. Each child window is associated with a tab, which the user may select to change the currently-displayed window.

24.2.5.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>option</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>height</td>
<td>If present and greater than zero, specifies the desired height of the pane area (not including internal padding or tabs). Otherwise, the maximum height of all panes is used.</td>
</tr>
<tr>
<td>padding</td>
<td>Specifies the amount of extra space to add around the outside of the notebook. The padding is a list of up to four length specifications: left top right bottom. If fewer than four elements are specified, bottom defaults to top, right defaults to left, and top defaults to left.</td>
</tr>
<tr>
<td>width</td>
<td>If present and greater than zero, specifies the desired width of the pane area (not including internal padding). Otherwise, the maximum width of all panes is used.</td>
</tr>
</tbody>
</table>

24.2.5.2. Tab Options

There are also specific options for tabs:

<table>
<thead>
<tr>
<th>option</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>state</td>
<td>Either “normal”, “disabled” or “hidden”. If “disabled”, then the tab is not selectable. If</td>
</tr>
</tbody>
</table>
“hidden”, then the tab is not shown.

- **sticky**
  Specifies how the child window is positioned within the pane area. Value is a string containing zero or more of the characters “n”, “s”, “e” or “w”. Each letter refers to a side (north, south, east or west) that the child window will stick to, as per the `grid()` geometry manager.

- **padding**
  Specifies the amount of extra space to add between the notebook and this pane. Syntax is the same as for the option padding used by this widget.

- **text**
  Specifies a text to be displayed in the tab.

- **image**
  Specifies an image to display in the tab. See the option image described in [Widget](#).

- **compound**
  Specifies how to display the image relative to the text, in the case both text and image options are present. See [Label Options](#) for legal values.

- **underline**
  Specifies the index (0-based) of a character to underline in the text string. The underlined character is used for mnemonic activation if `Notebook.enable_traversal()` is called.

### 24.2.5.3. Tab Identifiers

The `tab_id` present in several methods of `ttk.Notebook` may take any of the following forms:

- An integer between zero and the number of tabs.
- The name of a child window.
- A positional specification of the form “@x,y”, which identifies the tab.
- The literal string “current”, which identifies the currently-selected tab.
- The literal string “end”, which returns the number of tabs (only valid for `Notebook.index()`).
24.2.5.4. Virtual Events

This widget generates a \texttt{<<NotebookTabChanged>>} virtual event after a new tab is selected.

24.2.5.5. \texttt{ttk.Notebook}

class \texttt{ttk.Notebook}

\begin{description}
\item[add\texttt{(child, **kw)}] Adds a new tab to the notebook.
\begin{itemize}
\item If window is currently managed by the notebook but hidden, it is restored to its previous position.
\end{itemize}
\item[forget\texttt{(tab_id)}] Removes the tab specified by \texttt{tab_id}, unmaps and unmanages the associated window.
\item[hide\texttt{(tab_id)}] Hides the tab specified by \texttt{tab_id}.
\begin{itemize}
\item The tab will not be displayed, but the associated window remains managed by the notebook and its configuration remembered. Hidden tabs may be restored with the \texttt{add()} command.
\end{itemize}
\item[identify\texttt{(x, y)}] Returns the name of the tab element at position \texttt{x, y}, or the empty string if none.
\item[index\texttt{(tab_id)}] Returns the numeric index of the tab specified by \texttt{tab_id}, or the total number of tabs if \texttt{tab_id} is the string “end”.
\end{description}
**insert**(pos, child, **kw)**

Inserts a pane at the specified position.

*pos* is either the string “end”, an integer index, or the name of a managed child. If *child* is already managed by the notebook, moves it to the specified position.

See Tab Options for the list of available options.

**select**([*tab_id*])

Selects the specified *tab_id*.

The associated child window will be displayed, and the previously-selected window (if different) is unmapped. If *tab_id* is omitted, returns the widget name of the currently selected pane.

**tab**(*tab_id*[ , option=None[ , **kw]])

Query or modify the options of the specific *tab_id*.

If *kw* is not given, returns a dictionary of the tab option values. If *option* is specified, returns the value of that *option*. Otherwise, sets the options to the corresponding values.

**tabs**()

Returns a list of windows managed by the notebook.

**enable_traversal**()

Enable keyboard traversal for a toplevel window containing this notebook.

This will extend the bindings for the toplevel window containing the notebook as follows:

- Control-Tab: selects the tab following the currently
selected one.
- **Shift-Control-Tab**: selects the tab preceding the currently selected one.
- **Alt-K**: where K is the mnemonic (underlined) character of any tab, will select that tab.

Multiple notebooks in a single toplevel may be enabled for traversal, including nested notebooks. However, notebook traversal only works properly if all panes have the notebook they are in as master.
24.2.6. Progressbar

The ttk.Progressbar widget shows the status of a long-running operation. It can operate in two modes: determinate mode shows the amount completed relative to the total amount of work to be done, and indeterminate mode provides an animated display to let the user know that something is happening.

24.2.6.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>option</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orient</td>
<td>One of “horizontal” or “vertical”. Specifies the orientation of the progress bar.</td>
</tr>
<tr>
<td>length</td>
<td>Specifies the length of the long axis of the progress bar (width if horizontal, height if vertical).</td>
</tr>
<tr>
<td>mode</td>
<td>One of “determinate” or “indeterminate”.</td>
</tr>
<tr>
<td>maximum</td>
<td>A number specifying the maximum value. Defaults to 100.</td>
</tr>
<tr>
<td>value</td>
<td>The current value of the progress bar. In “determinate” mode, this represents the amount of work completed. In “indeterminate” mode, it is interpreted as modulo maximum; that is, the progress bar completes one “cycle” when its value increases by maximum.</td>
</tr>
<tr>
<td>variable</td>
<td>A name which is linked to the option value. If specified, the value of the progress bar is automatically set to the value of this name whenever the latter is modified.</td>
</tr>
<tr>
<td>phase</td>
<td>Read-only option. The widget periodically increments the value of this option whenever its value is greater than 0 and, in determinate mode, less than maximum. This option may be used by the</td>
</tr>
</tbody>
</table>
current theme to provide additional animation effects.

24.2.6.2. ttk.Progressbar

class ttk.Progressbar

    start([interval])
    Begin autoincrement mode: schedules a recurring timer event that calls Progressbar.step() every interval milliseconds. If omitted, interval defaults to 50 milliseconds.

    step([amount])
    Increments the progress bar's value by amount.

        amount defaults to 1.0 if omitted.

    stop()
    Stop autoincrement mode: cancels any recurring timer event initiated by Progressbar.start() for this progress bar.
24.2.7. Separator

The `ttk.Separator` widget displays a horizontal or vertical separator bar.

It has no other methods besides the ones inherited from `ttk.Widget`.

24.2.7.1. Options

This widget accepts the following specific option:

<table>
<thead>
<tr>
<th>option</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orient</td>
<td>One of “horizontal” or “vertical”. Specifies the orientation of the separator.</td>
</tr>
</tbody>
</table>
24.2.8. Sizegrip

The `ttk.Sizegrip` widget (also known as a grow box) allows the user to resize the containing toplevel window by pressing and dragging the grip.

This widget has neither specific options nor specific methods, besides the ones inherited from `ttk.Widget`.

24.2.8.1. Platform-specific notes

- On Mac OS X, toplevel windows automatically include a built-in size grip by default. Adding a `Sizegrip` is harmless, since the built-in grip will just mask the widget.

24.2.8.2. Bugs

- If the containing toplevel's position was specified relative to the right or bottom of the screen (e.g. ...), the `Sizegrip` widget will not resize the window.
- This widget supports only “southeast” resizing.
24.2.9. Treeview

The `ttk.Treeview` widget displays a hierarchical collection of items. Each item has a textual label, an optional image, and an optional list of data values. The data values are displayed in successive columns after the tree label.

The order in which data values are displayed may be controlled by setting the widget option `displaycolumns`. The tree widget can also display column headings. Columns may be accessed by number or symbolic names listed in the widget option columns. See Column Identifiers.

Each item is identified by an unique name. The widget will generate item IDs if they are not supplied by the caller. There is a distinguished root item, named `{}`. The root item itself is not displayed; its children appear at the top level of the hierarchy.

Each item also has a list of tags, which can be used to associate event bindings with individual items and control the appearance of the item.

The Treeview widget supports horizontal and vertical scrolling, according to the options described in Scrollable Widget Options and the methods `Treeview.xview()` and `Treeview.yview()`.

24.2.9.1. Options

This widget accepts the following specific options:

<table>
<thead>
<tr>
<th>option</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns</td>
<td>A list of column identifiers, specifying the number of columns and their names.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>displaycolumns</td>
<td>A list of column identifiers (either symbolic or integer indices) specifying which data columns are displayed and the order in which they appear, or the string “#all”.</td>
</tr>
<tr>
<td>height</td>
<td>Specifies the number of rows which should be visible. Note: the requested width is determined from the sum of the column widths.</td>
</tr>
<tr>
<td>padding</td>
<td>Specifies the internal padding for the widget. The padding is a list of up to four length specifications.</td>
</tr>
<tr>
<td>selectmode</td>
<td>Controls how the built-in class bindings manage the selection. One of “extended”, “browse” or “none”. If set to “extended” (the default), multiple items may be selected. If “browse”, only a single item will be selected at a time. If “none”, the selection will not be changed. Note that the application code and tag bindings can set the selection however they wish, regardless of the value of this option.</td>
</tr>
<tr>
<td>show</td>
<td>A list containing zero or more of the following values, specifying which elements of the tree to display.</td>
</tr>
<tr>
<td></td>
<td>• tree: display tree labels in column #0.</td>
</tr>
<tr>
<td></td>
<td>• headings: display the heading row.</td>
</tr>
<tr>
<td></td>
<td>The default is “tree headings”, i.e., show all elements.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: Column #0 always refers to the tree column, even if show=”tree” is not specified.</td>
</tr>
</tbody>
</table>
24.2.9.2. Item Options

The following item options may be specified for items in the insert and item widget commands.

<table>
<thead>
<tr>
<th>option</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>The textual label to display for the item.</td>
</tr>
<tr>
<td>image</td>
<td>A Tk Image, displayed to the left of the label.</td>
</tr>
<tr>
<td>values</td>
<td>The list of values associated with the item. Each item should have the same number of values as the widget option columns. If there are fewer values than columns, the remaining values are assumed empty. If there are more values than columns, the extra values are ignored.</td>
</tr>
<tr>
<td>open</td>
<td>True/False value indicating whether the item’s children should be displayed or hidden.</td>
</tr>
<tr>
<td>tags</td>
<td>A list of tags associated with this item.</td>
</tr>
</tbody>
</table>

24.2.9.3. Tag Options

The following options may be specified on tags:

<table>
<thead>
<tr>
<th>option</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>foreground</td>
<td>Specifies the text foreground color.</td>
</tr>
<tr>
<td>background</td>
<td>Specifies the cell or item background color.</td>
</tr>
<tr>
<td>font</td>
<td>Specifies the font to use when drawing text.</td>
</tr>
<tr>
<td>image</td>
<td>Specifies the item image, in case the item’s image option is empty.</td>
</tr>
</tbody>
</table>

24.2.9.4. Column Identifiers

Column identifiers take any of the following forms:
- A symbolic name from the list of columns option.
- An integer n, specifying the nth data column.
- A string of the form #n, where n is an integer, specifying the nth display column.

Notes:

- Item's option values may be displayed in a different order than the order in which they are stored.
- Column #0 always refers to the tree column, even if show="tree" is not specified.

A data column number is an index into an item's option values list; a display column number is the column number in the tree where the values are displayed. Tree labels are displayed in column #0. If option displaycolumns is not set, then data column n is displayed in column #n+1. Again, column #0 always refers to the tree column.

### 24.2.9.5. Virtual Events

The Treeview widget generates the following virtual events.

<table>
<thead>
<tr>
<th>event</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;&lt;TreeviewSelect&gt;&gt;</td>
<td>Generated whenever the selection changes.</td>
</tr>
<tr>
<td>&lt;&lt;TreeviewOpen&gt;&gt;</td>
<td>Generated just before setting the focus item to open=True.</td>
</tr>
<tr>
<td>&lt;&lt;TreeviewClose&gt;&gt;</td>
<td>Generated just after setting the focus item to open=False.</td>
</tr>
</tbody>
</table>

The **Treeview.focus()** and **Treeview.selection()** methods can be used to determine the affected item or items.

### 24.2.9.6. ttk.Treeview
class ttk.Treeview

bbox(item[, column=None])

Returns the bounding box (relative to the treeview widget's window) of the specified item in the form (x, y, width, height).

If column is specified, returns the bounding box of that cell. If the item is not visible (i.e., if it is a descendant of a closed item or is scrolled offscreen), returns an empty string.

get_children([item])

Returns the list of children belonging to item.

If item is not specified, returns root children.

set_children(item, *newchildren)

Replaces item's child with newchildren.

Children present in item that are not present in newchildren are detached from the tree. No items in newchildren may be an ancestor of item. Note that not specifying newchildren results in detaching item's children.

column(column[, option=None[, **kw]])

Query or modify the options for the specified column.

If kw is not given, returns a dict of the column option values. If option is specified then the value for that option is returned. Otherwise, sets the options to the corresponding values.

The valid options/values are:

- id
  Returns the column name. This is a read-only option.

- anchor: One of the standard Tk anchor values.
Specifies how the text in this column should be aligned with respect to the cell.

- **minwidth: width**
  The minimum width of the column in pixels. The treeview widget will not make the column any smaller than specified by this option when the widget is resized or the user drags a column.

- **stretch: True/False**
  Specifies whether the column’s width should be adjusted when the widget is resized.

- **width: width**
  The width of the column in pixels.

To configure the tree column, call this with column = “#0”

```python
def delete(*items)
    Delete all specified *items and all their descendants.

    The root item may not be deleted.

def detach(*items)
    Unlinks all of the specified *items from the tree.

    The items and all of their descendants are still present, and may be reinserted at another point in the tree, but will not be displayed.

    The root item may not be detached.

def exists(item)
    Returns True if the specified *item is present in the tree.

def focus([item=None])
```
If *item* is specified, sets the focus item to *item*. Otherwise, returns the current focus item, or '' if there is none.

**heading**(column[, option=None[, **kw]])

Query or modify the heading options for the specified *column*.

If *kw* is not given, returns a dict of the heading option values. If *option* is specified then the value for that *option* is returned. Otherwise, sets the options to the corresponding values.

The valid options/values are:

- **text**: text
  The text to display in the column heading.

- **image**: imageName
  Specifies an image to display to the right of the column heading.

- **anchor**: anchor
  Specifies how the heading text should be aligned.
  One of the standard Tk anchor values.

- **command**: callback
  A callback to be invoked when the heading label is pressed.

To configure the tree column heading, call this with column = "#0".

**identify**(component, x, y)

Returns a description of the specified *component* under the point given by *x* and *y*, or the empty string if no such *component* is present at that position.

**identify_row**(y)
Returns the item ID of the item at position \( y \).

**identify_column**\((x)\)

Returns the data column identifier of the cell at position \( x \).

The tree column has ID #0.

**identify_region**\((x, y)\)

Returns one of:

<table>
<thead>
<tr>
<th>region</th>
<th>meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>heading</td>
<td>Tree heading area.</td>
</tr>
<tr>
<td>separator</td>
<td>Space between two columns headings.</td>
</tr>
<tr>
<td>tree</td>
<td>The tree area.</td>
</tr>
<tr>
<td>cell</td>
<td>A data cell.</td>
</tr>
</tbody>
</table>

Availability: Tk 8.6.

**identify_element**\((x, y)\)

Returns the element at position \( x, y \).

Availability: Tk 8.6.

**index**\((item)\)

Returns the integer index of \( item \) within its parent’s list of children.

**insert**\((parent, index[, iid=None[, **kw]])\)

Creates a new item and returns the item identifier of the newly created item.

\( parent \) is the item ID of the parent item, or the empty string to create a new top-level item. \( index \) is an integer, or the value “end”, specifying where in the list of parent’s children to insert the new item. If \( index \) is less than or equal to zero, the new
node is inserted at the beginning; if index is greater than or equal to the current number of children, it is inserted at the end. If iid is specified, it is used as the item identifier; iid must not already exist in the tree. Otherwise, a new unique identifier is generated.

See Item Options for the list of available points.

item(item[, option[, **kw]])
Query or modify the options for the specified item.

If no options are given, a dict with options/values for the item is returned. If option is specified then the value for that option is returned. Otherwise, sets the options to the corresponding values as given by kw.

move(item, parent, index)
Moves item to position index in parent's list of children.

It is illegal to move an item under one of its descendants. If index is less than or equal to zero, item is moved to the beginning; if greater than or equal to the number of children, it is moved to the end. If item was detached it is reattached.

next(item)
Returns the identifier of item's next sibling, or '' if item is the last child of its parent.

parent(item)
Returns the ID of the parent of item, or '' if item is at the top level of the hierarchy.

prev(item)
Returns the identifier of item's previous sibling, or '' if item is the first child of its parent.
reattach(item, parent, index)
    An alias for Treeview.move().

see(item)
    Ensure that item is visible.

    Sets all of item's ancestors open option to True, and scrolls the widget if necessary so that item is within the visible portion of the tree.

selection(list([selop=None, items=None]))
    If selop is not specified, returns selected items. Otherwise, it will act according to the following selection methods.

selection_set(items)
    items becomes the new selection.

selection_add(items)
    Add items to the selection.

selection_remove(items)
    Remove items from the selection.

selection_toggle(items)
    Toggle the selection state of each item in items.

set(item[, column=None[, value=None]])
    With one argument, returns a dictionary of column/value pairs for the specified item. With two arguments, returns the current value of the specified column. With three arguments, sets the value of given column in given item to the specified value.

tag_bind(tagname[, sequence=None[, callback=None]])
    Bind a callback for the given event sequence to the tag tagname. When an event is delivered to an item, the callbacks
for each of the item’s tags option are called.

**tag_configure**(tagname[, option=None[, **kw]])

Query or modify the options for the specified tagname.

If kw is not given, returns a dict of the option settings for tagname. If option is specified, returns the value for that option for the specified tagname. Otherwise, sets the options to the corresponding values for the given tagname.

**tag_has**(tagname[, item])

If item is specified, returns 1 or 0 depending on whether the specified item has the given tagname. Otherwise, returns a list of all items that have the specified tag.

Availability: Tk 8.6

**xview**(args)

Query or modify horizontal position of the treeview.

**yview**(args)

Query or modify vertical position of the treeview.
24.2.10. Ttk Styling

Each widget in ttk is assigned a style, which specifies the set of elements making up the widget and how they are arranged, along with dynamic and default settings for element options. By default the style name is the same as the widget's class name, but it may be overridden by the widget's style option. If the class name of a widget is unknown, use the method Misc.winfo_class() (somewidget.winfo_class()).

**See also:**

Tcl'2004 conference presentation

This document explains how the theme engine works

---

**class ttk.Style**

This class is used to manipulate the style database.

**configure(style, query_opt=None, **kw)**

Query or set the default value of the specified option(s) in style.

Each key in kw is an option and each value is a string identifying the value for that option.

For example, to change every default button to be a flat button with some padding and a different background color do:

```python
import ttk
import Tkinter

root = Tkinter.Tk()
```
map(style, query_opt=None, **kw)

Query or sets dynamic values of the specified option(s) in style.

Each key in kw is an option and each value should be a list or a tuple (usually) containing statespecs grouped in tuples, lists, or something else of your preference. A statespec is a compound of one or more states and then a value.

An example:

```python
import Tkinter
import ttk

root = Tkinter.Tk()

style = ttk.Style()
style.map("C.TButton",
    foreground=[('pressed', 'red'), ('active', 'blue')],
    background=[('pressed', '!disabled', 'black'), ('active',])

colored_btn = ttk.Button(text="Test", style="C.TButton").

root.mainloop()
```

Note that the order of the (states, value) sequences for an option matters. In the previous example, if you change the order to [("active", 'blue'), ("pressed", 'red')] in the foreground option, for example, you would get a blue foreground when the widget is in the active or pressed states.
lookup(style, option[, state=None[, default=None]])

Returns the value specified for option in style.

If state is specified, it is expected to be a sequence of one or more states. If the default argument is set, it is used as a fallback value in case no specification for option is found.

To check what font a Button uses by default, do:

```python
import ttk
print ttk.Style().lookup("TButton", "font")
```

layout(style[, layoutspec=None])

Define the widget layout for given style. If layoutspec is omitted, return the layout specification for given style.

layoutspec, if specified, is expected to be a list or some other sequence type (excluding strings), where each item should be a tuple and the first item is the layout name and the second item should have the format described in Layouts.

To understand the format, see the following example (it is not intended to do anything useful):

```python
import ttk
import Tkinter

root = Tkinter.Tk()

style = ttk.Style()
style.layout("TMenubutton", [  ("Menubutton.background", None),  ("Menubutton.button",{"children":  [{"Menubutton.focus", {"children":  [["Menubutton.padding", {"children":  [["Menubutton.label", {"side": "left", "ex

```
\begin{verbatim}
mbtn = ttk.Menubutton(text='Text')
mbtn.pack()
root.mainloop()
\end{verbatim}

\textbf{element_create(elementname, etype, *args, **kw)}

Create a new element in the current theme, of the given \textit{etype} which is expected to be either “image”, “from” or “vsapi”. The latter is only available in Tk 8.6a for Windows XP and Vista and is not described here.

If “image” is used, \textit{args} should contain the default image name followed by statespec/value pairs (this is the imagespec), and \textit{kw} may have the following options:

- \textbf{border=padding}
  padding is a list of up to four integers, specifying the left, top, right, and bottom borders, respectively.

- \textbf{height=height}
  Specifies a minimum height for the element. If less than zero, the base image’s height is used as a default.

- \textbf{padding=padding}
  Specifies the element’s interior padding. Defaults to border’s value if not specified.

- \textbf{sticky=spec}
  Specifies how the image is placed within the final parcel. spec contains zero or more characters “n”, “s”, “w”, or “e”.

• width=width
  Specifies a minimum width for the element. If less than zero, the base image's width is used as a default.

If “from” is used as the value of etype, element_create() will clone an existing element. args is expected to contain a themename, from which the element will be cloned, and optionally an element to clone from. If this element to clone from is not specified, an empty element will be used. kw is discarded.

element_names()
  Returns the list of elements defined in the current theme.

element_options(elementname)
  Returns the list of elementname's options.

theme_create(themename[, parent=None[, settings=None]])
  Create a new theme.

  It is an error if themename already exists. If parent is specified, the new theme will inherit styles, elements and layouts from the parent theme. If settings are present they are expected to have the same syntax used for theme_settings().

theme_settings(themename, settings)
  Temporarily sets the current theme to themename, apply specified settings and then restore the previous theme.

  Each key in settings is a style and each value may contain the keys ‘configure’, ‘map’, ‘layout’ and ‘element create’ and they are expected to have the same format as specified by the methods Style.configure(), Style.map(), Style.layout() and Style.element_create() respectively.
As an example, let’s change the Combobox for the default theme a bit:

```python
import ttk
import Tkinter

root = Tkinter.Tk()

style = ttk.Style()
style.theme_settings("default", {
    "TCombobox": {
        "configure": {"padding": 5},
        "map": {
            "background": ["active", "green2"],
            "!disabled": "green4"],
            "fieldbackground": ["!disabled", "green3"],
            "foreground": ["focus", "OliveDrab1"],
            "!disabled": "OliveDrab2"]
    }
})

combo = ttk.Combobox().pack()

root.mainloop()
```

**theme_names()**

Returns a list of all known themes.

**theme_use([[themename]])**

If *themename* is not given, returns the theme in use. Otherwise, sets the current theme to *themename*, refreshes all widgets and emits a "<<ThemeChanged>>" event.

### 24.2.10.1. Layouts

A layout can be just None, if it takes no options, or a dict of options specifying how to arrange the element. The layout mechanism uses a simplified version of the pack geometry manager: given an initial cavity, each element is allocated a parcel. Valid options/values are:
- **side: whichside**
  Specifies which side of the cavity to place the element; one of top, right, bottom or left. If omitted, the element occupies the entire cavity.

- **sticky: nswe**
  Specifies where the element is placed inside its allocated parcel.

- **unit: 0 or 1**
  If set to 1, causes the element and all of its descendants to be treated as a single element for the purposes of `Widget.identify()` et al. It's used for things like scrollbar thumbs with grips.

- **children: [sublayout...]**
  Specifies a list of elements to place inside the element. Each element is a tuple (or other sequence type) where the first item is the layout name, and the other is a `Layout`. 
24.3. **Tix — Extension widgets for Tk**

The **Tix** (Tk Interface Extension) module provides an additional rich set of widgets. Although the standard Tk library has many useful widgets, they are far from complete. The **Tix** library provides most of the commonly needed widgets that are missing from standard Tk: **HList**, **ComboBox**, **Control** (a.k.a. SpinBox) and an assortment of scrollable widgets. **Tix** also includes many more widgets that are generally useful in a wide range of applications: **NoteBook**, **FileEntry**, **PanedWindow**, etc; there are more than 40 of them.

With all these new widgets, you can introduce new interaction techniques into applications, creating more useful and more intuitive user interfaces. You can design your application by choosing the most appropriate widgets to match the special needs of your application and users.

**Note:** **Tix** has been renamed to **tkinter.tix** in Python 3.0. The **2to3** tool will automatically adapt imports when converting your sources to 3.0.

**See also:**

**Tix Homepage**

The home page for **Tix**. This includes links to additional documentation and downloads.

**Tix Man Pages**

On-line version of the man pages and reference material.

**Tix Programming Guide**

On-line version of the programmer’s reference material.
**Tix Development Applications**

Tix applications for development of Tix and Tkinter programs. Tide applications work under Tk or Tkinter, and include **TixInspect**, an inspector to remotely modify and debug Tix/Tk/Tkinter applications.
24.3.1. Using Tix

```python
class Tix.Tix(screenName[, baseName[, className]])
```

Toplevel widget of Tix which represents mostly the main window of an application. It has an associated Tcl interpreter.

Classes in the Tix module subclasses the classes in the Tkinter module. The former imports the latter, so to use Tix with Tkinter, all you need to do is to import one module. In general, you can just import Tix, and replace the toplevel call to Tkinter.Tk with Tix.Tk:

```python
import Tix
from Tkconstants import *
root = Tix.Tk()
```

To use Tix, you must have the Tix widgets installed, usually alongside your installation of the Tk widgets. To test your installation, try the following:

```python
import Tix
root = Tix.Tk()
root.tk.eval('package require Tix')
```

If this fails, you have a Tk installation problem which must be resolved before proceeding. Use the environment variable TIX_LIBRARY to point to the installed Tix library directory, and make sure you have the dynamic object library (tix8183.dll or libtix8183.so) in the same directory that contains your Tk dynamic object library (tk8183.dll or libtk8183.so). The directory with the dynamic object library should also have a file called pkgIndex.tcl (case sensitive), which contains the line:
package ifneeded Tix 8.1 [list load "[file join $dir tix8183.dl"]"
24.3.2. Tix Widgets

Tix introduces over 40 widget classes to the Tkinter repertoire. There is a demo of all the tix widgets in the demo/tix directory of the standard distribution.

24.3.2.1. Basic Widgets

**class Tix.Balloon**
A Balloon that pops up over a widget to provide help. When the user moves the cursor inside a widget to which a Balloon widget has been bound, a small pop-up window with a descriptive message will be shown on the screen.

**class Tix.ButtonBox**
The ButtonBox widget creates a box of buttons, such as is commonly used for Ok Cancel.

**class Tix.ComboBox**
The ComboBox widget is similar to the combo box control in MS Windows. The user can select a choice by either typing in the entry subwidget or selecting from the listbox subwidget.

**class Tix.Control**
The Control widget is also known as the SpinBox widget. The user can adjust the value by pressing the two arrow buttons or by entering the value directly into the entry. The new value will be checked against the user-defined upper and lower limits.

**class Tix.LabelEntry**
The LabelEntry widget packages an entry widget and a label into one mega widget. It can be used to simplify the creation of “entry-form” type of interface.
class Tix.LabelFrame

The LabelFrame widget packages a frame widget and a label into one mega widget. To create widgets inside a LabelFrame widget, one creates the new widgets relative to the frame subwidget and manage them inside the frame subwidget.

class Tix.Meter

The Meter widget can be used to show the progress of a background job which may take a long time to execute.

class Tix.OptionMenu

The OptionMenu creates a menu button of options.

class Tix.PopupMenu

The PopupMenu widget can be used as a replacement of the tk_popup command. The advantage of the Tix PopupMenu widget is it requires less application code to manipulate.

class Tix.Select

The Select widget is a container of button subwidgets. It can be used to provide radio-box or check-box style of selection options for the user.

class Tix.StdButtonBox

The StdButtonBox widget is a group of standard buttons for Motif-like dialog boxes.

24.3.2.2. File Selectors

class Tix.DirList

The DirList widget displays a list view of a directory, its previous directories and its sub-directories. The user can choose one of the directories displayed in the list or change to another directory.

class Tix.DirTree
The **DirTree** widget displays a tree view of a directory, its previous directories and its sub-directories. The user can choose one of the directories displayed in the list or change to another directory.

**class** Tix.DirSelectDialog

The **DirSelectDialog** widget presents the directories in the file system in a dialog window. The user can use this dialog window to navigate through the file system to select the desired directory.

**class** Tix.DirSelectBox

The **DirSelectBox** is similar to the standard Motif(TM) directory-selection box. It is generally used for the user to choose a directory. DirSelectBox stores the directories mostly recently selected into a ComboBox widget so that they can be quickly selected again.

**class** Tix.ExFileSelectBox

The **ExFileSelectBox** widget is usually embedded in a tixExFileSelectDialog widget. It provides an convenient method for the user to select files. The style of the **ExFileSelectBox** widget is very similar to the standard file dialog on MS Windows 3.1.

**class** Tix.FileSelectBox

The **FileSelectBox** is similar to the standard Motif(TM) file-selection box. It is generally used for the user to choose a file. FileSelectBox stores the files mostly recently selected into a ComboBox widget so that they can be quickly selected again.

**class** Tix.FileEntry

The **FileEntry** widget can be used to input a filename. The user can type in the filename manually. Alternatively, the user can press the button widget that sits next to the entry, which will bring up a file selection dialog.
24.3.2.3. Hierarchical ListBox

*class* Tix.HList

The HList widget can be used to display any data that have a hierarchical structure, for example, file system directory trees. The list entries are indented and connected by branch lines according to their places in the hierarchy.

*class* Tix.CheckList

The CheckList widget displays a list of items to be selected by the user. CheckList acts similarly to the Tk checkbutton or radiobutton widgets, except it is capable of handling many more items than checkbuttons or radiobuttons.

*class* Tix.Tree

The Tree widget can be used to display hierarchical data in a tree form. The user can adjust the view of the tree by opening or closing parts of the tree.

24.3.2.4. Tabular ListBox

*class* Tix.TList

The TList widget can be used to display data in a tabular format. The list entries of a TList widget are similar to the entries in the Tk listbox widget. The main differences are (1) the TList widget can display the list entries in a two dimensional format and (2) you can use graphical images as well as multiple colors and fonts for the list entries.

24.3.2.5. Manager Widgets

*class* Tix.PanedWindow

The PanedWindow widget allows the user to interactively manipulate the sizes of several panes. The panes can be
arranged either vertically or horizontally. The user changes the sizes of the panes by dragging the resize handle between two panes.

class Tix.ListNoteBook

The ListNoteBook widget is very similar to the TixNoteBook widget: it can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages (windows). At one time only one of these pages can be shown. The user can navigate through these pages by choosing the name of the desired page in the hlist subwidget.

class Tix.NoteBook

The NoteBook widget can be used to display many windows in a limited space using a notebook metaphor. The notebook is divided into a stack of pages. At one time only one of these pages can be shown. The user can navigate through these pages by choosing the visual “tabs” at the top of the NoteBook widget.

24.3.2.6. Image Types

The Tix module adds:

- **pixmap** capabilities to all Tix and Tkinter widgets to create color images from XPM files.
- **Compound** image types can be used to create images that consists of multiple horizontal lines; each line is composed of a series of items (texts, bitmaps, images or spaces) arranged from left to right. For example, a compound image can be used to display a bitmap and a text string simultaneously in a Tk Button widget.

24.3.2.7. Miscellaneous Widgets
class Tix.InputOnly

The InputOnly widgets are to accept inputs from the user, which can be done with the bind command (Unix only).

24.3.2.8. Form Geometry Manager

In addition, Tix augments Tkinter by providing:

class Tix.Form

The Form geometry manager based on attachment rules for all Tk widgets.
24.3.3. Tix Commands

class Tix.tixCommand

The tix commands provide access to miscellaneous elements of Tix's internal state and the Tix application context. Most of the information manipulated by these methods pertains to the application as a whole, or to a screen or display, rather than to a particular window.

To view the current settings, the common usage is:

```python
import Tix
root = Tix.Tk()
print root.tix_configure()
```

tixCommand.tix_configure([cnf], **kw)

Query or modify the configuration options of the Tix application context. If no option is specified, returns a dictionary all of the available options. If option is specified with no value, then the method returns a list describing the one named option (this list will be identical to the corresponding sublist of the value returned if no option is specified). If one or more option-value pairs are specified, then the method modifies the given option(s) to have the given value(s); in this case the method returns an empty string. Option may be any of the configuration options.

tixCommand.tix_cget(option)

Returns the current value of the configuration option given by option. Option may be any of the configuration options.

tixCommand.tix_getbitmap(name)

Locates a bitmap file of the name name.xpm or name in one of the bitmap directories (see the tix_addbitmapdir() method). By
using `tix_getbitmap()`, you can avoid hard coding the pathnames of the bitmap files in your application. When successful, it returns the complete pathname of the bitmap file, prefixed with the character @. The returned value can be used to configure the `bitmap` option of the Tk and Tix widgets.

`tixCommand.tix_addbitmapdir(directory)`

Tix maintains a list of directories under which the `tix_getimage()` and `tix_getbitmap()` methods will search for image files. The standard bitmap directory is `$TIX_LIBRARY/bitmaps`. The `tix_addbitmapdir()` method adds `directory` into this list. By using this method, the image files of an applications can also be located using the `tix_getimage()` or `tix_getbitmap()` method.

`tixCommand.tix_filedialog([dlgclass])`  

Returns the file selection dialog that may be shared among different calls from this application. This method will create a file selection dialog widget when it is called the first time. This dialog will be returned by all subsequent calls to `tix_filedialog()`. An optional `dlgclass` parameter can be passed as a string to specified what type of file selection dialog widget is desired. Possible options are `tix`, `FileSelectDialog` or `tixExFileSelectDialog`.

`tixCommand.tix_getimage(self, name)`  

Locates an image file of the name `name.xpm`, `name.xbm` or `name.ppm` in one of the bitmap directories (see the `tix_addbitmapdir()` method above). If more than one file with the same name (but different extensions) exist, then the image type is chosen according to the depth of the X display: `xbm` images are chosen on monochrome displays and color images are chosen on color displays. By using `tix_getimage()`, you can
avoid hard coding the pathnames of the image files in your application. When successful, this method returns the name of the newly created image, which can be used to configure the image option of the Tk and Tix widgets.

```python
tixCommand.tix_option_get(name)
```
Gets the options maintained by the Tix scheme mechanism.

```python
tixCommand.tix_resetoptions(newScheme, newFontSet[, newScmPrio])
```
Resets the scheme and fontset of the Tix application to `newScheme` and `newFontSet`, respectively. This affects only those widgets created after this call. Therefore, it is best to call the resetoptions method before the creation of any widgets in a Tix application.

The optional parameter `newScmPrio` can be given to reset the priority level of the Tk options set by the Tix schemes.

Because of the way Tk handles the X option database, after Tix has been has imported and inited, it is not possible to reset the color schemes and font sets using the `tix_config()` method. Instead, the `tix_resetoptions()` method must be used.
24.4. `ScrolledText` — Scrolled Text Widget

*Platforms:* Tk

The `ScrolledText` module provides a class of the same name which implements a basic text widget which has a vertical scroll bar configured to do the “right thing.” Using the `ScrolledText` class is a lot easier than setting up a text widget and scroll bar directly. The constructor is the same as that of the `Tkinter.Text` class.

**Note:** `ScrolledText` has been renamed to `tkinter.scrolledtext` in Python 3.0. The `2to3` tool will automatically adapt imports when converting your sources to 3.0.

The text widget and scrollbar are packed together in a `Frame`, and the methods of the `Grid` and `Pack` geometry managers are acquired from the `Frame` object. This allows the `ScrolledText` widget to be used directly to achieve most normal geometry management behavior.

Should more specific control be necessary, the following attributes are available:

`ScrolledText.frame`

The frame which surrounds the text and scroll bar widgets.

`ScrolledText.vbar`

The scroll bar widget.
24.5. turtle — Turtle graphics for Tk
24.5.1. Introduction

Turtle graphics is a popular way for introducing programming to kids. It was part of the original Logo programming language developed by Wally Feurzig and Seymour Papert in 1966.

Imagine a robotic turtle starting at (0, 0) in the x-y plane. Give it the command `turtle.forward(15)`, and it moves (on-screen!) 15 pixels in the direction it is facing, drawing a line as it moves. Give it the command `turtle.left(25)`, and it rotates in-place 25 degrees clockwise.

By combining together these and similar commands, intricate shapes and pictures can easily be drawn.

The `turtle` module is an extended reimplementation of the same-named module from the Python standard distribution up to version Python 2.5.

It tries to keep the merits of the old turtle module and to be (nearly) 100% compatible with it. This means in the first place to enable the learning programmer to use all the commands, classes and methods interactively when using the module from within IDLE run with the `-n` switch.

The turtle module provides turtle graphics primitives, in both object-oriented and procedure-oriented ways. Because it uses Tkinter for the underlying graphics, it needs a version of Python installed with Tk support.

The object-oriented interface uses essentially two+two classes:

1. The `TurtleScreen` class defines graphics windows as a playground for the drawing turtles. Its constructor needs a
Tkinter.Canvas or a ScrolledCanvas as argument. It should be used when turtle is used as part of some application.

The function Screen() returns a singleton object of a TurtleScreen subclass. This function should be used when turtle is used as a standalone tool for doing graphics. As a singleton object, inheriting from its class is not possible.

All methods of TurtleScreen/Screen also exist as functions, i.e. as part of the procedure-oriented interface.

2. RawTurtle (alias: RawPen) defines Turtle objects which draw on a TurtleScreen. Its constructor needs a Canvas, ScrolledCanvas or TurtleScreen as argument, so the RawTurtle objects know where to draw.

Derived from RawTurtle is the subclass Turtle (alias: Pen), which draws on “the” Screen - instance which is automatically created, if not already present.

All methods of RawTurtle/Turtle also exist as functions, i.e. part of the procedure-oriented interface.

The procedural interface provides functions which are derived from the methods of the classes Screen and Turtle. They have the same names as the corresponding methods. A screen object is automatically created whenever a function derived from a Screen method is called. An (unnamed) turtle object is automatically created whenever any of the functions derived from a Turtle method is called.

To use multiple turtles an a screen one has to use the object-oriented interface.

Note: In the following documentation the argument list for
functions is given. Methods, of course, have the additional first argument `self` which is omitted here.
24.5.2. Overview over available Turtle and Screen methods

24.5.2.1. Turtle methods

Turtle motion

Move and draw

```
forward() | fd()
backward() | bk() | back()
right() | rt()
left() | lt()
goto() | setpos() | setposition()
setx()
sety()
setheading() | seth()
home()
circle()
dot()
stamp()
clearstamp()
clearstamps()
undo()
speed()
```

Tell Turtle’s state

```
position() | pos()
towards()
xcor()
ycor()
heading()
distance()
```
Setting and measurement

\[ \text{degrees()} \]
\[ \text{radians()} \]

Pen control

Drawing state

\[ \text{pendown()} | \text{pd()} | \text{down()} \]
\[ \text{penup()} | \text{pu()} | \text{up()} \]
\[ \text{pensize()} | \text{width()} \]
\[ \text{pen()} \]
\[ \text{isdown()} \]

Color control

\[ \text{color()} \]
\[ \text{pencolor()} \]
\[ \text{fillcolor()} \]

Filling

\[ \text{fill()} \]
\[ \text{begin_fill()} \]
\[ \text{end_fill()} \]

More drawing control

\[ \text{reset()} \]
\[ \text{clear()} \]
\[ \text{write()} \]

Turtle state

Visibility

\[ \text{showturtle()} | \text{st()} \]
\[ \text{hideturtle()} | \text{ht()} \]
\[ \text{isvisible()} \]

Appearance

\[ \text{shape()} \]
\[ \text{resizemode()} \]
shapesize() | turtlesize()
settiltangle()
tiltangle()
tilt()

Using events
onclick()
onrelease()
ondrag()

Special Turtle methods
begin_poly()
end_poly()
get_poly()
clone()
getturtle() | getpen()
getscreen()
setundobuffer()
undobufferentries()
tracer()
window_width()
window_height()

24.5.2.2. Methods of TurtleScreen/Screen

Window control
bgcolor()
bgpic()
clear() | clearscreenscreen()
reset() | resetscreen()
screensize()
setworldcoordinates()

Animation control
delay()
tracer()
update()

Using screen events
   listen()
onkey()
onclick() | onscreenclck()
ontimer()

Settings and special methods
   mode()
colormode()
getcanvas()
getshapes()
   register_shape() | addshape()
turtles()
window_height()
window_width()

Methods specific to Screen
   bye()
exitonclick()
setup()
title()
24.5.3. Methods of RawTurtle/Turtle and corresponding functions

Most of the examples in this section refer to a Turtle instance called turtle.

24.5.3.1. Turtle motion

turtle.**forward**(\textit{distance})
turtle.**fd**(\textit{distance})

\textbf{Parameter:} \textit{distance} – a number (integer or float)

Move the turtle forward by the specified \textit{distance}, in the direction the turtle is headed.

```
>>> turtle.position()
(0.00,0.00)
>>> turtle.forward(25)
>>> turtle.position()
(25.00,0.00)
>>> turtle.forward(-75)
>>> turtle.position()
(-50.00,0.00)
```

turtle.**back**(\textit{distance})
turtle.**bk**(\textit{distance})
turtle.**backward**(\textit{distance})

\textbf{Parameter:} \textit{distance} – a number

Move the turtle backward by \textit{distance}, opposite to the direction the turtle is headed. Do not change the turtle's heading.

```
>>> turtle.position()
(0.00,0.00)
>>> turtle.backward(30)
>>> turtle.position()
```
turtle.\texttt{right}(\textit{angle})
turtle.\texttt{rt}(\textit{angle})

\textbf{Parameter:} \textit{angle} – a number (integer or float)

Turn turtle right by \textit{angle} units. (Units are by default degrees, but can be set via the \texttt{degrees()} and \texttt{radians()} functions.) Angle orientation depends on the turtle mode, see \texttt{mode()}.

```python
>>> turtle.heading()
22.0
>>> turtle.right(45)
>>> turtle.heading()
337.0
```

turtle.\texttt{left}(\textit{angle})
turtle.\texttt{lt}(\textit{angle})

\textbf{Parameter:} \textit{angle} – a number (integer or float)

Turn turtle left by \textit{angle} units. (Units are by default degrees, but can be set via the \texttt{degrees()} and \texttt{radians()} functions.) Angle orientation depends on the turtle mode, see \texttt{mode()}.

```python
>>> turtle.heading()
22.0
>>> turtle.left(45)
>>> turtle.heading()
67.0
```

turtle.\texttt{goto}(\textit{x}, \textit{y}=\texttt{None})
turtle.\texttt{setpos}(\textit{x}, \textit{y}=\texttt{None})
turtle.\texttt{setposition}(\textit{x}, \textit{y}=\texttt{None})

\textbf{Parameters:}

- \textit{x} – a number or a pair/vector of numbers
- \textit{y} – a number or \texttt{None}

If \textit{y} is \texttt{None}, \textit{x} must be a pair of coordinates or a \texttt{Vec2D} (e.g. as
returned by `pos()`.

Move turtle to an absolute position. If the pen is down, draw line. Do not change the turtle's orientation.

```python
>>> tp = turtle.pos()
>>> tp
(0.00, 0.00)
>>> turtle.setpos(60, 30)
>>> turtle.pos()
(60.00, 30.00)
>>> turtle.setpos((20, 80))
>>> turtle.pos()
(20.00, 80.00)
>>> turtle.setpos(tp)
>>> turtle.pos()
(0.00, 0.00)
```

`turtle.setx(x)`

**Parameter:** `x` – a number (integer or float)

Set the turtle's first coordinate to `x`, leave second coordinate unchanged.

```python
>>> turtle.position()
(0.00, 240.00)
>>> turtle.setx(10)
>>> turtle.position()
(10.00, 240.00)
```

`turtle.sety(y)`

**Parameter:** `y` – a number (integer or float)

Set the turtle's second coordinate to `y`, leave first coordinate unchanged.

```python
>>> turtle.position()
(0.00, 40.00)
>>> turtle.sety(-10)
>>> turtle.position()
(0.00, -10.00)
```
turtle. **setheading**(to\_angle)
turtle. **seth**(to\_angle)

**Parameter:** to\_angle – a number (integer or float)

Set the orientation of the turtle to to\_angle. Here are some common directions in degrees:

<table>
<thead>
<tr>
<th>standard mode</th>
<th>logo mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - east</td>
<td>0 - north</td>
</tr>
<tr>
<td>90 - north</td>
<td>90 - east</td>
</tr>
<tr>
<td>180 - west</td>
<td>180 - south</td>
</tr>
<tr>
<td>270 - south</td>
<td>270 - west</td>
</tr>
</tbody>
</table>

```python
>>> turtle.setheading(90)
>>> turtle.heading()
90.0
```

turtle. **home**()

Move turtle to the origin – coordinates (0,0) – and set its heading to its start-orientation (which depends on the mode, see mode()).

```python
>>> turtle.heading()
90.0
>>> turtle.position()
(0.00, -10.00)
>>> turtle.home()
>>> turtle.position()
(0.00, 0.00)
>>> turtle.heading()
0.0
```

turtle. **circle**(radius, extent=None, steps=None)

**Parameters:**
- radius – a number
- extent – a number (or None)
- steps – an integer (or None)

Draw a circle with given radius. The center is radius units left of
the turtle; \textit{extent} – an angle – determines which part of the circle is drawn. If \textit{extent} is not given, draw the entire circle. If \textit{extent} is not a full circle, one endpoint of the arc is the current pen position. Draw the arc in counterclockwise direction if \textit{radius} is positive, otherwise in clockwise direction. Finally the direction of the turtle is changed by the amount of \textit{extent}.

As the circle is approximated by an inscribed regular polygon, \textit{steps} determines the number of steps to use. If not given, it will be calculated automatically. May be used to draw regular polygons.

\begin{verbatim}
>>> turtle.home()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
>>> turtle.circle(50)
>>> turtle.position()
(-0.00,0.00)
>>> turtle.heading()
0.0
>>> turtle.circle(120, 180)  # draw a semicircle
>>> turtle.position()
(0.00,240.00)
>>> turtle.heading()
180.0
\end{verbatim}

turtle.\texttt{dot}(\texttt{size=\texttt{None}}, \texttt{*\texttt{color}})

\begin{tabular}{|l|}
\hline
\textbf{Parameters:} \hline
\hspace{1cm} \textbullet \hspace{0.5cm} \textit{size} -- an integer $\geq 1$ (if given) \\
\hspace{1cm} \textbullet \hspace{0.5cm} \textit{color} -- a colorstring or a numeric color tuple \\
\hline
\end{tabular}

Draw a circular dot with diameter \textit{size}, using \textit{color}. If \textit{size} is not given, the maximum of pensize+4 and 2*pen size is used.

\begin{verbatim}
>>> turtle.home()
>>> turtle.dot()
>>> turtle.fd(50); turtle.dot(20, "blue"); turtle.fd(50)
>>> turtle.position()
(100.00,-0.00)
\end{verbatim}
turtle.\texttt{stamp()}

Stamp a copy of the turtle shape onto the canvas at the current turtle position. Return a stamp\_id for that stamp, which can be used to delete it by calling \texttt{clearstamp(stamp\_id)}.

```python
>>> turtle.color("blue")
>>> turtle.stamp()
11
>>> turtle.fd(50)
```

turtle.\texttt{clearstamp(stampid)}

\textbf{Parameter:} \texttt{stampid} – an integer, must be return value of previous \texttt{stamp()} call

Delete stamp with given \texttt{stampid}.

```python
>>> turtle.position()
(150.00,-0.00)
>>> turtle.color("blue")
>>> astamp = turtle.stamp()
>>> turtle.fd(50)
>>> turtle.position()
(200.00,-0.00)
>>> turtle.clearstamp(astamp)
>>> turtle.position()
(200.00,-0.00)
```

turtle.\texttt{clearstamps(n=None)}

\textbf{Parameter:} \texttt{n} – an integer (or \texttt{None})

Delete all or first/last \texttt{n} of turtle's stamps. If \texttt{n} is \texttt{None}, delete all stamps, if \texttt{n} > 0 delete first \texttt{n} stamps, else if \texttt{n} < 0 delete last \texttt{n} stamps.

```python
>>> for i in range(8):
...     turtle.stamp(); turtle.fd(30)
```

turtle.\texttt{heading()}

0.0
turtle. `undo()`

Undo (repeatedly) the last turtle action(s). Number of available undo actions is determined by the size of the undobuffer.

```python
>>> for i in range(4):
...    turtle.fd(50); turtle.lt(80)
...
>>> for i in range(8):
...    turtle.undo()
```

turtle. `speed(speed=None)`

**Parameter:** `speed` – an integer in the range 0..10 or a speedstring (see below)

Set the turtle’s speed to an integer value in the range 0..10. If no argument is given, return current speed.

If input is a number greater than 10 or smaller than 0.5, speed is set to 0. Speedstrings are mapped to speedvalues as follows:

- “fastest”: 0
- “fast”: 10
- “normal”: 6
- “slow”: 3
- “slowest”: 1

Speeds from 1 to 10 enforce increasingly faster animation of line drawing and turtle turning.
Attention: \textit{speed} = 0 means that no animation takes place. forward/back makes turtle jump and likewise left/right make the turtle turn instantly.

```python
>>> turtle.speed()
3
>>> turtle.speed('normal')
>>> turtle.speed()
6
>>> turtle.speed(9)
>>> turtle.speed()
9
```

### 24.5.3.2. Tell Turtle's state

- **turtle.\texttt{position}()**
- **turtle.\texttt{pos}()**
  
  Return the turtle's current location \((x,y)\) (as a \texttt{Vec2D} vector).

```python
>>> turtle.pos()
(440.00, -0.00)
```

- **turtle.\texttt{towards}(x, y=None)**

  **Parameters:**
  
  - \(x\) – a number or a pair/vector of numbers or a turtle instance
  - \(y\) – a number if \(x\) is a number, else \texttt{None}

  Return the angle between the line from turtle position to position specified by \((x,y)\), the vector or the other turtle. This depends on the turtle's start orientation which depends on the mode - "standard"/"world" or "logo".

```python
>>> turtle.goto(10, 10)
>>> turtle.towards(0, 0)
225.0
```

- **turtle.\texttt{xcor}()**
Return the turtle’s x coordinate.

```python
>>> turtle.home()
>>> turtle.left(50)
>>> turtle.forward(100)
>>> turtle.pos()
(64.28, 76.60)
>>> print turtle.xcor()
64.2787609687
```

turtle. ycor()

Return the turtle’s y coordinate.

```python
>>> turtle.home()
>>> turtle.left(60)
>>> turtle.forward(100)
>>> print turtle.pos()
(50.00, 86.60)
>>> print turtle.ycor()
86.6025403784
```

turtle. heading()

Return the turtle’s current heading (value depends on the turtle mode, see mode()).

```python
>>> turtle.home()
>>> turtle.left(67)
>>> turtle.heading()
67.0
```

turtle. distance(x, y=None)

**Parameters:**
- `x` – a number or a pair/vector of numbers or a turtle instance
- `y` – a number if `x` is a number, else `None`

Return the distance from the turtle to (x,y), the given vector, or the given other turtle, in turtle step units.

```python
>>> turtle.home()
```
24.5.3.3. Settings for measurement

**turtle.** *degrees*(**fullcircle**=360.0)

**Parameter:** **fullcircle** – a number

Set angle measurement units, i.e. set number of “degrees” for a full circle. Default value is 360 degrees.

```python
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.heading()
90.0
```

Change angle measurement unit to grad (also known as gon, grade, or gradian and equals 1/100-th of the right angle.)

```python
>>> turtle.degrees(400.0)
>>> turtle.heading()
100.0
>>> turtle.degrees(360)
>>> turtle.heading()
90.0
```

**turtle.** *radians*(

Set the angle measurement units to radians. Equivalent to *degrees*(2*`math.pi`).

```python
>>> turtle.home()
>>> turtle.left(90)
>>> turtle.heading()
90.0
>>> turtle.radians()
>>> turtle.heading()
```
24.5.3.4. Pen control

24.5.3.4.1. Drawing state

turtle. **pendown**
turtle. **pd**
turtle. **down**

    Pull the pen down – drawing when moving.

turtle. **penup**
turtle. **pu**
turtle. **up**

    Pull the pen up – no drawing when moving.

turtle. **pensize**(width=None)
turtle. **width**(width=None)

    **Parameter:** width – a positive number

    Set the line thickness to *width* or return it. If resizemode is set to “auto” and turtleshape is a polygon, that polygon is drawn with the same line thickness. If no argument is given, the current pensize is returned.

```python
>>> turtle.pensize()
1
>>> turtle.pensize(10)  # from here on lines of width 10 are drawn
```

turtle. **pen**(pen=None, **pendict**)

    **Parameters:**
    - *pen* – a dictionary with some or all of the below listed keys
    - *pendict* – one or more keyword-arguments with the below listed keys as keywords
Return or set the pen’s attributes in a “pen-dictionary” with the following key/value pairs:

- “shown”: True/False
- “pendown”: True/False
- “pencolor”: color-string or color-tuple
- “fillcolor”: color-string or color-tuple
- “pensize”: positive number
- “speed”: number in range 0..10
- “resizemode”: “auto” or “user” or “noresize”
- “stretchfactor”: (positive number, positive number)
- “outline”: positive number
- “tilt”: number

This dictionary can be used as argument for a subsequent call to `pen()` to restore the former pen-state. Moreover one or more of these attributes can be provided as keyword-arguments. This can be used to set several pen attributes in one statement.

```python
>>> turtle.pen(fillcolor="black", pencolor="red", pensize=10)
>>> sorted(turtle.pen().items())
[('fillcolor', 'black'), ('outline', 1), ('pencolor', 'red'), ('pendown', True), ('pensize', 10), ('resizemode', 'noresize'), ('shown', True), ('speed', 9), ('stretchfactor', (1, 1)),
>>> penstate=turtle.pen()  
>>> turtle.color("yellow", ")
>>> turtle.penup()  
>>> sorted(turtle.pen().items())
[('fillcolor', ''), ('outline', 1), ('pencolor', 'yellow'), ('pendown', False), ('pensize', 10), ('resizemode', 'noresize'), ('shown', True), ('speed', 9), ('stretchfactor', (1, 1)),
>>> turtle.pen(penstate, fillcolor="green")
>>> sorted(turtle.pen().items())
[('fillcolor', 'green'), ('outline', 1), ('pencolor', 'red'), ('pendown', True), ('pensize', 10), ('resizemode', 'noresize'), ('shown', True), ('speed', 9), ('stretchfactor', (1, 1)),
```

turtle.isdown()

Return `True` if pen is down, `False` if it’s up.
24.5.3.4.2. Color control

turtle. **pencolor**(*args*)

Return or set the pencolor.

Four input formats are allowed:

pencolor()  
Return the current pencolor as color specification string or as a tuple (see example). May be used as input to another color/pencolor/fillcolor call.

pencolor(colorstring)  
Set pencolor to *colorstring*, which is a Tk color specification string, such as "red", "yellow", or "#33cc8c".

pencolor((r, g, b))  
Set pencolor to the RGB color represented by the tuple of *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode, where colormode is either 1.0 or 255 (see `colormode()`).

pencolor(*r*, *g*, *b*)  
Set pencolor to the RGB color represented by *r*, *g*, and *b*. Each of *r*, *g*, and *b* must be in the range 0..colormode.

If turtleshape is a polygon, the outline of that polygon is drawn with the newly set pencolor.

```python
>>> turtle.penup()
>>> turtle.isdown()
False
>>> turtle.pendown()
>>> turtle.isdown()
True
```
turtle.pencolor("brown")
>>>

turtle.pencolor()
'brown'
>>>
tup = (0.2, 0.8, 0.55)
>>>
turtle.pencolor(tup)
>>>
turtle.pencolor()
(0.2, 0.8, 0.5490196078431373)
>>>
colormode(255)
>>>
turtle.pencolor()
(51, 204, 140)
>>>
turtle.pencolor('red')
>>>
turtle.pencolor()
(50, 193, 143)

turtle.fillcolor(*args)

Return or set the fillcolor.

Four input formats are allowed:

fillcolor()

Return the current fillcolor as color specification string, possibly in tuple format (see example). May be used as input to another color/pencolor/fillcolor call.

fillcolor(colorstring)

Set fillcolor to colorstring, which is a Tk color specification string, such as "red", "yellow", or "#33cc8c".

fillcolor((r, g, b))

Set fillcolor to the RGB color represented by the tuple of r, g, and b. Each of r, g, and b must be in the range 0..colormode, where colormode is either 1.0 or 255 (see colormode()).

fillcolor(r, g, b)

Set fillcolor to the RGB color represented by r, g, and b. Each of r, g, and b must be in the range 0..colormode.

If turtleshape is a polygon, the interior of that polygon is drawn with the newly set fillcolor.
turtle.color(*args)

Return or set pencolor and fillcolor.

Several input formats are allowed. They use 0 to 3 arguments as follows:

color()

Return the current pencolor and the current fillcolor as a pair of color specification strings or tuples as returned by pencolor() and fillcolor().

color(colorstring), color((r,g,b)), color(r,g,b)

Inputs as in pencolor(), set both, fillcolor and pencolor, to the given value.

color(colorstring1, colorstring2), color((r1,g1,b1), (r2,g2,b2))

Equivalent to pencolor(colorstring1) and fillcolor(colorstring2) and analogously if the other input format is used.

If turtleshape is a polygon, outline and interior of that polygon is drawn with the newly set colors.

>>> turtle.color("red", "green")
See also: Screen method `colormode()`.

### 24.5.3.4.3. Filling

**turtle.fill(flag)**

**Parameter:** `flag` – True/False (or 1/0 respectively)

Call `fill(True)` before drawing the shape you want to fill, and `fill(False)` when done. When used without argument: return `fillstate (True if filling, False else)`.

```python
>>> turtle.fill(True)
>>> for _ in range(3):
...     turtle.forward(100)
...     turtle.left(120)
...
>>> turtle.fill(False)
```

**turtle.begin_fill()**

Call just before drawing a shape to be filled. Equivalent to `fill(True)`.

**turtle.end_fill()**

Fill the shape drawn after the last call to `begin_fill()`. Equivalent to `fill(False)`.

```python
>>> turtle.color("black", "red")
>>> turtle.begin_fill()
>>> turtle.circle(80)
>>> turtle.end_fill()
```

### 24.5.3.4.4. More drawing control
turtle.**reset**()

Delete the turtle’s drawings from the screen, re-center the turtle and set variables to the default values.

```python
>>> turtle.goto(0,-22)
>>> turtle.left(100)
>>> turtle.position()
(0.00,-22.00)
>>> turtle.heading()
100.0
>>> turtle.reset()
>>> turtle.position()
(0.00,0.00)
>>> turtle.heading()
0.0
```

turtle.**clear**()

Delete the turtle’s drawings from the screen. Do not move turtle. State and position of the turtle as well as drawings of other turtles are not affected.

turtle.**write**(arg, move=False, align="left", font="Arial", 8, "normal")

**Parameters:**
- *arg* – object to be written to the TurtleScreen
- *move* – True/False
- *align* – one of the strings “left”, “center” or right
- *font* – a triple (fontname, fontsize, fonttype)

Write text - the string representation of *arg* - at the current turtle position according to *align* (“left”, “center” or right) and with the given font. If *move* is True, the pen is moved to the bottom-right corner of the text. By default, *move* is False.

```python
>>> turtle.write("Home = ", True, align="center")
>>> turtle.write((0,0), True)
```

### 24.5.3.5. Turtle state
24.5.3.5.1. Visibility

```python
turtle.hideturtle()
turtle.ht()
```

Make the turtle invisible. It’s a good idea to do this while you’re in the middle of doing some complex drawing, because hiding the turtle speeds up the drawing observably.

```python
>>> turtle.hideturtle()
```

```python
turtle.showturtle()
turtle.st()
```

Make the turtle visible.

```python
>>> turtle.showturtle()
```

```python
turtle.isvisible()
```

Return True if the Turtle is shown, False if it’s hidden.

```python
>>> turtle.hideturtle()
>>> turtle.isvisible()
False
>>> turtle.showturtle()
>>> turtle.isvisible()
True
```

24.5.3.5.2. Appearance

```python
turtle.shape(name=None)
```

**Parameter:** `name` – a string which is a valid shapename

Set turtle shape to shape with given `name` or, if name is not given, return name of current shape. Shape with `name` must exist in the TurtleScreen’s shape dictionary. Initially there are the following polygon shapes: “arrow”, “turtle”, “circle”, “square”,...
“triangle”, “classic”. To learn about how to deal with shapes see Screen method register_shape().

```python
>>> turtle.shape()
'classic'
>>> turtle.shape("turtle")
>>> turtle.shape()
'turtle'
```

turtle.**resizemode**(rmode=None)

**Parameter:**  
`rmode` – one of the strings “auto”, “user”, “noresize”

Set resizemode to one of the values: “auto”, “user”, “noresize”. If `rmode` is not given, return current resizemode. Different resizemodes have the following effects:

- “auto”: adapts the appearance of the turtle corresponding to the value of pensize.
- “user”: adapts the appearance of the turtle according to the values of stretchfactor and outlinewidth (outline), which are set by **shapesize**.
- “noresize”: no adaption of the turtle's appearance takes place.

resizemode("user") is called by **shapesize**() when used with arguments.

```python
>>> turtle.resizemode()
'noresize'
>>> turtle.resizemode("auto")
>>> turtle.resizemode()
'auto'
```

turtle.**shapesize**(stretch_wid=None, stretch_len=None, outline=None)
turtle.**turtlesize**(stretch_wid=None, stretch_len=None, outline=None)
Return or set the pen’s attributes x/y-stretchfactors and/or outline. Set resizemode to "user". If and only if resizemode is set to “user”, the turtle will be displayed stretched according to its stretchfactors: *stretch_wid* is stretchfactor perpendicular to its orientation, *stretch_len* is stretchfactor in direction of its orientation, *outline* determines the width of the shapes's outline.

```python
>>> turtle.shapesize()
(1, 1, 1)
>>> turtle.resizemode("user")
>>> turtle.shapesize(5, 5, 12)
>>> turtle.shapesize()
(5, 5, 12)
>>> turtle.shapesize(outline=8)
>>> turtle.shapesize()
(5, 5, 8)
```

turtle.**tilt**(angle)

**Parameter:** angle – a number

Rotate the turtleshape by *angle* from its current tilt-angle, but do *not* change the turtle's heading (direction of movement).

```python
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5,2)
>>> turtle.tilt(30)
>>> turtle.fd(50)
>>> turtle.tilt(30)
>>> turtle.fd(50)
```

turtle.**settiltangle**(angle)

**Parameter:** angle – a number

Rotate the turtleshape to point in the direction specified by angle, regardless of its current tilt-angle. *Do not* change the turtle’s
heading (direction of movement).

```python
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5, 2)
>>> turtle.settiltangle(45)
>>> turtle.fd(50)
>>> turtle.settiltangle(-45)
>>> turtle.fd(50)
```

**turtle.**tiltangle**()

Return the current tilt-angle, i.e. the angle between the orientation of the turtleshape and the heading of the turtle (its direction of movement).

```python
>>> turtle.reset()
>>> turtle.shape("circle")
>>> turtle.shapesize(5, 2)
>>> turtle.tilt(45)
>>> turtle.tiltangle()  
45.0
```

### 24.5.3.6. Using events

**turtle.**onclick**(**fun, btn=1, add=None)**

- **fun** – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- **num** – number of the mouse-button, defaults to 1 (left mouse button)
- **add** – True or False – if True, a new binding will be added, otherwise it will replace a former binding

Bind **fun** to mouse-click events on this turtle. If **fun** is **None**, existing bindings are removed. Example for the anonymous turtle, i.e. the procedural way:
```python
def turn(x, y):
    ... left(180)
...
>>> onclick(turn)  # Now clicking into the turtle will turn
>>> onclick(None)  # event-binding will be removed
```

```python
turtle.onrelease(fun, btn=1, add=None)
```

**Parameters:**
- `fun` – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- `num` – number of the mouse-button, defaults to 1 (left mouse button)
- `add` – True or False – if True, a new binding will be added, otherwise it will replace a former binding

Bind `fun` to mouse-button-release events on this turtle. If `fun` is `None`, existing bindings are removed.

```python
class MyTurtle(Turtle):
    ...
    def glow(self, x, y):
        ... self.fillcolor("red")
    ...
    def unglow(self, x, y):
        ... self.fillcolor("")
    ...
>>> turtle = MyTurtle()
>>> turtle.onclick(turtle.glow)  # clicking on turtle turns fillcolor red
>>> turtle.onrelease(turtle.unglow)  # releasing turns it to transparent
```

```python
turtle.ondrag(fun, btn=1, add=None)
```

**Parameters:**
- `fun` – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- `num` – number of the mouse-button, defaults to 1 (left mouse button)
- `add` – True or False – if True, a new binding will be added, otherwise it will replace a former binding
Bind *fun* to mouse-move events on this turtle. If *fun* is *None*, existing bindings are removed.

Remark: Every sequence of mouse-move-events on a turtle is preceded by a mouse-click event on that turtle.

```python
>>> turtle.ondrag(turtle.goto)
```

Subsequently, clicking and dragging the Turtle will move it across the screen thereby producing handdrawings (if pen is down).

### 24.5.3.7. Special Turtle methods

**turtle.*begin_poly()***

Start recording the vertices of a polygon. Current turtle position is first vertex of polygon.

**turtle.*end_poly()***

Stop recording the vertices of a polygon. Current turtle position is last vertex of polygon. This will be connected with the first vertex.

**turtle.*get_poly()***

Return the last recorded polygon.

```python
>>> turtle.home()
>>> turtle.begin_poly()
>>> turtle.fd(100)
>>> turtle.left(20)
>>> turtle.fd(30)
>>> turtle.left(60)
>>> turtle.fd(50)
>>> turtle.end_poly()
>>> p = turtle.get_poly()
>>> register_shape("myFavouriteShape", p)
```
turtle.**clone**()

Create and return a clone of the turtle with same position, heading and turtle properties.

```python
>>> mick = Turtle()
>>> joe = mick.clone()
```

turtle.**getturtleturtle**()  
turtle.**getpen**()

Return the Turtle object itself. Only reasonable use: as a function to return the “anonymous turtle”:

```python
>>> pet = getturtle()
>>> pet.fd(50)
>>> pet
<turtle.Turtle object at 0x...>
```

turtle.**getscreen**()

Return the **TurtleScreen** object the turtle is drawing on. TurtleScreen methods can then be called for that object.

```python
>>> ts = turtle.getscreen()
>>> ts
<turtle._Screen object at 0x...>
>>> tsbgcolor("pink")
```

turtle.**setundobuffer**(size)

**Parameter:** size – an integer or **None**

Set or disable undobuffer. If size is an integer an empty undobuffer of given size is installed. size gives the maximum number of turtle actions that can be undone by the **undo()** method/function. If size is **None**, the undobuffer is disabled.

```python
>>> turtle.setundobuffer(42)
```

turtle.**undobufferentries**()
Return number of entries in the undobuffer.

```python
>>> while undobufferentries():
...     undo()
```

`turtle.tracer(flag=None, delay=None)`
A replica of the corresponding TurtleScreen method.

*Deprecated since version 2.6.*

`turtle.window_width()`  
`turtle.window_height()`  
Both are replicas of the corresponding TurtleScreen methods.

*Deprecated since version 2.6.*

### 24.5.3.8. Excursus about the use of compound shapes

To use compound turtle shapes, which consist of several polygons of different color, you must use the helper class `Shape` explicitly as described below:

1. Create an empty `Shape` object of type “compound”.

2. Add as many components to this object as desired, using the `addcomponent()` method.

For example:

```python
>>> s = Shape("compound")  
>>> poly1 = ((0,0),(10,-5),(0,10),(-10,-5))  
>>> s.addcomponent(poly1, "red", "blue")  
>>> poly2 = ((0,0),(10,-5),(-10,-5))  
>>> s.addcomponent(poly2, "blue", "red")
```
3. Now add the Shape to the Screen’s shapelist and use it:

```python
>>> register_shape("myshape", s)
>>> shape("myshape")
```

**Note:** The *Shape* class is used internally by the `register_shape()` method in different ways. The application programmer has to deal with the *Shape* class *only* when using compound shapes like shown above!
24.5.4. Methods of TurtleScreen/Screen and corresponding functions

Most of the examples in this section refer to a TurtleScreen instance called screen.

24.5.4.1. Window control

turtle.bgcolor(*args)

**Parameter:** *args – a color string or three numbers in the range 0..colormode or a 3-tuple of such numbers

Set or return background color of the TurtleScreen.

```python
>>> screen.bgcolor("orange")
>>> screen.bgcolor()
'orange'
>>> screen.bgcolor("#800080")
>>> screen.bgcolor()
(128, 0, 128)
```

turtle.bgpic(picname=None)

**Parameter:** picname – a string, name of a gif-file or "nopic", or None

Set background image or return name of current background image. If picname is a filename, set the corresponding image as background. If picname is "nopic", delete background image, if present. If picname is None, return the filename of the current background image.

```python
>>> screen.bgpic()
'nopic'
>>> screen.bgpic("landscape.gif")
>>> screen.bgpic()
"landscape.gif"
```
turtle.\texttt{clear}()
turtle.\texttt{clearscreen}()

Delete all drawings and all turtles from the TurtleScreen. Reset the now empty TurtleScreen to its initial state: white background, no background image, no event bindings and tracing on.

\begin{center}
\textbf{Note:} This TurtleScreen method is available as a global function only under the name \texttt{clearscreen}. The global function \texttt{clear} is another one derived from the Turtle method \texttt{clear}.
\end{center}

turtle.\texttt{reset}()
turtle.\texttt{resetscreen}()

Reset all Turtles on the Screen to their initial state.

\begin{center}
\textbf{Note:} This TurtleScreen method is available as a global function only under the name \texttt{resetscreen}. The global function \texttt{reset} is another one derived from the Turtle method \texttt{reset}.
\end{center}

turtle.\texttt{screensize}(\texttt{canvwidth=None, canvheight=None, bg=None})

\begin{center}
\textbf{Parameters:}
\begin{itemize}
  \item \texttt{canvwidth} – positive integer, new width of canvas in pixels
  \item \texttt{canvheight} – positive integer, new height of canvas in pixels
  \item \texttt{bg} – colorstring or color-tuple, new background color
\end{itemize}
\end{center}

If no arguments are given, return current (canvaswidth, canvashheight). Else resize the canvas the turtles are drawing on. Do not alter the drawing window. To observe hidden parts of the canvas, use the scrollbars. With this method, one can make visible those parts of a drawing which were outside the canvas before.

\begin{center}
\texttt{>>> screen.screensize()}
\end{center}
```python
>>> screen.screensize(2000, 1500)
>>> screen.screensize()
(2000, 1500)
```

e.g. to search for an erroneously escaped turtle ;-)

turtle. `setworldcoordinates(llx, lly, urx, ury)`

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>llx</code></td>
<td>a number, x-coordinate of lower left corner of canvas</td>
</tr>
<tr>
<td><code>lly</code></td>
<td>a number, y-coordinate of lower left corner of canvas</td>
</tr>
<tr>
<td><code>urx</code></td>
<td>a number, x-coordinate of upper right corner of canvas</td>
</tr>
<tr>
<td><code>ury</code></td>
<td>a number, y-coordinate of upper right corner of canvas</td>
</tr>
</tbody>
</table>

Set up user-defined coordinate system and switch to mode “world” if necessary. This performs a `screen.reset()`. If mode “world” is already active, all drawings are redrawn according to the new coordinates.

**ATTENTION**: in user-defined coordinate systems angles may appear distorted.

```python
>>> screen.reset()
>>> screen.setworldcoordinates(-50, -7.5, 50, 7.5)
>>> for _ in range(72):
...    left(10)
...    ...
>>> for _ in range(8):
...    left(45); fd(2)  # a regular octagon
```

### 24.5.4.2. Animation control

turtle. `delay(delay=None)`

**Parameter**: `delay` – positive integer
Set or return the drawing \textit{delay} in milliseconds. (This is approximately the time interval between two consecutive canvas updates.) The longer the drawing delay, the slower the animation.

Optional argument:

```python
>>> screen.delay()
10
>>> screen.delay(5)
>>> screen.delay()
5
```

\texttt{turtle.tracer}(\texttt{n=None}, \texttt{delay=None})

\begin{itemize}
  \item \texttt{n} – nonnegative integer
  \item \texttt{delay} – nonnegative integer
\end{itemize}

Turn turtle animation on/off and set delay for update drawings. If \texttt{n} is given, only each \texttt{n}-th regular screen update is really performed. (Can be used to accelerate the drawing of complex graphics.) Second argument sets delay value (see \texttt{delay()}).

```python
>>> screen.tracer(8, 25)
>>> dist = 2
>>> for i in range(200):
...     fd(dist)
...     rt(90)
...     dist += 2
```

\texttt{turtle.update()}

Perform a TurtleScreen update. To be used when tracer is turned off.

See also the RawTurtle/Turtle method \texttt{speed()}. 

\textbf{24.5.4.3. Using screen events}

\texttt{turtle.listen}(\texttt{xdummy=None}, \texttt{ydummy=None})
Set focus on TurtleScreen (in order to collect key-events). Dummy arguments are provided in order to be able to pass `listen()` to the onclick method.

```
>>> def f():
...    fd(50)
...    lt(60)
...    
>>> screen.onkey(f, "Up")
>>> screen.listen()
```

`turtle.onkey(fun, key)`

**Parameters:**
- `fun` – a function with no arguments or `None`
- `key` – a string: key (e.g. “a”) or key-symbol (e.g. “space”)

Bind `fun` to key-release event of `key`. If `fun` is `None`, event bindings are removed. Remark: in order to be able to register key-events, `TurtleScreen` must have the focus. (See method `listen()`.)

`turtle.onclick(fun, btn=1, add=None)`
`turtle.onscreenclick(fun, btn=1, add=None)`

**Parameters:**
- `fun` – a function with two arguments which will be called with the coordinates of the clicked point on the canvas
- `num` – number of the mouse-button, defaults to 1 (left mouse button)
- `add` – `True` or `False` – if `True`, a new binding will be added, otherwise it will replace a former binding

Bind `fun` to mouse-click events on this screen. If `fun` is `None`, existing bindings are removed.

Example for a `TurtleScreen` instance named `screen` and a `Turtle` instance named `turtle`:
>>> screen.onclick(turtle.goto)  # Subsequently clicking into
>>> screen.onclick()            # make the turtle move to the
clicked point.
>>> screen.onclick(None)        # remove event binding again

Note: This TurtleScreen method is available as a global function only under the name onscreen_click. The global function onclick is another one derived from the Turtle method onclick.

turtle.ontimer(fun, t=0)

Parameters:
- `fun` – a function with no arguments
- `t` – a number >= 0

Install a timer that calls `fun` after `t` milliseconds.

>>> running = True
>>> def f():
...     if running:
...         fd(50)
...         lt(60)
...     screen.ontimer(f, 250)
>>> f()     ### makes the turtle march around
>>> running = False

24.5.4.4. Settings and special methods

turtle.mode(mode=None)

Parameter: `mode` – one of the strings “standard”, “logo” or “world”

Set turtle mode (“standard”, “logo” or “world”) and perform reset. If mode is not given, current mode is returned.

Mode “standard” is compatible with old turtle. Mode “logo” is compatible with most Logo turtle graphics. Mode “world” uses user-defined “world coordinates”. **Attention**: in this mode angles
appear distorted if \( x/y \) unit-ratio doesn’t equal 1.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Initial turtle heading</th>
<th>positive angles</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;standard&quot;</td>
<td>to the right (east)</td>
<td>counterclockwise</td>
</tr>
<tr>
<td>&quot;logo&quot;</td>
<td>upward (north)</td>
<td>clockwise</td>
</tr>
</tbody>
</table>

```python
g>>> mode("logo") # resets turtle heading to north
g>>> mode() 'logo'
```

**turtle.colormode(cmode=None)**

**Parameter:** cmode – one of the values 1.0 or 255

Return the colormode or set it to 1.0 or 255. Subsequently \( r, g, b \) values of color triples have to be in the range 0..\( cmode \).

```python
g>>> screen.colormode(1)
g>>> turtle.pencolor(240, 160, 80)
Traceback (most recent call last):
 ... 
TurtleGraphicsError: bad color sequence: (240, 160, 80)
g>>> screen.colormode()
1.0
g>>> screen.colormode(255)
g>>> screen.colormode() 255
g>>> turtle.pencolor(240, 160, 80)
```

**turtle.getcanvas()**

Return the Canvas of this TurtleScreen. Useful for insiders who know what to do with a Tkinter Canvas.

```python
g>>> cv = screen.getcanvas()
g>>> cv
<turtle.ScrolledCanvas instance at 0x...>```

**turtle.getshapes()**

Return a list of names of all currently available turtle shapes.
turtle.register_shape(name, shape=None)
turtle.addshape(name, shape=None)

There are three different ways to call this function:

1. *name* is the name of a gif-file and *shape* is *None*: Install the corresponding image shape.

```python
>>> screen.register_shape("turtle.gif")
```

**Note:** Image shapes *do not* rotate when turning the turtle, so they do not display the heading of the turtle!

2. *name* is an arbitrary string and *shape* is a tuple of pairs of coordinates: Install the corresponding polygon shape.

```python
>>> screen.register_shape("triangle", ((5,-3), (0,5), (-5,3))
```

3. *name* is an arbitrary string and shape is a (compound) *Shape* object: Install the corresponding compound shape.

Add a turtle shape to TurtleScreen’s shapelist. Only thusly registered shapes can be used by issuing the command `shape(shapename)`.

turtle.turtles()

Return the list of turtles on the screen.

```python
>>> for turtle in screen.turtles():
...     turtle.color("red")
```

turtle.window_height()

Return the height of the turtle window.
turtle.\texttt{window\_width}()

Return the width of the turtle window.

\begin{Verbatim}
>>> screen.window_width()
640
\end{Verbatim}

\textbf{24.5.4.5. Methods specific to Screen, not inherited from TurtleScreen}

turtle.\texttt{bye}()

Shut the turtlegraphics window.

turtle.\texttt{exitonclick}()

Bind \texttt{bye()} method to mouse clicks on the Screen.

If the value “using\_IDLE” in the configuration dictionary is \texttt{False} (default value), also enter mainloop. Remark: If IDLE with the \texttt{-n} switch (no subprocess) is used, this value should be set to \texttt{True} in \texttt{turtle.cfg}. In this case IDLE’s own mainloop is active also for the client script.

turtle.\texttt{setup}(\texttt{width=\_CFG[\texttt{"width"}], height=\_CFG[\texttt{"height"]}, startx=\_CFG[\texttt{"leftright"]}, starty=\_CFG[\texttt{"topbottom"]})

Set the size and position of the main window. Default values of arguments are stored in the configuration dictionary and can be changed via a \texttt{turtle.cfg} file.

- \texttt{width} – if an integer, a size in pixels, if a float, a fraction of the screen; default is 50\% of screen
- \texttt{height} – if an integer, the height in pixels, if a float, a fraction of the screen; default is 75\% of
Parameters:

- `startx` – if positive, starting position in pixels from the left edge of the screen, if negative from the right edge, if None, center window horizontally
- `starty` – if positive, starting position in pixels from the top edge of the screen, if negative from the bottom edge, if None, center window vertically

```python
>>> screen.setup (width=200, height=200, startx=0, starty=0)
>>> # sets window to 200x200 pixels, in upper left
>>> screen.setup(width=.75, height=0.5, startx=None, starty=None)
>>> # sets window to 75% of screen by 50% of screen
```

turtle. **title**(*titlestring*)

Parameter: *titlestring* – a string that is shown in the titlebar of the turtle graphics window

Set title of turtle window to *titlestring*.

```python
>>> screen.title("Welcome to the turtle zoo!")
```
24.5.5. The public classes of the module turtle

```python
class turtle.RawTurtle(canvas)
class turtle.RawPen(canvas)

Parameter: canvas — a Tkinter.Canvas, a ScrolledCanvas or a TurtleScreen

Create a turtle. The turtle has all methods described above as “methods of Turtle/RawTurtle”.

class turtle.Turtle

Subclass of RawTurtle, has the same interface but draws on a default Screen object created automatically when needed for the first time.

class turtle.TurtleScreen(cv)

Parameter: cv — a Tkinter.Canvas

Provides screen oriented methods like setbg() etc. that are described above.

class turtle.Screen

Subclass of TurtleScreen, with four methods added.

class turtle.ScrolledCanvas(master)

Parameter: master — some Tkinter widget to contain the ScrolledCanvas, i.e. a Tkinter-canvas with scrollbars added

Used by class Screen, which thus automatically provides a ScrolledCanvas as playground for the turtles.

class turtle.Shape(type_, data)

Parameter: type_ — one of the strings “polygon”, “image”,
```
**Parameter:** “compound”

Data structure modeling shapes. The pair \((\text{type}_\text{data})\) must follow this specification:

<table>
<thead>
<tr>
<th>(\text{type}_\text{data})</th>
<th>(\text{data})</th>
</tr>
</thead>
<tbody>
<tr>
<td>“polygon”</td>
<td>a polygon-tuple, i.e. a tuple of pairs of coordinates</td>
</tr>
<tr>
<td>“image”</td>
<td>an image (in this form only used internally!)</td>
</tr>
<tr>
<td>“compound”</td>
<td>None (a compound shape has to be constructed using the addcomponent() method)</td>
</tr>
</tbody>
</table>

**addcomponent** \((\text{poly}, \text{fill}, \text{outline}=\text{None})\)

**Parameters:**
- \(\text{poly}\) – a polygon, i.e. a tuple of pairs of numbers
- \(\text{fill}\) – a color the \(\text{poly}\) will be filled with
- \(\text{outline}\) – a color for the \(\text{poly}\)'s outline (if given)

Example:

```python
group1 = ((0,0),(10,-5),(0,10),(-10,-5))
s = Shape("compound")
s.addcomponent(poly, "red", "blue")
# ... add more components and then use register_shape()
```

See *Excursus about the use of compound shapes*.

**class** `turtle.Turtle Vec2D(x, y)`

A two-dimensional vector class, used as a helper class for implementing turtle graphics. May be useful for turtle graphics programs too. Derived from tuple, so a vector is a tuple!

Provides (for \(a, b\) vectors, \(k\) number):

- \(a + b\) vector addition
- \(a - b\) vector subtraction
- $a \cdot b$ inner product
- $k \cdot a$ and $a \cdot k$ multiplication with scalar
- $\text{abs}(a)$ absolute value of $a$
- $a.\text{rotate}(\text{angle})$ rotation
24.5.6. Help and configuration

24.5.6.1. How to use help

The public methods of the Screen and Turtle classes are documented extensively via docstrings. So these can be used as online-help via the Python help facilities:

- When using IDLE, tooltips show the signatures and first lines of the docstrings of typed in function-/method calls.

- Calling `help()` on methods or functions displays the docstrings:

```python
>>> help(Screen.bgcolor)
Help on method bgcolor in module turtle:
bgcolor(self, *args) unbound turtle.Screen method
    Set or return backgroundcolor of the TurtleScreen.
    Arguments (if given): a color string or three numbers
    in the range 0..colormode or a 3-tuple of such numbers.

>>> screen.bgcolor("orange")
>>> screen.bgcolor()
"orange"
>>> screen.bgcolor(0.5,0,0.5)
>>> screen.bgcolor()
"#800080"
```

```python
>>> help(Turtle.penup)
Help on method penup in module turtle:
penup(self) unbound turtle.Turtle method
    Pull the pen up -- no drawing when moving.
    Aliases: penup | pu | up
    No argument
```
• The docstrings of the functions which are derived from methods have a modified form:

```python
>>> turtle.penup()
```

These modified docstrings are created automatically together with the function definitions that are derived from the methods at import time.

**24.5.6.2. Translation of docstrings into different**
languages

There is a utility to create a dictionary the keys of which are the method names and the values of which are the docstrings of the public methods of the classes Screen and Turtle.

```python
turtle.write_docstringdict(filename="turtle_docstringdict")
```

**Parameter:** `filename` – a string, used as filename

Create and write docstring-dictionary to a Python script with the given filename. This function has to be called explicitly (it is not used by the turtle graphics classes). The docstring dictionary will be written to the Python script `filename.py`. It is intended to serve as a template for translation of the docstrings into different languages.

If you (or your students) want to use `turtle` with online help in your native language, you have to translate the docstrings and save the resulting file as e.g. `turtle_docstringdict_german.py`.

If you have an appropriate entry in your `turtle.cfg` file this dictionary will be read in at import time and will replace the original English docstrings.

At the time of this writing there are docstring dictionaries in German and in Italian. (Requests please to glingl@aon.at.)

**24.5.6.3. How to configure Screen and Turtles**

The built-in default configuration mimics the appearance and behaviour of the old turtle module in order to retain best possible compatibility with it.

If you want to use a different configuration which better reflects the features of this module or which better fits to your needs, e.g. for use
in a classroom, you can prepare a configuration file `turtle.cfg` which will be read at import time and modify the configuration according to its settings.

The built in configuration would correspond to the following turtle.cfg:

```plaintext
width = 0.5
height = 0.75
leftright = None
topbottom = None
canvwidth = 400
canvheight = 300
mode = standard
colormode = 1.0
delay = 10
undobuffersize = 1000
shape = classic
pencolor = black
fillcolor = black
resizemode = noresize
visible = True
language = english
exampleturtle = turtle
examplescreen = screen
title = Python Turtle Graphics
using_IDLE = False
```

Short explanation of selected entries:

- The first four lines correspond to the arguments of the `Screen.setup()` method.
- Line 5 and 6 correspond to the arguments of the method `Screen.screensize()`.
- `shape` can be any of the built-in shapes, e.g: arrow, turtle, etc. For more info try `help(shape)`.
- If you want to use no fillcolor (i.e. make the turtle transparent), you have to write `fillcolor = ""` (but all nonempty strings must not have quotes in the cfg-file).
- If you want to reflect the turtle its state, you have to use...
resizemode = auto.

- If you set e.g. `language = italian` the docstringdict `turtle_docstringdict_italian.py` will be loaded at import time (if present on the import path, e.g. in the same directory as `turtle`.
- The entries `exampleturtle` and `examplescreen` define the names of these objects as they occur in the docstrings. The transformation of method-docstrings to function-docstrings will delete these names from the docstrings.
- `using_IDLE`: Set this to `True` if you regularly work with IDLE and its `-n` switch (“no subprocess”). This will prevent `exitonclick()` to enter the mainloop.

There can be a `turtle.cfg` file in the directory where `turtle` is stored and an additional one in the current working directory. The latter will override the settings of the first one.

The Demo/turtle directory contains a `turtle.cfg` file. You can study it as an example and see its effects when running the demos (preferably not from within the demo-viewer).
There is a set of demo scripts in the turtledemo directory located in the Demo/turtle directory in the source distribution.

It contains:

- a set of 15 demo scripts demonstrating different features of the new module turtle
- a demo viewer turtleDemo.py which can be used to view the source code of the scripts and run them at the same time. 14 of the examples can be accessed via the Examples menu; all of them can also be run standalone.
- The example turtledemo_two_canvases.py demonstrates the simultaneous use of two canvases with the turtle module. Therefore it only can be run standalone.
- There is a turtle.cfg file in this directory, which also serves as an example for how to write and use such files.

The demoscripts are:

<table>
<thead>
<tr>
<th>Name</th>

</table>

Have fun!
24.6. IDLE

IDLE is the Python IDE built with the `tkinter` GUI toolkit.

IDLE has the following features:

- coded in 100% pure Python, using the `tkinter` GUI toolkit
- cross-platform: works on Windows and Unix
- multi-window text editor with multiple undo, Python colorizing
  and many other features, e.g. smart indent and call tips
- Python shell window (a.k.a. interactive interpreter)
- debugger (not complete, but you can set breakpoints, view and
  step)
24.6.1. Menus

24.6.1.1. File menu

New window
    create a new editing window

Open...
    open an existing file

Open module...
    open an existing module (searches sys.path)

Class browser
    show classes and methods in current file

Path browser
    show sys.path directories, modules, classes and methods

Save
    save current window to the associated file (unsaved windows have a * before and after the window title)

Save As...
    save current window to new file, which becomes the associated file

Save Copy As...
    save current window to different file without changing the associated file

Close
    close current window (asks to save if unsaved)

Exit
    close all windows and quit IDLE (asks to save if unsaved)

24.6.1.2. Edit menu
Undo
  Undo last change to current window (max 1000 changes)

Redo
  Redo last undone change to current window

Cut
  Copy selection into system-wide clipboard; then delete selection

Copy
  Copy selection into system-wide clipboard

Paste
  Insert system-wide clipboard into window

Select All
  Select the entire contents of the edit buffer

Find...
  Open a search dialog box with many options

Find again
  Repeat last search

Find selection
  Search for the string in the selection

Find in Files...
  Open a search dialog box for searching files

Replace...
  Open a search-and-replace dialog box

Go to line
  Ask for a line number and show that line

Indent region
  Shift selected lines right 4 spaces

Dedent region
  Shift selected lines left 4 spaces
Comment out region
 Insert ## in front of selected lines

Uncomment region
 Remove leading # or ## from selected lines

Tabify region
 Turns *leading* stretches of spaces into tabs

Untabify region
 Turn *all* tabs into the right number of spaces

Expand word
 Expand the word you have typed to match another word in the
 same buffer; repeat to get a different expansion

Format Paragraph
 Reformat the current blank-line-separated paragraph

Import module
 Import or reload the current module

Run script
 Execute the current file in the __main__ namespace

---

### 24.6.1.3. Windows menu

Zoom Height
 toggles the window between normal size (24x80) and maximum
 height.

The rest of this menu lists the names of all open windows; select one
to bring it to the foreground (deiconifying it if necessary).

### 24.6.1.4. Debug menu (in the Python Shell window only)

Go to file/line
look around the insert point for a filename and linenumber, open the file, and show the line.

Open stack viewer
  show the stack traceback of the last exception

Debugger toggle
  Run commands in the shell under the debugger

JIT Stack viewer toggle
  Open stack viewer on traceback
24.6.2. Basic editing and navigation

- **Backspace** deletes to the left; **Delete** deletes to the right
- **Arrow keys** and **Page Up/Page Down** to move around
- **Home/End** go to begin/end of line
- **C-Home/C-End** go to begin/end of file
- Some **Emacs** bindings may also work, including **C-B**, **C-P**, **C-A**, **C-E**, **C-D**, **C-L**

24.6.2.1. Automatic indentation

After a block-opening statement, the next line is indented by 4 spaces (in the Python Shell window by one tab). After certain keywords (break, return etc.) the next line is dedented. In leading indentation, **Backspace** deletes up to 4 spaces if they are there. **Tab** inserts 1-4 spaces (in the Python Shell window one tab). See also the indent/dedent region commands in the edit menu.

24.6.2.2. Python Shell window

- **C-c** interrupts executing command
- **C-d** sends end-of-file; closes window if typed at a `>>>` prompt
- **Alt-p** retrieves previous command matching what you have typed
- **Alt-n** retrieves next
- **Return** while on any previous command retrieves that command
- **Alt-/** (Expand word) is also useful here
24.6.3. Syntax colors

The coloring is applied in a background “thread,” so you may occasionally see uncolorized text. To change the color scheme, edit the [Colors] section in config.txt.

Python syntax colors:
- Keywords
  - orange
- Strings
  - green
- Comments
  - red
- Definitions
  - blue

Shell colors:
- Console output
  - brown
- stdout
  - blue
- stderr
  - dark green
- stdin
  - black
24.6.4. Startup

Upon startup with the `-s` option, IDLE will execute the file referenced by the environment variables `IDLESTARTUP` or `PYTHONSTARTUP`. Idle first checks for `IDLESTARTUP`; if `IDLESTARTUP` is present the file referenced is run. If `IDLESTARTUP` is not present, Idle checks for `PYTHONSTARTUP`. Files referenced by these environment variables are convenient places to store functions that are used frequently from the Idle shell, or for executing import statements to import common modules.

In addition, Tk also loads a startup file if it is present. Note that the Tk file is loaded unconditionally. This additional file is `.Idle.py` and is looked for in the user's home directory. Statements in this file will be executed in the Tk namespace, so this file is not useful for importing functions to be used from Idle's Python shell.

24.6.4.1. Command line usage

```
idle.py [-c command] [-d] [-e] [-s] [-t title] [arg] ...
```

- `-c command` run this command
- `-d` enable debugger
- `-e` edit mode; arguments are files to be edited
- `-s` run `$IDLESTARTUP` or `$PYTHONSTARTUP` first
- `-t title` set title of shell window

If there are arguments:

1. If `-e` is used, arguments are files opened for editing and `sys.argv` reflects the arguments passed to IDLE itself.
2. Otherwise, if `-c` is used, all arguments are placed in `sys.argv[1:...]`, with `sys.argv[0]` set to `-c`.
3. Otherwise, if neither `-e` nor `-c` is used, the first argument is a
script which is executed with the remaining arguments in
`sys.argv[1:]` and `sys.argv[0]` set to the script name. If the
script name is `'-`', no script is executed but an interactive Python
session is started; the arguments are still available in `sys.argv`. 
24. Graphical User Interfaces with Tk
24.7. Other Graphical User Interface Packages

There are an number of extension widget sets to Tkinter.

See also:

**Python megawidgets**

is a toolkit for building high-level compound widgets in Python using the Tkinter module. It consists of a set of base classes and a library of flexible and extensible megawidgets built on this foundation. These megawidgets include notebooks, comboboxes, selection widgets, paned widgets, scrolled widgets, dialog windows, etc. Also, with the Pmw.Blt interface to BLT, the busy, graph, stripchart, tabset and vector commands are be available.

The initial ideas for Pmw were taken from the Tk itcl extensions [incr Tk] by Michael McLennan and [incr Widgets] by Mark Ulferts. Several of the megawidgets are direct translations from the itcl to Python. It offers most of the range of widgets that [incr Widgets] does, and is almost as complete as Tix, lacking however Tix’s fast HList widget for drawing trees.

**Tkinter3000 Widget Construction Kit (WCK)**

is a library that allows you to write new Tkinter widgets in pure Python. The WCK framework gives you full control over widget creation, configuration, screen appearance, and event handling. WCK widgets can be very fast and light-weight, since they can operate directly on Python data structures, without having to transfer data through the Tk/Tcl layer.
The major cross-platform (Windows, Mac OS X, Unix-like) GUI toolkits that are also available for Python:

See also:

**PyGTK**

is a set of bindings for the GTK widget set. It provides an object oriented interface that is slightly higher level than the C one. It comes with many more widgets than Tkinter provides, and has good Python-specific reference documentation. There are also bindings to GNOME. One well known PyGTK application is PythonCAD. An online tutorial is available.

**PyQt**

PyQt is a sip-wrapped binding to the Qt toolkit. Qt is an extensive C++ GUI application development framework that is available for Unix, Windows and Mac OS X. sip is a tool for generating bindings for C++ libraries as Python classes, and is specifically designed for Python. The PyQt3 bindings have a book, *GUI Programming with Python: QT Edition* by Boudewijn Rempt. The PyQt4 bindings also have a book, *Rapid GUI Programming with Python and Qt*, by Mark Summerfield.

**wxPython**

wxPython is a cross-platform GUI toolkit for Python that is built around the popular wxWidgets (formerly wxWindows) C++ toolkit. It provides a native look and feel for applications on Windows, Mac OS X, and Unix systems by using each platform’s native widgets where ever possible, (GTK+ on Unix-like systems). In addition to an extensive set of widgets, wxPython provides classes for online documentation and context sensitive help, printing, HTML viewing, low-level device context drawing, drag and drop, system clipboard access, an XML-based resource format and more, including an ever growing library of user-contributed modules. wxPython has a book, *wxPython in Action*, by Noel Rappin and Robin Dunn.
PyGTK, PyQt, and wxPython, all have a modern look and feel and more widgets than Tkinter. In addition, there are many other GUI toolkits for Python, both cross-platform, and platform-specific. See the GUI Programming page in the Python Wiki for a much more complete list, and also for links to documents where the different GUI toolkits are compared.
The modules described in this chapter help you write software. For example, the `pydoc` module takes a module and generates documentation based on the module’s contents. The `doctest` and `unittest` modules contain frameworks for writing unit tests that automatically exercise code and verify that the expected output is produced. `2to3` can translate Python 2.x source code into valid Python 3.x code.

The list of modules described in this chapter is:

- **25.1. pydoc** — Documentation generator and online help system
- **25.2. doctest** — Test interactive Python examples
  - **25.2.1. Simple Usage: Checking Examples in Docstrings**
  - **25.2.2. Simple Usage: Checking Examples in a Text File**
  - **25.2.3. How It Works**
    - 25.2.3.1. Which Docstrings Are Examined?
    - 25.2.3.2. How are Docstring Examples Recognized?
    - 25.2.3.3. What’s the Execution Context?
    - 25.2.3.4. What About Exceptions?
    - 25.2.3.5. Option Flags and Directives
    - 25.2.3.6. Warnings
  - **25.2.4. Basic API**
  - **25.2.5. Unittest API**
  - **25.2.6. Advanced API**
    - 25.2.6.1. DocTest Objects
    - 25.2.6.2. Example Objects
    - 25.2.6.3. DocTestFinder objects
    - 25.2.6.4. DocTestParser objects
    - 25.2.6.5. DocTestRunner objects
    - 25.2.6.6. OutputChecker objects
  - **25.2.7. Debugging**
- 25.2.8. Soapbox
- **25.3. unittest — Unit testing framework**
  - 25.3.1. Basic example
  - 25.3.2. Command-Line Interface
    - 25.3.2.1. Command-line options
  - 25.3.3. Test Discovery
  - 25.3.4. Organizing test code
  - 25.3.5. Re-using old test code
  - 25.3.6. Skipping tests and expected failures
  - 25.3.7. Classes and functions
    - 25.3.7.1. Test cases
      - 25.3.7.1.1. Deprecated aliases
    - 25.3.7.2. Grouping tests
    - 25.3.7.3. Loading and running tests
      - 25.3.7.3.1. load_tests Protocol
  - 25.3.8. Class and Module Fixtures
    - 25.3.8.1. setUpClass and tearDownClass
    - 25.3.8.2. setUpModule and tearDownModule
  - 25.3.9. Signal Handling
- **25.4. 2to3 - Automated Python 2 to 3 code translation**
  - 25.4.1. Using 2to3
  - 25.4.2. Fixers
  - 25.4.3. **lib2to3 - 2to3's library**
- **25.5. test — Regression tests package for Python**
  - 25.5.1. Writing Unit Tests for the test package

25.1. **pydoc** — Documentation generator and online help system

*New in version 2.1.*

The **pydoc** module automatically generates documentation from Python modules. The documentation can be presented as pages of text on the console, served to a Web browser, or saved to HTML files.

The built-in function **help()** invokes the online help system in the interactive interpreter, which uses **pydoc** to generate its documentation as text on the console. The same text documentation can also be viewed from outside the Python interpreter by running **pydoc** as a script at the operating system’s command prompt. For example, running

```
pydoc sys
```

at a shell prompt will display documentation on the **sys** module, in a style similar to the manual pages shown by the Unix **man** command. The argument to **pydoc** can be the name of a function, module, or package, or a dotted reference to a class, method, or function within a module or module in a package. If the argument to **pydoc** looks like a path (that is, it contains the path separator for your operating system, such as a slash in Unix), and refers to an existing Python source file, then documentation is produced for that file.

**Note:** In order to find objects and their documentation, **pydoc** imports the module(s) to be documented. Therefore, any code on module level will be executed on that occasion. Use an **if**

```
__name__ == '__main__'
```

guard to only execute code when a file is
invoked as a script and not just imported.

Specifying a `-w` flag before the argument will cause HTML documentation to be written out to a file in the current directory, instead of displaying text on the console.

Specifying a `-k` flag before the argument will search the synopsis lines of all available modules for the keyword given as the argument, again in a manner similar to the Unix `man` command. The synopsis line of a module is the first line of its documentation string.

You can also use `pydoc` to start an HTTP server on the local machine that will serve documentation to visiting Web browsers. `pydoc -p 1234` will start a HTTP server on port 1234, allowing you to browse the documentation at `http://localhost:1234/` in your preferred Web browser. `pydoc -g` will start the server and additionally bring up a small `Tkinter`-based graphical interface to help you search for documentation pages.

When `pydoc` generates documentation, it uses the current environment and path to locate modules. Thus, invoking `pydoc spam` documents precisely the version of the module you would get if you started the Python interpreter and typed `import spam`.

Module docs for core modules are assumed to reside in `http://docs.python.org/library/`. This can be overridden by setting the `PYTHONDOCS` environment variable to a different URL or to a local directory containing the Library Reference Manual pages.
25.2. doctest — Test interactive Python examples

The `doctest` module searches for pieces of text that look like interactive Python sessions, and then executes those sessions to verify that they work exactly as shown. There are several common ways to use doctest:

- To check that a module’s docstrings are up-to-date by verifying that all interactive examples still work as documented.
- To perform regression testing by verifying that interactive examples from a test file or a test object work as expected.
- To write tutorial documentation for a package, liberally illustrated with input-output examples. Depending on whether the examples or the expository text are emphasized, this has the flavor of “literate testing” or “executable documentation”.

Here’s a complete but small example module:

```python
'''
This is the "example" module.

The example module supplies one function, `factorial()`. For example,

>>> factorial(5)
120
'''

def factorial(n):
    """Return the factorial of n, an exact integer >= 0.
    
    If the result is small enough to fit in an int, return an int.
    Else return a long.
    """
    [factorial(n) for n in range(6)]
    [1, 1, 2, 6, 24, 120]
    >>> [factorial(long(n)) for n in range(6)]
    [1, 1, 2, 6, 24, 120]
```
>>> factorial(30)
265252859812191058636308480000000L
>>> factorial(30L)
265252859812191058636308480000000L
>>> factorial(-1)
Traceback (most recent call last):
...
ValueError: n must be >= 0

Factorials of floats are OK, but the float must be an exact integer:
>>> factorial(30.1)
Traceback (most recent call last):
...
ValueError: n must be exact integer
>>> factorial(30.0)
265252859812191058636308480000000L

It must also not be ridiculously large:
>>> factorial(1e100)
Traceback (most recent call last):
...
OverflowError: n too large

import math
if not n >= 0:
    raise ValueError("n must be >= 0")
if math.floor(n) != n:
    raise ValueError("n must be exact integer")
if n+1 == n:  # catch a value like 1e300
    raise OverflowError("n too large")
result = 1
factor = 2
while factor <= n:
    result *= factor
    factor += 1
return result

if __name__ == "__main__":
    import doctest
doctest.testmod()

If you run example.py directly from the command line, doctest works its magic:
$ python example.py
$

There’s no output! That’s normal, and it means all the examples worked. Pass `-v` to the script, and `doctest` prints a detailed log of what it’s trying, and prints a summary at the end:

```
$ python example.py -v
Trying:
    factorial(5)
Expecting:
    120
ok
Trying:
    [factorial(n) for n in range(6)]
Expecting:
    [1, 1, 2, 6, 24, 120]
ok
Trying:
    [factorial(long(n)) for n in range(6)]
Expecting:
    [1, 1, 2, 6, 24, 120]
ok
And so on, eventually ending with:

```trying:
    factorial(1e100)
Expecting:
    Traceback (most recent call last):
      ...
      OverflowError: n too large
ok
2 items passed all tests:
    1 tests in __main__
    8 tests in __main__.factorial
9 tests in 2 items.
9 passed and 0 failed.
Test passed.
$```

That's all you need to know to start making productive use of
doctest! Jump in. The following sections provide full details. Note that there are many examples of doctests in the standard Python test suite and libraries. Especially useful examples can be found in the standard test file Lib/test/test_doctest.py.
25.2.1. Simple Usage: Checking Examples in Docstrings

The simplest way to start using doctest (but not necessarily the way you’ll continue to do it) is to end each module `M` with:

```python
if __name__ == "__main__":
    import doctest
doctest.testmod()
```

doctest then examines docstrings in module `M`.

Running the module as a script causes the examples in the docstrings to get executed and verified:

`python M.py`

This won’t display anything unless an example fails, in which case the failing example(s) and the cause(s) of the failure(s) are printed to stdout, and the final line of output is `***Test Failed*** N failures`, where `N` is the number of examples that failed.

Run it with the `-v` switch instead:

`python M.py -v`

and a detailed report of all examples tried is printed to standard output, along with assorted summaries at the end.

You can force verbose mode by passing `verbose=True` to `testmod()`, or prohibit it by passing `verbose=False`. In either of those cases, `sys.argv` is not examined by `testmod()` (so passing `-v` or not has no effect).
Since Python 2.6, there is also a command line shortcut for running `testmod()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the module name(s) on the command line:

```python
python -m doctest -v example.py
```

This will import `example.py` as a standalone module and run `testmod()` on it. Note that this may not work correctly if the file is part of a package and imports other submodules from that package.

For more information on `testmod()`, see section *Basic API*. 
Another simple application of doctest is testing interactive examples in a text file. This can be done with the `testfile()` function:

```python
import doctest
doctest.testfile("example.txt")
```

That short script executes and verifies any interactive Python examples contained in the file `example.txt`. The file content is treated as if it were a single giant docstring; the file doesn't need to contain a Python program! For example, perhaps `example.txt` contains this:

The ``example`` module
======================

Using ``factorial``
-------------------

This is an example text file in reStructuredText format. First ``factorial`` from the ``example`` module:

```python
>>> from example import factorial
```

Now use it:

```python
>>> factorial(6)
120
```

Running `doctest.testfile("example.txt")` then finds the error in this documentation:

```
File "./example.txt", line 14, in example.txt
Failed example:
    factorial(6)
```
As with `testmod()`, `testfile()` won’t display anything unless an example fails. If an example does fail, then the failing example(s) and the cause(s) of the failure(s) are printed to stdout, using the same format as `testmod()`.

By default, `testfile()` looks for files in the calling module’s directory. See section *Basic API* for a description of the optional arguments that can be used to tell it to look for files in other locations.

Like `testmod()`, `testfile()`’s verbosity can be set with the `-v` command-line switch or with the optional keyword argument `verbose`.

Since Python 2.6, there is also a command line shortcut for running `testfile()`. You can instruct the Python interpreter to run the doctest module directly from the standard library and pass the file name(s) on the command line:

```
python -m doctest -v example.txt
```

Because the file name does not end with `.py`, `doctest` infers that it must be run with `testfile()`, not `testmod()`.

For more information on `testfile()`, see section *Basic API*.
25.2.3. How It Works

This section examines in detail how doctest works: which docstrings it looks at, how it finds interactive examples, what execution context it uses, how it handles exceptions, and how option flags can be used to control its behavior. This is the information that you need to know to write doctest examples; for information about actually running doctest on these examples, see the following sections.

25.2.3.1. Which Docstrings Are Examined?

The module docstring, and all function, class and method docstrings are searched. Objects imported into the module are not searched.

In addition, if \texttt{M.__test__} exists and “is true”, it must be a dict, and each entry maps a (string) name to a function object, class object, or string. Function and class object docstrings found from \texttt{M.__test__} are searched, and strings are treated as if they were docstrings. In output, a key \texttt{K} in \texttt{M.__test__} appears with name

<name of M>.__test__.K

Any classes found are recursively searched similarly, to test docstrings in their contained methods and nested classes.

\textit{Changed in version 2.4:} A “private name” concept is deprecated and no longer documented.

25.2.3.2. How are Docstring Examples Recognized?

In most cases a copy-and-paste of an interactive console session works fine, but doctest isn’t trying to do an exact emulation of any
specific Python shell.

```python
>>> # comments are ignored
>>> x = 12
>>> x
12
>>> if x == 13:
...    print "yes"
... else:
...    print "no"
...    print "NO"
...    print "NO!!"
... no
NO
NO!!
```

Any expected output must immediately follow the final `>>>` or `...` line containing the code, and the expected output (if any) extends to the next `>>>` or all-whitespace line.

The fine print:

- Expected output cannot contain an all-whitespace line, since such a line is taken to signal the end of expected output. If expected output does contain a blank line, put `<BLANKLINE>` in your doctest example each place a blank line is expected.

  New in version 2.4: `<BLANKLINE>` was added; there was no way to use expected output containing empty lines in previous versions.

- All hard tab characters are expanded to spaces, using 8-column tab stops. Tabs in output generated by the tested code are not modified. Because any hard tabs in the sample output are expanded, this means that if the code output includes hard tabs, the only way the doctest can pass is if the `NORMALIZE_WHITESPACE`
option or directive is in effect. Alternatively, the test can be rewritten to capture the output and compare it to an expected value as part of the test. This handling of tabs in the source was arrived at through trial and error, and has proven to be the least error prone way of handling them. It is possible to use a different algorithm for handling tabs by writing a custom DocTestParser class.

*Changed in version 2.4:* Expanding tabs to spaces is new; previous versions tried to preserve hard tabs, with confusing results.

- Output to stdout is captured, but not output to stderr (exception tracebacks are captured via a different means).

- If you continue a line via backslashing in an interactive session, or for any other reason use a backslash, you should use a raw docstring, which will preserve your backslashes exactly as you type them:

```python
>>> def f(x):
...    r'''Backslashes in a raw docstring: m\n'''
>>> print f.__doc__
Backslashes in a raw docstring: m
```

Otherwise, the backslash will be interpreted as part of the string. For example, the "\" above would be interpreted as a newline character. Alternatively, you can double each backslash in the doctest version (and not use a raw string):

```python
>>> def f(x):
...    '''Backslashes in a raw docstring: m\\n'''
>>> print f.__doc__
Backslashes in a raw docstring: m
```

- The starting column doesn't matter:
and as many leading whitespace characters are stripped from the expected output as appeared in the initial '>>> ' line that started the example.

### 25.2.3.3. What's the Execution Context?

By default, each time doctest finds a docstring to test, it uses a shallow copy of M's globals, so that running tests doesn't change the module's real globals, and so that one test in M can't leave behind crumbs that accidentally allow another test to work. This means examples can freely use any names defined at top-level in M, and names defined earlier in the docstring being run. Examples cannot see names defined in other docstrings.

You can force use of your own dict as the execution context by passing `globs=your_dict` to `testmod()` or `testfile()` instead.

### 25.2.3.4. What About Exceptions?

No problem, provided that the traceback is the only output produced by the example: just paste in the traceback. [1] Since tracebacks contain details that are likely to change rapidly (for example, exact file paths and line numbers), this is one case where doctest works hard to be flexible in what it accepts.

Simple example:

```python
>>> [1, 2, 3].remove(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
ValueError: list.remove(x): x not in list
```
That doctest succeeds if `ValueError` is raised, with the
`list.remove(x): x not in list` detail as shown.

The expected output for an exception must start with a traceback
header, which may be either of the following two lines, indented the
same as the first line of the example:

```
Traceback (most recent call last):
Traceback (innermost last):
```

The traceback header is followed by an optional traceback stack,
whose contents are ignored by doctest. The traceback stack is
typically omitted, or copied verbatim from an interactive session.

The traceback stack is followed by the most interesting part: the
line(s) containing the exception type and detail. This is usually the
last line of a traceback, but can extend across multiple lines if the
exception has a multi-line detail:

```
>>> raise ValueError('multi
    line
detail')
Traceback (most recent call last):
    File "<stdin>", line 1, in ?
ValueError: multi
    line
detail
```

The last three lines (starting with `ValueError`) are compared against
the exception's type and detail, and the rest are ignored.

*Changed in version 2.4:* Previous versions were unable to handle
multi-line exception details.

Best practice is to omit the traceback stack, unless it adds significant
documentation value to the example. So the last example is probably
better as:
>>> raise ValueError('multi
  line\ndetail')
Traceback (most recent call last):
  ...
ValueError: multi
  line
detail

Note that tracebacks are treated very specially. In particular, in the rewritten example, the use of `...` is independent of doctest's **ELLIPSIS** option. The ellipsis in that example could be left out, or could just as well be three (or three hundred) commas or digits, or an indented transcript of a Monty Python skit.

Some details you should read once, but won’t need to remember:

- Doctest can’t guess whether your expected output came from an exception traceback or from ordinary printing. So, e.g., an example that expects `ValueError: 42 is prime` will pass whether `ValueError` is actually raised or if the example merely prints that traceback text. In practice, ordinary output rarely begins with a traceback header line, so this doesn’t create real problems.

- Each line of the traceback stack (if present) must be indented further than the first line of the example, or start with a non-alphanumeric character. The first line following the traceback header indented the same and starting with an alphanumeric is taken to be the start of the exception detail. Of course this does the right thing for genuine tracebacks.

- When the `IGNORE_EXCEPTION_DETAIL` doctest option is specified, everything following the leftmost colon and any module information in the exception name is ignored.

- The interactive shell omits the traceback header line for some `SyntaxError`s. But doctest uses the traceback header line to
distinguish exceptions from non-exceptions. So in the rare case where you need to test a SyntaxError that omits the traceback header, you will need to manually add the traceback header line to your test example.

- For some SyntaxErrors, Python displays the character position of the syntax error, using a ^ marker:

```
>>> 1 1
    File "<stdin>", line 1
    1 1
    ^
SyntaxError: invalid syntax
```

Since the lines showing the position of the error come before the exception type and detail, they are not checked by doctest. For example, the following test would pass, even though it puts the ^ marker in the wrong location:

```
>>> 1 1
    File "<stdin>", line 1
    1 1
    ^
SyntaxError: invalid syntax
```

25.2.3.5. Option Flags and Directives

A number of option flags control various aspects of doctest's behavior. Symbolic names for the flags are supplied as module constants, which can be or'ed together and passed to various functions. The names can also be used in doctest directives (see below).

The first group of options define test semantics, controlling aspects of how doctest decides whether actual output matches an example's expected output:
By default, if an expected output block contains just 1, an actual output block containing just 1 or just `True` is considered to be a match, and similarly for 0 versus `False`. When `DONT_ACCEPT_TRUE_FOR_1` is specified, neither substitution is allowed. The default behavior caters to that Python changed the return type of many functions from integer to boolean; doctests expecting “little integer” output still work in these cases. This option will probably go away, but not for several years.

By default, if an expected output block contains a line containing only the string `<BLANKLINE>`, then that line will match a blank line in the actual output. Because a genuinely blank line delimits the expected output, this is the only way to communicate that a blank line is expected. When `DONT_ACCEPT_BLANKLINE` is specified, this substitution is not allowed.

When specified, all sequences of whitespace (blanks and newlines) are treated as equal. Any sequence of whitespace within the expected output will match any sequence of whitespace within the actual output. By default, whitespace must match exactly. `NORMALIZE_WHITESPACE` is especially useful when a line of expected output is very long, and you want to wrap it across multiple lines in your source.

When specified, an ellipsis marker (…) in the expected output can match any substring in the actual output. This includes substrings that span line boundaries, and empty substrings, so it’s best to keep usage of this simple. Complicated uses can lead to the same kinds of “oops, it matched too much!” surprises that .* is prone to in regular expressions.
doctest. **IGNORE_EXCEPTION_DETAIL**

When specified, an example that expects an exception passes if an exception of the expected type is raised, even if the exception detail does not match. For example, an example expecting `ValueError: 42` will pass if the actual exception raised is `ValueError: 3*14`, but will fail, e.g., if `TypeError` is raised.

It will also ignore the module name used in Python 3 doctest reports. Hence both these variations will work regardless of whether the test is run under Python 2.7 or Python 3.2 (or later versions):

```python
>>> raise CustomError('message')  #doctest: +IGNORE_EXCEPTION_DETAIL
Traceback (most recent call last):
  CustomError: message
```

```python
>>> raise CustomError('message')  #doctest: +IGNORE_EXCEPTION_DETAIL
Traceback (most recent call last):
  my_module.CustomError: message
```

Note that **ELLIPSIS** can also be used to ignore the details of the exception message, but such a test may still fail based on whether or not the module details are printed as part of the exception name. Using **IGNORE_EXCEPTION_DETAIL** and the details from Python 2.3 is also the only clear way to write a doctest that doesn't care about the exception detail yet continues to pass under Python 2.3 or earlier (those releases do not support doctest directives and ignore them as irrelevant comments). For example,

```python
>>> (1, 2)[3] = 'moo'  #doctest: +IGNORE_EXCEPTION_DETAIL
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
  TypeError: object doesn't support item assignment
```

passes under Python 2.3 and later Python versions, even though
the detail changed in Python 2.4 to say “does not” instead of “doesn’t”.

*Changed in version 2.7:* `IGNORE_EXCEPTION_DETAIL` now also ignores any information relating to the module containing the exception under test.

**doctest.SKIP**

When specified, do not run the example at all. This can be useful in contexts where doctest examples serve as both documentation and test cases, and an example should be included for documentation purposes, but should not be checked. E.g., the example's output might be random; or the example might depend on resources which would be unavailable to the test driver.

The SKIP flag can also be used for temporarily “commenting out” examples.

*New in version 2.5.*

**doctest.COMPARISON_FLAGS**

A bitmask or’ing together all the comparison flags above.

The second group of options controls how test failures are reported:

**doctest.REPORT_UDIFF**

When specified, failures that involve multi-line expected and actual outputs are displayed using a unified diff.

**doctest.REPORT_CDIFF**

When specified, failures that involve multi-line expected and actual outputs will be displayed using a context diff.

**doctest.REPORT_NDIFF**

When specified, differences are computed by `difflib.Differ`, using the same algorithm as the popular `ndiff.py` utility. This is
the only method that marks differences within lines as well as across lines. For example, if a line of expected output contains digit \texttt{1} where actual output contains letter \texttt{l}, a line is inserted with a caret marking the mismatching column positions.

\texttt{doctest.REPORT ONLY FIRST FAILURE}

When specified, display the first failing example in each doctest, but suppress output for all remaining examples. This will prevent doctest from reporting correct examples that break because of earlier failures; but it might also hide incorrect examples that fail independently of the first failure. When \texttt{REPORT ONLY FIRST FAILURE} is specified, the remaining examples are still run, and still count towards the total number of failures reported; only the output is suppressed.

\texttt{doctest.REPORTING_FLAGS}

A bitmask or’ing together all the reporting flags above.

“Doctest directives” may be used to modify the option flags for individual examples. Doctest directives are expressed as a special Python comment following an example’s source code:

\begin{verbatim}
directive ::= "#" "doctest:" directive_options
directive_options ::= directive_option ("," directive_option)*
directive_option ::= on_or_off directive_option_name
on_or_off ::= "+" | "-"
directive_option_name ::= "DONT_ACCEPT_BLANKLINE" | "NORMALIZE_WHITESPACE"
\end{verbatim}

Whitespace is not allowed between the \texttt{+} or \texttt{-} and the directive option name. The directive option name can be any of the option flag names explained above.

An example’s doctest directives modify doctest’s behavior for that single example. Use \texttt{+} to enable the named behavior, or \texttt{-} to disable it.
For example, this test passes:

```python
>>> print range(20) # doctest: +NORMALIZE_WHITESPACE
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19]
```

Without the directive it would fail, both because the actual output doesn’t have two blanks before the single-digit list elements, and because the actual output is on a single line. This test also passes, and also requires a directive to do so:

```python
>>> print range(20) # doctest:+ELLIPSIS
[0, 1, ..., 18, 19]
```

Multiple directives can be used on a single physical line, separated by commas:

```python
>>> print range(20) # doctest:+ELLIPSIS, +NORMALIZE_WHITESPACE
[0, 1, ..., 18, 19]
```

If multiple directive comments are used for a single example, then they are combined:

```python
>>> print range(20) # doctest:+ELLIPSIS
... # doctest: +NORMALIZE_WHITESPACE
[0, 1, ..., 18, 19]
```

As the previous example shows, you can add `...` lines to your example containing only directives. This can be useful when an example is too long for a directive to comfortably fit on the same line:

```python
>>> print range(5) + range(10, 20) + range(30, 40) + range(50, 60)
... # doctest: +ELLIPSIS
[0, ..., 4, 10, ..., 19, 30, ..., 39, 50, ..., 59]
```

Note that since all options are disabled by default, and directives
apply only to the example they appear in, enabling options (via + in a directive) is usually the only meaningful choice. However, option flags can also be passed to functions that run doctests, establishing different defaults. In such cases, disabling an option via - in a directive can be useful.

*New in version 2.4:* Doctest directives and the associated constants `DONT_ACCEPT_BLANKLINE`, `NORMALIZE_WHITESPACE`, `ELLIPSIS`, `IGNORE_EXCEPTION_DETAIL`, `REPORT_UDIFF`, `REPORT_CDIFF`, `REPORT_NDIFF`, `REPORT_ONLY_FIRST_FAILURE`, `COMPARISON_FLAGS` and `REPORTING_FLAGS` were added.

There's also a way to register new option flag names, although this isn't useful unless you intend to extend `doctest` internals via subclassing:

```python
doctest.register_optionflag(name)
```

Create a new option flag with a given name, and return the new flag's integer value. `register_optionflag()` can be used when subclassing `OutputChecker` or `DocTestRunner` to create new options that are supported by your subclasses. `register_optionflag()` should always be called using the following idiom:

```python
MY_FLAG = register_optionflag('MY_FLAG')
```

*New in version 2.4.*

**25.2.3.6. Warnings**

`doctest` is serious about requiring exact matches in expected output. If even a single character doesn't match, the test fails. This will probably surprise you a few times, as you learn exactly what Python does and doesn’t guarantee about output. For example, when
printing a dict, Python doesn't guarantee that the key-value pairs will be printed in any particular order, so a test like

```python
>>> foo()
{'Hermione': 'hippogryph', 'Harry': 'broomstick'}
```

is vulnerable! One workaround is to do

```python
>>> foo() == {'Hermione': 'hippogryph', 'Harry': 'broomstick'}
True
```

instead. Another is to do

```python
>>> d = foo().items()
>>> d.sort()
>>> d
[('Harry', 'broomstick'), ('Hermione', 'hippogryph')]
```

There are others, but you get the idea.

Another bad idea is to print things that embed an object address, like

```python
>>> id(1.0) # certain to fail some of the time
7948648
>>> class C: pass
>>> C()  # the default repr() for instances embeds an address
<__main__.C instance at 0x00AC18F0>
```

The **ELLIPSIS** directive gives a nice approach for the last example:

```python
>>> C()  # doctest: +ELLIPSIS
<__main__.C instance at 0x...>
```

Floating-point numbers are also subject to small output variations across platforms, because Python defers to the platform C library for float formatting, and C libraries vary widely in quality here.

```python
>>> 1./7  # risky
0.14285714285714285
```
>>> print 1./7 # safer
0.142857142857
>>> print round(1./7, 6) # much safer
0.142857

Numbers of the form $\frac{1}{2} \times 10^j$ are safe across all platforms, and I often contrive doctest examples to produce numbers of that form:

>>> 3./4  # utterly safe
0.75

Simple fractions are also easier for people to understand, and that makes for better documentation.
25.2.4. Basic API

The functions `testmod()` and `testfile()` provide a simple interface to doctest that should be sufficient for most basic uses. For a less formal introduction to these two functions, see sections *Simple Usage: Checking Examples in Docstrings* and *Simple Usage: Checking Examples in a Text File*.

```
doctest.testfile(filename[, module_relative][, name][, package]
    [, globs][, verbose][, report][, optionflags][, extraglobs][,
    raise_on_error][, parser][, encoding])
```

All arguments except `filename` are optional, and should be specified in keyword form.

Test examples in the file named `filename`. Return `(failure_count, test_count)`.

Optional argument `module_relative` specifies how the `filename` should be interpreted:

- If `module_relative` is `True` (the default), then `filename` specifies an OS-independent module-relative path. By default, this path is relative to the calling module’s directory; but if the `package` argument is specified, then it is relative to that package. To ensure OS-independence, `filename` should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).
- If `module_relative` is `False`, then `filename` specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument `name` gives the name of the test; by default,
or if `None`, `os.path.basename(filename)` is used.

Optional argument *package* is a Python package or the name of a Python package whose directory should be used as the base directory for a module-relative filename. If no package is specified, then the calling module's directory is used as the base directory for module-relative filenames. It is an error to specify `package` if `module_relative` is `False`.

Optional argument *globals* gives a dict to be used as the globals when executing examples. A new shallow copy of this dict is created for the doctest, so its examples start with a clean slate. By default, or if `None`, a new empty dict is used.

Optional argument *extraglobs* gives a dict merged into the globals used to execute examples. This works like `dict.update()`: if `globals` and `extraglobs` have a common key, the associated value in `extraglobs` appears in the combined dict. By default, or if `None`, no extra globals are used. This is an advanced feature that allows parameterization of doctests. For example, a doctest can be written for a base class, using a generic name for the class, then reused to test any number of subclasses by passing an `extraglobs` dict mapping the generic name to the subclass to be tested.

Optional argument *verbose* prints lots of stuff if true, and prints only failures if false; by default, or if `None`, it's true if and only if `-v` is in *sys.argv*.

Optional argument *report* prints a summary at the end when true, else prints nothing at the end. In verbose mode, the summary is detailed, else the summary is very brief (in fact, empty if all tests passed).

Optional argument *optionflags* or’s together option flags. See
section *Option Flags and Directives.*

Optional argument *raise_on_error* defaults to false. If true, an exception is raised upon the first failure or unexpected exception in an example. This allows failures to be post-mortem debugged. Default behavior is to continue running examples.

Optional argument *parser* specifies a `DocTestParser` (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument *encoding* specifies an encoding that should be used to convert the file to unicode.

*New in version 2.4.*

*Changed in version 2.5:* The parameter *encoding* was added.

```python
doctest.testmod([m], name=None, globs=None, verbose=None, report=None,
optionflags=None, extraglobs=None, raise_on_error=None, exclude_empty=None)
```

All arguments are optional, and all except for *m* should be specified in keyword form.

Test examples in docstrings in functions and classes reachable from module *m* (or module `__main__` if *m* is not supplied or is `None`), starting with `m.__doc__`.

Also test examples reachable from dict `m.__test__`, if it exists and is not `None`. `m.__test__` maps names (strings) to functions, classes and strings; function and class docstrings are searched for examples; strings are searched directly, as if they were docstrings.

Only docstrings attached to objects belonging to module *m* are searched.
Return \((\text{failure\_count}, \text{test\_count})\).

Optional argument \textit{name} gives the name of the module; by default, or if \texttt{None}, \texttt{m.__name__} is used.

Optional argument \textit{exclude\_empty} defaults to false. If true, objects for which no doctests are found are excluded from consideration. The default is a backward compatibility hack, so that code still using \texttt{doctest.master.summarize()} in conjunction with \texttt{testmod()} continues to get output for objects with no tests. The \textit{exclude\_empty} argument to the newer \texttt{DocTestFinder} constructor defaults to true.

Optional arguments \textit{extraglobs}, \textit{verbose}, \textit{report}, \textit{optionflags}, \textit{raise\_on\_error}, and \textit{globs} are the same as for function \texttt{testfile()} above, except that \textit{globs} defaults to \texttt{m.__dict__}.

\textit{Changed in version 2.3}: The parameter \textit{optionflags} was added.

\textit{Changed in version 2.4}: The parameters \textit{extraglobs}, \textit{raise\_on\_error} and \textit{exclude\_empty} were added.

\textit{Changed in version 2.5}: The optional argument \textit{isprivate}, deprecated in 2.4, was removed.

There's also a function to run the doctests associated with a single object. This function is provided for backward compatibility. There are no plans to deprecate it, but it's rarely useful:

\texttt{doctest.run\_docstring\_examples(f, globs[, verbose][, name][, compileflags][, optionflags])}

Test examples associated with object \texttt{f}; for example, \texttt{f} may be a module, function, or class object.

A shallow copy of dictionary argument \textit{globs} is used for the
execution context.

Optional argument *name* is used in failure messages, and defaults to "NoName".

If optional argument *verbose* is true, output is generated even if there are no failures. By default, output is generated only in case of an example failure.

Optional argument *compileflags* gives the set of flags that should be used by the Python compiler when running the examples. By default, or if *None*, flags are deduced corresponding to the set of future features found in *globs*.

Optional argument *optionflags* works as for function *testfile()* above.
25.2.5. Unittest API

As your collection of doctest'ed modules grows, you'll want a way to run all their doctests systematically. Prior to Python 2.4, doctest had a barely documented Tester class that supplied a rudimentary way to combine doctests from multiple modules. Tester was feeble, and in practice most serious Python testing frameworks build on the unittest module, which supplies many flexible ways to combine tests from multiple sources. So, in Python 2.4, doctest's Tester class is deprecated, and doctest provides two functions that can be used to create unittest test suites from modules and text files containing doctests. To integrate with unittest test discovery, include a load_tests() function in your test module:

```python
import unittest
import doctest
import my_module_with_doctests

def load_tests(loader, tests, ignore):
    tests.addTests(doctest.DocTestSuite(my_module_with_doctests))
    return tests
```

There are two main functions for creating unittest.TestSuite instances from text files and modules with doctests:

```python
doctest.DocFileSuite(*paths[, module_relative][, package][, setUp][, tearDown][, globs][, optionflags][, parser][, encoding])
```

Convert doctest tests from one or more text files to a unittest.TestSuite.

The returned unittest.TestSuite is to be run by the unittest framework and runs the interactive examples in each file. If an example in any file fails, then the synthesized unit test fails, and a
**failureException** exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Pass one or more paths (as strings) to text files to be examined.

Options may be provided as keyword arguments:

Optional argument *module_relative* specifies how the filenames in *paths* should be interpreted:

- If *module_relative* is **True** (the default), then each filename in *paths* specifies an OS-independent module-relative path. By default, this path is relative to the calling module’s directory; but if the *package* argument is specified, then it is relative to that package. To ensure OS-independence, each filename should use `/` characters to separate path segments, and may not be an absolute path (i.e., it may not begin with `/`).

- If *module_relative* is **False**, then each filename in *paths* specifies an OS-specific path. The path may be absolute or relative; relative paths are resolved with respect to the current working directory.

Optional argument *package* is a Python package or the name of a Python package whose directory should be used as the base directory for module-relative filenames in *paths*. If no package is specified, then the calling module’s directory is used as the base directory for module-relative filenames. It is an error to specify *package* if *module_relative* is **False**.

Optional argument *setUp* specifies a set-up function for the test suite. This is called before running the tests in each file. The *setUp* function will be passed a **DocTest** object. The setUp function can access the test globals as the *glob* attribute of the test passed.
Optional argument `tearDown` specifies a tear-down function for the test suite. This is called after running the tests in each file. The `tearDown` function will be passed a `DocTest` object. The `setUp` function can access the test globals as the `globs` attribute of the test passed.

Optional argument `globs` is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, `globs` is a new empty dictionary.

Optional argument `optionflags` specifies the default doctest options for the tests, created by or-ing together individual option flags. See section `Option Flags and Directives`. See function `set_unittest_reportflags()` below for a better way to set reporting options.

Optional argument `parser` specifies a `DocTestParser` (or subclass) that should be used to extract tests from the files. It defaults to a normal parser (i.e., `DocTestParser()`).

Optional argument `encoding` specifies an encoding that should be used to convert the file to unicode.

*New in version 2.4.*

*Changed in version 2.5:* The global `__file__` was added to the globals provided to doctests loaded from a text file using `DocFileSuite()`.

*Changed in version 2.5:* The parameter `encoding` was added.

```python
doctest.**DocTestSuite**([module][, globs][, extraglobs][, test_finder][, setUp][, tearDown][, checker])
```

Convert doctest tests for a module to a `unittest.TestSuite`. 
The returned `unittest.TestSuite` is to be run by the unittest framework and runs each doctest in the module. If any of the doctests fail, then the synthesized unit test fails, and a `failureException` exception is raised showing the name of the file containing the test and a (sometimes approximate) line number.

Optional argument `module` provides the module to be tested. It can be a module object or a (possibly dotted) module name. If not specified, the module calling this function is used.

Optional argument `globs` is a dictionary containing the initial global variables for the tests. A new copy of this dictionary is created for each test. By default, `globs` is a new empty dictionary.

Optional argument `extraglobs` specifies an extra set of global variables, which is merged into `globs`. By default, no extra globals are used.

Optional argument `test_finder` is the `DocTestFinder` object (or a drop-in replacement) that is used to extract doctests from the module.

Optional arguments `setUp`, `tearDown`, and `optionflags` are the same as for function `DocFileSuite()` above.

*New in version 2.3.*

*Changed in version 2.4:* The parameters `globs`, `extraglobs`, `test_finder`, `setUp`, `tearDown`, and `optionflags` were added; this function now uses the same search technique as `testmod()`.

Under the covers, `DocTestSuite()` creates a `unittest.TestSuite` out of `doctest.DocTestCase` instances, and `DocTestCase` is a subclass of `unittest.TestCase`. `DocTestCase` isn’t documented here (it’s an
internal detail), but studying its code can answer questions about the exact details of unittest integration.

Similarly, `DocFileSuite()` creates a `unittest.TestSuite` out of `doctest.DocFileCase` instances, and `DocFileCase` is a subclass of `DocTestCase`.

So both ways of creating a `unittest.TestSuite` run instances of `DocTestCase`. This is important for a subtle reason: when you run `doctest` functions yourself, you can control the `doctest` options in use directly, by passing option flags to `doctest` functions. However, if you’re writing a `unittest` framework, `unittest` ultimately controls when and how tests get run. The framework author typically wants to control `doctest` reporting options (perhaps, e.g., specified by command line options), but there’s no way to pass options through `unittest` to `doctest` test runners.

For this reason, `doctest` also supports a notion of `doctest` reporting flags specific to `unittest` support, via this function:

```
```doctest.set_unittest_reportflags(flags)
Set the doctest reporting flags to use.

Argument flags or’s together option flags. See section Option Flags and Directives. Only “reporting flags” can be used.

This is a module-global setting, and affects all future doctests run by module `unittest`: the `runTest()` method of `DocTestCase` looks at the option flags specified for the test case when the `DocTestCase` instance was constructed. If no reporting flags were specified (which is the typical and expected case), `doctest`’s `unittest` reporting flags are or’ed into the option flags, and the option flags so augmented are passed to the `DocTestRunner`
instance created to run the doctest. If any reporting flags were specified when the DocTestCase instance was constructed, doctest's unittest reporting flags are ignored.

The value of the unittest reporting flags in effect before the function was called is returned by the function.

*New in version 2.4.*
25.2.6. Advanced API

The basic API is a simple wrapper that’s intended to make doctest easy to use. It is fairly flexible, and should meet most users’ needs; however, if you require more fine-grained control over testing, or wish to extend doctest’s capabilities, then you should use the advanced API.

The advanced API revolves around two container classes, which are used to store the interactive examples extracted from doctest cases:

- **Example**: A single Python *statement*, paired with its expected output.
- **DocTest**: A collection of Examples, typically extracted from a single docstring or text file.

Additional processing classes are defined to find, parse, and run, and check doctest examples:

- **DocTestFinder**: Finds all docstrings in a given module, and uses a DocTestParser to create a DocTest from every docstring that contains interactive examples.
- **DocTestParser**: Creates a DocTest object from a string (such as an object’s docstring).
- **DocTestRunner**: Executes the examples in a DocTest, and uses an OutputChecker to verify their output.
- **OutputChecker**: Compares the actual output from a doctest example with the expected output, and decides whether they match.

The relationships among these processing classes are summarized in the following diagram:
25.2.6.1. DocTest Objects

```python
class doctest.DocTest(examples, globs, name, filename, lineno, docstring)
```

A collection of doctest examples that should be run in a single namespace. The constructor arguments are used to initialize the member variables of the same names.

*New in version 2.4.*

`DocTest` defines the following member variables. They are initialized by the constructor, and should not be modified directly.

**examples**

A list of `Example` objects encoding the individual interactive Python examples that should be run by this test.

**globs**

The namespace (aka globals) that the examples should be run in. This is a dictionary mapping names to values. Any changes to the namespace made by the examples (such as binding new variables) will be reflected in `globs` after the test is run.

**name**

A string name identifying the `DocTest`. Typically, this is the name of the object or file that the test was extracted from.
filename
The name of the file that this DocTest was extracted from; or None if the filename is unknown, or if the DocTest was not extracted from a file.

lineno
The line number within filename where this DocTest begins, or None if the line number is unavailable. This line number is zero-based with respect to the beginning of the file.

docstring
The string that the test was extracted from, or ‘None’ if the string is unavailable, or if the test was not extracted from a string.

25.2.6.2. Example Objects

class doctest.Example(source, want[, exc_msg][, lineno][, indent][, options])
A single interactive example, consisting of a Python statement and its expected output. The constructor arguments are used to initialize the member variables of the same names.

New in version 2.4.

Example defines the following member variables. They are initialized by the constructor, and should not be modified directly.

source
A string containing the example’s source code. This source code consists of a single Python statement, and always ends with a newline; the constructor adds a newline when necessary.

want
The expected output from running the example's source code (either from stdout, or a traceback in case of exception). \texttt{want} ends with a newline unless no output is expected, in which case it's an empty string. The constructor adds a newline when necessary.

\texttt{exc\_msg}

The exception message generated by the example, if the example is expected to generate an exception; or \texttt{None} if it is not expected to generate an exception. This exception message is compared against the return value of \texttt{traceback.format_exception_only()}. \texttt{exc\_msg} ends with a newline unless it's \texttt{None}. The constructor adds a newline if needed.

\texttt{lineno}

The line number within the string containing this example where the example begins. This line number is zero-based with respect to the beginning of the containing string.

\texttt{indent}

The example's indentation in the containing string, i.e., the number of space characters that precede the example's first prompt.

\texttt{options}

A dictionary mapping from option flags to \texttt{True} or \texttt{False}, which is used to override default options for this example. Any option flags not contained in this dictionary are left at their default value (as specified by the \texttt{DocTestRunner}'s \texttt{optionflags}). By default, no options are set.

\section*{25.2.6.3. DocTestFinder objects}

\begin{verbatim}

class doctest.DocTestFinder([verbose][, parser][, recurse])[

\end{verbatim}
A processing class used to extract the DocTest$s that are relevant to a given object, from its docstring and the docstrings of its contained objects. DocTest$s can currently be extracted from the following object types: modules, functions, classes, methods, staticmethods, classmethods, and properties.

The optional argument verbose can be used to display the objects searched by the finder. It defaults to False (no output).

The optional argument parser specifies the DocTestParser object (or a drop-in replacement) that is used to extract doctests from docstrings.

If the optional argument recurse is false, then DocTestFinder.find() will only examine the given object, and not any contained objects.

If the optional argument exclude_empty is false, then DocTestFinder.find() will include tests for objects with empty docstrings.

New in version 2.4.

DocTestFinder defines the following method:

find(obj[, name][, module][, globs][, extraglobs])

Return a list of the DocTest$s that are defined by obj's docstring, or by any of its contained objects' docstrings.

The optional argument name specifies the object's name; this name will be used to construct names for the returned DocTest$s. If name is not specified, then obj.__name__ is used.
The optional parameter *module* is the module that contains the given object. If the module is not specified or is None, then the test finder will attempt to automatically determine the correct module. The object’s module is used:

- As a default namespace, if *globs* is not specified.
- To prevent the DocTestFinder from extracting DocTests from objects that are imported from other modules. (Contained objects with modules other than *module* are ignored.)
- To find the name of the file containing the object.
- To help find the line number of the object within its file.

If *module* is `False`, no attempt to find the module will be made. This is obscure, of use mostly in testing doctest itself: if *module* is `False`, or is `None` but cannot be found automatically, then all objects are considered to belong to the (non-existent) module, so all contained objects will (recursively) be searched for doctests.

The globals for each `DocTest` is formed by combining *globs* and *extraglobs* (bindings in *extraglobs* override bindings in *globs*). A new shallow copy of the globals dictionary is created for each `DocTest`. If *globs* is not specified, then it defaults to the module’s `_dict_`, if specified, or `{}` otherwise. If *extraglobs* is not specified, then it defaults to `{}`.

### 25.2.6.4. DocTestParser objects

```python
class doctest.DocTestParser
    A processing class used to extract interactive examples from a string, and use them to create a `DocTest` object.

    *New in version 2.4.*
```
**DocTestParser** defines the following methods:

**get_doctest**(string, globs, name, filename, lineno)
Extract all doctest examples from the given string, and collect them into a **DocTest** object.

*globs, name, filename, and lineno* are attributes for the new **DocTest** object. See the documentation for **DocTest** for more information.

**get_examples**(string[, name])
Extract all doctest examples from the given string, and return them as a list of **Example** objects. Line numbers are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

**parse**(string[, name])
Divide the given string into examples and intervening text, and return them as a list of alternating **Examples** and strings. Line numbers for the **Examples** are 0-based. The optional argument *name* is a name identifying this string, and is only used for error messages.

### 25.2.6.5. DocTestRunner objects

**class** doctest. **DocTestRunner**([checker][, verbose][, optionflags])
A processing class used to execute and verify the interactive examples in a **DocTest**.

The comparison between expected outputs and actual outputs is done by an **OutputChecker**. This comparison may be customized with a number of option flags; see section **Option Flags and Directives** for more information. If the option flags are insufficient,
then the comparison may also be customized by passing a subclass of `OutputChecker` to the constructor.

The test runner’s display output can be controlled in two ways. First, an output function can be passed to `TestRunner.run()`; this function will be called with strings that should be displayed. It defaults to `sys.stdout.write`. If capturing the output is not sufficient, then the display output can be also customized by subclassing `DocTestRunner`, and overriding the methods `report_start()`, `report_success()`, `report_unexpected_exception()`, and `report_failure()`.

The optional keyword argument `checker` specifies the `OutputChecker` object (or drop-in replacement) that should be used to compare the expected outputs to the actual outputs of doctest examples.

The optional keyword argument `verbose` controls the `DocTestRunner`'s verbosity. If `verbose` is `True`, then information is printed about each example, as it is run. If `verbose` is `False`, then only failures are printed. If `verbose` is unspecified, or `None`, then verbose output is used iff the command-line switch `-v` is used.

The optional keyword argument `optionflags` can be used to control how the test runner compares expected output to actual output, and how it displays failures. For more information, see section `Option Flags and Directives`.

*New in version 2.4.*

`DocTestParser` defines the following methods:

`report_start(out, test, example)`

Report that the test runner is about to process the given
example. This method is provided to allow subclasses of `DocTestRunner` to customize their output; it should not be called directly.

*example* is the example about to be processed. *test* is the test *containing example*. *out* is the output function that was passed to `DocTestRunner.run()`.

**report_success**(out, test, example, got)

Report that the given example ran successfully. This method is provided to allow subclasses of `DocTestRunner` to customize their output; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to `DocTestRunner.run()`.

**report_failure**(out, test, example, got)

Report that the given example failed. This method is provided to allow subclasses of `DocTestRunner` to customize their output; it should not be called directly.

*example* is the example about to be processed. *got* is the actual output from the example. *test* is the test containing *example*. *out* is the output function that was passed to `DocTestRunner.run()`.

**report_unexpected_exception**(out, test, example, exc_info)

Report that the given example raised an unexpected exception. This method is provided to allow subclasses of `DocTestRunner` to customize their output; it should not be called directly.
example is the example about to be processed. exc_info is a tuple containing information about the unexpected exception (as returned by sys.exc_info()). test is the test containing example. out is the output function that was passed to DocTestRunner.run().

run(test[, compileflags][, out][, clear_globs])
Run the examples in test (a DocTest object), and display the results using the writer function out.

The examples are run in the namespace test.globs. If clear_globs is true (the default), then this namespace will be cleared after the test runs, to help with garbage collection. If you would like to examine the namespace after the test completes, then use clear_globs=False.

compileflags gives the set of flags that should be used by the Python compiler when running the examples. If not specified, then it will default to the set of future-import flags that apply to globs.

The output of each example is checked using the DocTestRunner's output checker, and the results are formatted by the DocTestRunner.report_*() methods.

summarize([verbose])
Print a summary of all the test cases that have been run by this DocTestRunner, and return a named tuple TestResults(failed, attempted).

The optional verbose argument controls how detailed the summary is. If the verbosity is not specified, then the DocTestRunner's verbosity is used.
Changed in version 2.6: Use a named tuple.

25.2.6.6. OutputChecker objects

class doctest.OutputChecker

A class used to check the whether the actual output from a doctest example matches the expected output. OutputChecker defines two methods: check_output(), which compares a given pair of outputs, and returns true if they match; and output_difference(), which returns a string describing the differences between two outputs.

New in version 2.4.

OutputChecker defines the following methods:

check_output(want, got, optionflags)

Return True iff the actual output from an example (got) matches the expected output (want). These strings are always considered to match if they are identical; but depending on what option flags the test runner is using, several non-exact match types are also possible. See section Option Flags and Directives for more information about option flags.

output_difference(example, got, optionflags)

Return a string describing the differences between the expected output for a given example (example) and the actual output (got). optionflags is the set of option flags used to compare want and got.
25.2.7. Debugging

Doctest provides several mechanisms for debugging doctest examples:

- Several functions convert doctests to executable Python programs, which can be run under the Python debugger, `pdb`.

- The `DebugRunner` class is a subclass of `DocTestRunner` that raises an exception for the first failing example, containing information about that example. This information can be used to perform post-mortem debugging on the example.

- The `unittest` cases generated by `DocTestSuite()` support the `debug()` method defined by `unittest.TestCase`.

- You can add a call to `pdb.set_trace()` in a doctest example, and you'll drop into the Python debugger when that line is executed. Then you can inspect current values of variables, and so on. For example, suppose `a.py` contains just this module docstring:

  ```
  """
  >>> def f(x):
  ...     g(x*2)
  >>> def g(x):
  ...     print x+3
  ...     import pdb; pdb.set_trace()
  >>> f(3)
  g
  """
  ```

  Then an interactive Python session may look like this:

  ```
  >>> import a, doctest
  >>> doctest.testmod(a)
  --Return--
  > <doctest a[1]>(3)g()--None
  ```
-> import pdb; pdb.set_trace()
(Pdb) list
  1  def g(x):
  2   print x+3
  3  -> import pdb; pdb.set_trace()
[EOF]
(Pdb) print x
6
(Pdb) step
--Return--
> <doctest a[0]>(2)f()--None
-> g(x*2)
(Pdb) list
  1  def f(x):
  2  -> g(x*2)
[EOF]
(Pdb) print x
3
(Pdb) step
--Return--
> <doctest a[2]>(1)?()--None
-> f(3)
(Pdb) cont
(0, 3)
>>>

Changed in version 2.4: The ability to use `pdb.set_trace()` usefully inside doctests was added.

Functions that convert doctests to Python code, and possibly run the synthesized code under the debugger:

```
doctest.script_from_examples(s)
```

Convert text with examples to a script.

Argument `s` is a string containing doctest examples. The string is converted to a Python script, where doctest examples in `s` are converted to regular code, and everything else is converted to Python comments. The generated script is returned as a string. For example,

```
import doctest
```
print doctest.script_from_examples(r""
  Set x and y to 1 and 2.
  >>> x, y = 1, 2

  Print their sum:
  >>> print x+y
  3
"")

displays:

```
# Set x and y to 1 and 2.
x, y = 1, 2
#
# Print their sum:
print x+y
# Expected:
## 3
```

This function is used internally by other functions (see below), but can also be useful when you want to transform an interactive Python session into a Python script.

*New in version 2.4.*

doctest.**testsource**(module, name)

Convert the doctest for an object to a script.

Argument *module* is a module object, or dotted name of a module, containing the object whose doctests are of interest. Argument *name* is the name (within the module) of the object with the doctests of interest. The result is a string, containing the object's docstring converted to a Python script, as described for `script_from_examples()` above. For example, if module *a.py* contains a top-level function \texttt{f()}, then

```
import a, doctest
print doctest.testsource(a, "a.f")
```
prints a script version of function \( f() \)'s docstring, with doctests converted to code, and the rest placed in comments.

*New in version 2.3.*

```python
doctest.debug(module, name[, pm])
```

Debug the doctests for an object.

The `module` and `name` arguments are the same as for function `testsource()` above. The synthesized Python script for the named object’s docstring is written to a temporary file, and then that file is run under the control of the Python debugger, `pdb`.

A shallow copy of `module.__dict__` is used for both local and global execution context.

Optional argument `pm` controls whether post-mortem debugging is used. If `pm` has a true value, the script file is run directly, and the debugger gets involved only if the script terminates via raising an unhandled exception. If it does, then post-mortem debugging is invoked, via `pdb.post_mortem()`, passing the traceback object from the unhandled exception. If `pm` is not specified, or is false, the script is run under the debugger from the start, via passing an appropriate `execfile()` call to `pdb.run()`.

*New in version 2.3.*

*Changed in version 2.4:* The `pm` argument was added.

```python
doctest.debug_src(src[, pm][, globs])
```

Debug the doctests in a string.

This is like function `debug()` above, except that a string containing doctest examples is specified directly, via the `src` argument.
Optional argument *pm* has the same meaning as in function `debug()` above.

Optional argument *globs* gives a dictionary to use as both local and global execution context. If not specified, or `None`, an empty dictionary is used. If specified, a shallow copy of the dictionary is used.

*New in version 2.4.*

The `DebugRunner` class, and the special exceptions it may raise, are of most interest to testing framework authors, and will only be sketched here. See the source code, and especially `DebugRunner`'s docstring (which is a doctest!) for more details:

```python
class doctest. DebugRunner([checker][, verbose][, optionflags])
```

A subclass of `DocTestRunner` that raises an exception as soon as a failure is encountered. If an unexpected exception occurs, an `UnexpectedException` exception is raised, containing the test, the example, and the original exception. If the output doesn’t match, then a `DocTestFailure` exception is raised, containing the test, the example, and the actual output.

For information about the constructor parameters and methods, see the documentation for `DocTestRunner` in section *Advanced API*.

There are two exceptions that may be raised by `DebugRunner` instances:

```python
exception doctest. DocTestFailure(test, example, got)
```

An exception raised by `DocTestRunner` to signal that a doctest example's actual output did not match its expected output. The constructor arguments are used to initialize the member variables
of the same names.

**DocTestFailure** defines the following member variables:

DocTestFailure. **test**

The **DocTest** object that was being run when the example failed.

DocTestFailure. **example**

The **Example** that failed.

DocTestFailure. **got**

The example’s actual output.

*exception* doctest. **UnexpectedException**(*test, example, exc_info*)

An exception raised by **DocTestRunner** to signal that a doctest example raised an unexpected exception. The constructor arguments are used to initialize the member variables of the same names.

**UnexpectedException** defines the following member variables:

UnexpectedException. **test**

The **DocTest** object that was being run when the example failed.

UnexpectedException. **example**

The **Example** that failed.

UnexpectedException. **exc_info**

A tuple containing information about the unexpected exception, as returned by **sys.exc_info()**.
As mentioned in the introduction, doctest has grown to have three primary uses:

1. Checking examples in docstrings.
2. Regression testing.
3. Executable documentation / literate testing.

These uses have different requirements, and it is important to distinguish them. In particular, filling your docstrings with obscure test cases makes for bad documentation.

When writing a docstring, choose docstring examples with care. There's an art to this that needs to be learned—it may not be natural at first. Examples should add genuine value to the documentation. A good example can often be worth many words. If done with care, the examples will be invaluable for your users, and will pay back the time it takes to collect them many times over as the years go by and things change. I'm still amazed at how often one of my doctest examples stops working after a “harmless” change.

Doctest also makes an excellent tool for regression testing, especially if you don’t skimp on explanatory text. By interleaving prose and examples, it becomes much easier to keep track of what's actually being tested, and why. When a test fails, good prose can make it much easier to figure out what the problem is, and how it should be fixed. It's true that you could write extensive comments in code-based testing, but few programmers do. Many have found that using doctest approaches instead leads to much clearer tests. Perhaps this is simply because doctest makes writing prose a little easier than writing code, while writing comments in code is a little harder. I think it goes deeper than just that: the natural attitude when writing a doctest-based test is that you want to explain the fine points
of your software, and illustrate them with examples. This in turn naturally leads to test files that start with the simplest features, and logically progress to complications and edge cases. A coherent narrative is the result, instead of a collection of isolated functions that test isolated bits of functionality seemingly at random. It’s a different attitude, and produces different results, blurring the distinction between testing and explaining.

Regression testing is best confined to dedicated objects or files. There are several options for organizing tests:

- Write text files containing test cases as interactive examples, and test the files using `testfile()` or `DocFileSuite()`. This is recommended, although is easiest to do for new projects, designed from the start to use doctest.
- Define functions named `_regrtest_topic` that consist of single docstrings, containing test cases for the named topics. These functions can be included in the same file as the module, or separated out into a separate test file.
- Define a `_test_` dictionary mapping from regression test topics to docstrings containing test cases.

**Footnotes**

[1] Examples containing both expected output and an exception are not supported. Trying to guess where one ends and the other begins is too error-prone, and that also makes for a confusing test.
25.3. unittest — Unit testing framework

New in version 2.1.

(If you are already familiar with the basic concepts of testing, you might want to skip to the list of assert methods.)

The Python unit testing framework, sometimes referred to as “PyUnit,” is a Python language version of JUnit, by Kent Beck and Erich Gamma. JUnit is, in turn, a Java version of Kent’s Smalltalk testing framework. Each is the de facto standard unit testing framework for its respective language.

unittest supports test automation, sharing of setup and shutdown code for tests, aggregation of tests into collections, and independence of the tests from the reporting framework. The unittest module provides classes that make it easy to support these qualities for a set of tests.

To achieve this, unittest supports some important concepts:

test fixture

A test fixture represents the preparation needed to perform one or more tests, and any associate cleanup actions. This may involve, for example, creating temporary or proxy databases, directories, or starting a server process.

test case

A test case is the smallest unit of testing. It checks for a specific response to a particular set of inputs. unittest provides a base class, TestCase, which may be used to create new test cases.

test suite
A test suite is a collection of test cases, test suites, or both. It is used to aggregate tests that should be executed together.

test runner

A test runner is a component which orchestrates the execution of tests and provides the outcome to the user. The runner may use a graphical interface, a textual interface, or return a special value to indicate the results of executing the tests.

The test case and test fixture concepts are supported through the `TestCase` and `FunctionTestCase` classes; the former should be used when creating new tests, and the latter can be used when integrating existing test code with a `unittest`-driven framework. When building test fixtures using `TestCase`, the `setUp()` and `tearDown()` methods can be overridden to provide initialization and cleanup for the fixture. With `FunctionTestCase`, existing functions can be passed to the constructor for these purposes. When the test is run, the fixture initialization is run first; if it succeeds, the cleanup method is run after the test has been executed, regardless of the outcome of the test. Each instance of the `TestCase` will only be used to run a single test method, so a new fixture is created for each test.

Test suites are implemented by the `TestSuite` class. This class allows individual tests and test suites to be aggregated; when the suite is executed, all tests added directly to the suite and in “child” test suites are run.

A test runner is an object that provides a single method, `run()`, which accepts a `TestCase` or `TestSuite` object as a parameter, and returns a result object. The class `TestResult` is provided for use as the result object. `unittest` provides the `TextTestRunner` as an example test runner which reports test results on the standard error stream by default. Alternate runners can be implemented for other environments (such as graphical environments) without any need to
derive from a specific class.

25.3.1. Basic example

The unittest module provides a rich set of tools for constructing and running tests. This section demonstrates that a small subset of the tools suffice to meet the needs of most users.

Here is a short script to test three functions from the random module:

```python
import random
import unittest

class TestSequenceFunctions(unittest.TestCase):
    def setUp(self):
        self.seq = range(10)

    def test_shuffle(self):
        # make sure the shuffled sequence does not lose any elements
        random.shuffle(self.seq)
        self.seq.sort()
        self.assertEqual(self.seq, range(10))

    # should raise an exception for an immutable sequence
    self.assertRaises(TypeError, random.shuffle, (1,2,3))

    def test_choice(self):
        element = random.choice(self.seq)
        self.assertIn(element, self.seq)

    def test_sample(self):
        with self.assertRaises(ValueError):
            random.sample(self.seq, 20)
        for element in random.sample(self.seq, 5):
            self.assertIn(element, self.seq)

if __name__ == '__main__':
    unittest.main()
```

A testcase is created by subclassing unittest.TestCase. The three individual tests are defined with methods whose names start with the
This naming convention informs the test runner about which methods represent tests.

The crux of each test is a call to `assertEqual()` to check for an expected result; `assertTrue()` to verify a condition; or `assertRaises()` to verify that an expected exception gets raised. These methods are used instead of the `assert` statement so the test runner can accumulate all test results and produce a report.

When a `setUp()` method is defined, the test runner will run that method prior to each test. Likewise, if a `tearDown()` method is defined, the test runner will invoke that method after each test. In the example, `setUp()` was used to create a fresh sequence for each test.

The final block shows a simple way to run the tests. `unittest.main()` provides a command-line interface to the test script. When run from the command line, the above script produces an output that looks like this:

```
... 
Ran 3 tests in 0.000s
OK
```

Instead of `unittest.main()`, there are other ways to run the tests with a finer level of control, less terse output, and no requirement to be run from the command line. For example, the last two lines may be replaced with:

```
suite = unittest.TestLoader().loadTestsFromTestCase(TestSequenceFunctions)
suite = unittest.TextTestRunner(verbosity=2).run(suite)
```

Running the revised script from the interpreter or another script
produces the following output:

```python
test_choice (__main__.TestSequenceFunctions) ... ok
test_sample (__main__.TestSequenceFunctions) ... ok
test_shuffle (__main__.TestSequenceFunctions) ... ok
```

Ran 3 tests in 0.110s

OK

The above examples show the most commonly used `unittest` features which are sufficient to meet many everyday testing needs. The remainder of the documentation explores the full feature set from first principles.
25.3.2. Command-Line Interface

The unittest module can be used from the command line to run tests from modules, classes or even individual test methods:

```bash
python -m unittest test_module1 test_module2
python -m unittest test_module.TestClass
python -m unittest test_module.TestClass.test_method
```

You can pass in a list with any combination of module names, and fully qualified class or method names.

You can run tests with more detail (higher verbosity) by passing in the `-v` flag:

```bash
python -m unittest -v test_module
```

For a list of all the command-line options:

```bash
python -m unittest -h
```

*Changed in version 2.7:* In earlier versions it was only possible to run individual test methods and not modules or classes.

25.3.2.1. Command-line options

**unittest** supports these command-line options:

- `-b`, `--buffer`
  
  The standard output and standard error streams are buffered during the test run. Output during a passing test is discarded. Output is echoed normally on test fail or error and is added to the failure messages.

- `-c`, `--catch`
Control-C during the test run waits for the current test to end and then reports all the results so far. A second control-C raises the normal `KeyboardInterrupt` exception.

See [Signal Handling](#) for the functions that provide this functionality.

**-f, --failfast**

Stop the test run on the first error or failure.

*New in version 2.7:* The command-line options `-b, -c` and `-f` were added.

The command line can also be used for test discovery, for running all of the tests in a project or just a subset.
25.3.3. Test Discovery

New in version 2.7.

Unittest supports simple test discovery. In order to be compatible with test discovery, all of the test files must be modules or packages importable from the top-level directory of the project (this means that their filenames must be valid identifiers).

Test discovery is implemented in TestLoader.discover(), but can also be used from the command line. The basic command-line usage is:

```
cd project_directory
python -m unittest discover
```

The `discover` sub-command has the following options:

- `-v`, `--verbose`
  Verbose output

- `-s` directory
  Directory to start discovery (`.’ default)

- `-p` pattern
  Pattern to match test files (`test*.py’ default)

- `-t` directory
  Top level directory of project (defaults to start directory)

The `-s`, `-p`, and `-t` options can be passed in as positional arguments in that order. The following two command lines are equivalent:

```
python -m unittest discover -s project_directory -p '*_test.py'
python -m unittest discover project_directory '*_test.py'
```
As well as being a path it is possible to pass a package name, for example `myproject.subpackage.test`, as the start directory. The package name you supply will then be imported and its location on the filesystem will be used as the start directory.

**Caution:** Test discovery loads tests by importing them. Once test discovery has found all the test files from the start directory you specify it turns the paths into package names to import. For example `foo/bar/baz.py` will be imported as `foo.bar.baz`.

If you have a package installed globally and attempt test discovery on a different copy of the package then the import *could* happen from the wrong place. If this happens test discovery will warn you and exit.

If you supply the start directory as a package name rather than a path to a directory then discover assumes that whichever location it imports from is the location you intended, so you will not get the warning.

Test modules and packages can customize test loading and discovery by through the `load_tests` protocol.
25.3.4. Organizing test code

The basic building blocks of unit testing are test cases — single scenarios that must be set up and checked for correctness. In unittest, test cases are represented by instances of unittest's TestCase class. To make your own test cases you must write subclasses of TestCase, or use FunctionTestCase.

An instance of a TestCase-derived class is an object that can completely run a single test method, together with optional set-up and tidy-up code.

The testing code of a TestCase instance should be entirely self contained, such that it can be run either in isolation or in arbitrary combination with any number of other test cases.

The simplest TestCase subclass will simply override the runTest() method in order to perform specific testing code:

```python
import unittest
class DefaultWidgetSizeTestCase(unittest.TestCase):
    def runTest(self):
        widget = Widget('The widget')
        self.assertEqual(widget.size(), (50, 50), 'incorrect default size')
```

Note that in order to test something, we use the one of the assert*() methods provided by the TestCase base class. If the test fails, an exception will be raised, and unittest will identify the test case as a failure. Any other exceptions will be treated as errors. This helps you identify where the problem is: failures are caused by incorrect results - a 5 where you expected a 6. Errors are caused by incorrect code - e.g., a TypeError caused by an incorrect function call.
The way to run a test case will be described later. For now, note that to construct an instance of such a test case, we call its constructor without arguments:

```python
testCase = DefaultWidgetSizeTestCase()
```

Now, such test cases can be numerous, and their set-up can be repetitive. In the above case, constructing a `Widget` in each of 100 `Widget` test case subclasses would mean unsightly duplication.

Luckily, we can factor out such set-up code by implementing a method called `setUp()`, which the testing framework will automatically call for us when we run the test:

```python
import unittest
class SimpleWidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

class DefaultWidgetSizeTestCase(SimpleWidgetTestCase):
    def runTest(self):
        self.widget.resize(100, 150)
        self.assertEqual(self.widget.size(), (100, 150), 'wrong size after resize')

class WidgetResizeTestCase(SimpleWidgetTestCase):
    def runTest(self):
        self.widget.resize(100, 150)
        self.assertEqual(self.widget.size(), (100, 150), 'incorrect default size')

if the `setUp()` method raises an exception while the test is running, the framework will consider the test to have suffered an error, and the `runTest()` method will not be executed.

Similarly, we can provide a `tearDown()` method that tidies up after the `runTest()` method has been run:

```python
import unittest
```
class SimpleWidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def tearDown(self):
        self.widget.dispose()
        self.widget = None

If setUp() succeeded, the tearDown() method will be run whether runTest() succeeded or not.

Such a working environment for the testing code is called a fixture.

Often, many small test cases will use the same fixture. In this case, we would end up subclassing SimpleWidgetTestCase into many small one-method classes such as DefaultWidgetSizeTestCase. This is time-consuming and discouraging, so in the same vein as JUnit, unittest provides a simpler mechanism:

import unittest

class WidgetTestCase(unittest.TestCase):
    def setUp(self):
        self.widget = Widget('The widget')

    def tearDown(self):
        self.widget.dispose()
        self.widget = None

    def test_default_size(self):
        self.assertEqual(self.widget.size(), (50, 50), 'incorrect default size')

    def test_resize(self):
        self.widget.resize(100, 150)
        self.assertEqual(self.widget.size(), (100, 150), 'wrong size after resize')

Here we have not provided a runTest() method, but have instead provided two different test methods. Class instances will now each
run one of the `test_*( )` methods, with `self.widget` created and destroyed separately for each instance. When creating an instance we must specify the test method it is to run. We do this by passing the method name in the constructor:

```python
defaultSizeTestCase = WidgetTestCase('test_default_size')
resizeTestCase = WidgetTestCase('test_resize')```

Test case instances are grouped together according to the features they test. `unittest` provides a mechanism for this: the `test suite`, represented by `unittest's TestSuite class`:

```python
widgetTestSuite = unittest.TestSuite()
widgetTestSuite.addTest(WidgetTestCase('test_default_size'))
widgetTestSuite.addTest(WidgetTestCase('test_resize'))
```

For the ease of running tests, as we will see later, it is a good idea to provide in each test module a callable object that returns a pre-built test suite:

```python
def suite():
    suite = unittest.TestSuite()
    suite.addTest(WidgetTestCase('test_default_size'))
    suite.addTest(WidgetTestCase('test_resize'))
    return suite
```

or even:

```python
def suite():
    tests = ['test_default_size', 'test_resize']
    return unittest.TestSuite(map(WidgetTestCase, tests))
```

Since it is a common pattern to create a `TestCase` subclass with many similarly named test functions, `unittest` provides a `TestLoader` class that can be used to automate the process of creating a test suite and populating it with individual tests. For example,
suite = unittest.TestLoader().loadTestsFromTestCase(WidgetTestCase)

will create a test suite that will run
WidgetTestCase.test_default_size()  and
WidgetTestCase.test_resize. TestLoader uses the 'test' method name prefix to identify test methods automatically.

Note that the order in which the various test cases will be run is determined by sorting the test function names with respect to the built-in ordering for strings.

Often it is desirable to group suites of test cases together, so as to run tests for the whole system at once. This is easy, since TestSuite instances can be added to a TestSuite just as TestCase instances can be added to a TestSuite:

```
suite1 = module1.TheTestSuite()
suite2 = module2.TheTestSuite()
alltests = unittest.TestSuite([suite1, suite2])
```

You can place the definitions of test cases and test suites in the same modules as the code they are to test (such as widget.py), but there are several advantages to placing the test code in a separate module, such as test_widget.py:

- The test module can be run standalone from the command line.
- The test code can more easily be separated from shipped code.
- There is less temptation to change test code to fit the code it tests without a good reason.
- Test code should be modified much less frequently than the code it tests.
- Tested code can be refactored more easily.
- Tests for modules written in C must be in separate modules anyway, so why not be consistent?
- If the testing strategy changes, there is no need to change the source code.
25.3.5. Re-using old test code

Some users will find that they have existing test code that they would like to run from unittest, without converting every old test function to a TestCase subclass.

For this reason, unittest provides a FunctionTestCase class. This subclass of TestCase can be used to wrap an existing test function. Set-up and tear-down functions can also be provided.

Given the following test function:

```python
def testSomething():
    something = makeSomething()
    assert something.name is not None
    # ...
```

one can create an equivalent test case instance as follows:

```python
testcase = unittest.FunctionTestCase(testSomething)
```

If there are additional set-up and tear-down methods that should be called as part of the test case’s operation, they can also be provided like so:

```python
testcase = unittest.FunctionTestCase(testSomething,
                           setUp=makeSomethingDB,
                           tearDown=deleteSomethingDB)
```

To make migrating existing test suites easier, unittest supports tests raising AssertionError to indicate test failure. However, it is recommended that you use the explicit TestCase.fail*() and TestCase.assert*() methods instead, as future versions of unittest may treat AssertionError differently.
**Note:** Even though `FunctionTestCase` can be used to quickly convert an existing test base over to a `unittest`-based system, this approach is not recommended. Taking the time to set up proper `TestCase` subclasses will make future test refactorings infinitely easier.

In some cases, the existing tests may have been written using the `doctest` module. If so, `doctest` provides a `DocTestSuite` class that can automatically build `unittest.TestSuite` instances from the existing `doctest`-based tests.
25.3.6. Skipping tests and expected failures

*New in version 2.7.*

Unittest supports skipping individual test methods and even whole classes of tests. In addition, it supports marking a test as a “expected failure,” a test that is broken and will fail, but shouldn’t be counted as a failure on a `TestResult`.

Skipping a test is simply a matter of using the `skip()` decorator or one of its conditional variants.

Basic skipping looks like this:

```python
class MyTestCase(unittest.TestCase):
    # Class-level skipping
    @unittest.skip("demonstrating skipping")
    def test_nothing(self):
        self.fail("shouldn't happen")

    # Method-level skipping
    @unittest.skipIf(mylib.__version__ < (1, 3),
                     "not supported in this library version")
    def test_format(self):
        # Tests that work for only a certain version of the lib
        pass

    @unittest.skipUnless(sys.platform.startswith("win"), "requires Windows")
    def test_windows_support(self):
        # windows specific testing code
        pass
```

This is the output of running the example above in verbose mode:

```
test_format (__main__.MyTestCase) ... skipped 'not supported in this library version'
test_nothing (__main__.MyTestCase) ... skipped 'demonstrating skipping'
test_windows_support (__main__.MyTestCase) ... skipped 'requires Windows'
Ran 3 tests in 0.005s
```
Classes can be skipped just like methods:

```python
@skip("showing class skipping")
class MySkippedTestCase(unittest.TestCase):
    def test_not_run(self):
        pass
```

`TestCase.setUp()` can also skip the test. This is useful when a resource that needs to be set up is not available.

Expected failures use the `expectedFailure()` decorator.

```python
class ExpectedFailureTestCase(unittest.TestCase):
    @unittest.expectedFailure
    def test_fail(self):
        self.assertEqual(1, 0, "broken")
```

It's easy to roll your own skipping decorators by making a decorator that calls `skip()` on the test when it wants it to be skipped. This decorator skips the test unless the passed object has a certain attribute:

```python
def skipUnlessHasattr(obj, attr):
    if hasattr(obj, attr):
        return lambda func: func
    return unittest.skip("{0!r} doesn't have {1!r}".format(obj, attr))
```

The following decorators implement test skipping and expected failures:

```python
unittest.skip(reason)
```

Unconditionally skip the decorated test. `reason` should describe why the test is being skipped.
unittest. `skipIf(condition, reason)`
Skip the decorated test if `condition` is true.

unittest. `skipUnless(condition, reason)`
Skip the decorated test unless `condition` is true.

unittest. `expectedFailure()`
Mark the test as an expected failure. If the test fails when run, the test is not counted as a failure.

Skipped tests will not have `setUp()` or `tearDown()` run around them. Skipped classes will not have `setUpClass()` or `tearDownClass()` run.
25.3.7. Classes and functions

This section describes in depth the API of unittest.

25.3.7.1. Test cases

```python
class unittest.TestCase(methodName='runTest')

Instances of the `TestCase` class represent the smallest testable units in the `unittest` universe. This class is intended to be used as a base class, with specific tests being implemented by concrete subclasses. This class implements the interface needed by the test runner to allow it to drive the test, and methods that the test code can use to check for and report various kinds of failure.

Each instance of `TestCase` will run a single test method: the method named `methodName`. If you remember, we had an earlier example that went something like this:

```python
def suite():
suite = unittest.TestSuite()
suite.addTest(WidgetTestCase('test_default_size'))
suite.addTest(WidgetTestCase('test_resize'))
return suite
```

Here, we create two instances of `WidgetTestCase`, each of which runs a single test.

`methodName` defaults to `runTest()`.

`TestCase` instances provide three groups of methods: one group used to run the test, another used by the test implementation to check conditions and report failures, and some inquiry methods allowing information about the test itself to be gathered.
Methods in the first group (running the test) are:

**setUp()**
Method called to prepare the test fixture. This is called immediately before calling the test method; any exception raised by this method will be considered an error rather than a test failure. The default implementation does nothing.

**tearDown()**
Method called immediately after the test method has been called and the result recorded. This is called even if the test method raised an exception, so the implementation in subclasses may need to be particularly careful about checking internal state. Any exception raised by this method will be considered an error rather than a test failure. This method will only be called if the **setUp()** succeeds, regardless of the outcome of the test method. The default implementation does nothing.

**setUpClass()**
A class method called before tests in an individual class run. **setUpClass** is called with the class as the only argument and must be decorated as a **classmethod()**:

```python
@classmethod
def setUpClass(cls):
    ...
```

See [Class and Module Fixtures](#) for more details.

*New in version 2.7.*

**tearDownClass()**
A class method called after tests in an individual class have run. **tearDownClass** is called with the class as the only
argument and must be decorated as a `classmethod()`

```python
@classmethod
def tearDownClass(cls):
    ...
```

See [Class and Module Fixtures](#) for more details.

*New in version 2.7.*

**run** *(result=None)*

Run the test, collecting the result into the test result object passed as `result`. If `result` is omitted or `None`, a temporary result object is created (by calling the `defaultTestResult()` method) and used. The result object is not returned to `run()`'s caller.

The same effect may be had by simply calling the `TestCase` instance.

**skipTest** *(reason)*

Calling this during a test method or `setUp()` skips the current test. See [Skipping tests and expected failures](#) for more information.

*New in version 2.7.*

**debug()**

Run the test without collecting the result. This allows exceptions raised by the test to be propagated to the caller, and can be used to support running tests under a debugger.

The `TestCase` class provides a number of methods to check for and report failures, such as:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
</table>
assertEqual(a, b) | a == b
assertNotEqual(a, b) | a != b
assertTrue(x) | bool(x) is True
assertFalse(x) | bool(x) is False
assertIs(a, b) | a is b
assertIsNot(a, b) | a is not b
assertIsNone(x) | x is None
assertIsNotNone(x) | x is not None
assertIn(a, b) | a in b
assertNotIn(a, b) | a not in b
assertIsInstance(a, b) | isinstance(a, b)
assertNotIsInstance(a, b) | not isinstance(a, b)

All the assert methods (except assertRaises(), assertRaisesRegexp()) accept a msg argument that, if specified, is used as the error message on failure (see also longMessage).

assertEqual(first, second, msg=None)
Test that first and second are equal. If the values do not compare equal, the test will fail.

In addition, if first and second are the exact same type and one of list, tuple, dict, set, frozenset or unicode or any type that a subclass registers with addTypeEqualityFunc() the type specific equality function will be called in order to generate a more useful default error message (see also the list of type-specific methods).

Changed in version 2.7: Added the automatic calling of type specific equality function.

assertNotEqual(first, second, msg=None)
Test that first and second are not equal. If the values do compare equal, the test will fail.
assertTrue(expr, msg=None)
assertFalse(expr, msg=None)

Test that expr is true (or false).

Note that this is equivalent to bool(expr) is True and not to expr is True (use assertIs(expr, True) for the latter). This method should also be avoided when more specific methods are available (e.g. assertEqual(a, b) instead of assertTrue(a == b)), because they provide a better error message in case of failure.

assertIs(first, second, msg=None)
assertIsNot(first, second, msg=None)

Test that first and second evaluate (or don’t evaluate) to the same object.

New in version 2.7.

assertIsNone(expr, msg=None)
assertIsNotNone(expr, msg=None)

Test that expr is (or is not) None.

New in version 2.7.

assertIn(first, second, msg=None)
assertNotIn(first, second, msg=None)

Test that first is (or is not) in second.

New in version 2.7.

assertIsInstance(obj, cls, msg=None)
assertNotIsInstance(obj, cls, msg=None)

Test that obj is (or is not) an instance of cls (which can be a class or a tuple of classes, as supported by isinstance()).
New in version 2.7.

It is also possible to check that exceptions and warnings are raised using the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertRaises(exc, fun, *args, **kwds)</code></td>
<td><code>fun(*args, **kwds) raises exc</code></td>
<td></td>
</tr>
<tr>
<td><code>assertRaisesRegexp(exc, re, fun, *args, **kwds)</code></td>
<td><code>fun(*args, **kwds) raises exc and the message matches re</code></td>
<td>2.7</td>
</tr>
</tbody>
</table>

**assertRaises** *(exception, callable, *args, **kwds)*

**assertRaises** *(exception)*

Test that an exception is raised when `callable` is called with any positional or keyword arguments that are also passed to `assertRaises()`. The test passes if `exception` is raised, is an error if another exception is raised, or fails if no exception is raised. To catch any of a group of exceptions, a tuple containing the exception classes may be passed as `exception`.

If only the `exception` argument is given, returns a context manager so that the code under test can be written inline rather than as a function:

```python
with self.assertRaises(SomeException):
    do_something()
```

The context manager will store the caught exception object in its `exception` attribute. This can be useful if the intention is to perform additional checks on the exception raised:

```python
with self.assertRaises(SomeException) as cm:
    do_something()
```
the_exception = cm.exception
self.assertEqual(the_exception.error_code, 3)

*Changed in version 2.7:* Added the ability to use `assertRaises()` as a context manager.

`assertRaisesRegexp(exception, regexp, callable, *args, **kwds)`

`assertRaisesRegexp(exception, regexp)`

Like `assertRaises()` but also tests that `regexp` matches on the string representation of the raised exception. `regexp` may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`. Examples:

```python
self.assertRaisesRegexp(ValueError, 'invalid literal for.*XYZ$' int, 'XYZ')
```

or:

```python
with self.assertRaisesRegexp(ValueError, 'literal'): int('XYZ')
```

*New in version 2.7.*

There are also other methods used to perform more specific checks, such as:

<table>
<thead>
<tr>
<th>Method</th>
<th>Checks that</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertAlmostEqual(a, b)</code></td>
<td><code>round(a-b, 7) == 0</code></td>
<td></td>
</tr>
<tr>
<td><code>assertNotAlmostEqual(a, b)</code></td>
<td><code>round(a-b, 7) != 0</code></td>
<td></td>
</tr>
<tr>
<td><code>assertGreater(a, b)</code></td>
<td><code>a &gt; b</code></td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertGreaterEqual(a, b)</code></td>
<td><code>a &gt;= b</code></td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertLess(a, b)</code></td>
<td><code>a &lt; b</code></td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertLessEqual(a, b)</code></td>
<td><code>a &lt;= b</code></td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertRegexpMatches(s, re)</code></td>
<td><code>regex.search(s)</code></td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertNotRegexpMatches(s, re)</code></td>
<td><code>not regex.search(s)</code></td>
<td>2.7</td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
<td>Python Version</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td><code>assertItemsEqual(a, b)</code></td>
<td><code>sorted(a) == sorted(b)</code> and works with unhashable objs</td>
<td>2.7</td>
</tr>
<tr>
<td><code>assertDictContainsSubset(a, b)</code></td>
<td>all the key/value pairs in <code>a</code> exist in <code>b</code></td>
<td>2.7</td>
</tr>
</tbody>
</table>

### assertAlmostEqual

```python
assertAlmostEqual(first, second, places=7, msg=None, delta=None)
```

Test that `first` and `second` are approximately (or not approximately) equal by computing the difference, rounding to the given number of decimal places (default 7), and comparing to zero. Note that these methods round the values to the given number of decimal places (i.e. like the `round()` function) and not significant digits.

If `delta` is supplied instead of `places` then the difference between `first` and `second` must be less (or more) than `delta`.

Supplying both `delta` and `places` raises a `TypeError`.

*Changed in version 2.7:* `assertAlmostEqual()` automatically considers almost equal objects that compare equal. `assertNotAlmostEqual()` automatically fails if the objects compare equal. Added the `delta` keyword argument.

### assertGreater

```python
assertGreater(first, second, msg=None)
```

### assertGreaterEqual

```python
assertGreaterEqual(first, second, msg=None)
```

### assertLess

```python
assertLess(first, second, msg=None)
```

### assertLessEqual

```python
assertLessEqual(first, second, msg=None)
```

Test that `first` is respectively >, >=, < or <= than `second` depending on the method name. If not, the test will fail:

```python
>>> self.assertGreaterEqual(3, 4)
```
New in version 2.7.

**assertRegexpMatches**(text, regexp, msg=None)

Test that a `regexp` search matches `text`. In case of failure, the error message will include the pattern and the `text` (or the pattern and the part of `text` that unexpectedly matched). `regexp` may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`.

New in version 2.7.

**assertNotRegexpMatches**(text, regexp, msg=None)

Verifies that a `regexp` search does not match `text`. Fails with an error message including the pattern and the part of `text` that matches. `regexp` may be a regular expression object or a string containing a regular expression suitable for use by `re.search()`.

New in version 2.7.

**assertItemsEqual**(actual, expected, msg=None)

Test that sequence `expected` contains the same elements as `actual`, regardless of their order. When they don’t, an error message listing the differences between the sequences will be generated.

Duplicate elements are not ignored when comparing `actual` and `expected`. It verifies if each element has the same count in both sequences. It is the equivalent of `assertEqual(sorted(expected), sorted(actual))` but it works with sequences of unhashable objects as well.
New in version 2.7.

**assertDictContainsSubset**\((expected, actual, msg=None)\)
Tests whether the key/value pairs in dictionary \(actual\) are a superset of those in \(expected\). If not, an error message listing the missing keys and mismatched values is generated.

New in version 2.7.

*Deprecated since version 3.2.*

The **assertEqual()** method dispatches the equality check for objects of the same type to different type-specific methods. These methods are already implemented for most of the built-in types, but it's also possible to register new methods using **addTypeEqualityFunc()**:

**addTypeEqualityFunc**\((typeobj, function)\)
Registers a type-specific method called by **assertEqual()** to check if two objects of exactly the same \(typeobj\) (not subclasses) compare equal. \(function\) must take two positional arguments and a third \(msg=None\) keyword argument just as **assertEqual()** does. It must raise **self.failureException(msg)** when inequality between the first two parameters is detected – possibly providing useful information and explaining the inequalities in details in the error message.

New in version 2.7.

The list of type-specific methods automatically used by **assertEqual()** are summarized in the following table. Note that it's usually not necessary to invoke these methods directly.
<table>
<thead>
<tr>
<th>Method</th>
<th>Used to compare</th>
<th>New in</th>
</tr>
</thead>
<tbody>
<tr>
<td>assertMultiLineEqual(a, b)</td>
<td>strings</td>
<td>2.7</td>
</tr>
<tr>
<td>assertSequenceEqual(a, b)</td>
<td>sequences</td>
<td>2.7</td>
</tr>
<tr>
<td>assertListEqual(a, b)</td>
<td>lists</td>
<td>2.7</td>
</tr>
<tr>
<td>assertTupleEqual(a, b)</td>
<td>tuples</td>
<td>2.7</td>
</tr>
<tr>
<td>assertSetEqual(a, b)</td>
<td>sets or frozensets</td>
<td>2.7</td>
</tr>
<tr>
<td>assertDictEqual(a, b)</td>
<td>dicts</td>
<td>2.7</td>
</tr>
</tbody>
</table>

**assertMultiLineEqual(first, second, msg=None)**

Test that the multiline string `first` is equal to the string `second`. When not equal a diff of the two strings highlighting the differences will be included in the error message. This method is used by default when comparing strings with `assertEqual()`.

*New in version 2.7.*

**assertSequenceEqual(seq1, seq2, msg=None, seq_type=None)**

Tests that two sequences are equal. If a `seq_type` is supplied, both `seq1` and `seq2` must be instances of `seq_type` or a failure will be raised. If the sequences are different an error message is constructed that shows the difference between the two.

This method is not called directly by `assertEqual()`, but it’s used to implement `assertListEqual()` and `assertTupleEqual()`.

*New in version 2.7.*

**assertListEqual(list1, list2, msg=None)**

**assertTupleEqual(tuple1, tuple2, msg=None)**

Tests that two lists or tuples are equal. If not an error
message is constructed that shows only the differences between the two. An error is also raised if either of the parameters are of the wrong type. These methods are used by default when comparing lists or tuples with `assertEqual()`.

*New in version 2.7.*

**assertSetEqual** *(set1, set2, msg=None)*
Tests that two sets are equal. If not, an error message is constructed that lists the differences between the sets. This method is used by default when comparing sets or frozensets with `assertEqual()`.

Fails if either of `set1` or `set2` does not have a `set.difference()` method.

*New in version 2.7.*

**assertDictEqual** *(expected, actual, msg=None)*
Test that two dictionaries are equal. If not, an error message is constructed that shows the differences in the dictionaries. This method will be used by default to compare dictionaries in calls to `assertEqual()`.

*New in version 2.7.*

Finally the **TestCase** provides the following methods and attributes:

**fail**(msg=None)
Signals a test failure unconditionally, with `msg` or `None` for the error message.

**failureException**
This class attribute gives the exception raised by the test
method. If a test framework needs to use a specialized exception, possibly to carry additional information, it must subclass this exception in order to “play fair” with the framework. The initial value of this attribute is `AssertionError`.

**longMessage**

If set to `True` then any explicit failure message you pass in to the `assert` methods will be appended to the end of the normal failure message. The normal messages contain useful information about the objects involved, for example the message from `assertEqual` shows you the `repr` of the two unequal objects. Setting this attribute to `True` allows you to have a custom error message in addition to the normal one.

This attribute defaults to `False`, meaning that a custom message passed to an assert method will silence the normal message.

The class setting can be overridden in individual tests by assigning an instance attribute to `True` or `False` before calling the assert methods.

*New in version 2.7.*

**maxDiff**

This attribute controls the maximum length of diffs output by `assert` methods that report diffs on failure. It defaults to `80*8` characters. `assert` methods affected by this attribute are `assertSequenceEqual()` (including all the sequence comparison methods that delegate to it), `assertDictEqual()` and `assertMultiLineEqual()`.

Setting `maxDiff` to `None` means that there is no maximum length of diffs.
New in version 2.7.

Testing frameworks can use the following methods to collect information on the test:

**countTestCases()**

Return the number of tests represented by this test object. For `TestCase` instances, this will always be 1.

**defaultTestResult()**

Return an instance of the test result class that should be used for this test case class (if no other result instance is provided to the `run()` method).

For `TestCase` instances, this will always be an instance of `TestResult`; subclasses of `TestCase` should override this as necessary.

**id()**

Return a string identifying the specific test case. This is usually the full name of the test method, including the module and class name.

**shortDescription()**

Returns a description of the test, or `None` if no description has been provided. The default implementation of this method returns the first line of the test method’s docstring, if available, or `None`.

**addCleanup(function, *args, **kwargs)**

Add a function to be called after `tearDown()` to cleanup resources used during the test. Functions will be called in reverse order to the order they are added (LIFO). They are called with any arguments and keyword arguments passed into `addCleanup()` when they are added.
If `setUp()` fails, meaning that `tearDown()` is not called, then any cleanup functions added will still be called.

*New in version 2.7.*

**doCleanups()**

This method is called unconditionally after `tearDown()`, or after `setUp()` if `setUp()` raises an exception.

It is responsible for calling all the cleanup functions added by `addCleanup()`. If you need cleanup functions to be called *prior* to `tearDown()` then you can call `doCleanups()` yourself.

`doCleanups()` pops methods off the stack of cleanup functions one at a time, so it can be called at any time.

*New in version 2.7.*

```python
class unittest.FunctionTestCase(testFunc, setUp=None, tearDown=None, description=None)
```

This class implements the portion of the `TestCase` interface which allows the test runner to drive the test, but does not provide the methods which test code can use to check and report errors. This is used to create test cases using legacy test code, allowing it to be integrated into a `unittest`-based test framework.

### 25.3.7.1.1. Deprecated aliases

For historical reasons, some of the `TestCase` methods had one or more aliases that are now deprecated. The following table lists the correct names along with their deprecated aliases:

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Deprecated alias(es)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>assertEqual()</code></td>
<td><code>failUnlessEqual, assertEquals</code></td>
</tr>
</tbody>
</table>
assertNotEqual() failIfEqual
assertTrue() failUnless, assert_
assertFalse() failIf
assertRaises() failUnlessRaises
assertAlmostEqual() failUnlessAlmostEqual
assertNotAlmostEqual() failIfAlmostEqual

Deprecated since version 2.7: the aliases listed in the second column

25.3.7.2. Grouping tests

class unittest.TestSuite(tests=())

This class represents an aggregation of individual tests cases and test suites. The class presents the interface needed by the test runner to allow it to be run as any other test case. Running a TestSuite instance is the same as iterating over the suite, running each test individually.

If tests is given, it must be an iterable of individual test cases or other test suites that will be used to build the suite initially. Additional methods are provided to add test cases and suites to the collection later on.

TestSuite objects behave much like TestCase objects, except they do not actually implement a test. Instead, they are used to aggregate tests into groups of tests that should be run together. Some additional methods are available to add tests to TestSuite instances:

addTest(test)

Add a TestCase or TestSuite to the suite.
addTests(tests)
    Add all the tests from an iterable of TestCase and TestSuite instances to this test suite.

    This is equivalent to iterating over tests, calling addTest() for each element.

TestSuite shares the following methods with TestCase:

run(result)
    Run the tests associated with this suite, collecting the result into the test result object passed as result. Note that unlike testCase.run(), TestSuite.run() requires the result object to be passed in.

debug()
    Run the tests associated with this suite without collecting the result. This allows exceptions raised by the test to be propagated to the caller and can be used to support running tests under a debugger.

countTestCases()
    Return the number of tests represented by this test object, including all individual tests and sub-suites.

__iter__()
    Tests grouped by a TestSuite are always accessed by iteration. Subclasses can lazily provide tests by overriding __iter__(). Note that this method maybe called several times on a single suite (for example when counting tests or comparing for equality) so the tests returned must be the same for repeated iterations.

    Changed in version 2.7: In earlier versions the TestSuite accessed tests directly rather than through iteration, so
overriding `__iter__()` wasn't sufficient for providing tests.

In the typical usage of a `TestSuite` object, the `run()` method is invoked by a `TestRunner` rather than by the end-user test harness.

### 25.3.7.3. Loading and running tests

class `unittest.TestLoader`

The `TestLoader` class is used to create test suites from classes and modules. Normally, there is no need to create an instance of this class; the `unittest` module provides an instance that can be shared as `unittest.defaultTestLoader`. Using a subclass or instance, however, allows customization of some configurable properties.

`TestLoader` objects have the following methods:

`loadTestsFromTestCase(testCaseClass)`

Return a suite of all tests cases contained in the `TestCase`-derived `testCaseClass`.

`loadTestsFromModule(module)`

Return a suite of all tests cases contained in the given module. This method searches `module` for classes derived from `TestCase` and creates an instance of the class for each test method defined for the class.

**Note:** While using a hierarchy of `TestCase`-derived classes can be convenient in sharing fixtures and helper functions, defining test methods on base classes that are not intended to be instantiated directly does not play well with this method. Doing so, however, can be useful when the fixtures
are different and defined in subclasses.

If a module provides a `load_tests` function it will be called to load the tests. This allows modules to customize test loading. This is the `load_tests` protocol.

*Changed in version 2.7:* Support for `load_tests` added.

```python
loadTestsFromName(name, module=None)
```

Return a suite of all tests cases given a string specifier.

The specifier `name` is a “dotted name” that may resolve either to a module, a test case class, a test method within a test case class, a `TestSuite` instance, or a callable object which returns a `TestCase` or `TestSuite` instance. These checks are applied in the order listed here; that is, a method on a possible test case class will be picked up as “a test method within a test case class”, rather than “a callable object”.

For example, if you have a module `SampleTests` containing a `TestCase`-derived class `SampleTestCase` with three test methods (`test_one()`, `test_two()`, and `test_three()`), the specifier `'SampleTests.SampleTestCase'` would cause this method to return a suite which will run all three test methods. Using the specifier `'SampleTests.SampleTestCase.test_two'` would cause it to return a test suite which will run only the `test_two()` test method. The specifier can refer to modules and packages which have not been imported; they will be imported as a side-effect.

The method optionally resolves `name` relative to the given `module`.

```python
loadTestsFromNames(names, module=None)
```
Similar to `loadTestsFromName()`, but takes a sequence of names rather than a single name. The return value is a test suite which supports all the tests defined for each name.

**getTestCaseNames(testCaseClass)**

Return a sorted sequence of method names found within `testCaseClass`; this should be a subclass of `TestCase`.

**discover(start_dir, pattern='test*.py', top_level_dir=None)**

Find and return all test modules from the specified start directory, recursing into subdirectories to find them. Only test files that match `pattern` will be loaded. (Using shell style pattern matching.) Only module names that are importable (i.e. are valid Python identifiers) will be loaded.

All test modules must be importable from the top level of the project. If the start directory is not the top level directory then the top level directory must be specified separately.

If importing a module fails, for example due to a syntax error, then this will be recorded as a single error and discovery will continue.

If a test package name (directory with `__init__.py`) matches the pattern then the package will be checked for a `load_tests` function. If this exists then it will be called with `loader, tests, pattern`.

If `load_tests` exists then discovery does *not* recurse into the package, `load_tests` is responsible for loading all tests in the package.

The pattern is deliberately not stored as a loader attribute so that packages can continue discovery themselves. `top_level_dir` is stored so `load_tests` does not need to pass
this argument in to `loader.discover()`.

`start_dir` can be a dotted module name as well as a directory.

*New in version 2.7.*

The following attributes of a `TestLoader` can be configured either by subclassing or assignment on an instance:

**testMethodPrefix**
String giving the prefix of method names which will be interpreted as test methods. The default value is `'test'`.

This affects `getTestCaseNames()` and all the `loadTestsFrom*()` methods.

**sortTestMethodsUsing**
Function to be used to compare method names when sorting them in `getTestCaseNames()` and all the `loadTestsFrom*()` methods. The default value is the built-in `cmp()` function; the attribute can also be set to `None` to disable the sort.

**suiteClass**
Callable object that constructs a test suite from a list of tests. No methods on the resulting object are needed. The default value is the `TestSuite` class.

This affects all the `loadTestsFrom*()` methods.

**class** `unittest.TestResult`
This class is used to compile information about which tests have succeeded and which have failed.

A `TestResult` object stores the results of a set of tests. The `TestCase` and `TestSuite` classes ensure that results are properly recorded; test authors do not need to worry about recording the
outcome of tests.

Testing frameworks built on top of unittest may want access to the TestResult object generated by running a set of tests for reporting purposes; a TestResult instance is returned by the TestRunner.run() method for this purpose.

TestResult instances have the following attributes that will be of interest when inspecting the results of running a set of tests:

**errors**
A list containing 2-tuples of testCase instances and strings holding formatted tracebacks. Each tuple represents a test which raised an unexpected exception.

*Changed in version 2.2:* Contains formatted tracebacks instead of sys.exc_info() results.

**failures**
A list containing 2-tuples of testCase instances and strings holding formatted tracebacks. Each tuple represents a test where a failure was explicitly signalled using the testCase.fail*() or testCase.assert*() methods.

*Changed in version 2.2:* Contains formatted tracebacks instead of sys.exc_info() results.

**skipped**
A list containing 2-tuples of testCase instances and strings holding the reason for skipping the test.

*New in version 2.7.*

**expectedFailures**
A list containing 2-tuples of testCase instances and strings
holding formatted tracebacks. Each tuple represents an expected failure of the test case.

**unexpectedSuccesses**
A list containing `TestCase` instances that were marked as expected failures, but succeeded.

**shouldStop**
Set to `True` when the execution of tests should stop by `stop()`.

**testsRun**
The total number of tests run so far.

**buffer**
If set to true, `sys.stdout` and `sys.stderr` will be buffered in between `startTest()` and `stopTest()` being called. Collected output will only be echoed onto the real `sys.stdout` and `sys.stderr` if the test fails or errors. Any output is also attached to the failure / error message.

*New in version 2.7.*

**failfast**
If set to true `stop()` will be called on the first failure or error, halting the test run.

*New in version 2.7.*

**wasSuccessful()**
Return `True` if all tests run so far have passed, otherwise returns `False`.

**stop()**
This method can be called to signal that the set of tests being run should be aborted by setting the `shouldStop` attribute to
True. TestRunner objects should respect this flag and return without running any additional tests.

For example, this feature is used by the TextTestRunner class to stop the test framework when the user signals an interrupt from the keyboard. Interactive tools which provide TestRunner implementations can use this in a similar manner.

The following methods of the TestResult class are used to maintain the internal data structures, and may be extended in subclasses to support additional reporting requirements. This is particularly useful in building tools which support interactive reporting while tests are being run.

startTest(test)
    Called when the test case test is about to be run.

stopTest(test)
    Called after the test case test has been executed, regardless of the outcome.

startTestRun(test)
    Called once before any tests are executed.

    New in version 2.7.

stopTestRun(test)
    Called once after all tests are executed.

    New in version 2.7.

addError(test, err)
    Called when the test case test raises an unexpected exception err is a tuple of the form returned by sys.exc_info(): (type, value, traceback).
The default implementation appends a tuple \((\text{test}, \text{formatted\_err})\) to the instance's `errors` attribute, where `formatted\_err` is a formatted traceback derived from `err`.

**addFailure**(\text{test}, \text{err})
Called when the test case `test` signals a failure. `err` is a tuple of the form returned by `\text{sys.exc\_info()}`: \((\text{type}, \text{value}, \text{traceback})\).

The default implementation appends a tuple \((\text{test}, \text{formatted\_err})\) to the instance's `failures` attribute, where `formatted\_err` is a formatted traceback derived from `err`.

**addSuccess**(\text{test})
Called when the test case `test` succeeds.

The default implementation does nothing.

**addSkip**(\text{test}, \text{reason})
Called when the test case `test` is skipped. `reason` is the reason the test gave for skipping.

The default implementation appends a tuple \((\text{test}, \text{reason})\) to the instance's `skipped` attribute.

**addExpectedFailure**(\text{test}, \text{err})
Called when the test case `test` fails, but was marked with the `expectedFailure()` decorator.

The default implementation appends a tuple \((\text{test}, \text{formatted\_err})\) to the instance's `expectedFailures` attribute, where `formatted\_err` is a formatted traceback derived from `err`. 
addUnexpectedSuccess(test)
    Called when the test case `test` was marked with the `expectedFailure()` decorator, but succeeded.

    The default implementation appends the test to the instance’s `unexpectedSuccesses` attribute.

class unittest.TextTestResult(stream, descriptions, verbosity)
    A concrete implementation of `TestResult` used by the `TextTestRunner`.

    New in version 2.7: This class was previously named `_TextTestResult`. The old name still exists as an alias but is deprecated.

unittest.defaultTestLoader
    Instance of the `TestLoader` class intended to be shared. If no customization of the `TestLoader` is needed, this instance can be used instead of repeatedly creating new instances.

class unittest.TextTestRunner(stream=sys.stderr, descriptions=True, verbosity=1)
    A basic test runner implementation which prints results on standard error. It has a few configurable parameters, but is essentially very simple. Graphical applications which run test suites should provide alternate implementations.

    `_makeResult()`
    This method returns the instance of `TestResult` used by `run()`. It is not intended to be called directly, but can be overridden in subclasses to provide a custom `TestResult`.

    `_makeResult()` instantiates the class or callable passed in the `TextTestRunner` constructor as the `resultclass` argument. It
defaults to `TextTestResult` if no `resultclass` is provided. The result class is instantiated with the following arguments:

```
stream, descriptions, verbosity
```

```
unittest.main([module, defaultTest, argv, testRunner, testLoader, exit, verbosity, failfast, catchbreak, buffer])
```

A command-line program that runs a set of tests; this is primarily for making test modules conveniently executable. The simplest use for this function is to include the following line at the end of a test script:

```
if __name__ == '__main__':
    unittest.main()
```

You can run tests with more detailed information by passing in the verbosity argument:

```
if __name__ == '__main__':
    unittest.main(verbosity=2)
```

The `testRunner` argument can either be a test runner class or an already created instance of it. By default `main` calls `sys.exit()` with an exit code indicating success or failure of the tests run.

`main` supports being used from the interactive interpreter by passing in the argument `exit=False`. This displays the result on standard output without calling `sys.exit()`:

```
>>> from unittest import main
>>> main(module='test_module', exit=False)
```

The `failfast`, `catchbreak` and `buffer` parameters have the same effect as the same-name command-line options.
Calling `main` actually returns an instance of the `TestProgram` class. This stores the result of the tests run as the `result` attribute.

*Changed in version 2.7:* The `exit`, `verbosity`, `failfast`, `catchbreak` and `buffer` parameters were added.

### 25.3.7.3.1. load_tests Protocol

*New in version 2.7.*

Modules or packages can customize how tests are loaded from them during normal test runs or test discovery by implementing a function called `load_tests`.

If a test module defines `load_tests` it will be called by `TestLoader.loadTestsFromModule()` with the following arguments:

```python
load_tests(loader, standard_tests, None)
```

It should return a `TestSuite`.

`loader` is the instance of `TestLoader` doing the loading. `standard_tests` are the tests that would be loaded by default from the module. It is common for test modules to only want to add or remove tests from the standard set of tests. The third argument is used when loading packages as part of test discovery.

A typical `load_tests` function that loads tests from a specific set of `TestCase` classes may look like:

```python
test_cases = (TestCase1, TestCase2, TestCase3)

def load_tests(loader, tests, pattern):
    suite = TestSuite()
    for test_class in test_cases:
        ...
If discovery is started, either from the command line or by calling `TestLoader.discover()`, with a pattern that matches a package name then the package `__init__.py` will be checked for `load_tests`.

**Note:** The default pattern is ‘test*.py’. This matches all Python files that start with ‘test’ but *won’t* match any test directories.

A pattern like ‘test*’ will match test packages as well as modules.

If the package `__init__.py` defines `load_tests` then it will be called and discovery not continued into the package. `load_tests` is called with the following arguments:

```python
load_tests(loader, standard_tests, pattern)
```

This should return a `TestSuite` representing all the tests from the package. (`standard_tests` will only contain tests collected from `__init__.py`.)

Because the pattern is passed into `load_tests` the package is free to continue (and potentially modify) test discovery. A ‘do nothing’ `load_tests` function for a test package would look like:

```python
def load_tests(loader, standard_tests, pattern):
    # top level directory cached on loader instance
    this_dir = os.path.dirname(__file__)
    package_tests = loader.discover(start_dir=this_dir, pattern=pattern)
    standard_tests.addTests(package_tests)
    return standard_tests
```
Class and module level fixtures are implemented in TestSuite. When the test suite encounters a test from a new class then tearDownClass() from the previous class (if there is one) is called, followed by setUpClass() from the new class.

Similarly if a test is from a different module from the previous test then tearDownModule from the previous module is run, followed by setUpModule from the new module.

After all the tests have run the final tearDownClass and tearDownModule are run.

Note that shared fixtures do not play well with [potential] features like test parallelization and they break test isolation. They should be used with care.

The default ordering of tests created by the unittest test loaders is to group all tests from the same modules and classes together. This will lead to setUpClass / setUpModule (etc) being called exactly once per class and module. If you randomize the order, so that tests from different modules and classes are adjacent to each other, then these shared fixture functions may be called multiple times in a single test run.

Shared fixtures are not intended to work with suites with non-standard ordering. A BaseTestSuite still exists for frameworks that don’t want to support shared fixtures.

If there are any exceptions raised during one of the shared fixture functions the test is reported as an error. Because there is no corresponding test instance an _ErrorHolder object (that has the
same interface as a `TestCase`) is created to represent the error. If you are just using the standard unittest test runner then this detail doesn’t matter, but if you are a framework author it may be relevant.

### 25.3.8.1. setUpClass and tearDownClass

These must be implemented as class methods:

```python
import unittest

class Test(unittest.TestCase):
    @classmethod
    def setUpClass(cls):
        cls._connection = createExpensiveConnectionObject()

    @classmethod
    def tearDownClass(cls):
        cls._connection.destroy()
```

If you want the `setUpClass` and `tearDownClass` on base classes called then you must call up to them yourself. The implementations in `TestCase` are empty.

If an exception is raised during a `setUpClass` then the tests in the class are not run and the `tearDownClass` is not run. Skipped classes will not have `setUpClass` or `tearDownClass` run. If the exception is a `SkipTest` exception then the class will be reported as having been skipped instead of as an error.

### 25.3.8.2. setUpModule and tearDownModule

These should be implemented as functions:

```python
def setUpModule():
    createConnection()

def tearDownModule():
```
If an exception is raised in a `setUpModule` then none of the tests in the module will be run and the `tearDownModule` will not be run. If the exception is a `SkipTest` exception then the module will be reported as having been skipped instead of as an error.
25.3.9. Signal Handling

The `-c/--catch` command-line option to `unittest`, along with the `catchbreak` parameter to `unittest.main()`, provide more friendly handling of control-C during a test run. With catch break behavior enabled control-C will allow the currently running test to complete, and the test run will then end and report all the results so far. A second control-c will raise a `KeyboardInterrupt` in the usual way.

The control-c handling signal handler attempts to remain compatible with code or tests that install their own `signal.SIGINT` handler. If the `unittest` handler is called but isn’t the installed `signal.SIGINT` handler, i.e. it has been replaced by the system under test and delegated to, then it calls the default handler. This will normally be the expected behavior by code that replaces an installed handler and delegates to it. For individual tests that need `unittest` control-c handling disabled the `removeHandler()` decorator can be used.

There are a few utility functions for framework authors to enable control-c handling functionality within test frameworks.

`unittest.installHandler()`

Install the control-c handler. When a `signal.SIGINT` is received (usually in response to the user pressing control-c) all registered results have `stop()` called.

*New in version 2.7.*

`unittest.registerResult(result)`

Register a `TestResult` object for control-c handling. Registering a result stores a weak reference to it, so it doesn’t prevent the result from being garbage collected.
Registering a `TestResult` object has no side-effects if control-c handling is not enabled, so test frameworks can unconditionally register all results they create independently of whether or not handling is enabled.

*New in version 2.7.*

```
unittest.removeResult(result)
```

Remove a registered result. Once a result has been removed then `stop()` will no longer be called on that result object in response to a control-c.

*New in version 2.7.*

```
unittest.removeHandler(function=None)
```

When called without arguments this function removes the control-c handler if it has been installed. This function can also be used as a test decorator to temporarily remove the handler whilst the test is being executed:

```
@unittest.removeHandler
def test_signal_handling(self):
    ...
```

*New in version 2.7.*
25.4. 2to3 - Automated Python 2 to 3 code translation

2to3 is a Python program that reads Python 2.x source code and applies a series of fixers to transform it into valid Python 3.x code. The standard library contains a rich set of fixers that will handle almost all code. 2to3 supporting library lib2to3 is, however, a flexible and generic library, so it is possible to write your own fixers for 2to3. lib2to3 could also be adapted to custom applications in which Python code needs to be edited automatically.
25.4.1. Using 2to3

2to3 will usually be installed with the Python interpreter as a script. It is also located in the `Tools/scripts` directory of the Python root.

2to3’s basic arguments are a list of files or directories to transform. The directories are to recursively traversed for Python sources.

Here is a sample Python 2.x source file, `example.py`:

```python
def greet(name):
    print "Hello, {0}".format(name)
print "What's your name?"
name = raw_input()
greet(name)
```

It can be converted to Python 3.x code via 2to3 on the command line:

```
$ 2to3 example.py
```

A diff against the original source file is printed. 2to3 can also write the needed modifications right back to the source file. (A backup of the original file is made unless `-n` is also given.) Writing the changes back is enabled with the `-w` flag:

```
$ 2to3 -w example.py
```

After transformation, `example.py` looks like this:

```python
def greet(name):
    print("Hello, {0}".format(name))
print("What's your name?")
name = input()
greet(name)
```
Comments and exact indentation are preserved throughout the translation process.

By default, 2to3 runs a set of predefined fixers. The -l flag lists all available fixers. An explicit set of fixers to run can be given with -f. Likewise the -x explicitly disables a fixer. The following example runs only the imports and has_key fixers:

```
$ 2to3 -f imports -f has_key example.py
```

This command runs every fixer except the apply fixer:

```
$ 2to3 -x apply example.py
```

Some fixers are explicit, meaning they aren’t run by default and must be listed on the command line to be run. Here, in addition to the default fixers, the idioms fixer is run:

```
$ 2to3 -f all -f idioms example.py
```

Notice how passing all enables all default fixers.

Sometimes 2to3 will find a place in your source code that needs to be changed, but 2to3 cannot fix automatically. In this case, 2to3 will print a warning beneath the diff for a file. You should address the warning in order to have compliant 3.x code.

2to3 can also refactor doctests. To enable this mode, use the -d flag. Note that only doctests will be refactored. This also doesn’t require the module to be valid Python. For example, doctest like examples in a reST document could also be refactored with this option.

The -v option enables output of more information on the translation process.

Since some print statements can be parsed as function calls or
statements, 2to3 cannot always read files containing the print function. When 2to3 detects the presence of the `from __future__
import print_function` compiler directive, it modifies its internal grammar to interpret `print()` as a function. This change can also be enabled manually with the `-p` flag. Use `-p` to run fixers on code that already has had its print statements converted.
25.4.2. Fixers

Each step of transforming code is encapsulated in a fixer. The command `2to3 -l` lists them. As documented above, each can be turned on and off individually. They are described here in more detail.

**apply**

Removes usage of `apply()`. For example `apply(function, *args, **kwargs)` is converted to `function(*args, **kwargs).

**basestring**

Converts `basestring` to `str`.

**buffer**

Converts `buffer` to `memoryview`. This fixer is optional because the `memoryview` API is similar but not exactly the same as that of `buffer`.

**callable**

Converts `callable(x)` to `isinstance(x, collections.Callable)`, adding an import to `collections` if needed.

**dict**

Fixes dictionary iteration methods. `dict.iteritems()` is converted to `dict.items()`, `dict.iterkeys()` to `dict.keys()`, and `dict.itervalues()` to `dict.values()`. Similarly, `dict.viewitems()`, `dict.viewkeys()` and `dict.viewvalues()` are converted respectively to `dict.items()`, `dict.keys()` and `dict.values()`. It also wraps existing usages of `dict.items()`, `dict.keys()`, and `dict.values()` in a call to `list`.

**except**
Converts `except X, T` to `except X as T`.

**exec**

Converts the `exec` statement to the `exec()` function.

**execfile**

Removes usage of `execfile()`. The argument to `execfile()` is wrapped in calls to `open()`, `compile()`, and `exec()`.

**exitfunc**

Changes assignment of `sys.exitfunc` to use of the `atexit` module.

**filter**

Wraps `filter()` usage in a `list` call.

**funcattrs**

Fixes function attributes that have been renamed. For example, `my_function.func_closure` is converted to `my_function.__closure__`.

**future**

Removes `from __future__ import new_feature` statements.

**getcwdu**

Renames `os.getcwdu()` to `os.getcwd()`.

**has_key**

Changes `dict.has_key(key)` to `key in dict`.

**idioms**

This optional fixer performs several transformations that make Python code more idiomatic. Type comparisons like `type(x) is SomeClass` and `type(x) == SomeClass` are converted to `isinstance(x, SomeClass)`. `while 1` becomes `while True`. This
fixer also tries to make use of `sorted()` in appropriate places. For example, this block

```python
L = list(some_iterable)
L.sort()
```

is changed to

```python
L = sorted(some_iterable)
```

**import**
Detects sibling imports and converts them to relative imports.

**imports**
Handles module renames in the standard library.

**imports2**
Handles other modules renames in the standard library. It is separate from the `imports` fixer only because of technical limitations.

**input**
Converts `input(prompt)` to `eval(input(prompt))`

**intern**
Converts `intern()` to `sys.intern()`.

**isinstance**
Fixes duplicate types in the second argument of `isinstance()`. For example, `isinstance(x, (int, int))` is converted to `isinstance(x, (int))`.

**itertools_imports**
Removes imports of `itertools.ifilter()`, `itertools.izip()`, and `itertools.imap()`. Imports of `itertools.ifilterfalse()` are also changed to `itertools.filterfalse()`. 
itertools
Changes usage of `itertools.ifilter()`, `itertools.izip()` and `itertools.imap()` to their built-in equivalents. `itertools.ifilterfalse()` is changed to `itertools.filterfalse()`.

long
Strips the `L` prefix on long literals and renames `long` to `int`.

map
Wraps `map()` in a `list` call. It also changes `map(None, x)` to `list(x)`. Using `from future_builtins import map` disables this fixer.

metaclass
Converts the old metaclass syntax (`__metaclass__ = Meta` in the class body) to the new (`class X(metaclass=Meta)`).

methodattrs
Fixes old method attribute names. For example, `meth.im_func` is converted to `meth.__func__`.

ne
Converts the old not-equal syntax, `<>`, to `!=`.

next
Converts the use of iterator's `next()` methods to the `next()` function. It also renames `next()` methods to `__next__()`.

nonzero
Renames `__nonzero__()` to `__bool__()`.

numliterals
Converts octal literals into the new syntax.
paren
Add extra parenthesis where they are required in list comprehensions. For example, [x for x in 1, 2] becomes [x for x in (1, 2)].

print
Converts the print statement to the print() function.

raise
Converts raise E, V to raise E(V), and raise E, V, T to raise E(V).with_traceback(T). If E is a tuple, the translation will be incorrect because substituting tuples for exceptions has been removed in 3.0.

raw_input
Converts raw_input() to input().

reduce
Handles the move of reduce() to functools.reduce().

renames
Changes sys.maxint to sys.maxsize.

repr
Replaces backtick repr with the repr() function.

set_literal
Replaces use of the set constructor with set literals. This fixer is optional.

standard_error
Renames StandardError to Exception.

sys_exc
Changes the deprecated sys.exc_value, sys.exc_type,
sys.exc_traceback to use sys.exc_info().

throw
Fixes the API change in generator's throw() method.

tuple_params
Removes implicit tuple parameter unpacking. This fixer inserts temporary variables.

types
Fixes code broken from the removal of some members in the types module.

unicode
Renames unicode to str.

urllib
Handles the rename of urllib and urllib2 to the urllib package.

ws_comma
Removes excess whitespace from comma separated items. This fixer is optional.

xrange
Renames xrange() to range() and wraps existing range() calls with list.

xreadlines
Changes for x in file.xreadlines() to for x in file.

zip
Wraps zip() usage in a list call. This is disabled when from future_builtins import zip appears.
Note: The lib2to3 API should be considered unstable and may change drastically in the future.
25.5. test — Regression tests package for Python

**Note:** The test package is meant for internal use by Python only. It is documented for the benefit of the core developers of Python. Any use of this package outside of Python’s standard library is discouraged as code mentioned here can change or be removed without notice between releases of Python.

The test package contains all regression tests for Python as well as the modules test.test_support and test.regrtest. test.test_support is used to enhance your tests while test.regrtest drives the testing suite.

Each module in the test package whose name starts with test_ is a testing suite for a specific module or feature. All new tests should be written using the unittest or doctest module. Some older tests are written using a “traditional” testing style that compares output printed to `sys.stdout`; this style of test is considered deprecated.

**See also:**

**Module unittest**

Writing PyUnit regression tests.

**Module doctest**

Tests embedded in documentation strings.
25.5.1. Writing Unit Tests for the `test` package

It is preferred that tests that use the `unittest` module follow a few guidelines. One is to name the test module by starting it with `test_` and end it with the name of the module being tested. The test methods in the test module should start with `test_` and end with a description of what the method is testing. This is needed so that the methods are recognized by the test driver as test methods. Also, no documentation string for the method should be included. A comment (such as `# Tests function returns only True or False`) should be used to provide documentation for test methods. This is done because documentation strings get printed out if they exist and thus what test is being run is not stated.

A basic boilerplate is often used:

```python
import unittest
from test import test_support

class MyTestCase1(unittest.TestCase):
    # Only use setUp() and tearDown() if necessary

def setUp(self):
    ... code to execute in preparation for tests ...

def tearDown(self):
    ... code to execute to clean up after tests ...

def test_feature_one(self):
    # Test feature one.
    ... testing code ...

def test_feature_two(self):
    # Test feature two.
    ... testing code ...
```
This boilerplate code allows the testing suite to be run by \texttt{test.regrtest} as well as on its own as a script.

The goal for regression testing is to try to break code. This leads to a few guidelines to be followed:

- The testing suite should exercise all classes, functions, and constants. This includes not just the external API that is to be presented to the outside world but also “private” code.

- Whitebox testing (examining the code being tested when the tests are being written) is preferred. Blackbox testing (testing only the published user interface) is not complete enough to make sure all boundary and edge cases are tested.

- Make sure all possible values are tested including invalid ones. This makes sure that not only all valid values are acceptable but also that improper values are handled correctly.

- Exhaust as many code paths as possible. Test where branching occurs and thus tailor input to make sure as many different paths through the code are taken.
• Add an explicit test for any bugs discovered for the tested code. This will make sure that the error does not crop up again if the code is changed in the future.

• Make sure to clean up after your tests (such as close and remove all temporary files).

• If a test is dependent on a specific condition of the operating system then verify the condition already exists before attempting the test.

• Import as few modules as possible and do it as soon as possible. This minimizes external dependencies of tests and also minimizes possible anomalous behavior from side-effects of importing a module.

• Try to maximize code reuse. On occasion, tests will vary by something as small as what type of input is used. Minimize code duplication by subclassing a basic test class with a class that specifies the input:

```python
class TestFuncAcceptsSequences(unittest.TestCase):
    func = mySuperWhammyFunction

    def test_func(self):
        self.func(self.arg)

class AcceptLists(TestFuncAcceptsSequences):
    arg = [1, 2, 3]

class AcceptStrings(TestFuncAcceptsSequences):
    arg = 'abc'

class AcceptTuples(TestFuncAcceptsSequences):
    arg = (1, 2, 3)
```

See also:
Test Driven Development

A book by Kent Beck on writing tests before code.
The `test.regrtest` module can be run as a script to drive Python's regression test suite, thanks to the `-m` option: `python -m test.regrtest`. Running the script by itself automatically starts running all regression tests in the `test` package. It does this by finding all modules in the package whose name starts with `test_`, importing them, and executing the function `test_main()` if present. The names of tests to execute may also be passed to the script. Specifying a single regression test (`python -m test.regrtest test_spam`) will minimize output and only print whether the test passed or failed and thus minimize output.

Running `test.regrtest` directly allows what resources are available for tests to use to be set. You do this by using the `-u` command-line option. Run `python -m test.regrtest -u all` to turn on all resources; specifying `all` as an option for `-u` enables all possible resources. If all but one resource is desired (a more common case), a comma-separated list of resources that are not desired may be listed after `all`. The command `python -m test.regrtest -u all,-audio,-largefile` will run `test.regrtest` with all resources except the `audio` and `largefile` resources. For a list of all resources and more command-line options, run `python -m test.regrtest -h`.

Some other ways to execute the regression tests depend on what platform the tests are being executed on. On Unix, you can run `make test` at the top-level directory where Python was built. On Windows, executing `rt.bat` from your `PCBuild` directory will run all regression tests.
25.6. `test.test_support` — Utility functions for tests

**Note:** The `test.test_support` module has been renamed to `test.support` in Python 3.x.

The `test.test_support` module provides support for Python's regression tests.

This module defines the following exceptions:

- **`TestFailed`** exception
  
  Exception to be raised when a test fails. This is deprecated in favor of `unittest`-based tests and `unittest.TestCase`'s assertion methods.

- **`ResourceDenied`** exception
  
  Subclass of `unittest.SkipTest`. Raised when a resource (such as a network connection) is not available. Raised by the `requires()` function.

The `test.test_support` module defines the following constants:

- **`verbose`**
  
  `True` when verbose output is enabled. Should be checked when more detailed information is desired about a running test. `verbose` is set by `test.regrtest`.

- **`have_unicode`**
  
  `True` when Unicode support is available.

- **`is_jython`**
  
  `True` if the running interpreter is Jython.
test.test_support. **TESTFN**
   
   Set to a name that is safe to use as the name of a temporary file. Any temporary file that is created should be closed and unlinked (removed).

The **test.test_support** module defines the following functions:

**test.test_support. forget(module_name)**
   
   Remove the module named `module_name` from `sys.modules` and delete any byte-compiled files of the module.

**test.test_support. is_resource_enabled(resource)**
   
   Return `True` if `resource` is enabled and available. The list of available resources is only set when `test.regrtest` is executing the tests.

**test.test_support. requires(resource[, msg])**
   
   Raise `ResourceDenied` if `resource` is not available. `msg` is the argument to `ResourceDenied` if it is raised. Always returns `True` if called by a function whose `__name__` is `('__main__')`. Used when tests are executed by `test.regrtest`.

**test.test_support. findfile(filename)**

   Return the path to the file named `filename`. If no match is found `filename` is returned. This does not equal a failure since it could be the path to the file.

**test.test_support. run_unittest(*classes)**

   Execute `unittest.TestCase` subclasses passed to the function. The function scans the classes for methods starting with the prefix `test_` and executes the tests individually.

   It is also legal to pass strings as parameters; these should be keys in `sys.modules`. Each associated module will be scanned by
unittest.TestLoader.loadTestsFromModule(). This is usually seen in the following `test_main()` function:

```python
def test_main():
    test_support.run_unittest(__name__)
```

This will run all tests defined in the named module.

test.test_support. **check_warnings**(*filters, quiet=True*)

A convenience wrapper for `warnings.catch_warnings()` that makes it easier to test that a warning was correctly raised. It is approximately equivalent to calling `warnings.catch_warnings(record=True)` with `warnings.simplefilter()` set to `always` and with the option to automatically validate the results that are recorded.

`check_warnings` accepts 2-tuples of the form ("message regexp", WarningCategory) as positional arguments. If one or more filters are provided, or if the optional keyword argument `quiet` is `False`, it checks to make sure the warnings are as expected: each specified filter must match at least one of the warnings raised by the enclosed code or the test fails, and if any warnings are raised that do not match any of the specified filters the test fails. To disable the first of these checks, set `quiet` to `True`.

If no arguments are specified, it defaults to:

```python
check_warnings(("", Warning), quiet=True)
```

In this case all warnings are caught and no errors are raised.

On entry to the context manager, a `WarningRecorder` instance is returned. The underlying warnings list from `catch_warnings()` is available via the recorder object’s `warnings` attribute. As a convenience, the attributes of the object representing the most
recent warning can also be accessed directly through the recorder object (see example below). If no warning has been raised, then any of the attributes that would otherwise be expected on an object representing a warning will return None.

The recorder object also has a `reset()` method, which clears the warnings list.

The context manager is designed to be used like this:

```python
with check_warnings("assertion is always true", SyntaxWarning("", UserWarning)):
    exec('assert(False, "Hey!")')
    warnings.warn(UserWarning("Hide me!"))
```

In this case if either warning was not raised, or some other warning was raised, `check_warnings()` would raise an error.

When a test needs to look more deeply into the warnings, rather than just checking whether or not they occurred, code like this can be used:

```python
with check_warnings(quiet=True) as w:
    warnings.warn("foo")
    assert str(w.args[0]) == "foo"
    warnings.warn("bar")
    assert str(w.args[0]) == "bar"
    assert str(w.warnings[0].args[0]) == "foo"
    assert str(w.warnings[1].args[0]) == "bar"
    w.reset()
    assert len(w.warnings) == 0
```

Here all warnings will be caught, and the test code tests the captured warnings directly.

*New in version 2.6.*

*Changed in version 2.7:* New optional arguments `filters` and `quiet`. 
test.test_support.\texttt{check\_py3k\_warnings(*filters, quiet=False)}

Similar to \texttt{check\_warnings()}, but for Python 3 compatibility warnings. If \texttt{sys.py3kwarning == 1}, it checks if the warning is effectively raised. If \texttt{sys.py3kwarning == 0}, it checks that no warning is raised. It accepts 2-tuples of the form ("message regexp", WarningCategory) as positional arguments. When the optional keyword argument \texttt{quiet} is \texttt{True}, it does not fail if a filter catches nothing. Without arguments, it defaults to:

\begin{verbatim}
check_py3k_warnings(("", DeprecationWarning), quiet=False)
\end{verbatim}

\textit{New in version 2.7.}

\begin{verbatim}
with captured_stdout() as s:
    print "hello"
assert s.getvalue() == "hello"
\end{verbatim}

\textit{New in version 2.6.}

\texttt{test.test_support.import\_module(name, deprecated=False)}

This function imports and returns the named module. Unlike a normal import, this function raises \texttt{unittest.SkipTest} if the module cannot be imported.

Module and package deprecation messages are suppressed during this import if \texttt{deprecated} is \texttt{True}.

\textit{New in version 2.7.}
**t**est.t**e**st.s**u**pp**o**rt. **i**mport_**f**r**e**s**h** _**m**u**l**l**u**d**e**(name, fresh=(), blocked=(), deprecated=False)

This function imports and returns a fresh copy of the named Python module by removing the named module from `sys.modules` before doing the import. Note that unlike `reload()`, the original module is not affected by this operation.

`fresh` is an iterable of additional module names that are also removed from the `sys.modules` cache before doing the import.

`blocked` is an iterable of module names that are replaced with `0` in the module cache during the import to ensure that attempts to import them raise `ImportError`.

The named module and any modules named in the `fresh` and `blocked` parameters are saved before starting the import and then reinserted into `sys.modules` when the fresh import is complete.

Module and package deprecation messages are suppressed during this import if `deprecated` is `True`.

This function will raise `unittest.SkipTest` if the named module cannot be imported.

**Example use:**

```python
# Get copies of the warnings module for testing without
# affecting the version being used by the rest of the test suite
# One copy uses the C implementation, the other is forced to
# the pure Python fallback implementation
py_warnings = import_fresh_module('warnings', blocked=['_warnings'])
c_warnings = import_fresh_module('warnings', fresh=['_warnings'])
```

New in version 2.7.

The `test.test_support` module defines the following classes:
class test.test_support.TransientResource(exc[, **kwargs])

Instances are a context manager that raises ResourceDenied if the specified exception type is raised. Any keyword arguments are treated as attribute/value pairs to be compared against any exception raised within the with statement. Only if all pairs match properly against attributes on the exception is ResourceDenied raised.

New in version 2.6.

class test.test_support.EnvironmentVarGuard

Class used to temporarily set or unset environment variables. Instances can be used as a context manager and have a complete dictionary interface for querying/modifying the underlying os.environ. After exit from the context manager all changes to environment variables done through this instance will be rolled back.

New in version 2.6.

Changed in version 2.7: Added dictionary interface.

EnvironmentVarGuard.set(envvar, value)

Temporarily set the environment variable envvar to the value of value.

EnvironmentVarGuard.unset(envvar)

Temporarily unset the environment variable envvar.

class test.test_support.WarningsRecorder

Class used to record warnings for unit tests. See documentation of check_warnings() above for more details.

New in version 2.6.
26. Debugging and Profiling

These libraries help you with Python development: the debugger enables you to step through code, analyze stack frames and set breakpoints etc., and the profilers run code and give you a detailed breakdown of execution times, allowing you to identify bottlenecks in your programs.

    - **26.7.1.3. Filters**
  - **26.7.2. Programmatic Interface**
The **bdb** module handles basic debugger functions, like setting breakpoints or managing execution via the debugger.

The following exception is defined:

```python
exception bdb.BdbQuit
```

Exception raised by the **Bdb** class for quitting the debugger.

The **bdb** module also defines two classes:

```python
class bdb.Breakpoint(self, file, line[, temporary=0[, cond=None[, funcname=None]]]])
```

This class implements temporary breakpoints, ignore counts, disabling and (re-)enabling, and conditionals.

Breakpoints are indexed by number through a list called `bpbynumber` and by `(file, line)` pairs through `bplist`. The former points to a single instance of class `Breakpoint`. The latter points to a list of such instances since there may be more than one breakpoint per line.

When creating a breakpoint, its associated filename should be in canonical form. If a `funcname` is defined, a breakpoint hit will be counted when the first line of that function is executed. A conditional breakpoint always counts a hit.

**Breakpoint** instances have the following methods:

```python
deleteMe()
```

Delete the breakpoint from the list associated to a file/line. If it is the last breakpoint in that position, it also deletes the entry for the file/line.
enable()
   Mark the breakpoint as enabled.

disable()
   Mark the breakpoint as disabled.

pprint([out])
   Print all the information about the breakpoint:
   - The breakpoint number.
   - If it is temporary or not.
   - Its file,line position.
   - The condition that causes a break.
   - If it must be ignored the next N times.
   - The breakpoint hit count.

class bdb. Bdb(skip=None)
   The Bdb class acts as a generic Python debugger base class.

   This class takes care of the details of the trace facility; a derived class should implement user interaction. The standard debugger class (pdb.Pdb) is an example.

   The skip argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. Whether a frame is considered to originate in a certain module is determined by the __name__ in the frame globals.

   New in version 2.7: The skip argument.

   The following methods of Bdb normally don’t need to be overridden.

   canonic(filename)
Auxiliary method for getting a filename in a canonical form, that is, as a case-normalized (on case-insensitive filesystems) absolute path, stripped of surrounding angle brackets.

reset()
Set the botframe, stopframe, returnframe and quitting attributes with values ready to start debugging.

trace_dispatch(frame, event, arg)
This function is installed as the trace function of debugged frames. Its return value is the new trace function (in most cases, that is, itself).

The default implementation decides how to dispatch a frame, depending on the type of event (passed as a string) that is about to be executed. event can be one of the following:

- "line": A new line of code is going to be executed.
- "call": A function is about to be called, or another code block entered.
- "return": A function or other code block is about to return.
- "exception": An exception has occurred.
- "c_call": A C function is about to be called.
- "c_return": A C function has returned.
- "c_exception": A C function has raised an exception.

For the Python events, specialized functions (see below) are called. For the C events, no action is taken.

The arg parameter depends on the previous event.

See the documentation for sys.settrace() for more information on the trace function. For more information on code and frame objects, refer to The standard type hierarchy.
**dispatch_line(frame)**
If the debugger should stop on the current line, invoke the `user_line()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_line()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_call(frame, arg)**
If the debugger should stop on this function call, invoke the `user_call()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_call()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_return(frame, arg)**
If the debugger should stop on this function return, invoke the `user_return()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_return()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

**dispatch_exception(frame, arg)**
If the debugger should stop at this exception, invokes the `user_exception()` method (which should be overridden in subclasses). Raise a `BdbQuit` exception if the `Bdb.quitting` flag is set (which can be set from `user_exception()`). Return a reference to the `trace_dispatch()` method for further tracing in that scope.

Normally derived classes don't override the following methods,
but they may if they want to redefine the definition of stopping and breakpoints.

**stop_here(frame)**

This method checks if the frame is somewhere below botframe in the call stack. botframe is the frame in which debugging started.

**break_here(frame)**

This method checks if there is a breakpoint in the filename and line belonging to frame or, at least, in the current function. If the breakpoint is a temporary one, this method deletes it.

**breakAnywhere(frame)**

This method checks if there is a breakpoint in the filename of the current frame.

Derived classes should override these methods to gain control over debugger operation.

**user_call(frame, argument_list)**

This method is called from dispatch_call() when there is the possibility that a break might be necessary anywhere inside the called function.

**user_line(frame)**

This method is called from dispatch_line() when either stop_here() or break_here() yields True.

**user_return(frame, return_value)**

This method is called from dispatch_return() when stop_here() yields True.

**user_exception(frame, exc_info)**

This method is called from dispatch_exception() when
stop_here() yields True.

do_clear(arg)
Handle how a breakpoint must be removed when it is a temporary one.

This method must be implemented by derived classes.

Derived classes and clients can call the following methods to affect the stepping state.

set_step()
Stop after one line of code.

set_next(frame)
Stop on the next line in or below the given frame.

set_return(frame)
Stop when returning from the given frame.

set_until(frame)
Stop when the line with the line no greater than the current one is reached or when returning from current frame

set_trace([frame])
Start debugging from frame. If frame is not specified, debugging starts from caller’s frame.

set_continue()
Stop only at breakpoints or when finished. If there are no breakpoints, set the system trace function to None.

set_quit()
Set the quitting attribute to True. This raises BdbQuit in the next call to one of the dispatch_*() methods.
Derived classes and clients can call the following methods to manipulate breakpoints. These methods return a string containing an error message if something went wrong, or None if all is well.

```python
set_break(filename, lineno[, temporary=0[, cond[, funcname]]]])
    Set a new breakpoint. If the lineno line doesn't exist for the filename passed as argument, return an error message. The filename should be in canonical form, as described in the canonic() method.

clear_break(filename, lineno)
    Delete the breakpoints in filename and lineno. If none were set, an error message is returned.

clear_bpbynumber(arg)
    Delete the breakpoint which has the index arg in the Breakpoint.bpbynumber. If arg is not numeric or out of range, return an error message.

clear_all_file_breaks(filename)
    Delete all breakpoints in filename. If none were set, an error message is returned.

clear_all_breaks()
    Delete all existing breakpoints.

get_break(filename, lineno)
    Check if there is a breakpoint for lineno of filename.

get_breaks(filename, lineno)
    Return all breakpoints for lineno in filename, or an empty list if none are set.

get_file_breaks(filename)
    Return all breakpoints in filename, or an empty list if none are
set.

`get_all_breaks()`
Return all breakpoints that are set.

Derived classes and clients can call the following methods to get a data structure representing a stack trace.

`get_stack(f, t)`
Get a list of records for a frame and all higher (calling) and lower frames, and the size of the higher part.

`format_stack_entry(frame_lineno[, lprefix=': '])`
Return a string with information about a stack entry, identified by a `(frame, lineno)` tuple:

- The canonical form of the filename which contains the frame.
- The function name, or "<lambda>".
- The input arguments.
- The return value.
- The line of code (if it exists).

The following two methods can be called by clients to use a debugger to debug a `statement`, given as a string.

`run(cmd[, globals[, locals]])`
Debug a statement executed via the `exec` statement. `globals` defaults to `__main__.dict`, `locals` defaults to `globals`.

`runeval(expr[, globals[, locals]])`
Debug an expression executed via the `eval()` function. `globals` and `locals` have the same meaning as in `run()`.

`runctx(cmd, globals, locals)"
For backwards compatibility. Calls the `run()` method.

\[\texttt{runcall(func, *args, **kwds)}\]

Debug a single function call, and return its result.

Finally, the module defines the following functions:

\[\texttt{bdb.checkfuncname(b, frame)}\]

Check whether we should break here, depending on the way the breakpoint \(b\) was set.

If it was set via line number, it checks if \(b\.line\) is the same as the one in the frame also passed as argument. If the breakpoint was set via function name, we have to check we are in the right frame (the right function) and if we are in its first executable line.

\[\texttt{bdb.effective(file, line, frame)}\]

Determine if there is an effective (active) breakpoint at this line of code. Return a tuple of the breakpoint and a boolean that indicates if it is ok to delete a temporary breakpoint. Return \((\text{None, None})\) if there is no matching breakpoint.

\[\texttt{bdb.set_trace()}\]

Start debugging with a \texttt{Bdb} instance from caller’s frame.
26. Debugging and Profiling
The module `pdb` defines an interactive source code debugger for Python programs. It supports setting (conditional) breakpoints and single stepping at the source line level, inspection of stack frames, source code listing, and evaluation of arbitrary Python code in the context of any stack frame. It also supports post-mortem debugging and can be called under program control.

The debugger is extensible — it is actually defined as the class `Pdb`. This is currently undocumented but easily understood by reading the source. The extension interface uses the modules `bdb` and `cmd`.

The debugger’s prompt is `(Pdb)`. Typical usage to run a program under control of the debugger is:

```
>>> import pdb
>>> import mymodule
>>> pdb.run('mymodule.test()')
> <string>(0)?()
(Pdb) continue
> <string>(1)?()
(Pdb) continue
NameError: 'spam'
> <string>(1)?()
(Pdb)
```

`pdb.py` can also be invoked as a script to debug other scripts. For example:

```
python -m pdb myscript.py
```

When invoked as a script, `pdb` will automatically enter post-mortem debugging if the program being debugged exits abnormally. After post-mortem debugging (or after normal exit of the program), `pdb` will restart the program. Automatic restarting preserves `pdb`’s state (such
as breakpoints) and in most cases is more useful than quitting the debugger upon program's exit.

*New in version 2.4:* Restarting post-mortem behavior added.

The typical usage to break into the debugger from a running program is to insert

```
import pdb; pdb.set_trace()
```

at the location you want to break into the debugger. You can then step through the code following this statement, and continue running without the debugger using the `c` command.

The typical usage to inspect a crashed program is:

```
>>> import pdb
>>> import mymodule
>>> mymodule.test()
Traceback (most recent call last):
  File "<stdin>", line 1, in ?
  File "./mymodule.py", line 4, in test
test2()
  File "./mymodule.py", line 3, in test2
    print spam
NameError: spam
>>> pdb.pm()
> ./mymodule.py(3)test2()
-> print spam
(PDO)
```

The module defines the following functions; each enters the debugger in a slightly different way:

```
pdb.run(statement[, globals[, locals]])
```

Execute the `statement` (given as a string) under debugger control. The debugger prompt appears before any code is executed; you can set breakpoints and type `continue`, or you can
step through the statement using step or next (all these commands are explained below). The optional globals and locals arguments specify the environment in which the code is executed; by default the dictionary of the module __main__ is used. (See the explanation of the exec statement or the eval() built-in function.)

`pdb.runeval(expression[, globals[, locals]])`
Evaluate the expression (given as a string) under debugger control. When `runeval()` returns, it returns the value of the expression. Otherwise this function is similar to `run()`.

`pdb.runcall(function[, argument, ...])`
Call the function (a function or method object, not a string) with the given arguments. When `runcall()` returns, it returns whatever the function call returned. The debugger prompt appears as soon as the function is entered.

`pdb.set_trace()`
Enter the debugger at the calling stack frame. This is useful to hard-code a breakpoint at a given point in a program, even if the code is not otherwise being debugged (e.g. when an assertion fails).

`pdb.post_mortem([traceback])`
Enter post-mortem debugging of the given traceback object. If no traceback is given, it uses the one of the exception that is currently being handled (an exception must be being handled if the default is to be used).

`pdb.pm()`Enter post-mortem debugging of the traceback found in `sys.last_traceback`. 
The `run*` functions and `set_trace()` are aliases for instantiating the `Pdb` class and calling the method of the same name. If you want to access further features, you have to do this yourself:

```python
class pdb.Pdb(completekey='tab', stdin=None, stdout=None, skip=None)
```

`Pdb` is the debugger class.

The `completekey`, `stdin` and `stdout` arguments are passed to the underlying `cmd.Cmd` class; see the description there.

The `skip` argument, if given, must be an iterable of glob-style module name patterns. The debugger will not step into frames that originate in a module that matches one of these patterns. [1]

Example call to enable tracing with `skip`:

```python
import pdb; pdb.Pdb(skip=['django.*']).set_trace()
```

_New in version 2.7:_ The `skip` argument.

- `run(statement[, globals[, locals]])`
- `runeval(expression[, globals[, locals]])`
- `runcall(function[, argument, ...])`
- `set_trace()`

See the documentation for the functions explained above.
26.3. Debugger Commands

The debugger recognizes the following commands. Most commands can be abbreviated to one or two letters; e.g. `h(elp)` means that either `h` or `help` can be used to enter the help command (but not `he` or `hel`, nor `H` or `Help` or `HELP`). Arguments to commands must be separated by whitespace (spaces or tabs). Optional arguments are enclosed in square brackets ([ ] ) in the command syntax; the square brackets must not be typed. Alternatives in the command syntax are separated by a vertical bar (|).

Entering a blank line repeats the last command entered. Exception: if the last command was a `list` command, the next 11 lines are listed.

Commands that the debugger doesn’t recognize are assumed to be Python statements and are executed in the context of the program being debugged. Python statements can also be prefixed with an exclamation point (!). This is a powerful way to inspect the program being debugged; it is even possible to change a variable or call a function. When an exception occurs in such a statement, the exception name is printed but the debugger’s state is not changed.

Multiple commands may be entered on a single line, separated by `; ; `. (A single `;` is not used as it is the separator for multiple commands in a line that is passed to the Python parser.) No intelligence is applied to separating the commands; the input is split at the first `; ; ` pair, even if it is in the middle of a quoted string.

The debugger supports aliases. Aliases can have parameters which allows one a certain level of adaptability to the context under examination.

If a file `.pdbrc` exists in the user’s home directory or in the current
directory, it is read in and executed as if it had been typed at the debugger prompt. This is particularly useful for aliases. If both files exist, the one in the home directory is read first and aliases defined there can be overridden by the local file.

`help [command]`
Without argument, print the list of available commands. With a `command` as argument, print help about that command. `help pdb` displays the full documentation file; if the environment variable `PAGER` is defined, the file is piped through that command instead. Since the `command` argument must be an identifier, `help exec` must be entered to get help on the `!` command.

`where`
Print a stack trace, with the most recent frame at the bottom. An arrow indicates the current frame, which determines the context of most commands.

`down`
Move the current frame one level down in the stack trace (to a newer frame).

`up`
Move the current frame one level up in the stack trace (to an older frame).

`break` `[[filename:]lineno | function[, condition]]`
With a `lineno` argument, set a break there in the current file. With a `function` argument, set a break at the first executable statement within that function. The line number may be prefixed with a filename and a colon, to specify a breakpoint in another file (probably one that hasn’t been loaded yet). The file is searched on `sys.path`. Note that each breakpoint is assigned a number to which all the other breakpoint commands refer.

If a second argument is present, it is an expression which must evaluate to true before the breakpoint is honored.
Without argument, list all breaks, including for each breakpoint, the number of times that breakpoint has been hit, the current ignore count, and the associated condition if any.

tbreak [[filename:]lineno | function[, condition]]
Temporary breakpoint, which is removed automatically when it is first hit. The arguments are the same as break.

cl(ear) [filename:lineno | bpnumber [bpnumber ...]]
With a filename:lineno argument, clear all the breakpoints at this line. With a space separated list of breakpoint numbers, clear those breakpoints. Without argument, clear all breaks (but first ask confirmation).

disable [bpnumber [bpnumber ...]]
Disables the breakpoints given as a space separated list of breakpoint numbers. Disabling a breakpoint means it cannot cause the program to stop execution, but unlike clearing a breakpoint, it remains in the list of breakpoints and can be (re-)enabled.

enable [bpnumber [bpnumber ...]]
Enables the breakpoints specified.

ignore bpnumber [count]
Sets the ignore count for the given breakpoint number. If count is omitted, the ignore count is set to 0. A breakpoint becomes active when the ignore count is zero. When non-zero, the count is decremented each time the breakpoint is reached and the breakpoint is not disabled and any associated condition evaluates to true.

condition bpnumber [condition]
Condition is an expression which must evaluate to true before the breakpoint is honored. If condition is absent, any existing condition is removed; i.e., the breakpoint is made unconditional.

commands [bpnumber]
Specify a list of commands for breakpoint number \texttt{bpnumber}. The commands themselves appear on the following lines. Type a line containing just ‘end’ to terminate the commands. An example:

```
(Pdb) commands 1
(com) print some_variable
(com) end
(Pdb)
```

To remove all commands from a breakpoint, type \texttt{commands} and follow it immediately with \texttt{end}; that is, give no commands.

With no \texttt{bpnumber} argument, \texttt{commands} refers to the last breakpoint set.

You can use breakpoint commands to start your program up again. Simply use the \texttt{continue} command, or \texttt{step}, or any other command that resumes execution.

Specifying any command resuming execution (currently \texttt{continue}, \texttt{step}, \texttt{next}, \texttt{return}, \texttt{jump}, \texttt{quit} and their abbreviations) terminates the command list (as if that command was immediately followed by \texttt{end}). This is because any time you resume execution (even with a simple \texttt{next} or \texttt{step}), you may encounter another breakpoint–which could have its own command list, leading to ambiguities about which list to execute.

If you use the ‘silent’ command in the command list, the usual message about stopping at a breakpoint is not printed. This may be desirable for breakpoints that are to print a specific message and then continue. If none of the other commands print anything, you see no sign that the breakpoint was reached.

\textit{New in version 2.5.}

\texttt{s(tep)}

Execute the current line, stop at the first possible occasion (either
in a function that is called or on the next line in the current function).

**n(ext)**
Continue execution until the next line in the current function is reached or it returns. (The difference between `next` and `step` is that `step` stops inside a called function, while `next` executes called functions at (nearly) full speed, only stopping at the next line in the current function.)

**unt(ill)**
Continue execution until the line with the line number greater than the current one is reached or when returning from current frame.

*New in version 2.6.*

**r(eturn)**
Continue execution until the current function returns.

**c(ontinue)**
Continue execution, only stop when a breakpoint is encountered.

**j(ump) [lineno]**
Set the next line that will be executed. Only available in the bottom-most frame. This lets you jump back and execute code again, or jump forward to skip code that you don’t want to run.

It should be noted that not all jumps are allowed — for instance it is not possible to jump into the middle of a `for` loop or out of a `finally` clause.

**l(ist) [first[, last]]**
List source code for the current file. Without arguments, list 11 lines around the current line or continue the previous listing. With one argument, list 11 lines around at that line. With two arguments, list the given range; if the second argument is less
than the first, it is interpreted as a count.

a(rgs)
Print the argument list of the current function.

p expression
Evaluate the expression in the current context and print its value.

**Note:** print can also be used, but is not a debugger command — this executes the Python `print` statement.

pp expression
Like the p command, except the value of the expression is pretty-printed using the `pprint` module.

alias [name [command]]
Creates an alias called name that executes command. The command must not be enclosed in quotes. Replaceable parameters can be indicated by `%1`, `%2`, and so on, while `%*` is replaced by all the parameters. If no command is given, the current alias for name is shown. If no arguments are given, all aliases are listed.

Aliases may be nested and can contain anything that can be legally typed at the pdb prompt. Note that internal pdb commands can be overridden by aliases. Such a command is then hidden until the alias is removed. Aliasing is recursively applied to the first word of the command line; all other words in the line are left alone.

As an example, here are two useful aliases (especially when placed in the `.pdbrc` file):

```python
#Print instance variables (usage "pi classInst")
alias pi for k in %1.__dict__.keys(): print "%1." , k,"=",%1.__
#Print instance variables in self
alias ps pi self
```
unalias *name*

   Deletes the specified alias.

[*!]**statement**

   Execute the (one-line) **statement** in the context of the current stack frame. The exclamation point can be omitted unless the first word of the statement resembles a debugger command. To set a global variable, you can prefix the assignment command with a `global` command on the same line, e.g.:

   ```
   (Pdb) global list_options; list_options = ['-l']
   (Pdb)
   ```

**run** [**args ...**]

   Restart the debugged Python program. If an argument is supplied, it is split with “shlex” and the result is used as the new `sys.argv`. History, breakpoints, actions and debugger options are preserved. “restart” is an alias for “run”.

   *New in version 2.6.*

**q(uit)**

   Quit from the debugger. The program being executed is aborted.

**Footnotes**

**[1]** Whether a frame is considered to originate in a certain module is determined by the **__name__** in the frame globals.

26.4.1. Introduction to the profilers

A profiler is a program that describes the run time performance of a program, providing a variety of statistics. This documentation describes the profiler functionality provided in the modules cProfile, profile and pstats. This profiler provides deterministic profiling of Python programs. It also provides a series of report generation tools to allow users to rapidly examine the results of a profile operation.

The Python standard library provides three different profilers:

1. cProfile is recommended for most users; it's a C extension with reasonable overhead that makes it suitable for profiling long-running programs. Based on lspath, contributed by Brett Rosen and Ted Czotter.

   New in version 2.5.

2. profile, a pure Python module whose interface is imitated by cProfile. Adds significant overhead to profiled programs. If you're trying to extend the profiler in some way, the task might be easier with this module. Copyright © 1994, by InfoSeek Corporation.

   Changed in version 2.4: Now also reports the time spent in calls to built-in functions and methods.

3. hotshot was an experimental C module that focused on minimizing the overhead of profiling, at the expense of longer data post-processing times. It is no longer maintained and may be dropped in a future version of Python.

   Changed in version 2.5: The results should be more meaningful than in the past: the timing core contained a critical bug.
The `profile` and `cProfile` modules export the same interface, so they are mostly interchangeable; `cProfile` has a much lower overhead but is newer and might not be available on all systems. `cProfile` is really a compatibility layer on top of the internal `_lsprof` module. The `hotshot` module is reserved for specialized usage.
26.4.2. Instant User’s Manual

This section is provided for users that “don’t want to read the manual.” It provides a very brief overview, and allows a user to rapidly perform profiling on an existing application.

To profile an application with a main entry point of `foo()`, you would add the following to your module:

```python
import cProfile
cProfile.run('foo()')
```

(Use `profile` instead of `cProfile` if the latter is not available on your system.)

The above action would cause `foo()` to be run, and a series of informative lines (the profile) to be printed. The above approach is most useful when working with the interpreter. If you would like to save the results of a profile into a file for later examination, you can supply a file name as the second argument to the `run()` function:

```python
import cProfile
cProfile.run('foo()', 'fooprof')
```

The file `cProfile.py` can also be invoked as a script to profile another script. For example:

```bash
python -m cProfile myscript.py
```

`cProfile.py` accepts two optional arguments on the command line:

```bash
cProfile.py [-o output_file] [-s sort_order]
```

`-s` only applies to standard output (`-o` is not supplied). Look in the
Stats documentation for valid sort values.

When you wish to review the profile, you should use the methods in the pstats module. Typically you would load the statistics data as follows:

```python
import pstats
p = pstats.Stats('fooprof')
```

The class stats (the above code just created an instance of this class) has a variety of methods for manipulating and printing the data that was just read into p. When you ran cProfile.run() above, what was printed was the result of three method calls:

```python
p.strip_dirs().sort_stats(-1).print_stats()
```

The first method removed the extraneous path from all the module names. The second method sorted all the entries according to the standard module/line/name string that is printed. The third method printed out all the statistics. You might try the following sort calls:

```python
p.sort_stats('name')
p.print_stats()
```

The first call will actually sort the list by function name, and the second call will print out the statistics. The following are some interesting calls to experiment with:

```python
p.sort_stats('cumulative').print_stats(10)
```

This sorts the profile by cumulative time in a function, and then only prints the ten most significant lines. If you want to understand what algorithms are taking time, the above line is what you would use.

If you were looking to see what functions were looping a lot, and taking a lot of time, you would do:
to sort according to time spent within each function, and then print
the statistics for the top ten functions.

You might also try:

```
p.sort_stats('time').print_stats(10)
```

This will sort all the statistics by file name, and then print out
statistics for only the class init methods (since they are spelled with
`__init__` in them). As one final example, you could try:

```
p.sort_stats('file').print_stats('__init__')
```

This line sorts statistics with a primary key of time, and a secondary
key of cumulative time, and then prints out some of the statistics. To
be specific, the list is first culled down to 50% (re: .5) of its original
size, then only lines containing `init` are maintained, and that sub-
sub-list is printed.

If you wondered what functions called the above functions, you could
now (`p` is still sorted according to the last criteria) do:

```
p.print_callers(.5, 'init')
```

and you would get a list of callers for each of the listed functions.

If you want more functionality, you’re going to have to read the
manual, or guess what the following functions do:

```
p.print_callees()
p.add('fooprof')
```

Invoked as a script, the `pstats` module is a statistics browser for
reading and examining profile dumps. It has a simple line-oriented
interface (implemented using cmd) and interactive help.
26.4.3. What Is Deterministic Profiling?

Deterministic profiling is meant to reflect the fact that all function call, function return, and exception events are monitored, and precise timings are made for the intervals between these events (during which time the user’s code is executing). In contrast, statistical profiling (which is not done by this module) randomly samples the effective instruction pointer, and deduces where time is being spent. The latter technique traditionally involves less overhead (as the code does not need to be instrumented), but provides only relative indications of where time is being spent.

In Python, since there is an interpreter active during execution, the presence of instrumented code is not required to do deterministic profiling. Python automatically provides a hook (optional callback) for each event. In addition, the interpreted nature of Python tends to add so much overhead to execution, that deterministic profiling tends to only add small processing overhead in typical applications. The result is that deterministic profiling is not that expensive, yet provides extensive run time statistics about the execution of a Python program.

Call count statistics can be used to identify bugs in code (surprising counts), and to identify possible inline-expansion points (high call counts). Internal time statistics can be used to identify “hot loops” that should be carefully optimized. Cumulative time statistics should be used to identify high level errors in the selection of algorithms. Note that the unusual handling of cumulative times in this profiler allows statistics for recursive implementations of algorithms to be directly compared to iterative implementations.
26.4.4. Reference Manual – profile and cProfile

The primary entry point for the profiler is the global function `profile.run()` (resp. `cProfile.run()`). It is typically used to create any profile information. The reports are formatted and printed using methods of the class `pstats.Stats`. The following is a description of all of these standard entry points and functions. For a more in-depth view of some of the code, consider reading the later section on Profiler Extensions, which includes discussion of how to derive “better” profilers from the classes presented, or reading the source code for these modules.

**cProfile.**`run(command[, filename])`

This function takes a single argument that can be passed to the `exec` statement, and an optional file name. In all cases this routine attempts to `exec` its first argument, and gather profiling statistics from the execution. If no file name is present, then this function automatically prints a simple profiling report, sorted by the standard name string (file/line/function-name) that is presented in each line. The following is a typical output from such a call:

```
2706 function calls (2004 primitive calls) in 4.504 CPU seconds
Ordered by: standard name

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
2      0.006    0.003    0.953    0.477 pobject.py:75(save_objects)
43/3   0.533    0.012    0.749    0.250 pobject.py:99(evaluate)
...```

The first line indicates that 2706 calls were monitored. Of those calls, 2004 were *primitive*. We define *primitive* to mean that the
call was not induced via recursion. The next line: ordered by: standard name, indicates that the text string in the far right column was used to sort the output. The column headings include:

ncalls
for the number of calls,
tottime
for the total time spent in the given function (and excluding time made in calls to sub-functions),
percall
is the quotient of tottime divided by ncalls
cumtime
is the total time spent in this and all subfunctions (from invocation till exit). This figure is accurate even for recursive functions.

When there are two numbers in the first column (for example, 43/3), then the latter is the number of primitive calls, and the former is the actual number of calls. Note that when the function does not recurse, these two values are the same, and only the single figure is printed.

cProfile.runctx(command, globals, locals[, filename])
This function is similar to run(), with added arguments to supply the globals and locals dictionaries for the command string.

Analysis of the profiler data is done using the Stats class.
Note: The `Stats` class is defined in the `pstats` module.

```python
class pstats.Stats(filename[, stream=sys.stdout[, ...]])
```

This class constructor creates an instance of a "statistics object" from a `filename` (or set of filenames). `Stats` objects are manipulated by methods, in order to print useful reports. You may specify an alternate output stream by giving the keyword argument, `stream`.

The file selected by the above constructor must have been created by the corresponding version of `profile` or `cProfile`. To be specific, there is no file compatibility guaranteed with future versions of this profiler, and there is no compatibility with files produced by other profilers. If several files are provided, all the statistics for identical functions will be coalesced, so that an overall view of several processes can be considered in a single report. If additional files need to be combined with data in an existing `Stats` object, the `add()` method can be used.

*Changed in version 2.5:* The `stream` parameter was added.

### 26.4.4.1. The `Stats` Class

`Stats` objects have the following methods:

- `Stats.strip_dirs()`
