</tbody>
</table>
Detailed Description

File I/O object used for creating, reading, and writing XML documents.

A SimXMLDocument is a container of various XML nodes. The Document level may contain a header (sometimes called a declaration), comments and child Elements. Elements may contain attributes, data (or text) and child Elements.

You build new Elements using addNewElement(). This makes the new Element the current one you're working with. You then use setAttribute() to add attributes to the Element. You use addData() or addText() to write to the text area of an Element.

Example:

```xml
<?xml version="1.0" encoding="utf-8" standalone="yes"?>
<DataTables>
  <table tableName="2DShapes">
    <rec id="1">Triangle</rec>
    <rec id="2">Square</rec>
    <rec id="3">Circle</rec>
  </table>
  <table tableName="3DShapes">
    <rec id="1">Pyramid</rec>
    <rec id="2">Cube</rec>
    <rec id="3">Sphere</rec>
  </table>
</DataTables>
```

```javascript
function readXmlExample(%filename) {
  // Using SimXMLDocument by itself
}
```
```javascript
%xml = new SimXMLDocument() {}; %xml.loadFile(%filename);

%xml.pushChildElement("DataTables");
%xml.pushFirstChildElement("table");
while (true)
{
    echo("TABLE:" SPC %xml.attribute("tableName");
    %xml.pushFirstChildElement("rec");
    while (true)
    {
        %id = %xml.attribute("id");
        %desc = %xml.getData();
        echo(" Shape" SPC %id SPC %desc);
        if (!%xml.nextSiblingElement("rec")
    }
    %xml.popElement();
    if (!%xml.nextSiblingElement("table")
}

// Thanks to Scott Peal for this example
// Using FileObject in conjunction with SimXML
// This example uses an XML file with a format of:
// <Models>
//    <Model category="" name="" path="" />
// </Models>
function getModelsInCategory()
{
    %file = "./Catalog.xml";
    %fo = new FileObject();
    %text = "";
```
if(%fo.openForRead(%file))
{
    while(!%fo.isEOF())
    {
        %text = %text @ %fo.readLine();
        if (!%fo.isEOF()) %text = %text @ "\n"
    }
}
else
{
    echo("Unable to locate the file: " @ ':
    
%fo.delete();

%xml = new SimXMLDocument(){};
%xml.parse(%text);
// "Get" inside of the root element, "Model"
%xml.pushChildElement(0);

// "Get" into the first child element
if (%xml.pushFirstChildElement("Model"))
{
    while (true)
    {
        //
        // Here, i read the element's attributes.
        // You might want to save these values into an array
        // if you have a different XML structure.

        %catagory = %xml.attribute("catagory";
        %name = %xml.attribute("name";
        %path = %xml.attribute("path";
// now, read the next "Model"
if (!%xml.nextSiblingElement("Model

Note:

SimXMLDocument is a wrapper around TinyXml, a standard XML library. If you're familiar with its concepts, you'll find they also apply here.

See also:

FileObject
Member Function Documentation

```cpp
void SimXMLDocument::addComment(string comment)
```

Add the given comment as a child of the document.

**Parameters:**

- `comment` String containing the comment.

**Example:**

```cpp
// Create a new XML document with a header
SimXMLDocument *x = new SimXMLDocument();
x->addHeader();
x->addComment("This is a test comment");
x->addElement("NewElement");
x->saveFile("test.xml");

// Produces the following file:
// <?xml version="1.0" encoding="utf-8" standalone="yes"
// <!--This is a test comment-->
// <NewElement />
```

See also:

- `readComment()`

```cpp
void SimXMLDocument::addData(string text)
```

Add the given text as a child of current Element.

Use `getData()` to retrieve any text from the current Element.

`addData()` and `addText()` may be used interchangeably. As there is no difference between data and text, you may also use...
removeText() to clear any data from the current Element.

**Parameters:**

*text* String containing the text.

**Example:**

```cpp
// Create a new XML document with a header
// with some added data.
%x = new SimXMLDocument();
%x.addHeader();
%x.addNewElement("NewElement");
%x.addData("Some text");
%x.saveFile("test.xml");

// Produces the following file:
// <?xml version="1.0" encoding="utf-8" standalone="yes"?>
// <NewElement>Some text</NewElement>
```

See also:

- `getData()`
- `addText()`
- `getText()`
- `removeText()`

```cpp
void SimXMLDocument::addHeader( )
```

Add a XML header to a document.

Sometimes called a declaration, you typically add a standard header to the document before adding any elements. **SimXMLDocument** always produces the following header:

```xml
<?xml version="1.0" encoding="utf-8" standalone="yes" ?>
```

**Example:**
Create a new XML document with just a header and single element.

```cpp
SimXMLDocument %x = new SimXMLDocument();
%x.addHeader();
%x.addNewElement("NewElement");
%x.saveFile("test.xml");
```

// Produces the following file:
// <?xml version="1.0" encoding="utf-8" standalone="yes" ?>
// <NewElement />

### void SimXMLDocument::addNewElement(string name)

Create a new element with the given name as child of current Element's parent and push it onto the Element stack making it the current one.

**Note:**

This differs from `pushNewElement()` in that it adds the new Element to the current Element's parent (or document if there is no parent Element). This makes the new Element a sibling of the current one.

**Parameters:**

- `name` XML tag for the new Element.

**See also:**

- `pushNewElement()`

### void SimXMLDocument::addText(string text)

Add the given text as a child of current Element.

Use `getText()` to retrieve any text from the current Element and
removeText() to clear any text.

addText() and addData() may be used interchangeably.

**Parameters:**

*text*  String containing the text.

**Example:**

```cpp
// Create a new XML document with a header with some added text.
%x = new SimXMLDocument();
%x.addHeader();
%x.addNewElement("NewElement");
%x.addText("Some text");
%x.saveFile("test.xml");

// Produces the following file:
// <?xml version="1.0" encoding="utf-8" standalone="yes">
// <NewElement>Some text</NewElement>
```

**See also:**

getText()
removeText()
addData()
getData()

```cpp
text SimXMLDocument::attribute(string attributeName )
```

Get a string attribute from the current Element on the stack.

**Parameters:**

*attributeName*  Name of attribute to retrieve.

**Returns:**
The attribute string if found. Otherwise returns an empty string.

```cpp
bool SimXMLDocument::attributeExists(string attributeName)
```

Tests if the requested attribute exists.

**Parameters:**
- `attributeName` Name of attribute being queried for.

**Returns:**
- True if the attribute exists.

```cpp
float SimXMLDocument::attributeF32(string attributeName)
```

Get float attribute from the current Element on the stack.

**Parameters:**
- `attributeName` Name of attribute to retrieve.

**Returns:**
- The value of the given attribute in the form of a float.

```cpp
int SimXMLDocument::attributeS32(string attributeName)
```

Get int attribute from the current Element on the stack.

**Parameters:**
- `attributeName` Name of attribute to retrieve.

**Returns:**
- The value of the given attribute in the form of an integer.
void SimXMLDocument::clear()

Set this document to its default state.
Clears all Elements from the documents. Equivalent to using reset()

See also:
reset()

void SimXMLDocument::clearError()

Clear the last error description.

string SimXMLDocument::elementValue()

Get the Element's value if it exists.
Usually returns the text from the Element.

Returns:
The value from the Element, or an empty string if none is found.

string SimXMLDocument::firstAttribute()

Obtain the name of the current Element's first attribute.

Returns:
String containing the first attribute's name, or an empty string if none is found.

See also:
string SimXMLDocument::getData() 

Gets the text from the current Element.

Use addData() to add text to the current Element.

getData() and getText() may be used interchangeably. As there is no difference between data and text, you may also use removeText() to clear any data from the current Element.

Returns:
String containing the text in the current Element.

Example:

// Using the following test.xml file as an example:
// <?xml version="1.0" encoding="utf-8" standalone="yes"?>
// <NewElement>Some data</NewElement>

// Load in the file
%x = new SimXMLDocument();
%x.loadFile("test.xml");

// Make the first Element the current one
%x.pushFirstChildElement("NewElement");

// Store the current Element's data ('Some data') into 'result'
%result = %x.getData();
echo( %result );
See also:
addData()
addText()
getText()
removeText()

string SimXMLDocument::getErrorDesc( )

Get last error description.

**Returns:**
A string of the last error message.

string SimXMLDocument::getText( )

Gets the text from the current Element.

Use addText() to add text to the current Element and removeText() to clear any text.

**Returns:**
String containing the text in the current Element.

**Example:**

```c++
// Using the following test.xml file as an example:
// <?xml version="1.0" encoding="utf-8" standalone="yes"?>
// <NewElement>Some text</NewElement>

// Load in the file
%x = new SimXMLDocument();
%x.loadFile("test.xml");
```
// Make the first Element the current one
%x.pushFirstChildElement("NewElement");

// Store the current Element's text ('Some
// into 'result'
%result = %x.getText();
echo( %result );

See also:
  addText()
  removeText()
  addData()
  getData()

string SimXMLDocument::lastAttribute( )

Obtain the name of the current Element's last attribute.

Returns:
  String containing the last attribute's name, or an empty string
  if none is found.

See also:
  prevAttribute()
  firstAttribute()
  lastAttribute()

bool SimXMLDocument::loadFile(string fileName )

Load in given filename and prepare it for use.

Note:
  Clears the current document's contents.
Parameters:

fileName  Name and path of XML document

Returns:

True if the file was loaded successfully.

string SimXMLDocument::nextAttribute()  

Get the name of the next attribute for the current Element after a call to firstAttribute().

Returns:

String containing the next attribute's name, or an empty string if none is found.

See also:

firstAttribute()
lastAttribute()
prevAttribute()

bool SimXMLDocument::nextSiblingElement(string name )  

Put the next sibling Element with the given name on the stack, making it the current one.

Parameters:

name  String containing name of the next sibling.

Returns:

True if the Element was found and made the current one.

void SimXMLDocument::parse(string xmlString )
Create a document from a XML string.

**Note:**
Clears the current document's contents.

**Parameters:**
- *xmlString* Valid XML to parse and store as a document.

```cpp
void SimXMLDocument::popElement()  
```

Pop the last Element off the stack.

```cpp
string SimXMLDocument::prevAttribute()  
```

Get the name of the previous attribute for the current Element after a call to `lastAttribute()`.

**Returns:**
String containing the previous attribute's name, or an empty string if none is found.

**See also:**
- `lastAttribute()`
- `firstAttribute()`
- `nextAttribute()`

```cpp
bool SimXMLDocument::pushChildElement(int index)  
```

Push the child Element at the given index onto the stack, making it the current one.

**Parameters:**
Push the first child Element with the given name onto the stack, making it the current Element.

**Parameters:**

- *name*  String containing name of the child Element.

**Returns:**

True if the Element was found and made the current one.

**Example:**

```plaintext
// Using the following test.xml file as an example:
<?xml version="1.0" encoding="utf-8" standalone="yes" ?>
<NewElement>Some text</NewElement>

// Load in the file
%x = new SimXMLDocument();
%x.loadFile("test.xml");

// Make the first Element the current one
%x.pushFirstChildElement("NewElement");

// Store the current Element's text ('Some text' in this example) into 'result'
%result = %x.getText();
echo( %result );
```
void SimXMLDocument::pushNewElement(string name)

Create a new element with the given name as child of current Element and push it onto the Element stack making it the current one.

**Note:**
This differs from `addNewElement()` in that it adds the new Element as a child of the current Element (or a child of the document if no Element exists).

**Parameters:**
- *name*  XML tag for the new Element.

**See also:**
- `addNewElement()`

string SimXMLDocument::readComment(int index)

Gives the comment at the specified index, if any.

Unlike `addComment()` that only works at the document level, `readComment()` may read comments from the document or any child Element. The current Element (or document if no Elements have been pushed to the stack) is the parent for any comments, and the provided index is the number of comments in to read back.

**Parameters:**
- *index*  Comment index number to query from the current Element stack

**Returns:**
- String containing the comment, or an empty string if no comment is found.
void SimXMLDocument::removeText()

Remove any text on the current Element.

Use `getText()` to retrieve any text from the current Element and `addText()` to add text to the current Element. As `getData()` and `addData()` are equivalent to `getText()` and `addText()`, `removeText()` will also remove any data from the current Element.

See also:
addText()
gText()
addData()
getData()

void SimXMLDocument::reset()

Set this document to its default state.

Clears all Elements from the documents. Equivalent to using `clear()`

See also:
clear()

bool SimXMLDocument::saveFile(string fileName)

Save document to the given file name.

Parameters:

`fileName` Path and name of XML file to save to.
Returns:
True if the file was successfully saved.

```cpp
void SimXMLDocument::setAttribute(string attributeName, string value)
```

Set the attribute of the current Element on the stack to the given value.

**Parameters:**
- `attributeName` Name of attribute being changed
- `value` New value to assign to the attribute

```cpp
void SimXMLDocument::setObjectAttributes(string objectId)
```

Add the given SimObject's fields as attributes of the current Element on the stack.

**Parameters:**
- `objectId` ID of SimObject being copied.

---
Detailed Description

This class is used for creating any type of game object, assigning it a class, datablock, and other properties when it is spawned.

Torque 3D uses a simple spawn system, which can be easily modified to spawn any kind of object (of any class). Each new level already contains at least one SpawnSphere, which is represented by a green octahedron in stock Torque 3D. The spawnClass field determines the object type, such as Player, AIPlayer, etc. The spawnDataBlock field applies the pre-defined datablock to each spawned object instance. The really powerful feature of this class is provided by the spawnScript field which allows you to define a simple script (multiple lines) that will be executed once the object has been spawned.

Example:

```cpp
// Define an SpawnSphere that essentially
// $SpawnObject = new Player()
//{
//  dataBlock = "DefaultPlayerData";
//  name = "Bob";
//  lifeTotal = 3;
//};
//echo("Spawned a Player: " @ $SpawnObject)

new SpawnSphere(DefaultSpawnSphere)
{
  spawnClass = "Player";
  spawnDatablock = "DefaultPlayerData";
  spawnScript = "echo("Spawned a Player: "$SpawnObject);
  spawnProperties = "name = "Bob";lifeTotal = 3;"
  autoSpawn = "1";
  dataBlock = "SpawnSphereMarker";
  position = "-0.77266 -19.882 17.8153";
```
rotation = "1 0 0 0";
scale = "1 1 1";
canSave = "1";
canSaveDynamicFields = "1";
};

// Because autoSpawn is set to true in the
// of code will execute AFTER the Player o
echo("Object Spawned");
echo("Hello World");

See also:
MissionMarker
MissionMarkerData
Member Function Documentation

```cpp
void SpawnSphere::onAdd(int objectId)
```

Called when the `SpawnSphere` is being created.

**Parameters:**

`objectId` The unique SimObjectId generated when `SpawnSphere` is created (%this in script)

```cpp
bool SpawnSphere::spawnObject(string additionalProps)
```

Dynamically create a new game object with a specified class, datablock, and optional properties.

This is called on the actual `SpawnSphere`, not to be confused with the `Sim::spawnObject()` global function.

**Parameters:**

Optional set of semicolon delimited `additionalProps` parameters applied to the spawn object during creation.

**Example:**

```cpp
// Use the SpawnSphere::spawnObject function
// No additional properties assigned
%player = DefaultSpawnSphere.spawnObject();
```

Detailed Description

Acts as the physical point in space in white a Splash is created from.
Member Data Documentation

**float SplashData::acceleration**

Constant acceleration value to place upon the splash effect.

**ColorF SplashData::colors[4]**

Color values to set the splash effect, rgba. Up to 4 allowed. Will transition through colors based on values set in the times value. Example: colors[0] = "0.6 1.0 1.0 0.5".

**int SplashData::delayMS**

Time to delay, in milliseconds, before actually starting this effect.

**int SplashData::delayVariance**

Time variance for delayMS.

**float SplashData::ejectionAngle**

Rotational angle to create a splash ring.

**float SplashData::ejectionFreq**

Frequency in which to emit splash rings.

**ParticleEmitterData SplashData::emitter[3]**
List of particle emitters to create at the point of this *Splash* effect.

**ExplosionData SplashData::Explosion**

*ExplosionData* object to create at the creation position of this splash effect.

**float SplashData::height**

Height for the splash to reach.

**int SplashData::lifetimeMS**

Lifetime for this effect, in milliseconds.

**int SplashData::lifetimeVariance**

Time variance for lifetimeMS.

**int SplashData::numSegments**

Number of ejection points in the splash ring.

**float SplashData::ringLifetime**

Lifetime, in milliseconds, for a splash ring.

**Point3F SplashData::scale**
The scale of this splashing effect, defined as the F32 points X, Y, Z.

Detailed Description

Lighting object which emits conical light in a direction.

SpotLight is one of the two types of lighting objects that can be added to a Torque 3D level, the other being PointLight. Unlike directional or point lights, the SpotLights emits lighting in a specific direction within a cone. The distance of the cone is controlled by the SpotLight::range variable.

Example:

```cpp
// Declaration of a point light in script,
new SpotLight(SampleSpotLight)
{
    range = "10";
    innerAngle = "40";
    outerAngle = "45";
    isEnabled = "1";
    color = "1 1 1 1";
    brightness = "1";
    castShadows = "0";
    priority = "1";
    animate = "1";
    animationPeriod = "1";
    animationPhase = "1";
    flareType = "LightFlareExample0";
    flareScale = "1";
    attenuationRatio = "0 1 1";
    shadowType = "Spot";
    texSize = "512";
    overDarkFactor = "2000 1000 500 100";
    shadowDistance = "400";
    shadowSoftness = "0.15";
    numSplits = "1";
}
```
logWeight = "0.91";
fadeStartDistance = "0";
lastSplitTerrainOnly = "0"
representedInLightmap = "0"
shadowDarkenColor = "0 0 0 -1"
includeLightmappedGeometryInShadow = "0"
position = "-29.4362 -5.86289 5.58602"
rotation = "1 0 0 0";

};

## Static Public Attributes

<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>static bool</td>
<td>isRenderable</td>
<td>Disables rendering of all instances of this type.</td>
</tr>
<tr>
<td>static bool</td>
<td>isSelectable</td>
<td>Disables selection of all instances of this type.</td>
</tr>
</tbody>
</table>

**Detailed Description**

The most basic 3D shape with a datablock available in Torque 3D.

When it comes to placing 3D objects in the scene, you technically have two options:

1. **TSStatic** objects

2. **ShapeBase** derived objects

Since **ShapeBase** and **ShapeBaseData** are not meant to be instantiated in script, you will use one of its child classes instead. Several game related objects are derived from **ShapeBase: Player, Vehicle, Item**, and so on.

When you need a 3D object with datablock capabilities, you will use an object derived from **ShapeBase**. When you need an object with extremely low overhead, and with no other purpose than to be a 3D object in the scene, you will use **TSStatic**.

The most basic child of **ShapeBase** is **StaticShape**. It does not introduce any of the additional functionality you see in **Player, Item, Vehicle** or the other game play heavy classes. At its core, it is comparable to a **TSStatic**, but with a datbalock. Having a datablock provides a location for common variables as well as having access to various **ShapeBaseData, GameBaseData** and **SimDataBlock** callbacks.

**Example:**

```cpp
// Create a StaticShape using a datablock
datablock StaticShapeData(BasicShapeData)
{
    shapeFile = "art/shapes/items/kit/healthkit.dts"
    testVar = "Simple string, not a stock variable"
};
```
new StaticShape()
{
    dataBlock = "BasicShapeData";
    position = "0.0 0.0 0.0";
    rotation = "1 0 0 0";
    scale = "1 1 1";
};

Detailed Description

The most basic ShapeBaseData derived shape datablock available in Torque 3D.

When it comes to placing 3D objects in the scene, you effectively have two options:

1. TSStatic objects

2. ShapeBase derived objects

Since ShapeBase and ShapeBaseData are not meant to be instantiated in script, you will use one of its child classes instead. Several game related objects are derived from ShapeBase: Player, Vehicle, Item, and so on.

When you need a 3D object with datablock capabilities, you will use an object derived from ShapeBase. When you need an object with extremely low overhead, and with no other purpose than to be a 3D object in the scene, you will use TSStatic.

The most basic child of ShapeBase is StaticShape. It does not introduce any of the additional functionality you see in Player, Item, Vehicle or the other game play heavy classes. At its core, it is comparable to a TSStatic, but with a datablock. Having a datablock provides a location for common variables as well as having access to various ShapeBaseData, GameBaseData and SimDataBlock callbacks.

Example:

```cpp
// Create a StaticShape using a datablock
datablock StaticShapeData(BasicShapeData) {
    shapeFile = "art/shapes/items/kit/healthkit.dts"
    testVar = "Simple string, not a stock var";
};
```
new StaticShape()
{
    dataBlock = "BasicShapeData";
    position = "0.0 0.0 0.0";
    rotation = "1 0 0 0";
    scale = "1 1 1";
};

StaticShape
ShapeBaseData
TSStatic
Member Data Documentation

**int StaticShapeData::dynamicType**

An integer value which, if specified, is added to the value returned by `getType()`.

This allows you to extend the type mask for a `StaticShape` that uses this datablock. Type masks are used for container queries, etc.

**bool StaticShapeData::noIndividualDamage**

Deprecated.

<td></td>
</tr>
</tbody>
</table>
Write out a string with a default maximum length of 256 characters.
**Detailed Description**

Base class for working with streams.

You do not instantiate a `StreamObject` directly. Instead, it is used as part of a `FileStreamObject` and `ZipObject` to support working with uncompressed and compressed files respectively.

**Example:**

```cpp
// You cannot actually declare a StreamObject
// Instead, use the derived class "FileStreamObject"
%fsObject = FileStreamObject();
```

**See also:**

- `FileStreamObject` for the derived class usable in script.
- `ZipObject` where `StreamObject` is used to read and write to files within a zip archive.
Member Function Documentation

```cpp
bool StreamObject::copyFrom(SimObject other)
```

Copy from another `StreamObject` into this `StreamObject`.

**Parameters:**
- `other` The `StreamObject` to copy from.

**Returns:**
- True if the copy was successful.

```cpp
int StreamObject::getPosition()
```

Gets the position in the stream.

The easiest way to visualize this is to think of a cursor in a text file. If you have moved the cursor by five characters, the current position is 5. If you move ahead 10 more characters, the position is now 15. For `StreamObject`, when you read in the line the position is increased by the number of characters parsed, the null terminator, and a newline.

**Example:**

```cpp
// Create a file stream object for reading
%fsObject = new FileStreamObject();

// Open a file for reading
// This file contains two lines of text repeating
// Hello World
// Hello World
%fsObject.open("./test.txt", "read");

// Read in the first line
```
%line = %fsObject.readLine();

// Get the position of the stream
%position = %fsObject.getPosition();

// Print the current position
// Should be 13, 10 for the words, 1 for \t
echo(%position);

// Always remember to close a file stream
%fsObject.close();

**Returns:**
Number of bytes which stream has parsed so far, null terminators and newlines are included

**See also:**
setPosition()

---

**string StreamObject::getStatus( )**

Gets a printable string form of the stream's status.

**Example:**

```
// Create a file stream object for reading
%fsObject = new FileStreamObject();

// Open a file for reading
%fsObject.open("./test.txt", "read");

// Get the status and print it
%status = %fsObject.getStatus();
echo(%status);
```
// Always remember to close a file stream
%fsObject.close();

**Returns:**
String containing status constant, one of the following:

OK - Stream is active and no file errors

IOError - Something went wrong during read or writing the stream

EOS - End of Stream reached (mostly for reads)

IllegalCall - An unsupported operation used. Always w/ accompanied by AssertWarn

Closed - Tried to operate on a closed stream (or detached filter)

UnknownError - Catch all for an error of some kind

Invalid - Entire stream is invalid

```cpp
int StreamObject::getStreamSize()
```

Gets the size of the stream.

The size is dependent on the type of stream being used. If it is a file stream, returned value will be the size of the file. If it is a memory stream, it will be the size of the allocated buffer.

**Example:**
```cpp
// Create a file stream object for reading
%fsObject = new FileStreamObject();

// Open a file for reading
// This file contains the following two lines:
```
// HelloWorld
// HelloWorld
%fsObject.open("./test.txt", "read");

// Found out how large the file stream is
// Then print it to the console
// Should be 22
%streamSize = %fsObject.getStreamSize();
echo(%streamSize);

// Always remember to close a file stream
%fsObject.close();

**Returns:**
Size of stream, in bytes

```c++
bool StreamObject::isEOF() 
```

Tests if the stream has reached the end of the file.

This is an alternative name for isEOS. Both functions are interchangeable. This simply exists for those familiar with some C++ file I/O standards.

**Example:**
```c++
// Create a file stream object for reading
%fsObject = new FileStreamObject();

// Open a file for reading
%fsObject.open("./test.txt", "read");

// Keep reading until we reach the end of
while( !%fsObject.isEOF() )
```
{  
    %line = %fsObject.readLine();  
    echo(%line);  
}

// Made it to the end  
echo("Finished reading file");  

// Always remember to close a file stream  
%fsObject.close();

Returns:  
True if the parser has reached the end of the file, false otherwise

See also:  
isEOS()
while(!%fsObject.isEOS()) {
    %line = %fsObject.readLine();
    echo(%line);
}
// Made it to the end
echo("Finished reading file");

// Always remember to close a file stream
%fsObject.close();

**Returns:**

True if the parser has reached the end of the file, false otherwise

**See also:**

isEOF()

**string StreamObject::readLine( )**

Read a line from the stream.

Emphasis on *line*, as in you cannot parse individual characters or chunks of data. There is no limitation as to what kind of data you can read.

**Example:**

```
// Create a file stream object for reading
// This file contains the following two lines:
// HelloWorld
// HelloWorld
%fsObject = new FileStreamObject();
```
%fsObject.open("./test.txt", "read");

// Read in the first line
%line = %fsObject.readLine();

// Print the line we just read
echo(%line);

// Always remember to close a file stream
%fsObject.close();

**Returns:**
String containing the line of data that was just read

**See also:**
writeLine()

---

String StreamObject::readLongString(int maxLength)

Read in a string up to the given maximum number of characters.

**Parameters:**

`maxLength` The maximum number of characters to read in.

**Returns:**
The string that was read from the stream.

**See also:**
writeLongString()

**Note:**
When working with these particular string reading and writing methods, the stream begins with the length of the string followed by the string itself, and does not include a NULL
String StreamObject::readString()

Read a string up to a maximum of 256 characters.

**Returns:**

The string that was read from the stream.

**See also:**

writeString()

**Note:**

When working with these particular string reading and writing methods, the stream begins with the length of the string followed by the string itself, and does not include a NULL terminator.

String StreamObject::readSTString(bool caseSensitive = false)

Read in a string and place it on the string table.

**Parameters:**

If false then case will not be taken into account

*caseSensitive* when attempting to match the read in string with what is already in the string table.

**Returns:**

The string that was read from the stream.

**See also:**

writeString()

**Note:**
When working with these particular string reading and writing
methods, the stream begins with the length of the string
followed by the string itself, and does not include a NULL
terminator.

```cpp
bool StreamObject::setPosition(int newPosition)
```

Gets the position in the stream.

The easiest way to visualize this is to think of a cursor in a text file. If you have moved the cursor by five characters, the current position is 5. If you move ahead 10 more characters, the position is now 15. For `StreamObject`, when you read in the line the position is increased by the number of characters parsed, the null terminator, and a newline. Using `setPosition` allows you to skip to specific points of the file.

Example:

```cpp
// Create a file stream object for reading
%fsObject = new FileStreamObject();

// Open a file for reading
// This file contains the following two lines:
// 11111111111
// Hello World
%fsObject.open("./test.txt", "read");

// Skip ahead by 12, which will bypass the first line
%fsObject.setPosition(12);

// Read in the next line
%line = %fsObject.readLine();

// Print the line just read in, should be "Hello World"
```
echo(%line);

// Always remember to close a file stream
%fsObject.close();

Returns:
Number of bytes which stream has parsed so far, null terminators and newlines are included

See also:
ggetPosition()

void StreamObject::writeLine(string line)

Write a line to the stream, if it was opened for writing.

There is no limit as to what kind of data you can write. Any format and data is allowable, not just text. Be careful of what you write, as whitespace, current values, and literals will be preserved.

Parameters:

  line  The data we are writing out to file.

Example:

  // Create a file stream
  %fsObject = new FileStreamObject();

  // Open the file for writing
  // If it does not exist, it is created. If
  %fsObject.open("./test.txt", "write");

  // Write a line to the file
  %fsObject.writeLine("Hello World");
// Write another line to the file
%fsObject.writeLine("Documentation Rocks!");

// Always remember to close a file stream
%fsObject.close();

See also:
readLine()

void StreamObject::writeLongString(int maxLength,
                                  string string
                                  )

Write out a string up to the maximum number of characters.

Parameters:
  maxLength  The maximum number of characters that will be written.
  string     The string to write out to the stream.

See also:
readLongString()

Note:
When working with these particular string reading and writing methods, the stream begins with the length of the string followed by the string itself, and does not include a NULL terminator.

void StreamObject::writeString(string string,
                                int maxLength = 256
                                )
Write out a string with a default maximum length of 256 characters.

**Parameters:**

- `string`: The string to write out to the stream
- `maxLength`: The maximum string length to write out with a default of 256 characters. This value should not be larger than 256 as it is written to the stream as a single byte.

**See also:**

- `readString()`

**Note:**

When working with these particular string reading and writing methods, the stream begins with the length of the string followed by the string itself, and does not include a NULL terminator.

**Detailed Description**

A global light affecting your entire scene and optionally renders a corona effect.

**Sun** is both the directional and ambient light for your entire scene.

</table>
This toggles only terrain being rendered to the last split of a PSSM shadow map.

**float** `Sun::logWeight`

The logarithmic PSSM split distance factor.

**int** `Sun::numSplits`

The logarithmic PSSM split distance factor.

**Point4F** `Sun::overDarkFactor`

The ESM shadow darkening factor.

**bool** `Sun::representedInLightmap`

This light is represented in lightmaps (static light, default: false).

**ColorF** `Sun::shadowDarkenColor`

The color that should be used to multiply-blend dynamic shadows onto lightmapped geometry (ignored if ‘representedInLightmap’ is false).

**float** `Sun::shadowDistance`

The distance from the camera to extend the PSSM shadow.
float Sun::shadowSoftness

ShadowType Sun::shadowType

The type of shadow to use on this light.

int Sun::texSize

The texture size of the shadow map.

</tbody>
</table>
Detailed Description

Allows communications between the game and a server using TCP/IP protocols.

To use **TCPObj**ect you set up a connection to a server, send data to the server, and handle each line of the server's response using a callback. Once you are done communicating with the server, you disconnect.

**TCPObj**ect is intended to be used with text based protocols which means you'll need to delineate the server's response with an end-of-line character. i.e. the newline character `\n`. You may optionally include the carriage return character `\r` prior to the newline and **TCPObj**ect will strip it out before sending the line to the callback. If a newline character is not included in the server's output, the received data will not be processed until you disconnect from the server (which flushes the internal buffer).

**TCPObj**ect may also be set up to listen to a specific port, making Torque into a TCP server. When used in this manner, a callback is received when a client connection is made. Following the outside connection, text may be sent and lines are processed in the usual manner.

If you want to work with HTTP you may wish to use **HTTPObj**ect instead as it handles all of the HTTP header setup and parsing.

Example:

```c
// In this example we'll retrieve the new // feed from garagegames.com. As we're us. // raw text response will be received from // the HTTP header.

// Define callbacks for our specific TCPOb // name (RSSFeed) as the namespace.
```
// Handle an issue with resolving the server's name
function RSSFeed::onDNSFailed(%this)
{
    // Store this state
    %this.lastState = "DNSFailed";

    // Handle DNS failure
}

function RSSFeed::onConnectFailed(%this)
{
    // Store this state
    %this.lastState = "ConnectFailed";

    // Handle connection failure
}

function RSSFeed::onDNSResolved(%this)
{
    // Store this state
    %this.lastState = "DNSResolved";
}

function RSSFeed::onConnected(%this)
{
    // Store this state
    %this.lastState = "Connected";
}

function RSSFeed::onDisconnect(%this)
{
// Store this state
%this.lastState = "Disconnected";

} // Handle a line from the server
function RSSFeed::onLine(%this, %line)
{
   // Print the line to the console
   echo( %line );
}

// Create the TCPObject
%rss = new TCPObject(RSSFeed);

// Define a dynamic field to store the last connection state
%rss.lastState = "None";

// Connect to the server
%rss.connect("www.garagegames.com:80");

// Send the RSS feed request to the server
// handled in onLine() callback above
%rss.send("GET /feeds/rss/threads HTTP/1.1

See also:
HTTPObject
Member Function Documentation

void TCPObject::connect(string address )

Connect to the given address.

Parameters:

  address Server address (including port) to connect to.

Example:

```cpp
// Set the address.
%address = "www.garagegames.com:80";

// Inform this TCPObject to connect to the
%thisTCPObj.connect(%address);
```

void TCPObject::disconnect( )

Disconnect from whatever this TCPObject is currently connected to, if anything.

Example:

```cpp
// Inform this TCPObject to disconnect from
%thisTCPObj.disconnect();
```

void TCPObject::listen(int port )

Start listening on the specified port for connections.

This method starts a listener which looks for incoming TCP connections to a port. You must overload the onConnectionRequest callback to create a new TCPObject to
read, write, or reject the new connection.

**Parameters:**

*port*  
Port for this TCPObj ect to start listening for connections on.

**Example:**

```c
// Create a listener on port 8080.  
new TCPObj ect( TCPListener );  
TCPListener.listen( 8080 );

function TCPListener::onConnectionRequest( )  
{  
    // Create a new object to manage the connection.  
    new TCPObj ect( TCPClient, %id );  
}

function TCPClient::onLine( %this, %line );  
{  
    // Print the line of text from client.  
    echo( %line );  
}
```

**void TCPObj ect::onConnected( )**

Called whenever a connection is established with a server.

**void TCPObj ect::onConnectFailed( )**

Called whenever a connection has failed to be established with a server.
void TCPObject::onConnectionRequest(string address, string ID)

Called whenever a connection request is made.

This callback is used when the TCPObject is listening to a port and a client is attempting to connect.

Parameters:

- **address**
  Server address connecting from.
- **ID**
  Connection ID

See also:

listen()

void TCPObject::onDisconnect()

Called whenever the TCPObject disconnects from whatever it is currently connected to.

void TCPObject::onDNSFailed()

Called whenever the DNS has failed to resolve.

void TCPObject::onDNSResolved()

Called whenever the DNS has been resolved.

void TCPObject::onLine(string line)

Called whenever a line of data is sent to this TCPObject.
This callback is called when the received data contains a newline \n character, or the connection has been disconnected and the TCPObj's buffer is flushed.

**Parameters:**

- `line` Data sent from the server.

```cpp
void TCPObj::send(string data )
```

Transmits the data string to the connected computer.

This method is used to send text data to the connected computer regardless if we initiated the connection using `connect()`, or listening to a port using `listen()`.

**Parameters:**

- `data` The data string to send.

**Example:**

```cpp
// Set the command data
%data = "GET " @ $RSSFeed::serverURL @ " HTTP/1.0\r\n"
%data = %data @ "Host: " @ $RSSFeed::servername @ 
%data = %data @ "User-Agent: " @ $RSSFeed::userAgent @ 

// Send the command to the connected server
%thisTCPObj.send(%data);
```

</tr>
</tbody>
</table>
Detailed Description

The TerrainMaterial class organizes the material settings for a single terrain material layer.

Note:

You should not be creating TerrainMaterials by hand in code. All TerrainMaterials should be created in the editors, as intended by the system.

Example:

```java
// Created by the Terrain Painter tool in the World Editor
new TerrainMaterial()
{
    internalName = "grass1";
    diffuseMap = "art/terrains/Test/grass1"
    detailMap = "art/terrains/Test/grass1_d"
    detailSize = "10"
    isManaged = "1"
    detailBrightness = "1"
    Enabled = "1"
    diffuseSize = "200"
};
```

  TriggerData
Member Function Documentation

```cpp
int Trigger::getNumObjects()
```

Get the number of objects that are within the Trigger's bounds.

**See also:**
`getObject()`

```cpp
int Trigger::getObject(int index)
```

Retrieve the requested object that is within the Trigger's bounds.

**Parameters:**

- `index` Index of the object to get (range is 0 to `getNumObjects()` - 1)

**Returns:**

The SimObjectID of the object, or -1 if the requested index is invalid.

**See also:**
`getNumObjects()`

```cpp
void Trigger::onAdd(int objectId)
```

Called when the Trigger is being created.

**Parameters:**

- `objectId` the object id of the Trigger being created

```cpp
void Trigger::onRemove(int objectId)
```
Called just before the Trigger is deleted.

**Parameters:**

- `objectId` the object id of the Trigger being deleted
Member Data Documentation

string Trigger::enterCommand

The command to execute when an object enters this trigger. Object id stored in %obj. Maximum 1023 characters.

string Trigger::leaveCommand

The command to execute when an object leaves this trigger. Object id stored in %obj. Maximum 1023 characters.

floatList Trigger::polyhedron

Defines a non-rectangular area for the trigger.

Rather than the standard rectangular bounds, this optional parameter defines a quadrilateral trigger area. The quadrilateral is defined as a corner point followed by three vectors representing the edges extending from the corner.

string Trigger::tickCommand

The command to execute while an object is inside this trigger. Maximum 1023 characters.

# Callbacks

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bool <code>clientSide</code></td>
<td>Forces <code>Trigger</code> callbacks to only be called on clients.</td>
</tr>
<tr>
<td>int <code>tickPeriodMS</code></td>
<td>Time in milliseconds between calls to <code>onTickTrigger()</code> while at least one object is within a Trigger's bounds.</td>
</tr>
</tbody>
</table>

```c
void onEnterTrigger (Trigger trigger, GameBase obj)
```

Called when an object enters the volume of the `Trigger` instance using this `TriggerData`.

```c
void onLeaveTrigger (Trigger trigger, GameBase obj)
```

Called when an object leaves the volume of the `Trigger` instance using this `TriggerData`.

```c
void onTickTrigger (Trigger trigger)
```

Called every `tickPeriodMS` number of milliseconds (as specified in the `TriggerData`) whenever one or more objects are inside the volume of the trigger.
Detailed Description

Defines shared properties for Trigger objects.

The primary focus of the TriggerData datablock is the callbacks it provides when an object is within or leaves the Trigger bounds.

  Trigger.
Member Function Documentation

```cpp
void TriggerData::onEnterTrigger (Trigger trigger, GameBase obj )
```

Called when an object enters the volume of the Trigger instance using this TriggerData.

**Parameters:**

- `trigger` the Trigger instance whose volume the object entered
- `obj` the object that entered the volume of the Trigger instance

```cpp
void TriggerData::onLeaveTrigger (Trigger trigger, GameBase obj )
```

Called when an object leaves the volume of the Trigger instance using this TriggerData.

**Parameters:**

- `trigger` the Trigger instance whose volume the object left
- `obj` the object that left the volume of the Trigger instance

```cpp
void TriggerData::onTickTrigger (Trigger trigger )
```

Called every tickPeriodMS number of milliseconds (as specified in the TriggerData) whenever one or more objects are inside the volume of the trigger.

The Trigger has methods to retrieve the objects that are within the Trigger's bounds if you want to do something with them in this callback.
Parameters:

trigger the Trigger instance whose volume the object is inside

</tbody>
</table>
Detailed Description

An object used to modify a DTS or COLLADA shape model after it has been loaded by Torque.

TSShapeConstructor is a special object used to modify a DTS or COLLADA shape model after it has been loaded by Torque, but before it is used by any other object.

It is often used to share animations from DSQ files between shapes with a common skeleton.

It may also be used to 'Torquify' a model that is missing the nodes and/or sequences required to function as a particular Torque object. A model used for a Player character for example should have an eye and a cam node, but these might not be present in a model not specifically created for Torque. TSShapeConstructor allows the missing nodes to be added and positioned so that the shape does not need to be re-worked or re-exported by an artist.

Note:

In T3D, TSShapeConstructor is no longer a SimDataBlock (like in TGE and TGEA), but a SimObject instead. This means that all declarations of TSShapeConstructor should use the singleton keyword instead of the datablock keyword.

TSShapeConstructor also includes features to aid in loading COLLADA models, such as allowing the <up_axis> and <unit> elements to be overridden, and can also apply a user specified prefix to the names of COLLADA materials as shown below. Prefixing material names is useful to avoid name clashes, particularly for 3D apps like Google SketchUp that export models with generic material names like "material0". These options are most easily accessed using the COLLADA import gui, which will be displayed automatically the first time a COLLADA model is imported into Torque.
Settings from the import gui are automatically saved to a `TSShapeConstructor` script in the same folder as the model.

To create your own `TSShapeConstructor` object, simply create a TorqueScript file in the same folder as your DTS or COLLADA model, with the same filename but .cs extension. For example, if your model file was called `myShape.dts`, you would create a file called `myShape.cs`. Some example appear below:

```plaintext
singleton TSShapeConstructor(MyShapeDae)
{
    baseShape = "./myShape.dae";
    upAxis = "DEFAULT"; // use <up_axis
    unit = "1.0"; // override <unit>
    matNamePrefix = ""; // no prefix
};

singleton TSShapeConstructor(MyShape2Dae)
{
```
The name of the `TSShapeConstructor` object (MyShapeDae and MyShape2Dae in the code samples above) is up to you, but you should choose a name that does not conflict with other objects or datablocks. A common convention for `TSShapeConstructor` objects is the name of the shape file. eg. MyShapeDae for a file called myshape.dae.

When Torque loads a DTS (.dts) or COLLADA (.dae) file, it first looks in the same folder for a TorqueScript file with the same filename (but .cs extension) in order to create the `TSShapeConstructor` object. Such scripts are executed automatically by Torque 3D, so there is no need to manually call exec("myShape.cs") from another script. Also, you should avoid adding other object and datablock declarations to this script because it will be executed every time the model is loaded, which may cause unexpected results if the datablocks already exist.

After Torque has loaded the model from the DTS or COLLADA file, it executes the `TSShapeConstructor` onLoad method to apply the desired set of changes to the shape. It should be noted that the changes are applied to the loaded model in memory rather than to the DTS or COLLADA file itself. This means the model can be re-exported to DTS or COLLADA without overwriting the `TSShapeConstructor` changes. `TSShapeConstructor` should be thought of as a post-export processing step, and is intended to be used alongside existing object and datablock setups.

Note that DSQ sequences may still be specified within the `TSShapeConstructor` object as normal:

```
singleton TSShapeConstructor( PlayerDts )
{
  baseShape = "./myShape2.dae";
  upAxis = "Y_AXIS";  // override <
  unit = -1;         // use <unit>
  matNamePrefix = "myShape2_"; // prefix all
}
```
baseShape = "./player.dts";
sequence = "/art/shapes/actors/animations/player_root.dsq	root
sequence = "/art/shapes/actors/animations/player_forward.dsq	run

function PlayerDts::onLoad( %this )
{
    %this.addCollisionDetail( -1, "box", "bounds"
    %this.addSequence( "walk", "walk_short", 1
    %this.addTrigger( "walk_short", 3, 4 );
    %this.renameSequence( "walk", "walk_long"
    %this.renameNode( "Bip Pelvis", "pelvis" )
    %this.addNode( "mount5", "Bip L Hand" );
    %this.dumpShape();
}

Note that most of the features in TSShapeConstructor are far more easily accessible in the Shape Editor tool. This tool uses TSShapeConstructor 'under-the-hood' to edit the nodes, sequences and details of a shape, and the changes are saved to a TSShapeConstructor script object.
Shape Terminology

The following definitions should be understood before reading the TSShapeConstructor examples and function reference:

node

A node is a place-holder for transform (position and rotation) information. Nodes are arranged in a parent/child hierarchy allowing complex skeleton structures to be built up.

sequence

A sequence is a set of keyframed node transforms and object states (eg. visibility).

detail level

Level-of-Detail (LOD) is very important to maintain good rendering performance. When a shape is rendered, Torque automatically picks a single detail level based on that shape's on-screen size. Only the sub-meshes belonging to that detail level are rendered.

object

An object is a collection of meshes, each at a different detail level. Each object is attached to a certain node, and is rendered at that node's current transform.

mesh

A mesh is a piece of geometry, and may be a rigid body or a skin (vertex weighted mesh). Each mesh is associated with an object and a certain detail level.
Example 1: Adding a Collision Mesh To an Existing Shape

Imagine you have a model that you want to add to the scene as a `StaticShape`, but it is missing a collision mesh. `TSShapeConstructor` makes it simple to modify an existing DTS shape to add a collision (or line-of-sight collision) detail level.

First, define the `StaticShapeData` datablock as normal. Create a script called `myShape.cs` in the `art/datablocks` folder, and define the datablock:

```plaintext
datablock StaticShapeData( MyShapeData ) {
    category = "Misc";
    shapeFile = "art/shapes/myShape/myShape.dts"
};
```

We need to tell Torque to execute this script so add `exec("./myShape.cs");` to `art/datablocks/datablockExec.cs`.

Now we define the `TSShapeConstructor` object by creating a new script called `myShape.cs` in the `art/shapes/myShape` folder:

```plaintext
singleton TSShapeConstructor( MyShapeDts ) {
    baseShape = "~/art/shapes/myShape/myShape.dts"
};

function MyShapeDts::onLoad( %this ) {
    %this.addCollisionDetail( -1, "box", "boun
```

This script will add a box mesh with the same center and dimensions as the original model using the "Col" detail level at size -1. The
negative detail size means that the mesh will not be rendered in-game, and the use of the special "Col" name means that this mesh will be detected as a collision mesh by the Torque engine.

When a Torque mission is started, the following steps occur:

1. On the server, Torque executes
   art/datablocks/datablockExec.cs, which in turn executes
   art/datablocks/myShape.cs
2. Executing art/datablocks/myShape.cs causes the MyShapeData datablock to attempt to load the DTS file
3. Before loading the DTS file, Torque executes
   art/shapes/myShape/myShape.cs, which creates the
   TSShapeConstructor object
4. After loading the DTS file, Torque executes
   MyShapeDts::onLoad, which adds the collision detail level to the shape
5. The StaticShape object can now be added to the scene (it will appear in the world editor (in the "Misc" category under the Library/Scripted tab)
Example 2: Adding a Mesh From an Existing DTS File

The image below shows a boulder.dts shape in the Torque Show Tool Pro (TSTPro). The circled items indicate the geometry and material that will be copied into a different shape using TSShapeConstructor.

The following shows how to include the boulder1 mesh in another shape:

```
singleton TSShapeConstructor( TestShapeDts )
{
    baseShape = "~/art/shapes/rocks/rock1.dts"
}
```
function TestShapeDts::onLoad( %this )
{
    %this.addMesh( "test128", "~/art/shapes/ro
        %this.dumpShape();
}

The output of the dumpShape command is shown below:

Shape Hierarchy:

Details:
- detail128, Subtree 0, objectDetail 0, size 128
- detail2, Subtree 0, objectDetail 1, size 2
- collision-1, Subtree 0, objectDetail 2,

Subtrees:
- Subtree 0
  - Rock2 --> Object Rock with following
    --> Object test with following
    col-1 --> Object col with following

Sequences:

%Material list:
- material #0: 'rock2'.
- material #1: 'MossyRock02'.

Note that the new detail ("detail128"), object ("test") and material ("MossyRock02") have been added to the normal rock1.dts shape.
Example 3: Auto-loading animations

Instead of manually specifying all of the animations to load, it's easy to write some TorqueScript that will scan a folder for any matching animations and add them to the shape automatically. Imagine that we have the following shape (DTS) and sequence (DSQ) files:

- `art/shapes/actors/ForgeSoldier/ForgeSoldier.dts`
- `art/shapes/actors/animations/player_root.dsq`
- `art/shapes/actors/animations/player_run.dsq`
- `art/shapes/actors/animations/player_back.dsq`
- `art/shapes/actors/animations/player_side.dsq`
- `art/shapes/actors/animations/player_death0.dsq`

The following script will scan the `animations` folder and add the sequences to the shape.

```torquescript
singleton TSShapeConstructor( ForgeSoldierDts ) {
    baseShape = "~/art/shapes/actors/ForgeSoldier/ForgeSoldier.dts";
}

function ForgeSoldierDts::onLoad( %this ) {
    AddAnimations( %this );
}

function AddAnimations( %shape ) {
    // Scan for all player_*_.dsq files and add
    // Sequence names are taken from the base
    // player_run.dsq would add a sequence cal

    %filePatterns = "art/shapes/actors/animations/player_*_.dsq"
    %fullPath = findFirstFileMultiExpr( %filePatterns )

    if( %fullPath ) {
        %sequenceNames = split( %fullPath, "\"" )
        %sequenceNames = %sequenceNames[1]

        %shape.addAnimation( %sequenceNames, %fullPath );
    }
}
```
while ( %fullPath !$= '"' )
{
    // add this animation to the shape
    %fullPath = makeRelativePath( %fullPath
    %seq_name = strreplace( filebase( %full
    %shape.addSequence( %fullpath, %seq_name
    %fullPath = findNextFileMultiExpr( %fil

}
Example 4: Splitting COLLADA animations

Many COLLADA exporters do not support the `<animation_clip>` element, meaning that animated models imported into Torque appear to have only a single sequence containing all of the animations. **TSShapeConstructor** can be used to split this combined animation into individual sequences. This is most easily done using the Shape Editor tool, but can also be done manually as follows:

```plaintext
singleton TSShapeConstructor( PlayerModelDts
{

    baseShape = "~/art/shapes/collada/myPlayer.dae"

};

function PlayerModelDts::onLoad( %this )
{

    // Split animations from combined "ambient"
    %this.addSequence( "ambient", "root", 0, 1
    %this.addSequence( "ambient", "run", 16, 4
    %this.addSequence( "ambient", "back", 41,
    %this.addSequence( "ambient", "side", 56,
    %this.addSequence( "ambient", "death0", 80

    // Remove combined "ambient" sequence => we
    %this.removeSequence( "ambient" );

```
Example 5: LOD using separate files

In the past, using LOD required the artist to export all detail levels into a single DTS file. Using TSShapeConstructor, we can combine separate model files together. In fact, we can even use the folder-scanning approach from Example 3 to automatically construct the shape detail levels using all of the model files in the folder!

Note that the detail level models must contain the same object name, and for skinned models, the skin must be applied to the same skeleton for this script to work.

Imagine that we have the following shape (DAE) files:

- `art/shapes/actors/soldier/soldier.dae` (the base model, highest detail level size=1024)
- `art/shapes/actors/soldier/soldier_512.dae`
- `art/shapes/actors/soldier/soldier_256.dae`
- `art/shapes/actors/soldier/soldier_64.dae`

```singleton TSShapeConstructor( SoldierDae )
{
    baseShape = "~/art/shapes/actors/soldier.dae"
};

function SoldierDae::onLoad( %this )
{
    %objName = %this.getObjectName( 0 );
    AddDetails( %this, %objName );
}

// Scan for all DAE files in the folder with // skinned mesh from that file to the input s // is taken from the end of the filename. eg. // level 30 to the shape.
// Note that this function can be in a differ```
multiple TSShapeConstructor objects...

function AddDetails( %shape, %objName )
{
    // Determine the base name of the input file
    // soldier.dae is 'soldier'.
    %inputBase = fileBase( %shape.baseShape );

    %filePatterns = filePath( %shape.baseShape );
    %fullPath = findFirstFileMultiExpr( %filePatterns );
    while (%fullPath !=$)
    {
        %fullPath = makeRelativePath( %fullPath );

        // Determine the detail size, then add
        %size = strreplace( fileBase( %fullPath );
        %shape.addMesh( %objName SPC %size, %fullPath);

        %fullPath = findNextFileMultiExpr( %filePatterns );
    }
}
Example 6: Add lights to the scene

Although most often used to modify a shape before it is used, TSShapeConstructor can also be used as a general purpose interface to a 3D shape. For example, a 3D modeling package could be used to layout positions for lights in the scene. On import, the shape hierarchy might look like this:

```
base01
  +-start01
    +-Lights
      +-lightA
      +-lightB
      +-lightC
      ...
```

The following code demonstrates how to create a TSShapeConstructor object on-demand in order to access the 3D shape data. This example adds lights to the current scene at position of the lightX nodes in the shape:

```plaintext
function AddLights( %obj )
{
  // Get a TSShapeConstructor for this object
  // utility functions to create one if it d
  %shapePath = ShapeEditor.getObjectShapeFile( %obj );
  %shape = ShapeEditor.findConstructor( %shapePath );
  if ( !isObject( %shape ) )
  %shape = ShapeEditor.createConstructor( %shapePath );
  if ( !isObject( %shape ) )
  {
    echo( "Failed to create TSShapeConstructor" );
    return;
  }
```
%objTransform = %obj.getTransform();

%lightsGroup = "Lights";
%count = %shape.getNodeChildCount( %lightsGroup)
for ( %i = 0; %i < %count; %i++ )
{
   // get node transform in object space,
   %child = %shape.getNodeChildName( %lightsGroup, %i)
   %txfm = %shape.getNodeTransform( %child)
   %txfm = MatrixMultiply( %objTransform, %txfm)

   // create a new light at the object node
   %light = new PointLight() {
      position = getWords( %txfm, 0, 2 );
      rotation = getWords( %txfm, 3, 6 );
   };
   MissionGroup.add( %light );
}

The original shape can be placed anywhere in the scene, then AddLights is called to create and place a PointLight at each node.
Example 7: Rigid-body Player Character

Using the addNode and addMesh functions, it is possible to create a rigid-body (ie. non-skinned) player model compatible with the default animations, completely from TorqueScript!

The default player skeleton node transforms were obtained by adding the following code to the TSShapeConstructor onLoad function for a shape that already contained the default skeleton:

```
%count = %this.getNodeCount();
for ( %i = 0; %i < %count; %i++ )
{
    %name = %this.getNodeName( %i );
    echo( "%shape.addNode("" @ %name @ "," , 
          %this.getNodeTransform( %name ) @ "")
}
```

The contents of the console can then be copied and pasted into a new script. The script below shows the player model creation process: first pick a dummy dts file (rock1.dts in this case), and delete its existing nodes and meshes. Then create the default player skeleton. Finally, some box meshes are added at certain nodes to build up a rigid-body player character.

```
// Create the default Torque skeleton (compat function CreateDefaultSkeleton( %shape )
{
    %shape.addNode( "Bip01 Pelvis", "", "Bip0
    %shape.addNode( "Bip01 Spine", "Bip0
    %shape.addNode( "Bip01 Spine1", "Bip0
    %shape.addNode( "Bip01 Spine2", "Bip0
    %shape.addNode( "Bip01 Neck", "Bip0
    %shape.addNode( "Bip01 Head", "Bip0
    %shape.addNode( "Eye", "Bip0
```
// Create a new box mesh at the specified node
function CreateBoxObject( %shape, %name, %node, %offset ) {
  if ( %offset $= "" )
    %offset = "0 0 0";

  %shape.addPrimitive( %name @ "2", "box", %offset );
}

// Create a simple (rigid) player model using
function CreateRigidPlayer( %shape )
{
  CreateBoxObject( %shape, "head",
  CreateBoxObject( %shape, "upper_torso",
  CreateBoxObject( %shape, "lower_torso",
  CreateBoxObject( %shape, "left_thigh",
  CreateBoxObject( %shape, "left_leg",
  CreateBoxObject( %shape, "left_foot",
  CreateBoxObject( %shape, "right_thigh",
  CreateBoxObject( %shape, "right_leg",
  CreateBoxObject( %shape, "right_foot",
  CreateBoxObject( %shape, "left_upper_arm",
  CreateBoxObject( %shape, "left_forearm",
  CreateBoxObject( %shape, "left_hand",
  CreateBoxObject( %shape, "right_upper_arm"
  CreateBoxObject( %shape, "right_forearm",
  CreateBoxObject( %shape, "right_hand",

  // create collision mesh
  %shape.addCollisionDetail( -1, "box", "box"

}

singleton TSShapeConstructor( TestModelDts )
{
  baseShape = "~/art/shapes/rocks/rock1.dts"
};

function TestModelDts::onLoad( %this )
{  
// remove the existing nodes and geometry
%count = %this.getObjectCount();
for ( %i = %count-1; %i >= 0; %i-- )
  %this.removeObject( %this.getObjectName( %i ) );
%count = %this.getNodeCount();
for ( %i = %count-1; %i >= 0; %i-- )
  %this.removeNode( %this.getNodeName( %i ) );

// create the player skeleton and rigid body parts
CreateDefaultSkeleton( %this );
CreateRigidPlayer( %this );

// now load the default sequences
%this.addSequence( "~/art/shapes/actors/animations/player_root.dsq" );
%this.addSequence( "~/art/shapes/actors/animations/player_forward.dsq" );
%this.dumpShape();
}

// The player model definition
singleton PlayerData( TestModelData : Default ) {
  renderFirstPerson = false;
  emap = true;

  // className = Armor;
  shapeFile = "~/art/shapes/rocks/rock1.dts"
};

PlayerDatasGroup.add( TestModelData );
This produces the following shape:

Shape Hierarchy:

Member Function Documentation

```cpp
bool TSShapeConstructor::addCollisionDetail(int size,
                                          string type,
                                          string target,
                                          int depth = 4,
                                          float merge = 30,
                                          float concavity = 30,
                                          int maxVerts = 32,
                                          float boxMaxError = 0,
                                          float sphereMaxError =
                                          float capsuleMaxError =
                                      )
```

Autofit a mesh primitive or set of convex hulls to the shape geometry. Hulls may optionally be converted to boxes, spheres and/or capsules based on their volume.

**Parameters:**

- `size`: size for this detail level
- `type`: one of: box, sphere, capsule, 10-dop x, 10-dop y, 10-dop z, 18-dop, 26-dop, convex hulls. See the Shape Editor documentation for more details about these types.
- `target`: geometry to fit collision mesh(es) to; either "bounds" (for the whole shape), or the name of an object in the shape
- `depth`: maximum split recursion depth (hulls only)
- `merge`: volume % threshold used to merge hulls together (hulls only)
- `concavity`: volume % threshold used to detect concavity (hulls only)
- `maxVerts`: maximum number of vertices per hull (hulls only)
- `boxMaxError`: max % volume difference for a hull to be converted to a box (hulls only)
sphereMaxError  max % volume difference for a hull to be converted to a sphere (hulls only)
capsuleMaxError  max % volume difference for a hull to be converted to a capsule (hulls only)

Returns:
true if successful, false otherwise

Example:

```cpp
%this.addCollisionDetail( -1, "box", "bounds"
%this.addCollisionDetail( -1, "convex hull"
%this.addCollisionDetail( -1, "convex hull"
```

```cpp
int TSShapeConstructor::addImposter(int size,
    int equatorSteps,
    int polarSteps,
    int dl,
    int dim,
    bool includePoles,
    float polarAngle
)
```

Add (or edit) an imposter detail level to the shape.

If the shape already contains an imposter detail level, this command will simply change the imposter settings

Parameters:

- **size**: size of the imposter detail level
  defines the number of snapshots to take around the equator. Imagine the object being rotated around the vertical axis, then a snapshot taken at regularly spaced intervals.
  defines the number of snapshots taken between the poles (top and bottom), at each
polarSteps
equator step. eg. At each equator snapshot, snapshots are taken at regular intervals between the poles.

the detail level to use when generating the snapshots. Note that this is an array index rather than a detail size. So if an object has detail sizes of: 200, 150, and 40, then setting dl to 1 will generate the snapshots using detail size 150.

dl
defines the size of the imposter images in pixels. The larger the number, the more detailed the billboard will be.

dim
flag indicating whether to include the "pole" snapshots. ie. the views from the top and bottom of the object.

includePoles
if pole snapshots are active (includePoles is true), this parameter defines the camera angle (in degrees) within which to render the pole snapshot. eg. if polar_angle is set to 25 degrees, then the snapshot taken at the pole (looking directly down or up at the object) will be rendered when the camera is within 25 degrees of the pole.

polar_angle

Returns:
true if successful, false otherwise

Example:

%this.addImposter( 2, 4, 0, 0, 64, false, %this.addImposter( 2, 4, 2, 0, 64, true, :

bool TSShapeConstructor::addMesh (string meshName, string srcShape, string srcMesh )
Add geometry from another DTS or DAE shape file into this shape.

Any materials required by the source mesh are also copied into this shape.

**Parameters:**

- **meshName**
  full name (object name + detail size) of the new mesh. If no detail size is present at the end of the name, a value of 2 is used.

- **srcShape**
  name of a shape file (DTS or DAE) that contains the mesh.

- **srcMesh**
  the full name (object name + detail size) of the mesh to copy from the DTS/DAE file into this shape.

**Returns:**

true if successful, false otherwise

**Example:**

```plaintext
%this.addMesh(  "ColMesh-1",  "./collision.dts"
%this.addMesh(  "SimpleShape10",  "./testShape.dae"
```

```plaintext
bool TSShapeConstructor::addNode(string name,
string parentName,
TransformF txfm = TransformF::Identity,
bool isWorld = false
)
```

Add a new node.

**Parameters:**
**name**
name for the new node (must not already exist)

**parentName**
name of an existing node to be the parent of the new node. If empty (""), the new node will be at the root level of the node hierarchy.

**txfm**
(optional) transform string of the form: "pos.x pos.y pos.z rot.x rot.y rot.z rot.angle"

**isworld**
(optional) flag to set the local-to-parent or the global transform. If false, or not specified, the position and orientation are treated as relative to the node's parent.

**Returns:**
true if successful, false otherwise

**Example:**

```plaintext
%this.addNode( "Nose", "Bip01 Head", "0 2
%this.addNode( "myRoot", "", "0 0 4 0 0 1
%this.addNode( "Nodes", "Bip01 Head", "0 2
```

```cpp
bool TSShapeConstructor::addPrimitive(string meshName, string type, string params, TransformF txfm, string nodeName)
```

Add a new mesh primitive to the shape.

**Parameters:**

- **meshName**
  full name (object name + detail size) of the new mesh. If no detail size is present at the end of the name, a value of 2 is used.

- **meshName**
  An underscore before the number at the end of the name will be interpreted as a negative sign. eg. "MyMesh_4" will be interpreted as "MyMesh-"
4".

type one of: "box", "sphere", "capsule"

mesh primitive parameters:
  • for box: "size_x size_y size_z"
  • for sphere: "radius"
  • for capsule: "height radius"

params

txfm local transform offset from the node for this mesh

nodeName name of the node to attach the new mesh to (will
change the object's node if adding a new mesh
to an existing object)

Returns:
true if successful, false otherwise

Example:

```plaintext
%this.addMesh( "Box4", "box", "2 4 2", "0
%this.addMesh( "Sphere256", "sphere", "2",
%this.addMesh( "MyCapsule-1", "capsule", '

bool TSShapeConstructor::addSequence( string source,
    string name,
    int start = 0,
    int end = -1,
    bool padRot = true,
    bool padTrans = false
)

Add a new sequence to the shape.

Parameters:

source the name of an existing sequence, or the name of
a DTS or DAE shape or DSQ sequence file. When
the shape file contains more than one sequence,
the desired sequence can be specified by
appending the name to the end of the shape file.
eg. "myShape.dts run" would select the "run" sequence from the "myShape.dts" file.

<table>
<thead>
<tr>
<th>name</th>
<th>name of the new sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>start</td>
<td>(optional) first frame to copy. Defaults to 0, the first frame in the sequence.</td>
</tr>
<tr>
<td>end</td>
<td>(optional) last frame to copy. Defaults to -1, the last frame in the sequence.</td>
</tr>
<tr>
<td>padRot</td>
<td>(optional) copy root-pose rotation keys for non-animated nodes. This is useful if the source sequence data has a different root-pose to the target shape, such as if one character was in the T pose, and the other had arms at the side. Normally only nodes that are actually rotated by the source sequence have keyframes added, but setting this flag will also add keyframes for nodes that are not animated, but have a different root-pose rotation to the target shape root pose.</td>
</tr>
<tr>
<td>padTrans</td>
<td>(optional) copy root-pose translation keys for non-animated nodes. This is useful if the source sequence data has a different root-pose to the target shape, such as if one character was in the T pose, and the other had arms at the side. Normally only nodes that are actually moved by the source sequence have keyframes added, but setting this flag will also add keyframes for nodes that are not animated, but have a different root-pose position to the target shape root pose.</td>
</tr>
</tbody>
</table>

**Returns:**

true if successful, false otherwise

**Example:**

```plaintext
%this.addSequence( "./testShape.dts ambient"
%this.addSequence( "./myPlayer.dae run", '
%this.addSequence( "./player_look.dsq", "
%this.addSequence( "walk", "walk_shortA",
%this.addSequence( "walk", "walk_shortB",
```
bool TSShapeConstructor::addTrigger(string name, int keyframe, int state)

Add a new trigger to the sequence.

**Parameters:**
- *name* name of the sequence to modify
- *keyframe* keyframe of the new trigger
- *state* of the new trigger

**Returns:**
- true if successful, false otherwise

**Example:**
```cpp
%this.addTrigger( "walk", 3, 1 );
%this.addTrigger( "walk", 5, -1 );
```

```cpp
void TSShapeConstructor::dumpShape(string filename = "")
```

Dump the shape hierarchy to the console or to a file. Useful for reviewing the result of a series of construction commands.

**Parameters:**
- *filename* Destination filename. If not specified, dump to console.

**Example:**
```cpp
%this.dumpShape(); // dump to console
%this.dumpShape( "./dump.txt" ); // dump to file
```
Get the bounding box for the shape.

**Returns:**

Bounding box "minX minY minZ maxX maxY maxZ"

Get the total number of detail levels in the shape.

**Returns:**

the number of detail levels in the shape

Get the index of the detail level with a given size.

**Parameters:**

size  size of the detail level to lookup

**Returns:**

index of the detail level with the desired size, or -1 if no such detail exists

**Example:**

```cpp
if ( %this.getDetailLevelSize( 32 ) == -1 )
    echo( "Error: This shape does not have..."
```

Get the name of the indexed detail level.
Parameters:

\textit{index} detail level index (valid range is 0 - \texttt{getDetailLevelCount()-1})

Returns:

the detail level name

Example:

```
// print the names of all detail levels in the shape
%count = %this.getDetailLevelCount();
for ( %i = 0; %i < %count; %i++)
    echo( %i SPC %this.getDetailLevelName(%i));
```

\begin{Verbatim}
int TSShapeConstructor::getDetailLevelSize(int index )
\end{Verbatim}

Get the size of the indexed detail level.

Parameters:

\textit{index} detail level index (valid range is 0 - \texttt{getDetailLevelCount()-1})

Returns:

the detail level size

Example:

```
// print the sizes of all detail levels in the shape
%count = %this.getDetailLevelCount();
for ( %i = 0; %i < %count; %i++)
    echo( "Detail" @ %i @ " has size " @ %t
```

\begin{Verbatim}
int TSShapeConstructor::getImposterDetailLevel( )
\end{Verbatim}
Get the index of the imposter (auto-billboard) detail level (if any).

**Returns:**

imposter detail level index, or -1 if the shape does not use imposters.

```cpp
string TSShapeConstructor::getImposterSettings(int index)
```

Get the settings used to generate imposters for the indexed detail level.

**Parameters:**

- `index` index of the detail level to query (does not need to be an imposter detail level)

**Returns:**

string of the form: "valid eqSteps pSteps dl dim poles angle",

where:

- **valid**
  1 if this detail level generates imposters, 0 otherwise

- **eqSteps**
  number of steps around the equator

- **pSteps**
  number of steps between the poles

- **dl**
  index of the detail level used to generate imposters

- **dim**
  size (in pixels) of each imposter image

- **poles**
  1 to include pole images, 0 otherwise

- **angle**
  angle at which to display pole images

**Example:**
// print the imposter detail level setting
%index = %this.getImposterDetailLevel();
if ( %index != -1 )
  echo( "Imposter settings: " @ %this.get

int TSShapeConstructor::getMeshCount(string name )
Get the number of meshes (detail levels) for the specified object.

Parameters:
  name  name of the object to query

Returns:
  the number of meshes for this object.

Example:
  %count = %this.getMeshCount( "SimpleShape"

string TSShapeConstructor::getMeshMaterial(string name )
Get the name of the material attached to a mesh. Note that only
the first material used by the mesh is returned.

Parameters:
  name  full name (object name + detail size) of the mesh to
        query

Returns:
  name of the material attached to the mesh (suitable for use
  with the Material mapTo field)

Example:
string TSShapeConstructor::getMeshName(string name, int index)

Get the name of the indexed mesh (detail level) for the specified object.

**Parameters:**

- *name*  name of the object to query
- *index*  index of the mesh (valid range is 0 - `getMeshCount()` - 1)

**Returns:**

the mesh name.

**Example:**

```cpp
// print the names of all meshes in the shape
%objCount = %this.getObjectCount();
for ( %i = 0; %i < %objCount; %i++ )
{
    %objName = %this.getObjectName( %i );
    %meshCount = %this.getMeshCount( %objName );
    for ( %j = 0; %j < %meshCount; %j++ )
        echo( %this.getMeshName( %objName, %j ) );
}
```

int TSShapeConstructor::getMeshSize(string name, int index)

Get the detail level size of the indexed mesh for the specified object.

**Parameters:**

- **name**  name of the object to query
- **index**  index of the mesh (valid range is 0 - `getMeshCount()-1`)

**Returns:**

the mesh detail level size.

**Example:**

```c++
// print sizes for all detail levels of this object
%objName = "trunk";
%count = %this.getMeshCount( %objName );
for ( %i = 0; %i < %count; %i++ )
  echo( %this.getMeshSize( %objName, %i ) );
```

---

**string TSShapeConstructor::getMeshType (string name )**

Get the display type of the mesh.

**Parameters:**

- **name**  name of the mesh to query

**Returns:**

the string returned is one of:

- **normal**  a normal 3D mesh
- **billboard**  a mesh that always faces the camera
- **billboardzaxis**  a mesh that always faces the camera in the Z-axis
Example:

```php
echo( "Mesh type is " @ %this->getMeshType() );
```

```cpp
int TSShapeConstructor::getNodeChildCount(string name )
```

Get the number of children of this node.

**Parameters:**

`name` name of the node to query.

**Returns:**

the number of child nodes.

**Example:**

```cpp
%count = %this->getNodeChildCount( "Bip01" )
```

```cpp
string TSShapeConstructor::getNodeChildName(string name, int index )
```

Get the name of the indexed child node.

**Parameters:**

`name` name of the parent node to query.

`index` index of the child node (valid range is 0 - `getNodeChildName()`-1).

**Returns:**

the name of the indexed child node.

**Example:**

```cpp
function dumpNode( %shape, %name, %indent
```
{ echo( %indent @ %name );
  %count = %shape.getNodeChildCount( %name );
  for ( %i = 0; %i < %count; %i++ )
    dumpNode( %shape, %shape.getNodeChild(%name) );
}

function dumpShape( %shape )
{
  // recursively dump node hierarchy
  %count = %shape.getNodeCount();
  for ( %i = 0; %i < %count; %i++ )
  {
    // dump top level nodes
    %name = %shape.getNodeName( %i );
    if ( %shape.getNodeParentName( %name ) )
      dumpNode( %shape, %name, "" );
  }
}

int TSShapeConstructor::getNodeCount( )

Get the total number of nodes in the shape.

Returns:
  the number of nodes in the shape.

Example:
  %count = %this.getNodeCount();

int TSShapeConstructor::getNodeIndex(string name )
Get the index of the node.

**Parameters:**

*name* name of the node to lookup.

**Returns:**

the index of the named node, or -1 if no such node exists.

**Example:**

```c
// get the index of Bip01 Pelvis node in the shape
%index = %this.getNodeIndex( "Bip01 Pelvis"
```

---

Get the name of the indexed node.

**Parameters:**

*index* index of the node to lookup (valid range is 0 - getNodeCount()-1).

**Returns:**

the name of the indexed node, or "" if no such node exists.

**Example:**

```c
// print the names of all the nodes in the shape
%count = %this.getNodeCount();
for (%i = 0; %i < %count; %i++)
  echo(%i SP %this.getNodeName(%i));
```

---

Get the number of geometry objects attached to this node.
Parameters:

    name  name of the node to query.

Returns:

    the number of attached objects.

Example:

    int count = this.getNodeObjectCount("Bip01 Head");

```
string TSShapeConstructor::getNodeObjectName(string name, int index)
```

Get the name of the indexed object.

Parameters:

    name  name of the node to query.
    index index of the object (valid range is 0 -
            getNodeObjectCount()-1).

Returns:

    the name of the indexed object.

Example:

    // print the names of all objects attached to the node
    int count = this.getNodeObjectCount("Bip01 Head");
    for (int i = 0; i < count; i++)
        echo(this.getNodeObjectName("Bip01 Head"));

```
string TSShapeConstructor::getNodeParentName(string name )
```

Get the name of the node's parent. If the node has no parent (ie. it
is at the root level), return an empty string.

**Parameters:**

- `name` name of the node to query.

**Returns:**

- the name of the node's parent, or "" if the node is at the root level

**Example:**

```cpp
echo( "Bip01 Pelvis parent = " @ %this.getNodeParentName( "Bip01 Pelvis" ) );
```

**TransformF TSShapeConstructor::getNodeTransform**

Get the base (ie. not animated) transform of a node.

**Parameters:**

- `name` name of the node to query.
- `isWorld` true to get the global transform, false (or omitted) to get the local-to-parent transform.

**Returns:**

- the node transform in the form "pos.x pos.y pos.z rot.x rot.y rot.z rot.angle".

**Example:**

```cpp
%ret = %this.getNodeTransform( "mount0" );
%this.setNodeTransform( "mount4", %ret );
```

**int TSShapeConstructor::getObjectCount**
Get the total number of objects in the shape.

**Returns:**
the number of objects in the shape.

**Example:**

```cpp
%count = %this.getObjectCount();
```

---

```cpp
int TSShapeConstructor::getObjectIndex(string name )
```

Get the index of the first object with the given name.

**Parameters:**
- `name` name of the object to get.

**Returns:**
the index of the named object.

**Example:**

```cpp
%index = %this.getObjectIndex( "Head" );
```

---

```cpp
string TSShapeConstructor::getObjectName(int index )
```

Get the name of the indexed object.

**Parameters:**
- `index` index of the object to get (valid range is 0 - `getObjectCount()`-1).

**Returns:**
the name of the indexed object.
Example:
```c++
// print the names of all objects in the shape
%count = %this.getObjectCount();
for ( %i = 0; %i < %count; %i++ )
    echo( %i SPC %this.getObjectName( %i )
```

string TSShapeConstructor::getObjectNode(string name )

Get the name of the node this object is attached to.

**Parameters:**

- *name* name of the object to get.

**Returns:**

the name of the attached node, or an empty string if this object is not attached to a node (usually the case for skinned meshes).

Example:
```c++
echo( "Hand is attached to " @ %this.getObjectNode( "Hand" )
```

string TSShapeConstructor::getSequenceBlend(string name )

Get information about blended sequences.

**Parameters:**

- *name* name of the sequence to query

**Returns:**

TAB delimited string of the form: "isBlend blendSeq blendFrame", where:

- **blend_flag**
a boolean flag indicating whether this sequence is a blend

**blend_seq_name**

the name of the sequence that contains the reference frame (empty for blend sequences embedded in DTS files)

**blend_seq_frame**

the blend reference frame (empty for blend sequences embedded in DTS files)

**Note:**

Note that only sequences set to be blends using the `setSequenceBlend` command will contain the blendSeq and blendFrame information.

**Example:**

```plaintext
%blendData = %this.getSequenceBlend( "look" if ( getField( %blendData, 0 ) )
    echo( "look is a blend, reference: " @
```

---

**int TSShapeConstructor::getSequenceCount( )**

Get the total number of sequences in the shape.

**Returns:**

the number of sequences in the shape

---

**bool TSShapeConstructor::getSequenceCyclic(string name )**

Check if this sequence is cyclic (looping).

**Parameters:**

name name of the sequence to query
Returns:
true if this sequence is cyclic, false if not

Example:
```cpp
if (!%this.getSequenceCyclic( "ambient" ))
    error( "ambient sequence is not cyclic!"
```

```cpp
int TSShapeConstructor::getSequenceFrameCount(string name)
```

Get the number of keyframes in the sequence.

Parameters:
- `name` name of the sequence to query

Returns:
number of keyframes in the sequence

Example:
```cpp
echo( "Run has " @ %this.getSequenceFrameCount( "ambient"
```

```cpp
string TSShapeConstructor::getSequenceGroundSpeed(string name)
```

Get the ground speed of the sequence.

Note:
Note that only the first 2 ground frames of the sequence are examined; the speed is assumed to be constant throughout the sequence.

Parameters:
- `name` name of the sequence to query

Returns:
string of the form: "trans.x trans.y trans.z rot.x rot.y rot.z"

Example:

```cpp
%speed = VectorLen( getWords( %this.getSequenceGroundSpeed() ) )

String echo( "Run moves at " @ %speed @ " units per frame"
```

```cpp
int TSShapeConstructor::getSequenceIndex( string name )

Find the index of the sequence with the given name.

Parameters:

- `name`  name of the sequence to lookup

Returns:

index of the sequence with matching name, or -1 if not found

Example:

```cpp
if ( %this.getSequenceIndex( "walk" ) == -1 )
    echo( "Could not find 'walk' sequence"
```

```cpp
string TSShapeConstructor::getSequenceName( int index )

Get the name of the indexed sequence.

Parameters:

- `index`  index of the sequence to query (valid range is 0 - getSequenceCount()-1)

Returns:

the name of the sequence

Example:
```
// print the name of all sequences in the shape
%count = %this.getSequenceCount();
for ( %i = 0; %i < %count; %i++ )
    echo( %i SPC %this.getSequenceName( %i ) );

float TSShapeConstructor::getSequencePriority(string name )

Get the priority setting of the sequence.

Parameters:

    name name of the sequence to query

Returns:

    priority value of the sequence

string TSShapeConstructor::getSequenceSource(string name )

Get information about where the sequence data came from.

For example, whether it was loaded from an external DSQ file.

Parameters:

    name name of the sequence to query

Returns:

    TAB delimited string of the form: "from reserved start end total", where:
    from
        the source of the animation data, such as the path to a DSQ file, or the name of an existing sequence in the shape. This field will be empty for sequences already embedded in the DTS or DAE file.
    reserved
reserved value

**start**
the first frame in the source sequence used to create this sequence

**end**
the last frame in the source sequence used to create this sequence

**total**
the total number of frames in the source sequence

**Example:**

```javascript
// print the source for the walk animation
echo( "walk source:" SPC getField( %this.
```

```c
int TSShapeConstructor::getTargetCount( )
```

Get the number of materials in the shape.

**Returns:**
the number of materials in the shape.

**Example:**

```c
%count = %this.getTargetCount();
```

```c
string TSShapeConstructor::getTargetName(int index )
```

Get the name of the indexed shape material.

**Parameters:**

`index`  index of the material to get (valid range is 0 -
`getTargetCount()-1`.

**Returns:**
the name of the indexed material.

Example:

```cpp
%count = %this.getTargetCount();
for ( %i = 0; %i < %count; %i++ )
    echo( "Target " @ %i @ ": " @ %this.get
```

Get information about the indexed trigger.

**Parameters:**

- `name` name of the sequence to query
- `index` index of the trigger (valid range is 0 - `getTriggerCount()-1`)

**Returns:**

string of the form "frame state"

**Example:**

```cpp
// print all triggers in the sequence
%count = %this.getTriggerCount( "back" );
for ( %i = 0; %i < %count; %i++ )
    echo( %i SPC %this.getTrigger( "back",
```

Get the number of triggers in the specified sequence.

**Parameters:**
name name of the sequence to query

**Returns:**
number of triggers in the sequence

```cpp
void TSShapeConstructor::notifyShapeChanged()
```

Notify game objects that this shape file has changed, allowing them to update internal data if needed.

```cpp
void TSShapeConstructor::onLoad()
```

Called immediately after the DTS or DAE file has been loaded; before the shape data is available to any other object (StaticShape, Player etc). This is where you should put any post-load commands to modify the shape in-memory such as addNode, renameSequence etc.

```cpp
void TSShapeConstructor::onUnload()
```

Called when the DTS or DAE resource is flushed from memory. Not normally required, but may be useful to perform cleanup.

```cpp
bool TSShapeConstructor::removeDetailLevel(int index)
```

Remove the detail level (including all meshes in the detail level).

**Parameters:**
- size size of the detail level to remove

**Returns:**
- true if successful, false otherwise
Example:

```cpp
%this.removeDetailLevel( 2 );
```

```cpp
bool TSShapeConstructor::removeImposter()
```

Remove the imposter detail level (if any) from the shape.

**Returns:**
true if successful, false otherwise

```cpp
bool TSShapeConstructor::removeMesh(string name)
```

Remove a mesh from the shape.

If all geometry is removed from an object, the object is also removed.

**Parameters:**
- `name` full name (object name + detail size) of the mesh to remove

**Returns:**
true if successful, false otherwise

Example:

```cpp
%this.removeMesh( "SimpleShape128" );
```

```cpp
bool TSShapeConstructor::removeNode(string name)
```

Remove a node from the shape.

The named node is removed from the shape, including from any
sequences that use the node. Child nodes and objects attached to the node are re-assigned to the node's parent.

**Parameters:**

*name* name of the node to remove.

**Returns:**

true if successful, false otherwise.

**Example:**

```cpp
%this.removeNode( "Nose" );
```

bool TSShapeConstructor::removeObject(string name)

Remove an object (including all meshes for that object) from the shape.

**Parameters:**

*name* name of the object to remove.

**Returns:**

true if successful, false otherwise.

**Example:**

```cpp
// clear all objects in the shape
%count = %this.getObjectCount();
for ( %i = %count-1; %i >= 0; %i-- )
    %this.removeObject( %this.getObjectName
```

bool TSShapeConstructor::removeSequence(string name)

Remove the sequence from the shape.
Parameters:

- *name* name of the sequence to remove

Returns:

true if successful, false otherwise

```cpp
bool TSShapeConstructor::removeTrigger (string name,
                                         int   keyframe,
                                         int   state)
```

Remove a trigger from the sequence.

Parameters:

- *name* name of the sequence to modify
- *keyframe* keyframe of the trigger to remove
- *state* of the trigger to remove

Returns:

true if successful, false otherwise

Example:

```cpp
%this.removeTrigger( "walk", 3, 1 );
```

```cpp
bool TSShapeConstructor::renameDetailLevel(string oldName,
                                          string newName)
```

Rename a detail level.

Note:

Note that detail level names must be unique, so this command will fail if there is already a detail level with the
desired name

Parameters:

oldName  current name of the detail level
newName  new name of the detail level

Returns:

true if successful, false otherwise

Example:

%this.renameDetailLevel( "detail-1", "collision-1"

bool TSShapeConstructor::renameNode(string oldName, string newName)

Rename a node.

Note:

Note that node names must be unique, so this command will fail if there is already a node with the desired name

Parameters:

oldName  current name of the node
newName  new name of the node

Returns:

true if successful, false otherwise

Example:

%this.renameNode( "Bip01 L Hand", "mount5"

bool TSShapeConstructor::renameObject(string oldName,
**renameObject**

```cpp
string newName
)
```

Rename an object.

**Note:**
Note that object names must be unique, so this command will fail if there is already an object with the desired name.

**Parameters:**
- `oldName` current name of the object
- `newName` new name of the object

**Returns:**
true if successful, false otherwise

**Example:**
```cpp
%this.renameObject( "MyBox", "Box" );
```

**renameSequence**

```cpp
bool TSShapeConstructor::renameSequence(string oldName, string newName
)
```

Rename a sequence.

**Note:**
Note that sequence names must be unique, so this command will fail if there is already a sequence with the desired name.

**Parameters:**
- `oldName` current name of the sequence
- `newName` new name of the sequence

**Returns:**
true if successful, false otherwise

Example:

%this.renameSequence( "walking", "walk" );

void TSShapeConstructor::saveShape(string filename )

Save the shape (with all current changes) to a new DTS file.

Parameters:

filename Destination filename.

Example:

%this.saveShape( "/myShape.dts" );

bool TSShapeConstructor::setBounds(Box3F bbox )

Set the shape bounds to the given bounding box.

Parameters:

Bounding box "minX minY minZ maxX maxY maxZ"

Returns:

true if successful, false otherwise

int TSShapeConstructor::setDetailLevelSize(int index, int newSize )

Change the size of a detail level.

Note:
Note that detail levels are always sorted in decreasing size order, so this command may cause detail level indices to change.

**Parameters:**

- `index` index of the detail level to modify
- `newSize` new size for the detail level

**Returns:**

new index for this detail level

**Example:**

```
%this.setDetailLevelSize( 2, 256 );
```

```cpp
bool TSShapeConstructor::setMeshMaterial(string meshName, string matName)
```

Set the name of the material attached to the mesh.

**Parameters:**

- `meshName` full name (object name + detail size) of the mesh to modify
- `matName` name of the material to attach. This could be the base name of the diffuse texture (eg. "test_mat" for "test_mat.jpg"), or the name of a Material object already defined in script.

**Returns:**

true if successful, false otherwise

**Example:**

```
// set the mesh material
%this.setMeshMaterial( "SimpleShape128", ''
```
bool TSShapeConstructor::setMeshSize(string name,
int size)

Change the detail level size of the named mesh.

**Parameters:**

- `name` full name (object name + current size) of the mesh to modify
- `size` new detail level size

**Returns:**

true if successful, false otherwise.

**Example:**

```cpp
%this.setMeshSize( "SimpleShape128", 64 );
```

---

bool TSShapeConstructor::setMeshType(string name,
string type)

Set the display type for the mesh.

**Parameters:**

- `name` full name (object name + detail size) of the mesh to modify
- `type` the new type for the mesh: "normal", "billboard" or "billboardzaxis"

**Returns:**

true if successful, false otherwise

**Example:**

---

```cpp
```
// set the mesh to be a billboard
%this.setMeshType( "SimpleShape64", "billboard"

bool TSShapeConstructor::setNodeParent(string name, string parentName)

Set the parent of a node.

**Parameters:**
- `name`  
  name of the node to modify
- `parentName`  
  name of the parent node to set (use "" to move the node to the root level)

**Returns:**
true if successful, false if failed

**Example:**
%this.setNodeParent( "Bip01 Pelvis", "start01"

bool TSShapeConstructor::setNodeTransform(string name, TransformF txfm, bool isWorld = f)

Set the base transform of a node. That is, the transform of the node when in the root (not-animated) pose.

**Parameters:**
- `name`  
  name of the node to modify
- `txfm`  
  transform string of the form: "pos.x pos.y pos.z rot.x rot.y rot.z rot.angle"  
  (optional) flag to set the local-to-parent or the global
isworld transform. If false, or not specified, the position and orientation are treated as relative to the node's parent.

**Returns:**
true if successful, false otherwise

**Example:**

```%this.setNodeTransform( "mount0", "0 0 1 0"
%this.setNodeTransform( "mount0", "0 0 0 0"
%this.setNodeTransform( "mount0", "1 0 0 0"
```

---

```bool TSShapeConstructor::setObjectNode (string objName, string nodeName)
```

Set the node an object is attached to.

When the shape is rendered, the object geometry is rendered at the node's current transform.

**Parameters:**

- `objName` name of the object to modify
- `nodeName` name of the node to attach the object to

**Returns:**
true if successful, false otherwise

**Example:**

```%this.setObjectNode( "Hand", "Bip01 LeftHand"
```
Mark a sequence as a blend or non-blend.

A blend sequence is one that will be added on top of any other playing sequences. This is done by storing the animated node transforms relative to a reference frame, rather than as absolute transforms.

**Parameters:**

- **name** name of the sequence to modify
- **blend** true to make the sequence a blend, false for a non-blend
- **blendSeq** the name of the sequence that contains the blend reference frame
- **blendFrame** the reference frame in the blendSeq sequence

**Returns:**

true if successful, false otherwise

**Example:**

```c++
%this.setSequenceBlend( "look", true, "root"
```

```c++
bool TSShapeConstructor::setSequenceCyclic(string name,
                                          bool cyclic )
```

Mark a sequence as cyclic or non-cyclic.

**Parameters:**

- **name** name of the sequence to modify
- **cyclic** true to make the sequence cyclic, false for non-cyclic
Returns:
true if successful, false otherwise

Example:

```cpp
%this.setSequenceCyclic( "ambient", true );
%this.setSequenceCyclic( "shoot", false );
```

```cpp
bool TSShapeConstructor::setSequenceGroundSpeed( string name, Point3F transSpeed, Point3F rotSpeed )
```

Set the translation and rotation ground speed of the sequence.

The ground speed of the sequence is set by generating ground transform keyframes. The ground translational and rotational speed is assumed to be constant for the duration of the sequence. Existing ground frames for the sequence (if any) will be replaced.

**Parameters:**

- `name` name of the sequence to modify
- `transSpeed` translational speed (trans.x trans.y trans.z) in Torque units per frame
- `rotSpeed` (optional) rotational speed (rot.x rot.y rot.z) in radians per frame. Default is "0 0 0"

**Returns:**
true if successful, false otherwise

**Example:**

```cpp
%this.setSequenceGroundSpeed( "run", "5 0 0" );
%this.setSequenceGroundSpeed( "spin", "0 0 0" );
```
bool TSShapeConstructor::setSequencePriority(string name, float priority)

Set the sequence priority.

**Parameters:**
- *name* name of the sequence to modify
- *priority* new priority value

**Returns:**
- true if successful, false otherwise

void TSShapeConstructor::writeChangeSet()

Write the current change set to a TSShapeConstructor script file. The name of the script file is the same as the model, but with .cs extension. eg. myShape.cs for myShape.dts or myShape.dae.
Member Data Documentation

bool TSShapeConstructor::adjustCenter

Translate COLLADA model on import so the origin is at the center. No effect for DTS files.

bool TSShapeConstructor::adjustFloor

Translate COLLADA model on import so origin is at the (Z axis) bottom of the model. No effect for DTS files.

This can be used along with adjustCenter to have the origin at the center of the bottom of the model.

See also:
   adjustCenter

string TSShapeConstructor::alwaysImport

TAB separated patterns of nodes to import even if in neverImport list. No effect for DTS files.

Torque allows unwanted nodes in COLLADA (.dae) files to to be ignored during import. This field contains a TAB separated list of patterns to match node names. Any node that matches one of the patterns in the list will always be imported, even if it also matches the neverImport list

See also:
   neverImport

Example:

singleton TSShapeConstructor(MyShapeDae)
string TSShapeConstructor::alwaysImportMesh

TAB separated patterns of meshes to import even if in neverImportMesh list. No effect for DTS files.

Torque allows unwanted meshes in COLLADA (.dae) files to be ignored during import. This field contains a TAB separated list of patterns to match mesh names. Any mesh that matches one of the patterns in the list will **always** be imported, even if it also matches the neverImportMesh list

**See also:**
neverImportMesh

**Example:**

```cpp
singleton TSShapeConstructor(MyShapeDae)
{
    baseShape = "./myShape.dae"
    alwaysImportMesh = "body*" TAB "armor"
    neverImportMesh = "*-dummy"
}
```

**filename TSShapeConstructor::baseShape**

Specifies the path to the DTS or DAE file to be operated on by this object.
Since the **TSShapeConstructor** script must be in the same folder as the DTS or DAE file, it is recommended to use a relative path so that the shape and script files can be copied to another location without having to modify the path.

```
bool TSShapeConstructor::forceUpdateMaterials
```

Forces update of the materials.cs file in the same folder as the COLLADA (.dae) file, even if Materials already exist. No effect for DTS files.

Normally only Materials that are not already defined are written to materials.cs.

```
bool TSShapeConstructor::ignoreNodeScale
```

Ignore `<scale>` elements inside COLLADA `<node>`s. No effect for DTS files.

This field is a workaround for certain exporters that generate bad node scaling, and is not usually required.

```
TSShapeConstructorLodType TSShapeConstructor::lodType
```

Control how the COLLADA (.dae) importer interprets LOD in the model. No effect for DTS files.

Set to one of the following values:

**DetectDTS**

The default value. Instructs the importer to search for a 'baseXXX->startXXX' node hierarchy at the root level. If found, the importer acts as if "TrailingNumber" was set. Otherwise, all geometry is imported at a single detail size.

**SingleSize**
All geometry is imported at a fixed detail size. Numbers at the end of geometry node's are ignored.

**TrailingNumber**

Numbers at the end of geometry node's name are interpreted as the detail size (similar to DTS exporting). Geometry instances with the same base name but different trailing number are grouped into the same object.

**DEFAULT**

The default value. Use the value in the .dae file (defaults to Z_AXIS if the <up_axis> element is not present).

---

**string TSShapeConstructor::matNamePrefix**

Prefix to apply to all material map names in the COLLADA (.dae) file. No effect for DTS files.

This field is useful to avoid material name clashes for exporters that generate generic material names like "texture0" or "material1".

---

**string TSShapeConstructor::neverImport**

TAB separated patterns of nodes to ignore on loading. No effect for DTS files.

Torque allows unwanted nodes in COLLADA (.dae) files to to be ignored during import. This field contains a TAB separated list of patterns to match node names. Any node that matches one of the patterns in the list will not be imported (unless it matches the alwaysImport list.

**See also:**

alwaysImport

---

**string TSShapeConstructor::neverImportMesh**
TAB separated patterns of meshes to ignore on loading. No effect for DTS files.

Torque allows unwanted meshes in COLLADA (.dae) files to be ignored during import. This field contains a TAB separated list of patterns to match mesh names. Any mesh that matches one of the patterns in the list will not be imported (unless it matches the alwaysImportMesh list).

**See also:**
- alwaysImportMesh

<table>
<thead>
<tr>
<th>filename TSShapeConstructor::sequence</th>
</tr>
</thead>
</table>

Legacy method of adding sequences to a DTS or DAE shape after loading.

**Example:**

```cpp
singleton TSShapeConstructor(MyShapeDae) {
    baseShape = ".//myShape.dae";
    sequence = "../anims/root.dae root";
    sequence = "../anims/walk.dae walk";
    sequence = "../anims/jump.dsq jump";
}
```

<table>
<thead>
<tr>
<th>int TSShapeConstructor::singleDetailSize</th>
</tr>
</thead>
</table>

Sets the detail size when lodType is set to SingleSize. No effect otherwise, and no effect for DTS files.

**See also:**
- lodType
**float TSShapeConstructor::unit**

Override the `<unit>` element in the COLLADA (.dae) file. No effect for DTS files.

COLLADA (.dae) files usually contain a `<unit>` element that indicates the 'real world' units that the model is described in. It means you can work in sensible and meaningful units in your modeling app.

For example, if you were modeling a small object like a cup, it might make sense to work in inches (1 MAX unit = 1 inch), but if you were modeling a building, it might make more sense to work in feet (1 MAX unit = 1 foot). If you export both models to COLLADA, T3D will automatically scale them appropriately: 1 T3D unit = 1 meter, so the cup would be scaled down by 0.0254, and the building scaled down by 0.3048, given them both the correct scale relative to each other.

Omit the field or set to -1 to use the value in the .dae file (1.0 if the `<unit>` element is not present)

**TSShapeConstructorUpAxis TSShapeConstructor::upAxis**

Override the `<up_axis>` element in the COLLADA (.dae) file. No effect for DTS files.

Set to one of the following values:

**X_AXIS**

Positive X points up. Model will be rotated into Torque's coordinate system (Z up).

**Y_AXIS**

Positive Y points up. Model will be rotated into Torque's coordinate system (Z up).

**Z_AXIS**

Positive Z points up. No rotation will be applied to the model.

**DEFAULT**
The default value. Use the value in the .dae file (defaults to Z_AXIS if the <up_axis> element is not present).

**Detailed Description**

A static object derived from a 3D model file and placed within the game world.

**TSStatic** is the most basic 3D shape in Torque. Unlike **StaticShape** it doesn't make use of a datablock. It derives directly from **SceneObject**. This makes **TSStatic** extremely light weight, which is why the Tools use this class when you want to drop in a DTS or DAE object.

While a **TSStatic** doesn't provide any motion -- it stays were you initially put it -- it does allow for a single ambient animation sequence to play when the object is first added to the scene.

**Example:**

```cpp
new TSStatic(Team1Base) {
    shapeName = "art/shapes/desertStructures/station01.dts"
    playAmbient = "1";
    receiveSunLight = "1";
    receiveLMLighting = "1";
    useCustomAmbientLighting = "0";
    customAmbientLighting = "0 0 0 1";
    collisionType = "Visible Mesh";
    decalType = "Collision Mesh";
    allowPlayerStep = "1";
    renderNormals = "0";
    forceDetail = "-1";
    position = "315.18 -180.418 244.313";
    rotation = "0 0 1 195.952";
    scale = "1 1 1";
    isRenderEnabled = "true";
    canSaveDynamicFields = "1";
};
```
Member Function Documentation

void TSStatic::changeMaterial (string mapTo = "", Material oldMat = NULL, Material newMat = NULL)

Change one of the materials on the shape.

This method changes materials per mapTo with others. The material that is being replaced is mapped to unmapped_mat as a part of this transition.

Note:
Warning, right now this only sort of works. It doesn't do a live update like it should.

Parameters:
- **mapTo** the name of the material target to remap (from getTargetName)
- **oldMat** the old Material that was mapped
- **newMat** the new Material to map

Example:

```
// remap the first material in the shape
%mapTo = %obj.getTargetName( 0 );
%obj.changeMaterial( %mapTo, 0, MyMaterial ]
```

string TSStatic::getModelFile( )

Get the model filename used by this shape.

Returns:
- the shape filename
Example:

```cpp
// Acquire the model filename used on this
modelFilename = %obj.getModelFile();
```

```cpp
int TSStatic::getTargetCount( )
```

Get the number of materials in the shape.

**Returns:**

the number of materials in the shape.

**See also:**

`getTargetName()`

```cpp
string TSStatic::getTargetName(int index = 0 )
```

Get the name of the indexed shape material.

**Parameters:**

\[ index \] index of the material to get (valid range is 0 - `getTargetCount()-1`).

**Returns:**

the name of the indexed material.

**See also:**

`getTargetCount()`

<td>Enables detailed culling of meshes within the <strong>TSStatic</strong>. Should only be used with large complex shapes like buildings which contain many submeshes.</td>
</tr>
<tr>
<td><code>bool TSStatic::originSort</code></td>
<td></td>
</tr>
</tbody>
</table>
Enables translucent sorting of the `TSStatic` by its origin instead of the bounds.

```cpp
bool TSStatic::playAmbient
```

Enables automatic playing of the animation sequence named "ambient" (if it exists) when the `TSStatic` is loaded.

```cpp
float TSStatic::renderNormals
```

Debug rendering mode shows the normals for each point in the `TSStatic`'s mesh.

```cpp
filename TSStatic::shapeName
```

Path and filename of the model file (.DTS, .DAE) to use for this `TSStatic`.

```cpp
string TSStatic::skin
```

The skin applied to the shape.

'Skinning' the shape effectively renames the material targets, allowing different materials to be used on different instances of the same model.

Any material targets that start with the old skin name have that part of the name replaced with the new skin name. The initial old skin name is "base". For example, if a new skin of "blue" was applied to a model that had material targets `base_body` and `face`, the new targets would be `blue_body` and `face`. Note that `face` was not renamed since it did not start with the old skin name of "base".
To support models that do not use the default "base" naming convention, you can also specify the part of the name to replace in the skin field itself. For example, if a model had a material target called `shapemat`, we could apply a new skin "shape=blue", and the material target would be renamed to `bluemat` (note "shape" has been replaced with "blue").

Multiple skin updates can also be applied at the same time by separating them with a semicolon. For example: "base=blue;face=happy_face".

Material targets are only renamed if an existing Material maps to that name, or if there is a diffuse texture in the model folder with the same name as the new target.

Detailed Description

Base turret class.

Uses the TurretShapeData datablock for common properties.

The TurretShape class provides a player mountable turret. It also forms the base forAITurretShape, an AI controlled turret. It is based on the Item class, which allows turrets to be treated as any other Item by the Player, such as throwing smaller turrets. When used directly, TurretShape takes input moves from the player's GameConnection to rotate the turret and trigger its weapons.

A turret consists of two components. There is the TurretShape object (or AITurretShape), and then there are one or more ShapeBaseImageData objects that are mounted to the turret. The TurretShape provides the weapons platform that rotates towards a target. The ShapeBaseImageData provides the actual weapon that fires at the target. Any standard ShapeBaseImageData weapon may be used.
Shape File Nodes

The shape file used for the TurretShape needs to have a number of defined nodes. The first node is named 'heading'. The heading node is special in that it is controlled by the TurretShape code. This means that it should not be animated by the artist, nor should it have anything but the default transform applied to it. This doesn't stop the heading node's parent or its children from being animated, however.

The second special node is named 'pitch'. The pitch node is also controlled by the TurretShape code so it too should not be animated within the shape file. Typically the pitch node will be a child of the heading node, although it need not be a direct child. The pitch node is also optional if you don't want the TurretShape to pitch towards its target. In this case you may be doing something special with the mounted weapon to have its projectiles automatically aim towards the target.

The next set of nodes are weaponMount0 through weaponMount3. These provide up to four mounting points for weapons on the turret. Typically these are children of the pitch nodes, although they need not be direct children of that node. You do not need to have all of these weapon mount point nodes defined within the shape. Only as many as you need for the weapons. The mounted ShapeBaseImageData weapons' mountPoint node will mount to these nodes.

There are four optional nodes named pitch0 through pitch3 that may be used in special cases. These nodes are also controlled by the TurretShape code and have the same restrictions. Their rotation exactly matches that of the standard pitch node. These exist for mounted weapons that may not all rotate about the same x axis. For example, a turret may have two sets of weapons, one mounted above the other. These two sets of weapons could all share the same point of rotation (the pitch node) which means they'll rotate as a group. Or the top weapons could be attached to the pitch node while the bottom weapons could be attached to the pitch0 node. This makes the two sets of weapons rotate about their own centers and provides an entirely different look.
You could also use these additional pitchN nodes to animate some non-weapon attachments on the turret, such as a radar dish or targeting scope. TurretShape also supports four optional heading0 through heading3 nodes that operate in the same way as the pitchN nodes.
Weapon Mounting

*TurretShape* weapon mounting is done within the *TurretShapeData::onAdd()* script method. This method makes use of datablock fields that are only defined in script and are not passed along to the client. The first field is *numWeaponMountPoints* that defines the number of weapons that will be mounted and the number of *weaponMountN* nodes to expect within the turret's shape file.

The other fields that are required to mount weapons are the *weapon[]*, *weaponAmmo[]* and *weaponAmmoAmount[]* arrays -- one of each per weapon to mount. The *weapon[]* array points to an *ItemData* datablock that defines the weapon (just like any *Player* weapon). The *weaponAmmo[]* array points to an *ItemData* datablock that defines the ammo to use for the weapon. Finally, the *weaponAmmoAmount[]* array is the quantity of ammo the turret has for that weapon.

As turrets use the same inventory system as players, you also need to define the maximum number of weapons and ammo that the turret may possess. Here is an example of setting up three weapons and their ammo for a turret (a *TurretShapeData* fragment):

**Example:**

```cpp
// Weapon mounting
numWeaponMountPoints = 3;

weapon[0] = TurretWeapon;
weaponAmmo[0] = BulletAmmo;
weaponAmmoAmount[0] = 10000;

weapon[1] = TurretWeaponB;
weaponAmmo[1] = BulletAmmo;
weaponAmmoAmount[1] = 10000;

```
weaponAmmo[2] = BulletAmmo;
weaponAmmoAmount[2] = 10000;

maxInv[TurretWeaponB] = 1;
maxInv[TurretWeapon] = 2;
maxInv[BulletAmmo] = 10000;
Mounted Weapon States

There are a couple of things to be aware of so that an turret's mounted weapons play along with the turret's states, especially for AI turrets. Setting `TurretShapeData::startLoaded` to true indicates that all mounted weapons will start loaded when their state machines start up. A static turret placed with the World Editor would normally begin this way. Setting `TurretShapeData::startLoaded` to false causes all mounted weapons to not start in a loaded state. This can be used to have the mounted weapons begin in some folded state when a deployable turret is thrown by the player. When a thrown turret comes to rest and begins to deploy, all mounted weapons are automatically set to the loaded state so they may also unfold, start up, or show some other method that the weapon is becoming ready to fight. This could also be used for player mountable turrets so that the weapons come to life when a player mounts the turret.

The default scripts for `AITurretShapeData` also fires the first image generic trigger on all mounted weapons when the turret is destroyed. This shows up as `stateTransitionGeneric0In` within a weapon image's state machine. This allows for all weapons to show that they are destroyed or shutting down. Something similar could be done for general `TurretShapeData` turrets.

Weapons can also feed back to the turret they are mounted on. `TurretShape` supports the standard `ShapeBaseImageData` stateRecoil and will play the indicated animation, if available. You can also use `ShapeBaseImageData`'s `stateShapeSequence` field to play a generic sequence on the turret at any time from a mounted weapon.
**Player Mounting**

Turrets act very similar to vehicles when it comes to player mounting. By default colliding with a turret causes the player to mount it, if the turret is free.

When it comes to firing the turret's weapons there are a number of methods that are triggered based on the weaponLinkType on the TurretShapeData datablock. Setting this field to FireTogether causes all weapons to fire at once based on the input from trigger 0. Using GroupedFire will make weaponMount0 and weaponMount2 mounted weapons fire on trigger 0, and weaponMount1 and weaponMount3 mounted weapons fire on trigger 1. Finally, IndividualFire will have each weaponMountN mounted weapons fire based on their own trigger (0 through 3). This provides exact control over which turret weapon will fire when there are multiple weapons mounted.

The player mounting callbacks are done using the TurretBaseData datablock on the server, and in a special case on the TurretBase object on the client. The server side makes use of the standard TurretBaseData::onMountObject() and TurretBaseData::onUnmountObject() callbacks. See those for more information.

When a player mounted turret is destroyed the TurretShapeData::damage() method will automatically kill all mounted players. To modify this behaviour -- such as only dismounting players from a destroyed turret -- you'll need to create your own damage() method for your turret's datablock.

On the client side the special turretMountCallback() callback function is called for the TurretShape object that is being mounted. This callback receives the SimObjectID of the turret object, the SimObjectID of the player doing the mounting or unmounting, and a Boolean set to true if mounting and false if unmounting. As this callback is made on the client, it allows the client to set up any action maps, make HUD changes, etc.

**Example:**
// Turret Support

// Called by the TurretShape class when a player mounts or unmounts it.
// %turret = The turret that was mounted
// %player = The player doing the mounting
// %mounted = True if the turret was mounted

function turretMountCallback(%turret, %player, %mounted)
{
    echo ( "\c4turretMountCallback -> " @ %1, %mounted );

    if (%mounted)
    {
        // Push the action map
        turretMap.push();
    }
    else
    {
        // Pop the action map
        turretMap.pop();
    }
}
Turret Destruction

When a turret is destroyed the default TurretBaseData::onDestroyed() method is called. This causes the turret to sit in a Dead state for TurretBase::DestroyedFadeDelay milliseconds, and then the turret will fade away. If the turret is marked to respawn -- TurretShape::doRespawn() returns true -- then the turret is respawned after TurretShape::RespawnTime milliseconds. By default all turrets placed in the World Editor are marked to respawn.
Turret Optional Animation Sequences

If present in the TurretShape's shape, the optional 'heading' and 'pitch' sequences will be played as the turret rotates. These sequences are given a timeline position that corresponds to the turret's rotation within its minimum and maximum ranges. These sequences could be used to rotate wheels or gears on the turret as it rotates, for example.

### Member Function Documentation

#### bool TurretShape::doRespawn( )

Does the turret respawn after it has been destroyed.

**Returns:**

- True if the turret respawns.

#### bool TurretShape::getAllowManualFire( )

Get if the turret is allowed to fire through moves.

**Returns:**

- True if the turret is allowed to fire through moves.

#### bool TurretShape::getAllowManualRotation( )

Get if the turret is allowed to rotate through moves.

**Returns:**

- True if the turret is allowed to rotate through moves.

#### string TurretShape::getState( )

Get the name of the turret's current state.

The state is one of the following:

- Dead - The TurretShape is destroyed.
- Mounted - The TurretShape is mounted to an object such as a vehicle.
- Ready - The TurretShape is free to move. The usual state.
**Returns:**
The current state; one of: "Dead", "Mounted", "Ready"

**Point3F TurretShape::getTurretEulerRotation( )**
Get Euler rotation of this turret's heading and pitch nodes.

**Returns:**
the orientation of the turret's heading and pitch nodes in the form of rotations around the X, Y and Z axes in degrees.

**void TurretShape::setAllowManualFire(bool allow )**
Set if the turret is allowed to fire through moves.

**Parameters:**
*allow* If true then the turret may be fired through moves.

**void TurretShape::setAllowManualRotation(bool allow )**
Set if the turret is allowed to rotate through moves.

**Parameters:**
*allow* If true then the turret may be rotated through moves.

**void TurretShape::setTurretEulerRotation(Point3F rot )**
Set Euler rotation of this turret's heading and pitch nodes in degrees.

**Parameters:**
The rotation in degrees. The pitch is the X component and
rot the heading is the Z component. The Y component is ignored.
Member Data Documentation

bool TurretShape::respawn

Respawn the turret after it has been destroyed.

If true, the turret will respawn after it is destroyed.

Detailed Description

Defines properties for a TurretShape object.

See also:

TurretShape
TurretShapeData
void TurretShapeData::onMountObject (TurretShape turret, SceneObject obj, int node)

Informs the TurretShapeData object that a player is mounting it.

**Parameters:**
- *turret* The TurretShape object.
- *obj* The player that is mounting.
- *node* The node the player is mounting to.

**Note:**
Server side only.

void TurretShapeData::onStickyCollision (TurretShape obj)

Informs the TurretData object that it is now sticking to another object.

This callback is only called if the TurretData::sticky property for this Turret is true.

**Parameters:**
- *obj* The Turret object that is colliding.

**Note:**
Server side only.

**See also:**
TurretShape, TurretData
**void TurretShapeData::onUnmountObject(TurretShape turret, SceneObject obj)**

Informs the *TurretShapeData* object that a player is unmounting it.

**Parameters:**

- `turret` The *TurretShape* object.
- `obj` The player that is unmounting.

**Note:**

Server side only.

`ShapeBase::setImageLoaded()`

```cpp
TurretShapeFireLinkType TurretShapeData::weaponLinkType
```

Set how the mounted weapons are linked and triggered.

- **FireTogether**: All weapons fire under trigger 0.
- **GroupedFire**: Weapon mounts 0,2 fire under trigger 0, mounts 1,3 fire under trigger 1.
- **IndividualFire**: Each weapon mount fires under its own trigger 0-3.

See also:

`TurretShapeFireLinkType`

```cpp
bool TurretShapeData::zRotOnly
```

Should the turret allow only z rotations.

True indicates that the turret may only be rotated on its z axis, just like the `Item` class. This keeps the turret always upright regardless
of the surface it lands on.

Detailed Description

Base functionality shared by all Vehicles (FlyingVehicle, HoverVehicle, WheeledVehicle).

This object implements functionality shared by all Vehicle types, but should not be instantiated directly. Create a FlyingVehicle, HoverVehicle, or WheeledVehicle instead.

Note:

The model used for any Vehicle must include a collision mesh at detail size -1.
Member Data Documentation

**bool Vehicle::disableMove**

When this flag is set, the vehicle will ignore throttle changes.

**float Vehicle::workingQueryBoxSizeMultiplier [static]**

How much larger the mWorkingQueryBox should be made when updating the working collision list.

The larger this number the less often the working list will be updated due to motion, but any non-static shape that moves into the query box will not be noticed.

**int Vehicle::workingQueryBoxStaleThreshold [static]**

The maximum number of ticks that go by before the mWorkingQueryBox is considered stale and needs updating.

Other factors can cause the collision working query box to become invalidated, such as the vehicle moving far enough outside of this cached box. The smaller this number, the more times the working list of triangles that are considered for collision is refreshed. This has the greatest impact with colliding with high triangle count meshes.

**Note:**

Set to -1 to disable any time-based forced check.

**Detailed Description**

Base properties shared by all Vehicles (*FlyingVehicle*, *HoverVehicle*, *WheeledVehicle*).

This datablock defines properties shared by all Vehicle types, but should not be instantiated directly. Instead, set the desired properties in the *FlyingVehicleData*, *HoverVehicleData* or *WheeledVehicleData* datablock.
Damage

The VehicleData class extends the basic energy/damage functionality provided by ShapeBaseData to include damage from collisions, as well as particle emitters activated automatically when damage levels reach user specified thresholds.

The example below shows how to setup a Vehicle to:

- take damage when colliding with another object
- emit gray smoke particles from two locations on the Vehicle when damaged above 50%
- emit black smoke particles from two locations on the Vehicle when damaged above 85%
- emit bubbles when any active damage emitter point is underwater

Example:

```csharp
// damage from collisions
collDamageMultiplier = 0.05;
collDamageThresholdVel = 15;

// damage levels
damageLevelTolerance[0] = 0.5;
damageEmitter[0] = GraySmokeEmitter; //
damageLevelTolerance[1] = 0.85;
damageEmitter[1] = BlackSmokeEmitter; //
damageEmitter[2] = DamageBubbleEmitter; //

// emit offsets (used for all active damage)
damageEmitterOffset[0] = "0.5 3 1";
damageEmitterOffset[1] = "-0.5 3 1";
numDmgEmitterAreas = 2;
```
Member Function Documentation

```cpp
void VehicleData::onEnterLiquid(Vehicle obj,  
    float coverage,  
    string type)
```

Called when the vehicle enters liquid.

**Parameters:**

- `obj` the `Vehicle` object
- `coverage` percentage of the vehicle's bounding box covered by the liquid
- `type` type of liquid the vehicle has entered

```cpp
void VehicleData::onLeaveLiquid(Vehicle obj,  
    string type)
```

Called when the vehicle leaves liquid.

**Parameters:**

- `obj` the `Vehicle` object
- `type` type of liquid the vehicle has left
Member Data Documentation

**float VehicleData::bodyFriction**

Collision friction coefficient.

How well this object will slide against objects it collides with.

**float VehicleData::bodyRestitution**

Collision 'bounciness'.

Normally in the range 0 (not bouncy at all) to 1 (100% bounciness).

**float VehicleData::cameraDecay**

How quickly the camera moves back towards the vehicle when stopped.

**See also:**

cameraLag.

**float VehicleData::cameraLag**

How much the camera lags behind the vehicle depending on vehicle speed.

Increasing this value will make the camera fall further behind the vehicle as it accelerates away.

**See also:**

cameraDecay.
<table>

<tr>
<td><code>VehicleData::contactTol</code></td>
<td>Maximum relative velocity between objects for collisions to be</td>
</tr>
</tbody>
</table>
resolved as contacts.

Velocities greater than this are handled as collisions.

ParticleEmitterData VehicleData::damageEmitter[3]

Array of particle emitters used to generate damage (dust, smoke etc) effects.

Currently, the first two emitters (indices 0 and 1) are used when the damage level exceeds the associated damageLevelTolerance. The 3rd emitter is used when the emitter point is underwater.

See also:

damageEmitterOffset

Point3F VehicleData::damageEmitterOffset[2]

Object space "x y z" offsets used to emit particles for the active damageEmitter.

Example:

```cpp
// damage levels
damageLevelTolerance[0] = 0.5;
damageEmitter[0] = SmokeEmitter;
// emit offsets (used for all active damageEmitter)
damageEmitterOffset[0] = "0.5 3 1";
damageEmitterOffset[1] = "-0.5 3 1";
numDmgEmitterAreas = 2;
```

float VehicleData::damageLevelTolerance[2]

Damage levels (as a percentage of maxDamage) above which to
begin emitting particles from the associated damageEmitter.

Levels should be in order of increasing damage.

**See also:**
- damageEmitterOffset

**ParticleEmitterData VehicleData::dustEmitter**

Dust particle emitter.

**See also:**
- triggerDustHeight
- dustHeight

**float VehicleData::dustHeight**

Height above ground at which to emit particles from the dustEmitter.

**SFXProfile VehicleData::exitingWater**

Sound to play when exiting the water.

**float VehicleData::exitSplashSoundVelocity**

Minimum velocity when leaving the water for the exitingWater sound to play.

**SFXProfile VehicleData::hardImpactSound**
Sound to play on a 'hard' impact.

This sound is played if the impact speed \( \geq \) hardImpactSpeed.

**See also:**

- hardImpactSpeed

---

**float VehicleData::hardImpactSpeed**

Minimum collision speed for the hardImpactSound to be played.

---

**float VehicleData::hardSplashSoundVelocity**

Minimum velocity when entering the water for the imapactWaterHard sound to play.

**See also:**

- impactWaterHard

---

**SFXProfile VehicleData::impactWaterEasy**

Sound to play when entering the water with speed \( \geq \) softSplashSoundVelocity and \( < \) mediumSplashSoundVelocity.

---

**SFXProfile VehicleData::impactWaterHard**

Sound to play when entering the water with speed \( \geq \) hardSplashSoundVelocity.

---

**SFXProfile VehicleData::impactWaterMedium**
Sound to play when entering the water with speed \( \geq \) mediumSplashSoundVelocity and \( < \) hardSplashSoundVelocity.

**int VehicleData::integration**

Number of integration steps per tick.

Increase this to improve simulation stability (also increases simulation processing time).

**float VehicleData::jetEnergyDrain**

Energy amount to drain for each tick the vehicle is jetting.

Once the vehicle's energy level reaches 0, it will no longer be able to jet.

**float VehicleData::jetForce**

Additional force applied to the vehicle when it is jetting.

For WheeledVehicles, the force is applied in the forward direction. For FlyingVehicles, the force is applied in the thrust direction.

**Point3F VehicleData::massBox**

Define the box used to estimate the vehicle's moment of inertia.

Currently only used by WheeledVehicle; other vehicle types use a unit sphere to compute inertia.

**Point3F VehicleData::massCenter**
Defines the vehicle's center of mass (offset from the origin of the model).

```
float VehicleData::maxDrag
```

Maximum drag coefficient.
Currently unused.

```
float VehicleData::maxSteeringAngle
```

Maximum yaw (horizontal) and pitch (vertical) steering angle in radians.

```
float VehicleData::mediumSplashSoundVelocity
```

Minimum velocity when entering the water for the impactWaterMedium sound to play.

**See also:**

impactWaterMedium

```
float VehicleData::minDrag
```

Minimum drag coefficient.
Currently only used by FlyingVehicle.

```
float VehicleData::minImpactSpeed
```

Minimum collision speed for the onImpact callback to be invoked.
**float VehicleData::minJetEnergy**

Minimum vehicle energy level to begin jetting.

**float VehicleData::minRollSpeed**

Unused.

**float VehicleData::numDmgEmitterAreas**

Number of damageEmitterOffset values to use for each damageEmitter.

*See also:*  
`damageEmitterOffset`

**SFXProfile VehicleData::softImpactSound**

Sound to play on a 'soft' impact.

This sound is played if the impact speed is `< hardImpactSpeed` and `>= softImpactSpeed`.

*See also:*  
`softImpactSpeed`

**float VehicleData::softImpactSpeed**

Minimum collision speed for the softImpactSound to be played.
**float VehicleData::softSplashSoundVelocity**

Minimum velocity when entering the water for the `impactWaterEasy` sound to play.

**See also:**

`impactWaterEasy`

---

**ParticleEmitterData VehicleData::splashEmitter[2]**

Array of particle emitters used to generate splash effects.

---

**float VehicleData::splashFreqMod**

Number of splash particles to generate based on vehicle speed.

This value is multiplied by the current speed to determine how many particles to generate each frame.

---

**float VehicleData::splashVelEpsilon**

Minimum speed when moving through water to generate splash particles.

---

**float VehicleData::triggerDustHeight**

Maximum height above surface to emit dust particles.

If the vehicle is less than `triggerDustHeight` above a static surface with a material that has 'showDust' set to true, the vehicle will emit particles from the `dustEmitter`. 
SFXProfile VehicleData::waterWakeSound

Looping sound to play while moving through the water.
**WaterBlock Class Reference**

**[Water]**

A block shaped water volume defined by a 3D scale and orientation.

Detailed Description

Abstract base class for representing a body of water.

WaterObject is abstract and may not be created. It defines functionality shared by its derived classes.

WaterObject exposes many fields for controlling it visual quality.

WaterObject surface rendering has the following general features:

- Waves represented by vertex undulation and user parameters.
- Ripples represented by a normal map and user parameters.
- Refraction of underwater objects.
- Dynamic planar reflection or static cubemap reflection.
- Paramable water fog and color shift.

It will, however, look significantly different depending on the LightingManager that is active. With Basic Lighting, we do not have a prepass texture to lookup per-pixel depth and therefore cannot use our rendering techniques that depend on it.

In particular, the following field groups are not used under Basic Lighting:

- Underwater Fogging
- Misc
- Distortion
- And foam related fields under the WaterObject group.

WaterObject also defines several fields for gameplay use and objects that support buoyancy.

</table>
The texture size used for reflections (square).

**Point2F WaterObject::rippleDir[3]**

Modifies the direction of ripples on the surface.

**float WaterObject::rippleMagnitude[3]**

Intensifies the vertext modification of the surface.

**float WaterObject::rippleSpeed[3]**

Modifies speed of surface ripples.

**filename WaterObject::rippleTex**

Normal map used to simulate small surface ripples.

**Point2F WaterObject::rippleTexScale[3]**

Intensifies the affect of the normal map applied to the surface.

**SFXAmbience WaterObject::soundAmbience**

Ambient sound environment when listener is submerged.

**ColorF WaterObject::specularColor**
Color used for specularity on the water surface (sun only).

**float WaterObject::specularPower**

Power used for specularity on the water surface (sun only).

**ColorI WaterObject::underwaterColor**

Changes the color shading of objects beneath the water surface.

**bool WaterObject::useOcclusionQuery**

Turn off reflection rendering when occluded (delayed).

**float WaterObject::viscosity**

Affects drag force applied to an object submerged in this container.

**float WaterObject::waterFogDensity**

Intensity of underwater fogging.

**float WaterObject::waterFogDensityOffset**

Delta, or limit, applied to waterFogDensity.

**Point2F WaterObject::waveDir[3]**
Direction waves flow toward shores.

float WaterObject::waveMagnitude[3]

Height of water undulation.

float WaterObject::waveSpeed[3]

Speed of water undulation.

float WaterObject::wetDarkening

The refract color intensity scaled at wetDepth.

float WaterObject::wetDepth

The depth in world units at which full darkening will be received, giving a wet look to objects underwater.

</tbody>
</table>
Detailed Description

Represents a large body of water stretching to the horizon in all directions.

WaterPlane's position is defined only height, the z element of position, it is infinite in xy and depth. WaterPlane is designed to represent the ocean on an island scene and viewed from ground level; other uses may not be appropriate and a WaterBlock may be used.

See also:

   WaterObject for inherited functionality.

Limitations:

Because WaterPlane cannot be projected exactly to the far-clip distance, other objects nearing this distance can have noticeable artifacts as they clip through first the WaterPlane and then the far plane.

To avoid this large objects should be positioned such that they will not line up with the far-clip from vantage points the player is expected to be. In particular, your TerrainBlock should be completely contained by the far-clip distance.

Viewing WaterPlane from a high altitude with a tight far-clip distance will accentuate this limitation. WaterPlane is primarily designed to be viewed from ground level.
Member Data Documentation

float WaterPlane::gridElementSize

Duplicate of gridElementSize for backwards compatibility.

int WaterPlane::gridSize

Spacing between vertices in the WaterBlock mesh.

</tr>
</tbody>
</table>
**Detailed Description**

Special type of marker, distinguished by a name and team ID number.

The original Torque engines were built from a multi-player game called Tribes. The Tribes series featured various team based game modes, such as capture the flag. The `WayPoint` class survived the conversion from game (Tribes) to game engine (Torque).

Essentially, this is a `MissionMarker` with the addition of two variables: `markerName` and `team`. Whenever a `WayPoint` is created, it is added to a unique global list called `WayPointSet`. You can iterate through this set, seeking out specific markers determined by their `markerName` and `team` ID. This avoids the overhead of constantly calling `commandToClient` and `commandToServer` to determine a `WayPoint` object's name, unique ID, etc.

**Note:**

The `markerName` field was previously called `name`, but was changed because this conflicted with the `SimObject` name field. Existing scripts that relied on the `WayPoint` name field will need to be updated.

**Example:**

```plaintext
new WayPoint()
{
    team = "1";
    dataBlock = "WayPointMarker";
    position = "-0.0224786 1.53471 2.93219"
    rotation = "1 0 0 0"
    scale = "1 1 1"
    canSave = "1"
    canSaveDynamicFields = "1"
};
```

**Detailed Description**

A wheeled vehicle.

A multi-wheeled vehicle.

The model used for the **WheeledVehicle** should contain the elements shown below. Only the collision mesh and hub nodes are actually required for the object to be added to the simulation, but the suspension will look strange if the spring animations are not present.

**Collision mesh**

A convex collision mesh at detail size -1.

**Hub nodes**

The model must contain a node for each wheel called hubN, where N is an integer value starting from 0. For example, a four wheeled vehicle would have nodes: hub0, hub1, hub2, and hub3. The wheel model (specified by **WheeledVehicleTire**) is positioned at the hub node, and automatically rotated to the right orientation (whether on the left or right side of the vehicle).

**Spring animations**

To visualise the suspension action, the vehicle model should contain a non-cyclic animation sequence for each wheel that animates the appropriate hub node from t=0 (fully compressed to t=1 (fully extended). The sequences must be called springN, where N matches the wheel hub index.

**Steering animation**

Optional non-cyclic animation called 'steering' that animates from t=0 (full right) to t=0.5 (center) to t=1 (full left).

**Brakelight animation**

Optional non-cyclic animation called 'brakeLight' that animates from t=0 (off) to t=1 (braking). This is usually a 2-frame animation controlling the visibility of a quad or mesh to represent each brake light.

"
The example below shows the datablocks required for a simple 4-wheeled vehicle. The script should be executed on the server, and the vehicle can then be added to the simulation programmatically from the level startup scripts, or by selecting the MyCar datablock from the World Editor (Library->ScriptedObjects->Vehicles).

Example:

```plaintext
datablock WheeledVehicleTire( MyCarTire )
{
    shapeFile = "art/shapes/wheel.dts";
    staticFriction = 4.2;
    kineticFriction = 1.0;

    lateralForce = 18000;
    lateralDamping = 6000;
    lateralRelaxation = 1;

    longitudinalForce = 18000;
    longitudinalDamping = 4000;
    longitudinalRelaxation = 1;
    radius = 0.61;
};

datablock WheeledVehicleSpring( MyCarSpring )
{
    length = 0.5;
    force = 2800;
    damping = 3600;
    antiSwayForce = 3;
};

datablock WheeledVehicleData( MyCar )
{
    category = "Vehicles";
```
shapeFile = "art/shapes/car.dts";

maxSteeringAngle = 0.585;

// 3rd person camera settings
cameraRoll = false;
cameraMaxDist = 7.8;
cameraOffset = 1.0;
cameraLag = 0.3;
cameraDecay = 1.25;

useEyePoint = true;

// Rigid Body
mass = "400";
massCenter = "0 -0.2 0";
massBox = "0 0 0";

drag = 0.6;
bodyFriction = 0.6;
bodyRestitution = 0.4;
minImpactSpeed = 5;
softImpactSpeed = 5;
hardImpactSpeed = 15;
integration = 8;
collisionTol = 0.05;
contactTol = 0.4;

// Engine
engineTorque = 4300;
engineBrake = 5000;
brakeTorque = 10000;
maxWheelSpeed = 50;
// Energy
maxEnergy = 100;
jetForce = 3000;
minJetEnergy = 30;
jetEnergyDrain = 2;

// Sounds
engineSound = CarEngineSnd;
squealSound = CarSquealSnd;
softImpactSound = SoftImpactSnd;
hardImpactSound = HardImpactSnd;

// Particles
tireEmitter = "CarTireEmitter";
dustEmitter = "CarTireEmitter";
dustHeight = "1";
}

// This function is executed when the WheeledVehicle object is added to the simulation.
function MyCar::onAdd( %this, %obj )
{
    Parent::onAdd( %this, %obj );

    // Setup the car with some tires & springs
    for ( %i = %obj.getWheelCount() - 1; %i >= 0; %i-- )
    {
        %obj.setWheelTire( %i, MyCarTire );
        %obj.setWheelSpring( %i, MyCarSpring );
        %obj.setWheelPowered( %i, true );
    }
// Steer with the front tires only
%obj.setWheelSteering( 0, 1 );
%obj.setWheelSteering( 1, 1 );
}
**Member Function Documentation**

```cpp
int WheeledVehicle::getWheelCount()
```

Get the number of wheels on this vehicle.

**Returns:**
the number of wheels (equal to the number of hub nodes defined in the model)

```cpp
bool WheeledVehicle::setWheelPowered(int wheel, bool powered)
```

Set whether the wheel is powered (has torque applied from the engine).

A rear wheel drive car for example would set the front wheels to false, and the rear wheels to true.

**Parameters:**
- `wheel` index of the wheel to set (hub node #)
- `powered` flag indicating whether to power the wheel or not

**Returns:**
true if successful, false if failed

```cpp
bool WheeledVehicle::setWheelSpring(int wheel, WheeledVehicleSpring spring)
```

Set the `WheeledVehicleSpring` datablock for this wheel.

**Parameters:**
Returns:
true if successful, false if failed

Example:
```cpp
%obj.setWheelSpring( 0, FrontSpring );
```

```
bool WheeledVehicle::setWheelSteering(int wheel, float steering )
```

Set how much the wheel is affected by steering.

The steering factor controls how much the wheel is rotated by the vehicle steering. For example, most cars would have their front wheels set to 1.0, and their rear wheels set to 0 since only the front wheels should turn.

Negative values will turn the wheel in the opposite direction to the steering angle.

Parameters:

- `wheel`  index of the wheel to set (hub node #)
- `steering` steering factor from -1 (full inverse) to 1 (full)

Returns:
true if successful, false if failed

```
bool WheeledVehicle::setWheelTire(int wheel, WheeledVehicleTire tire )
```
Set the `WheeledVehicleTire` datablock for this wheel.

**Parameters:**

- `wheel` index of the wheel to set (hub node #)
- `tire` `WheeledVehicleTire` datablock

**Returns:**

- true if successful, false if failed

**Example:**

```plaintext
%obj.setWheelTire( 0, FrontTire );
```

Detailed Description

Defines the properties of a **WheeledVehicle**.
Member Data Documentation

**float** `WheeledVehicleData::brakeTorque`

Torque applied when braking.

This controls how fast the vehicle will stop when the brakes are applied.

**float** `WheeledVehicleData::engineBrake`

Braking torque applied by the engine when the throttle and brake are both 0.

This controls how quickly the vehicle will coast to a stop.

**SFXTrack** `WheeledVehicleData::engineSound`

Looping engine sound.

The pitch is dynamically adjusted based on the current engine RPM

**float** `WheeledVehicleData::engineTorque`

Torque available from the engine at 100% throttle.

This controls vehicle acceleration. ie. how fast it will reach maximum speed.

**SFXTrack** `WheeledVehicleData::jetSound`
Looping sound played when the vehicle is jetting.

`float WheeledVehicleData::maxWheelSpeed`

Maximum linear velocity of each wheel.
This caps the maximum speed of the vehicle.

`SFXTrack WheeledVehicleData::squealSound`

Looping sound played while any of the wheels is slipping.
The volume is dynamically adjusted based on how much the wheels are slipping.

`ParticleEmitterData WheeledVehicleData::tireEmitter`

`ParticleEmitterData` datablock used to generate particles from each wheel when the vehicle is moving and the wheel is in contact with the ground.

`SFXTrack WheeledVehicleData::WheelImpactSound`

Sound played when the wheels impact the ground.
Currently unused.

Detailed Description

Defines the properties of a WheeledVehicle tire.

Tires act as springs and generate lateral and longitudinal forces to move the vehicle. These distortion/spring forces are what convert wheel angular velocity into forces that act on the rigid body.
## Member Data Documentation

### float WheeledVehicleTire::kineticFriction

Tire friction when the wheel is slipping (no traction).

### float WheeledVehicleTire::lateralDamping

Damping force applied against lateral forces generated by the tire.

**See also:**

lateralForce

### float WheeledVehicleTire::lateralForce

Tire force perpendicular to the direction of movement.

Lateral force can in simple terms be considered left/right steering force. WheeledVehicles are acted upon by forces generated by their tires and the lateralForce measures the magnitude of the force exerted on the vehicle when the tires are deformed along the x-axis. With real wheeled vehicles, tires are constantly being deformed and it is the interplay of deformation forces which determines how a vehicle moves. In Torque's simulation of vehicle physics, tire deformation obviously can't be handled with absolute realism, but the interplay of a vehicle's velocity, its engine's torque and braking forces, and its wheels' friction, lateral deformation, lateralDamping, lateralRelaxation, longitudinal deformation, longitudinalDamping, and longitudinalRelaxation forces, along with its wheels' angular velocity are combined to create a robust real-time physical simulation.

For this field, the larger the value supplied for the lateralForce, the larger the effect steering maneuvers can have. In Torque tire forces are applied at a vehicle's wheel hubs.
float WheeledVehicleTire::lateralRelaxation

Relaxing force applied against lateral forces generated by the tire.

The lateralRelaxation force measures how strongly the tire effectively un-deforms.

See also:
  lateralForce

float WheeledVehicleTire::longitudinalDamping

Damping force applied against longitudinal forces generated by the tire.

See also:
  longitudinalForce

float WheeledVehicleTire::longitudinalForce

Tire force in the direction of movement.

Longitudinal force can in simple terms be considered forward/backward movement force. WheeledVehicles are acted upon by forces generated by their tires and the longitudinalForce measures the magnitude of the force exerted on the vehicle when the tires are deformed along the y-axis.

For this field, the larger the value, the larger the effect acceleration/deceleration inputs have.

See also:
  lateralForce
float *WheeledVehicleTire::longitudinalRelaxation

Relaxing force applied against longitudinal forces generated by the tire.

The longitudinalRelaxation force measures how strongly the tire effectively un-deforms.

See also:

longitudinalForce

float *WheeledVehicleTire::mass

The mass of the wheel.

Currently unused.

float *WheeledVehicleTire::radius

The radius of the wheel.

The radius is determined from the bounding box of the shape provided in the shapefile field, and does not need to be specified in script. The tire should be built with its hub axis along the object's Y-axis.

float *WheeledVehicleTire::restitution

Tire restitution.

Currently unused.
filename `WheeledVehicleTire::shapeFile`

The path to the shape to use for the wheel.

`float WheeledVehicleTire::staticFriction`

Tire friction when the wheel is not slipping (has traction).

Detailed Description

Provides access to a zip file.

A ZipObject add, delete and extract files that are within a zip archive. You may also read and write directly to the files within the archive by obtaining a StreamObject for the file.

Example:

```java
// Open a zip archive, creating it if it doesn't exist
%archive = new ZipObject();
%archive.openArchive("testArchive.zip", Write);

// Add a file to the archive with the given name
%archive.addFile("./water.png", "water.png";

// Close the archive to save the changes
%archive.closeArchive();
```

Note:

Behind the scenes all of the work is being done with the ZipArchive and StreamObject classes.

See also:

StreamObject when using methods such as openFileForRead() and openFileForWrite()
Member Function Documentation

```cpp
bool ZipObject::addFile (string filename, string pathInZip, bool replace = true )
```

Add a file to the zip archive.

**Parameters:**

- `filename`: The path and name of the file to add to the zip archive.
- `pathInZip`: The path and name to be given to the file within the zip archive.
- `replace`: If a file already exists within the zip archive at the same location as this new file, this parameter indicates if it should be replaced. By default, it will be replaced.

**Returns:**

True if the file was successfully added to the zip archive.

```cpp
void ZipObject::closeArchive ( )
```

Close an already opened zip archive.

**See also:**

- `openArchive()`

```cpp
void ZipObject::closeFile (SimObject stream )
```

Close a previously opened file within the zip archive.

**Parameters:**
stream The StreamObject of a previously opened file within the zip archive.

See also:
openFileForRead()
openFileForWrite()

bool ZipObject::deleteFile (string pathInZip )

Deleted the given file from the zip archive.

Parameters:

pathInZip The path and name of the file to be deleted from the zip archive.

Returns:
True of the file was successfully deleted.

Note:
Files that have been deleted from the archive will still show up with a getFileEntryCount() until you close the archive. If you need to have the file count up to date with only valid files within the archive, you could close and then open the archive again.

See also:
getFileEntryCount()
closeArchive()
openArchive()

bool ZipObject::extractFile (string pathInZip, string filename)

Extract a file from the zip archive and save it to the requested
location.

**Parameters:**

- pathInZip The path and name of the file to be extracted within the zip archive.
- filename The path and name to give the extracted file.

**Returns:**
True if the file was successfully extracted.

```java
String ZipObject::getFileEntry(int index)
```

Get information on the requested file within the zip archive.

This methods provides five different pieces of information for the requested file:

- filename - The path and name of the file within the zip archive
- uncompressed size
- compressed size
- compression method
- CRC32

Use `getFileNameEntryCount()` to obtain the total number of files within the archive.

**Parameters:**

- index The index of the file within the zip archive. Use `getFileNameEntryCount()` to determine the number of files.

**Returns:**
A tab delimited list of information on the requested file, or an empty string if the file could not be found.

**See also:**
`getFileNameEntryCount()`
int ZipObject::getFileEntryCount()

Get the number of files within the zip archive.

Use `getFileEntry()` to retrieve information on each file within the archive.

**Returns:**

The number of files within the zip archive.

**Note:**

The returned count will include any files that have been deleted from the archive using `deleteFile()`. To clear out all deleted files, you could close and then open the archive again.

**See also:**

`getFileEntry()`, `closeArchive()`, `openArchive()`

---

bool ZipObject::openArchive(string filename,
                             string accessMode = "read")

Open a zip archive for manipulation.

Once a zip archive is opened use the various `ZipObject` methods for working with the files within the archive. Be sure to close the archive when you are done with it.

**Parameters:**

- `filename` The path and file name of the zip archive to open.
- `accessMode` One of read, write or readwrite
Returns:
True is the archive was successfully opened.

Note:
If you wish to make any changes to the archive, be sure to open it with a write or readwrite access mode.

See also:
closeArchive()

SimObject ZipObject::openFileForRead (string filename)

Open a file within the zip archive for reading.
Be sure to close the file when you are done with it.

Parameters:

filename The path and name of the file to open within the zip archive.

Returns:
A standard StreamObject is returned for working with the file.

Note:
You must first open the zip archive before working with files within it.

See also:
closeFile()
oopenArchive()

SimObject ZipObject::openFileForWrite (string filename)

Open a file within the zip archive for writing to.
Be sure to close the file when you are done with it.

**Parameters:**

*filename*  The path and name of the file to open within the zip archive.

**Returns:**

A standard *StreamObject* is returned for working with the file.

**Note:**

You must first open the zip archive before working with files within it.

Detailed Description

An object that represents an interior space.

A zone is an invisible volume that encloses an interior space. All objects that have their world space axis-aligned bounding boxes (AABBs) intersect the zone's volume are assigned to the zone. This assignment happens automatically as objects are placed and transformed. Also, assignment is not exclusive meaning that an object can be assigned to many zones at the same time if it intersects all of them.

In itself, the volume of a zone is fully sealed off from the outside. This means that while viewing the scene from inside the volume, only objects assigned to the zone are rendered while when viewing the scene from outside the volume, objects exclusively only assigned the zone are not rendered.

Usually, you will want to connect zones to each other by means of portals. A portal overlapping with a zone

Example:

```// Example declaration of a Zone. This creates a box-shaped zone.
new Zone( TestZone )
{
    position = "3.61793 -1.01945 14.7442";
    rotation = "1 0 0 0";
    scale = "10 10 10";
};```
Zone Groups

Normally, Zones will not connect to each other when they overlap. This means that if viewing the scene from one zone, the contents of the other zone will not be visible except when there is a portal connecting the zones. However, sometimes it is convenient to represent a single interior space through a combination of Zones so that when any of these zones is visible, all other zones that are part of the same interior space are visible. This is possible by employing "zone groups".

- Portal
Member Function Documentation

**void Zone::dumpZoneState(bool updateFirst = true)**

Dump a list of all objects assigned to the zone to the console as well as a list of all connected zone spaces.

**Parameters:**

*updateFirst*  
Whether to update the contents of the zone before dumping. Since zoning states of objects are updated on demand, the zone contents can be outdated.

**int Zone::getZoneId( )**

Get the unique numeric ID of the zone in its scene.

**Returns:**

The ID of the zone.
Member Data Documentation

**ColorF** Zone::ambientLightColor

Color of ambient lighting in this zone.
Only used if `useAmbientLightColor` is true.

**string** Zone::edge

For internal use only.

**string** Zone::plane

For internal use only.

**string** Zone::point

For internal use only.

**SFXAmbience** Zone::soundAmbience

Ambient sound environment for the space.

**bool** Zone::useAmbientLightColor

Whether to use `ambientLightColor` for ambient lighting in this zone or the global ambient color.
int Zone::zoneGroup

ID of group the zone is part of.

$pref::TS Namespace Reference
## Variables

**float** `detailAdjust`  
User preference for scaling the TSShape level of detail. The smaller the value the closer the camera must get to see the highest LOD. This setting can have a huge impact on performance in mesh heavy scenes. The default value is 1.

**int** `maxInstancingVerts`  
Enables mesh instancing on non-skin meshes that have less that this count of verts. The default value is 200. Higher values can degrade performance.

**int** `skipLoadDLs`  
User preference which causes TSShapes to skip loading higher lods. This potentially reduces the GPU resources and materials generated as well as limits the LODs rendered. The default value is 0.

**int** `skipRenderDLs`  
User preference which causes TSShapes to skip rendering higher lods. This will reduce the number of draw calls and triangles rendered and improve rendering performance when proper LODs have been created for your models. The default value is 0.

**float** `smallestVisiblePixelSize`  
User preference which sets the smallest pixel size at which TSShapes will skip rendering. This will force all shapes to stop rendering when they get smaller than this size. The default value is -1 which disables it.

Variable Documentation

| int $ProxMine::autoDeleteTicks |

Number of ticks until an exploded mine is deleted on the server.

After a mine has exploded it remains in the server's scene graph for a time to allow its exploded state to be passed along to each client. This variable controls how long a mine remains before it is deleted. Any client that has not received the exploded state by then (perhaps due to lag) will not see any explosion produced by the mine.

Graph Legend

This page explains how to interpret the graphs that are generated by doxygen.

Consider the following example:

```cpp
/*! Invisible class because of truncation */
class Invisible { };

/*! Truncated class, inheritance relation is hidden */
class Truncated : public Invisible { };

/*! Class not documented with doxygen comments */
class Undocumented { };

/*! Class that is inherited using public inheritance */
class PublicBase : public Truncated { };

/*! A template class */
template<class T> class Templ { };

/*! Class that is inherited using protected inheritance */
class ProtectedBase { };

/*! Class that is inherited using private inheritance */
class PrivateBase { };

/*! Class that is used by the Inherited class */
class Used { };

/*! Super class that inherits a number of other classes */
class Inherited : public PublicBase,
```
protected ProtectedBase,
private PrivateBase,
public Undocumented,
public Templ<int>
{
    private:
        Used *m_usedClass;
};

This will result in the following graph:

The boxes in the above graph have the following meaning:

- A filled gray box represents the struct or class for which the graph is generated.
- A box with a black border denotes a documented struct or class.
- A box with a grey border denotes an undocumented struct or class.
- A box with a red border denotes a documented struct or class for which not all inheritance/containment relations are shown. A graph is truncated if it does not fit within the specified boundaries.

The arrows have the following meaning:

- A dark blue arrow is used to visualize a public inheritance relation between two classes.
- A dark green arrow is used for protected inheritance.
• A dark red arrow is used for private inheritance.
• A purple dashed arrow is used if a class is contained or used by another class. The arrow is labeled with the variable(s) through which the pointed class or struct is accessible.
• A yellow dashed arrow denotes a relation between a template instance and the template class it was instantiated from. The arrow is labeled with the template parameters of the instance.
# ActionMap Member List

This is the complete list of members for `ActionMap`, including all inherited members.

<table>
<thead>
